Rearrangement

Bond re-organization to give a structural isomer of the original compound.

It often involves migration of a group (an atom) from one atom to another within the molecule.

Very often, rearrangment led to a significant structural modification.

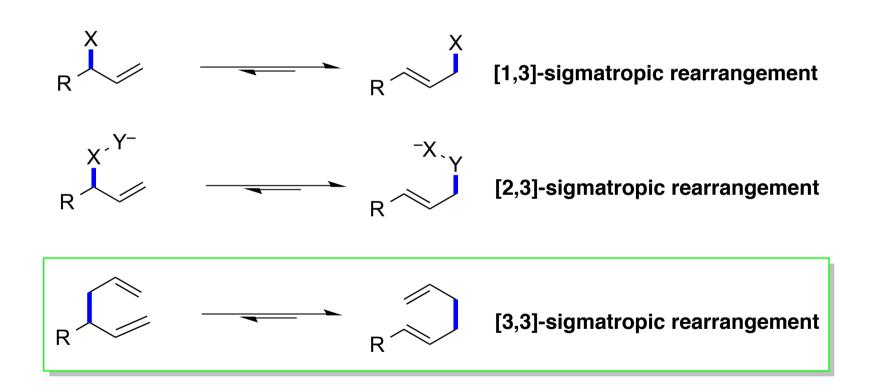

Reminder: reaction types we've already learnt:

Acid-base; Addition; Substitution; Elimination;

Condensation...

Sigmatropic Rearrangement

Those reactions in which a sigma bond and associated substituent interchanges termini on a conjugated π -system

Cope Rearrangement

A thermal isomerization of 1,5-diene to a regioisomeric 1,5-diene. It is a pericyclic reaction with a concerted molecular rearrangement: $4\pi e^- + 2\sigma$ bonds. Consequently, the transition state has "aromatic character". It belongs to a family of [3,3]-sigmatropic rearrangements

Cope rearrangement is an equilibrium process leading to thermodynamically more stable isomer

Definition of a pericyclic reactions:

Having a cyclic transition state and proceeding in a concerted manner.

Cope Rearrangement

Key: To recognize the 1,5-diene unit

B is thermodymanically more stable

Driving force: Release of ring strain

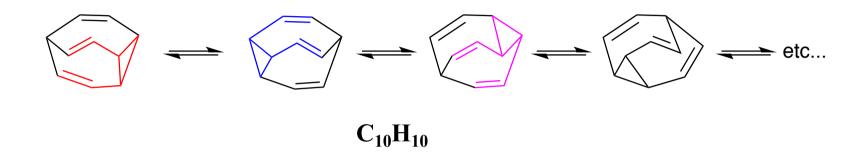

Cyclopropane ring strain: 27 kcal/mol

Cope Rearrangement

Key: For linear 1,5-diene, the rearrangement generally went through a chair-like transition state. The TS conformation determines the stereochemistry of the new double bonds

Very similar to Zimmerman-Traxler transition state for the aldol reaction Avoid 1,3-diaxial interaction in drawing your transition state

Degenerative Cope Rearrangement: Case of Bullevalene

Doring's Prediction:

If each of the 10 CH groups of the molecule were individually labeled, there would be 1,209,600 arrangements of the molecule.

Oxy-Cope rearrangement

oxy-Cope rearrangement: aldehyde formation is the driving force

The carbonyl tautomer is more stable, removing the enol from the equilibrium.

The oxy-Cope rearrangement is significantly accelerated when the hydroxy group is converted to alkoxide. The base-catalyzed reaction is called: **anionic oxy-Cope rearrangement**

Oxy-Cope rearrangement: Example of complete structural re-organizaiton

KH, THF, reflux

$$\begin{array}{c} \text{KH, THF} \\ \text{3} \\ \text{2} \\ \text{3} \end{array}$$

Claisen rearrangement

Claisen rearrangement involving a vinyl allyl ether is essentially the same as Cope rearrangement. However, the equilibrium is driven to the product (4-pentenal) which is thermadynamically more stable.

Driving force of the reaction = carbonyl group formation Comparing the bond dissociation energies: C=C 146 kcal/mol, C=O 172 kcal/mol

Example:

Claisen rearrangement

Aromatic Claisen rearrangement:

When the ortho-positions are occupied:

Industrial Application: Synthesis of Citral

Citral A is a key intermediate in the synthesis of Vitamine A

Cationic Rearrangements:

Recapitulation on the stability of carbenium ions:

Possible reactions with a cationic intermediate:

Add a nucleophile (S_N1 substitution), Loss a proton (Elimination) and Rearrangement

Driving forces and selectivity factors for cationic rearrangements:

- *Reaction proceeds to form a better stabilized carbenium ion
- *Release of ring strain
- *Cleavage/release of small and uncharged molecules, for example: CO or CO₂

Wagner-Meerwein rearrangement: A cationic 1,2-rearrangement involving the migration of an alkyl or a hydride

1,2-Hydride Shift (migration of a hydride)

Mechanism:

1,2-Alkyl shift (migration of an alkyl group)

better stabilized

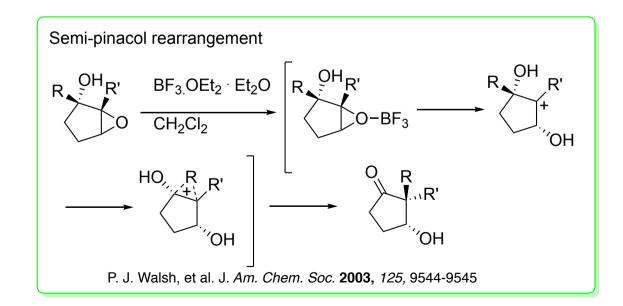

Mechanism:

Example:

Pinacol Rearrangement
