

# ANALYSE DES POLLUANTS DANS L'ENVIRONNEMENT

## PART I

Dr. Florian Breider, EPFL - Central Environmental Laboratory

&

Pascale Mulattieri - Biol'Eau Sàrl

2024

# Program - Part I

**Day 1:** Introduction (chemical analysis + sampling of macrozoobenthos) (GC D0386)

**Day 2:** Field work (water and sediment sampling) (**Sept. 18**)

Analysis of macro-pollutants in water (Lab GR C0 528)

**Day 3:** Analysis of organic and inorganic micro-pollutants in  
sediments (Lab GR C0 528) (2 groups **Sept 25<sup>th</sup> or Oct. 2<sup>nd</sup>**)

**Day 4:** Macrozoobenthos identification (Lab GR C0 528) (2 groups **Oct. 9<sup>th</sup> or Oct. 16<sup>th</sup>**)

**Day 5:** Discussion and report (GC D0 386) (**Oct. 30<sup>th</sup>**)

13h15-19h

# Objective of the course - Part I

The aims of this course:

- Learn how to collect and analyze environmental samples
- Learn how to interpret analytical data (critical thinking)
- Be able to assess the environmental quality of surface waters

Evaluation: **Scientific report (3.5 points part I and 2.5 points part II – total 6 points)**

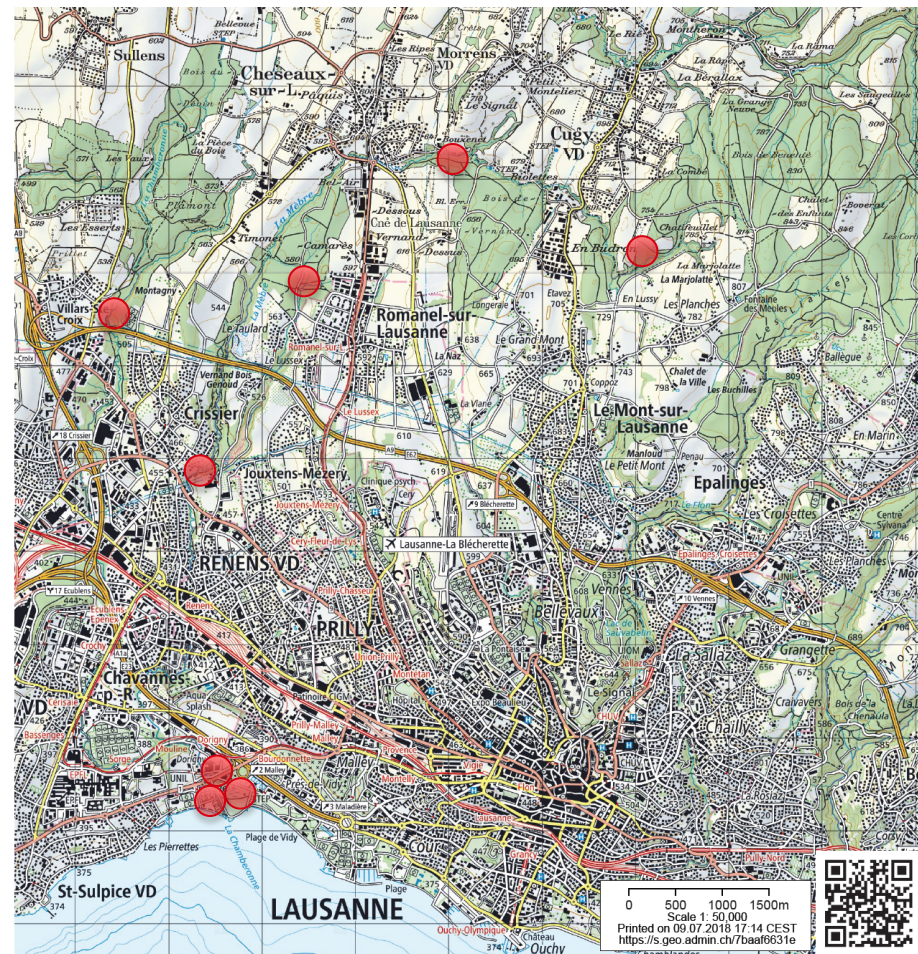

**The final report should be submitted at the latest on December 13<sup>th</sup> (23:59) 2024**

# Lab and field work

14-15 groups of 3 students / 13 sites

Septembre 18th (Field work)

meeting at the north entrance (C) of the GR building with your boots or hiking shoes...

# Modular Stepwise Procedure (Système Modulaire Gradu )

## Methods to assess the environmental quality of streams

- General aspect
- Ecomorphology
- Physico-chemical analysis and nutrients
- Macrozoobenthos

# Report

- One report per group (in french or english)
  1. Introduction (goals, context)
  2. Material and methods (sampling, sample preparation, analytical methods, etc.)
  3. Macropollutants analysis (methods, results and discussion )
  4. Micropollutants analysis (methods, results and discussion )
  5. Macrozoobenthos (results, dicusssion and link with the concentration of pollutants)
  6. Discussion (comparison with previous reports and the littérature)
  7. Conclusion
  8. References
  9. Supporting information (chromatograms, tables, etc.)

# Summary

1. General introduction
2. Macro-pollutants
3. Organic micro-pollutants
4. Inorganic micro-pollutants
5. Analytical methods in environmental chemistry
6. Biological quality of streams and rivers (P. Mulattieri)

# Définitions (1)

- Paracelsus (16e siècle): « Toutes les substances sont des poisons. La dose juste différencie un poison d'un médicament ».
- Selon Chapman\* (2007), on parle de **contamination** lorsque les substances chimiques trouvées dans les sédiments ne sont pas habituelles ou lorsque les concentrations ne sont pas habituellement si élevées, alors qu'on parle de **pollution** lorsque la contamination provoque des effets biologiques délétères.

## Définitions (2)

- **Macropolluants:** On appelle macropolluants des molécules naturelles qui sont présentes localement et/ou temporairement dans l'environnement à une concentration ne s'inscrivant pas dans l'intervalle habituel. Les réactions biochimiques impliquant ces molécules n'en seront pas changées, mais leurs cinétiques seront différentes.
- **Micropolluants:** On appelle micropolluants les molécules anthropiques présentes dans l'environnement à des concentrations  $<1\text{mg/L}$ . Les micropolluants peuvent être toxiques à de très faibles concentrations et peuvent causer des effets chroniques. Ils nécessitent en général des moyens sophistiqués et coûteux pour leur analyse.

## Définitions (3)

- **Bioaccumulation:** phénomène par lequel une substance présente dans un biotope pénètre dans un organisme.
- **Bioconcentration:** phénomène par lequel des êtres vivants absorbent des substances naturellement présentes dans leur biotope ou polluantes et les accumulent dans leur organisme à des concentrations supérieures à celles se rencontrant dans le milieu naturel.
- **Bioamplification:** phénomène par lequel une substance naturelle ou un contaminant présent dans un biotope connaît un accroissement de sa concentration au fur et à mesure qu'il circule vers les maillons supérieurs d'un réseau trophique.

# Définitions (3)

## Bioaccumulation

■ Contaminant levels

■ Contaminant levels

## Biomagnification

# Macro/Micro-pollutants

# Macro-pollutants

Inorganic:  $\text{PO}_4^-$ ,  $\text{NO}_3^-$ ,  $\text{NO}_2^-$ ,  $\text{SO}_4^{2-}$ ,  $\text{Cl}^-$  ...

Organic: plastics, surfactants, polymers, organic matter (feces, industries...)

# Macro-pollutants

The orthophosphate concentration is an indicator of the level of pollution of rivers by human activities.

# Macro-polluants

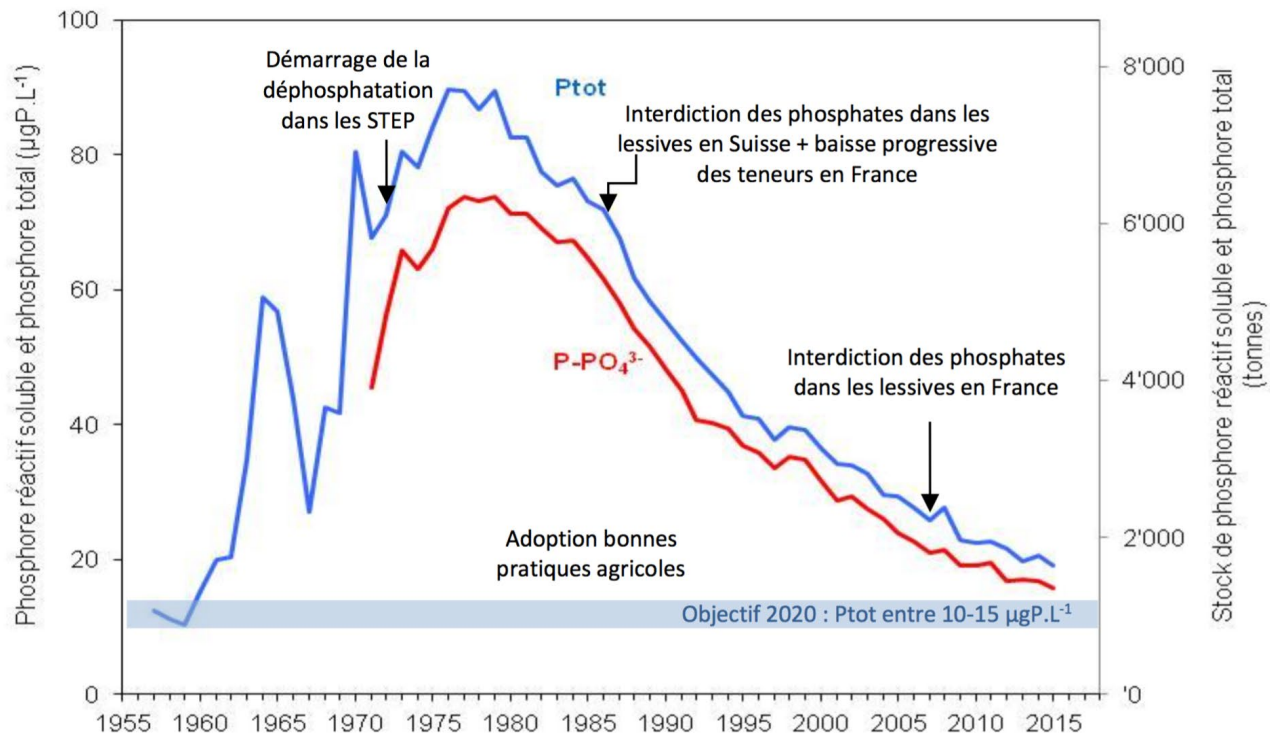

Figure 31 : Evolution de la concentration moyenne annuelle pondérée et du stock de phosphore réactif soluble et de phosphore total pour l'ensemble de la masse d'eau du lac de 1957 à 2015, Léman - Grand Lac (SHL2)

# Macro-pollutants

## Nitrogen Cycle

# Macro-pollutants

## $\text{NO}_2^-/\text{NO}_3^-$

High nitrite concentrations in freshwater ecosystems may cause toxicity to aquatic animals. These living organisms can take nitrite up from water through their chloride cells, subsequently suffering oxidation of their respiratory pigments (hemoglobin, hemocyanin). Because  $\text{NO}_2^-$  and  $\text{Cl}^-$  ions compete for the same active transport site, elevated chloride concentrations in the aquatic environment have the potential of reducing nitrite toxicity.

Hemocyanin	Hemoglobin
Performs better in cold environments with low oxygen pressure	Performs better in oxygen rich environments
Contains copper linking other parts of the molecule	Contains iron surrounded by atoms of carbon, nitrogen, and hydrogen
Binds with oxygen non co-operatively most of the time (when non co-operatively, is one quarter as efficient as hemoglobin)	Binds with oxygen co-operatively all of the time
Free floating in blood	Connected to red blood cells

# Macro-pollutants

$\text{NO}_2^-/\text{NO}_3^-$

## Antagonist effect of chloride on nitrite toxicity

Mean percentages (+SD) of mortality (a) and affected individuals (b) for *Eulimnogammarus toletanus* exposed to 5.1 ppm  $\text{NO}_2\text{-N}$  through seven different exposure times (hours) and at four different chloride concentrations (ppm  $\text{Cl}^-$ )

*Eulimnogammarus toletanus*

Appréciation	Nitrites [mg/L N] <sup>1</sup> (<10 mg/L Cl <sup>-</sup> )	Nitrites [mg/L N] (10 à 20 mg/L Cl <sup>-</sup> )	Nitrites [mg/L N] (>20 mg/L Cl <sup>-</sup> )
Très bon	jusqu'à < 0,01	jusqu'à < 0,02	jusqu'à < 0,05
bon	0,01 à < 0,02	0,02 à < 0,05	0,05 à < 0,10
moyen	0,02 à < 0,03	0,05 à < 0,075	0,10 à < 0,15
médiocre	0,03 à < 0,04	0,075 à < 0,10	0,15 à < 0,20
mauvais	0,04 et plus	0,10 et plus	0,20 et plus

Système Modulaire Gradué

# Macro-pollutants

Blue baby syndrome (methemoglobinemia) is caused by exposure to elevated levels of nitrite in infants <6 years.

Nitrite and nitrate can lead to the formation of *N*-nitrosamines (potent carcinogenic compounds) under certain conditions (e.g. gastric fluid, oxidative water treatment).

**Blue baby syndrome** Nitrates in water are ingested by an infant and converted to nitrite by the digestive system. The nitrite then reacts with oxyhemoglobin to form methemoglobin, which cannot carry oxygen

# Macro-pollutants

Corrosion of water distribution systems.

Sulfate in drinking-water can also result in a noticeable taste.

Salinization

Indicates the level of pollution caused by municipal wastewater or leaching of crop lands.

Formation of chloramines during water chlorination.

# Macro-pollutants

## Alkaline earth metals and (post)transition metals

Level	Concentration range	Exemples
Major	1-100%	Al 1-30% Ca 0.01-10% Fe 0.7-15%
Minor	0.01-1%	Mg 0.06-0.6% Mn 0.03-0.3%
Traces	0.1-100 ppm	Cu 2-100 ppm Zn 10-300 ppm Pb 2-200 ppm
Ultra-traces	<0.1 ppm (<100 ppb)	Hg 0.01-0.8 ppm Ag 0.01-0.1 ppm

# Macro-pollutants

## Alkaline earth metals and (post)transition metals

Figure 9 : Evolution de la teneur en mercure dans les poissons du Léman de 1975 à 2012.

# Micro-pollutants

Micropollutants refer to residue from organic and inorganic substances, used everyday in modern society, including for example pharmaceuticals and personal care products (PPCPs), hormones, pesticides and industrial chemicals.

## Concentration range

mg/L to ng/L or ppm to ppt

Effects at 10 ng/L

Olympic sized swimming pool  
2,500,000 L

Measure of pH, conductivity and dissolved oxygen

# How pH is measured?

Pure water dissociates into hydronium ions ( $\text{H}_3\text{O}^+$ ) and hydroxide ions ( $\text{OH}^-$ ). This dissociation is called autoprotolysis of water:

water is an acid:  $\text{H}_2\text{O} = \text{H}^+(\text{aq}) + \text{OH}^-(\text{aq})$

water is a base:  $\text{H}_2\text{O} + \text{H}^+(\text{aq}) = \text{H}_3\text{O}^+(\text{aq})$

hence the reaction:  $2 \text{H}_2\text{O} = \text{H}_3\text{O}^+(\text{aq}) + \text{OH}^-(\text{aq})$

the dissociation constant of water ( $K_w$ ) is  $10^{-14}$  and corresponds to the sum of the activity of the hydronium and hydroxide ions.

$$K_w = a_{\text{H}^+} + a_{\text{OH}^-} = 1 \times 10^{-14}$$

For a neutral solution  $a_{\text{H}^+} = a_{\text{OH}^-} = 10^{-7}$  at  $25^\circ\text{C}$ . Because the concentration of hydronium ions is  $1 \times 10^{-7}$  M, the pH of pure water is 7.00 at  $25^\circ\text{C}$ . This forms the basis of the pH scale.

# How pH is measured?

The source of the potential is measured by the electrode. The measuring system consists of a glass measuring electrode whose voltage varies proportionally to the activity of the hydronium ions contained in the solution and a reference electrode which produces a constant and stable voltage. The measuring electrode and the reference electrode can be housed in the same body (referred to as combined electrodes) or mounted separately (separate electrodes). The pH meter measures the potential difference between the two electrodes and displays the results either in mV or, after conversion, in pH units.

Conversion is based on the following equations

$$E_{\text{obs}} = E_c + N_f \text{Log } a_{\text{H}^+}$$

Where

$E_{\text{obs}}$  is the observed potential

$E_c$  is the reference potential including other stable and fixed potentials

$N_f$  is the Nernstian factor of the slope

$a_{\text{H}^+}$  is the activity of hydronium ions

The degree of the slope  $N_f$  is the Nernstian factor, and is also a characteristic of the glass membrane, i.e. :  $N_f = 2.3RT/nF$

where:

$R$ =perfect gas constant = 8.313 J.K<sup>-1</sup>.mol<sup>-1</sup>,  $T$ =temperature in degrees Kelvin,  $F$ =Faraday constant = 9.65x10<sup>4</sup> C.mol<sup>-1</sup>,

$n$ =valency factor ( $n=1$  for hydrogen)

# How water conductivity is measured?

An alternating current is applied to 2 electrodes (included in the conductivity cell) immersed in the sample and the resulting voltage is measured. The anions move towards the positive electrode and the cations towards the negative electrode. The sample behaves like an electrical conductor.

In practice, conductivity meters measure conductance. After performing the conversion operations, they display the conductivity.

Depending on the application, it may be preferable to measure resistivity (the inverse of conductivity), as in the case of pure water containing very few ions. The degree of conductivity of a solution depends on several factors:

- the ion concentration
- the valency of the ions
- their mobility
- the temperature of the solution.

# How dissolved oxygen (DO) is measured?

Probes for measuring dissolved oxygen consist of a cell containing two electrodes (anode and cathode), linked by an electrolyte providing the electrical bridge and insulated from the sample by a gas-permeable membrane.

There are 2 types of cell:

- the polarographic cell, to which a polarisation voltage is applied to perform the measurement,
- the galvanic cell, where the electrode/electrolyte system is designed to generate its own potential, albeit with the help of an external power supply.

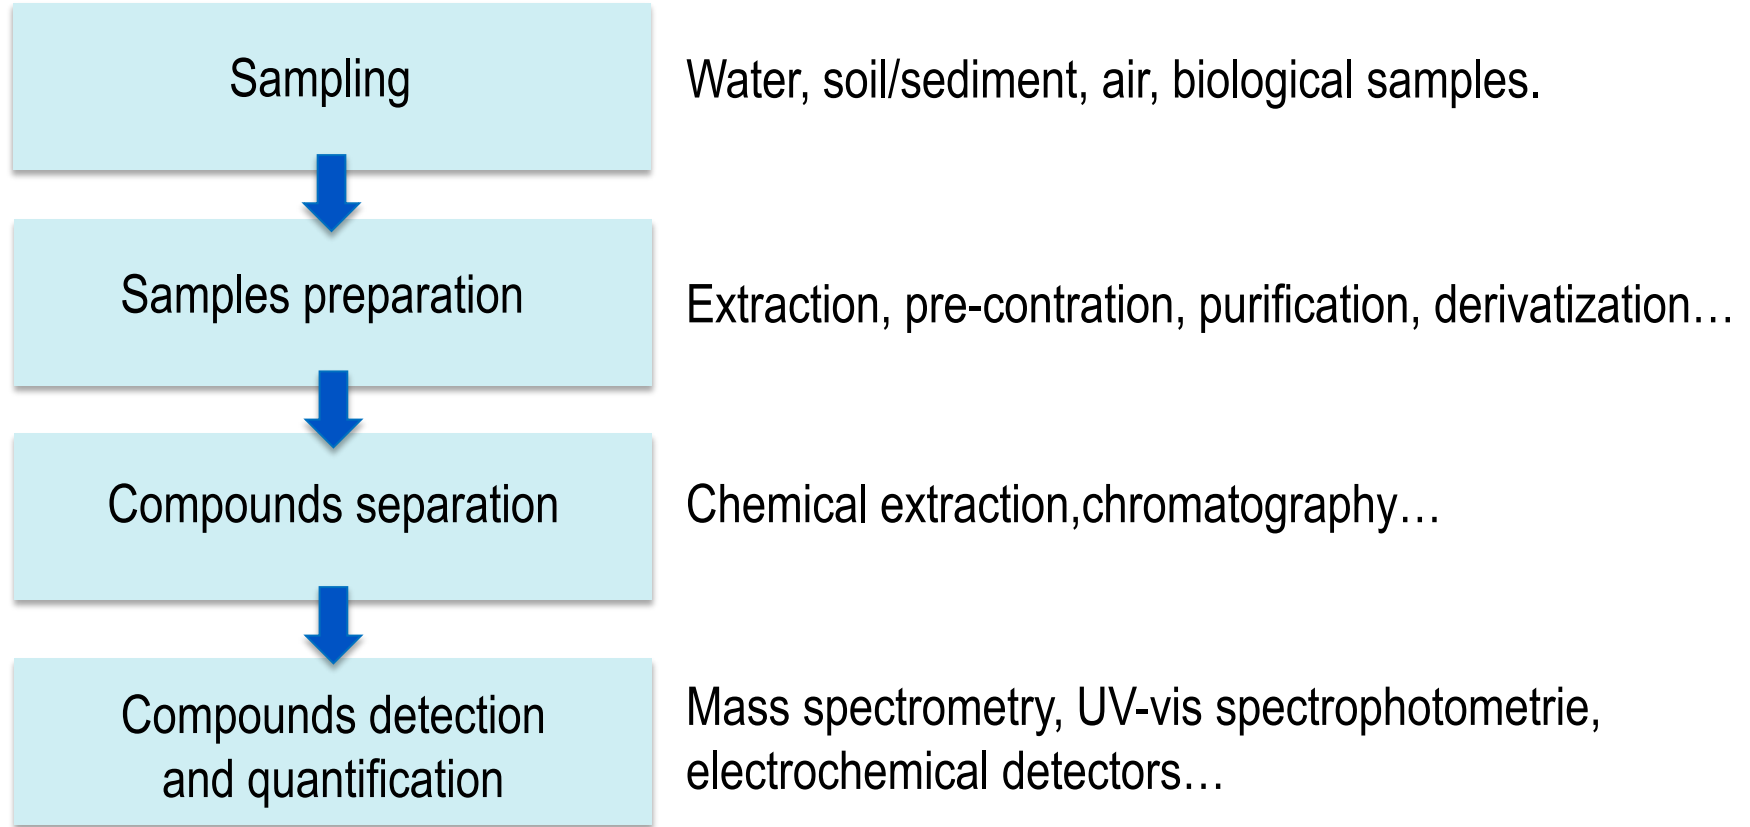

The 2 types of cell operate on the same electrochemical principle, the reduction of oxygen at the cathode.

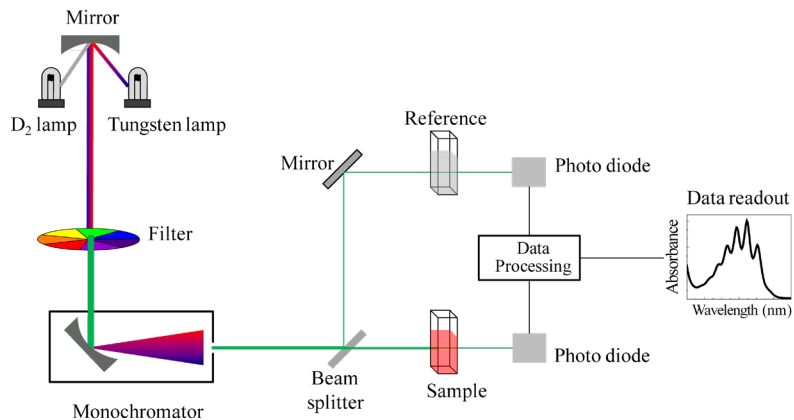

# Samples preparation and Analytical methods

# From sampling to the quantification of the analytes

# Compounds detection and quantification

UV-vis detector

For any particular wavelength,

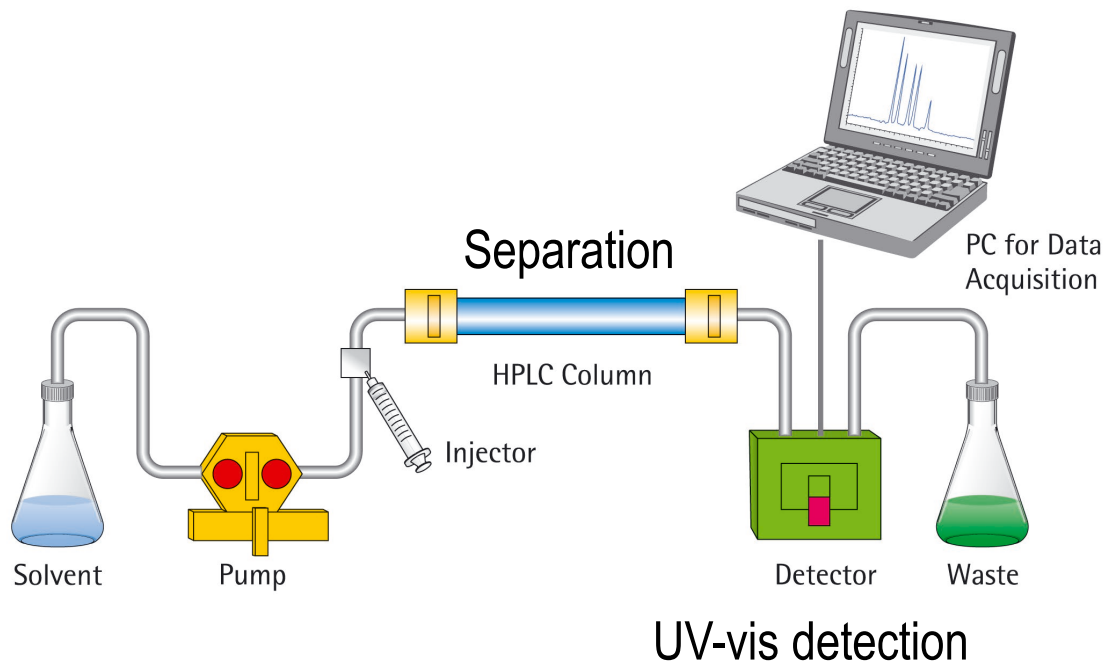

$$A = \epsilon b C$$

Labels for the equation:  $A$  is Absorbance;  $\epsilon$  is Molar absorptivity  $\rightarrow L/(\text{mol cm})$ ;  $b$  is Path length  $\rightarrow \text{cm}$ ;  $C$  is Concentration  $\text{Mol/L}$ .

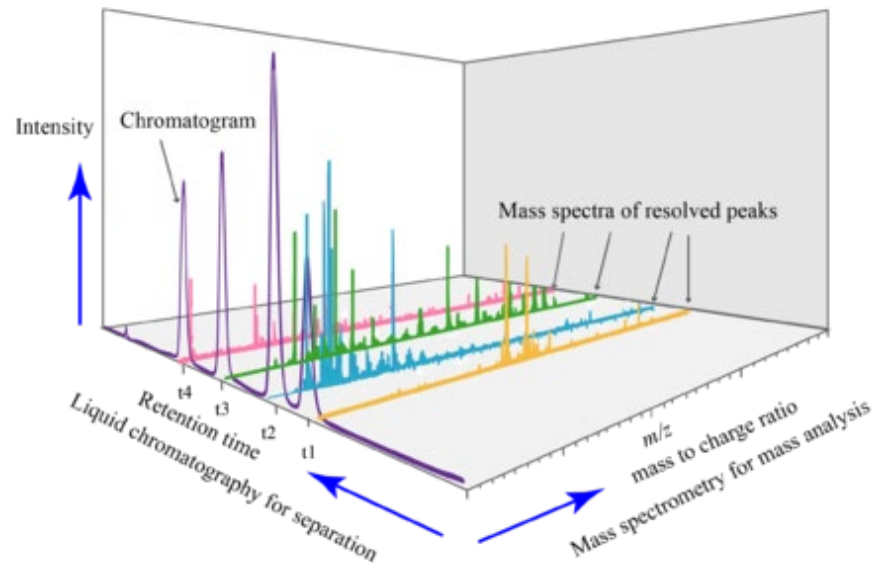

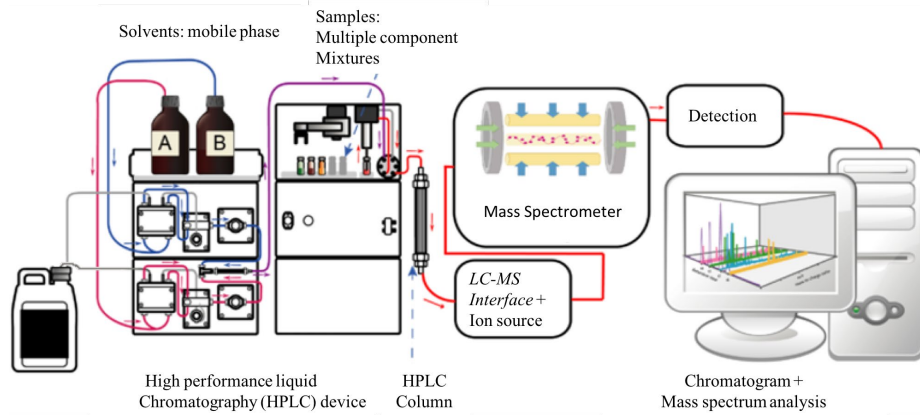

Mass detector

# High Performance Liquid Chromatography (HPLC)

# Liquid Chromatography – Mass Spectrometry (LC-MS)

# Liquid Chromatography – Mass Spectrometry (LC-MS)

- LC is a method for separating a complex mixture into its components
- The high sensitivity of mass spectrometry provides the information for the identification of compounds or structural elucidation of compounds
- Combination of these two techniques is LC-MS
- In most cases the interface used in LC-MS are ionization sources (electron, photon or chemical ionization)

# Gas Chromatography – Mass Spectrometry (GC-MS)

For low molecular weight and volatile/semi-volatile compounds

# LC-MS vs. GC-MS

<b>GC/MS</b>	<b>GC/MS or LC/MS</b>	<b>LC/MS</b>
<b>MW &lt; 700</b>	<b>100 &lt; MW &lt; 800</b>	<b>50 &lt; MW &lt; 50k</b>
<b>Highly volatile</b>	<b>Moderately volatile</b>	<b>Non-volatile</b>
<b>Non-polar</b>	<b>Moderately polar</b>	<b>Thermally labile</b>
<b>Moderately polar</b>		<b>Highly polar</b>
<b>Hydrocarbons</b>	<b>Most pesticides</b>	<b>Proteins/peptides</b>
<b>Flavors</b>	<b>Many drugs</b>	<b>DNA</b>
<b>Fragrances</b>	<b>Many industrial cpds</b>	<b>Oligosaccharides</b>
<b>Pesticides</b>	<b>Some vitamins</b>	<b>Surfactants</b>
<b>Some drugs</b>		<b>Dyes</b>
	<b>With derivatization</b>	<b>Drug glucuronides</b>
	<b>Many more!</b>	<b>Glyphosate</b>
		<b>Chlormequat</b>

# LC-MS vs. GC-MS

<b>GC/MS</b>	<b>EI 70eV</b>	<b>Hard</b>	<b>Large number of fragments (best finger print); M+ varies, maybe zero</b>
<b>GC/MS</b>	<b>PCI</b>	<b>Soft - varied</b>	<b>M+H dominant; fragments with "harder" reagents</b>
<b>GC/MS</b>	<b>NCI</b>	<b>Very soft</b>	<b>M- dominant; may fragment to yield electroneg groups</b>
<b>LC/MS</b>	<b>ESI</b>	<b>Very soft</b>	<b>Mol ion and adducts (+ or -) Few fragments</b>
<b>LC/MS</b>	<b>APCI</b>	<b>Soft - varied</b>	<b>Mol ion and adducts (+ or -) Few fragments</b>

# Typical ion chromatography system (anions)

# Atomic spectroscopy (AAS, ICP-OES, ICP-MS...)

## ATOMIC SPECTROSCOPY

Absorption Spectroscopy  
AAS

Emission Spectroscopy

analysis of elements *directly* in digestion solution using ICP-OES

# Accuracy vs. Precision

Not accurate or precise.  
Random.

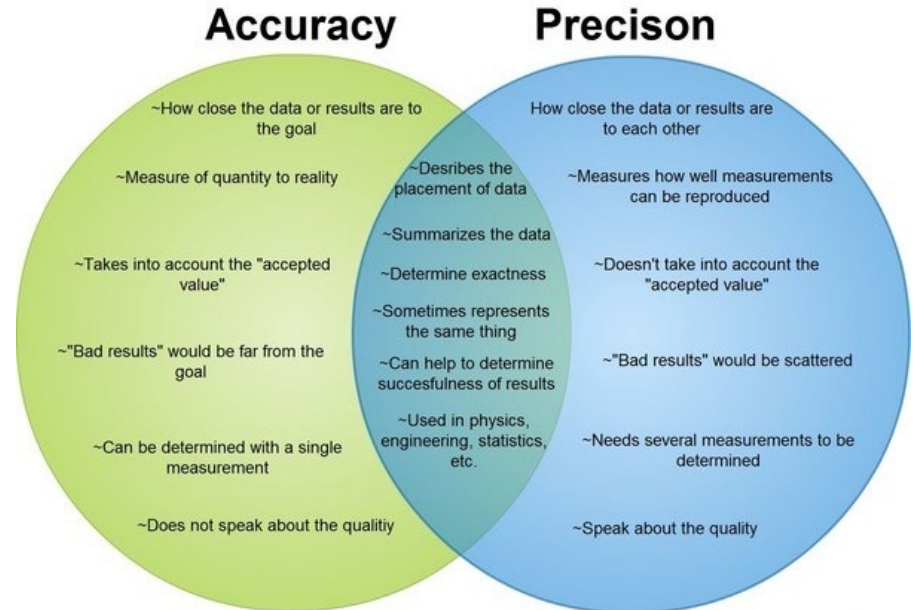

Accurate but not precise.  
The 'average' position  
hits the bullseye.

Precise, but not accurate.  
Clustered together but  
missed the bullseye.

Both accurate  
and precise.

# Calibration

It is not reliable to extrapolate any calibration curve, linear or non-linear. Measure standards in the entire concentration range of interests.

# Limits of Detection and Quantification (LOD/LOQ)

$$\text{LOD} = 3.3 \sigma / \text{Slope}$$

$$\text{LOQ} = 10 \sigma / \text{Slope}$$

Where:  $\sigma$  = the standard deviation of the response at low concentrations

Slope = the slope of the calibration curve.

- The LOD is the lowest quantity of a substance that can be distinguished from the absence of that substance (a blank value) with a stated confidence level (generally 99%).
- The LOQ of an individual analytical procedure is the lowest amount of analyte in a sample which can be quantified with suitable precision and accuracy.
