# Fonction et réaction organiques II, week 2

# 1.2. Electrophilic aromatic substitution S<sub>E</sub>Ar

General reaction:

- $E_1 = H$
- Rare cases where  $E_1 = SiR_3$ , tBu,  $SO_3H$  is then called ipso-substitution
- Formally, the reaction is the substitution of H<sup>+</sup> by an electrophile E<sup>+</sup>
- Mechanistically, it is an addition / elimination process

# 1.2.1. General principles

## Polanyi-Hammond postulate:

When two neighboring species on the reaction coordinate are related in their energy, they are as well in their structure.

TS2 much closer to the  $\sigma$ -complex than to the  $\pi$ -complex

## Applications:

- → Lowering the activation barrier makes a reaction faster
- $\rightarrow$  For S<sub>F</sub>Ar: TS2 looks rather similar to the  $\sigma$ -complex
- $\rightarrow$  Everything stabilizing the  $\sigma$ -complex accelerates the reaction rate
- $\rightarrow$  Everything destabilizing the  $\sigma$ -complex decrease the reaction rate

# 1.2.1. General principles

How can one speed up the reaction? How are the substituents chosen?

Substituents are generally divided in two groups:

- EDG (Electron Donating Group) e.g. –OMe, having +M / +I effect
- EWG (Electron Withdrawing Group) e.g. –COOMe, having -M / -I effect

EDG stabilizes the  $\sigma$ -complex making the reaction faster EWG destabilizes the  $\sigma$ -complex making the reaction slower (how much faster/slower is depending on the substituent properties)

Examples of EDG / EWG:

EDG with +M effect:  $-NR_2$ ,  $-NH_2$ , -OH, -OR

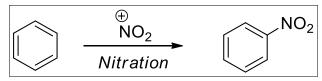

EDG with +I effect: -Alkyl, -SiR<sub>3</sub>

EWG with -M effect: -NO<sub>2</sub>, -COOR, -COR, -CHO, -CN, -SO<sub>3</sub>H, -SO<sub>2</sub>R

EWG with –I effect: -NH<sub>3</sub>+, -NR<sub>3</sub>+, -CF<sub>3</sub>

## 1.2.2.1. Nitration

• Electrophile =  $NO_2^+$ , nitronium ion  $O_{N=0}^+$ 

- Practical methods to generate the electrophile:
  - Mild: autoprotolysis of nitric acid, in concentrated HNO<sub>3</sub> (68%) the amount of NO<sub>2</sub><sup>+</sup> is 3-4%  $2HNO_3 \leftrightarrow NO_2 + H_2O + NO_3$
  - More forcing conditions: mixture of concentrated  $HNO_3$  + concentrated  $H_2SO_4$  (nitrosulfuric acid)  $HNO_3 + 2H_2SO_4 \xrightarrow{+} NO_2 + H_3O^+ + 2HSO_4^-$
  - Strongest conditions: nitroniumtetrafluoroborat salt NO<sub>2</sub><sup>+</sup> BF<sub>4</sub><sup>-</sup>
- Examples for activated substrates: mild conditions are used

5

## 1.2.2.1. Nitration

Examples for non-activated substrates: more forcing conditions are required

$$\begin{array}{c|c} & \text{HNO}_3 \text{ conc} \\ & \text{H}_2 \text{SO}_4 \text{ conc} \\ \hline & \text{non- activated} \\ & \text{substrate} \\ \end{array}$$

• Examples for deactivated substrates:

• Example for an ipso-substitution :

## 1.2.2.1. Nitration

Nitro groups are important synthetic intermediates

Application for dyes, explosives (TNT, picric acid) and basic industrial processes

Most important follow-up reaction: reduction of the nitro group to an aniline with a variety of reducing reagents

# 1.2.2.2. Halogenation: bromination / chlorination

- Electrophile = Br<sup>+</sup> / Cl<sup>+</sup>
  - Fluorination: not controlable
  - lodination: requires promoters
- Practical methods to generate the electrophile:
  - Bromination:  $Br \longrightarrow Br + Or \longrightarrow Br \begin{bmatrix} FeBr_3 \\ Or \\ AlBr_3 \end{bmatrix}$  catalytic
  - Chlorination: CI——CI + AICI<sub>3</sub> → CI AICI<sub>4</sub>

para bromophenol

Typical examples:

substrate

OMe 
$$Br_2$$
,  $CCI_4$   $Br_2$ ,  $CCI_4$   $Br_3$  in this case LA =  $Br_2$ 

- Friedel-Crafts alkylation:  $E^+ = R_3C^+$  (carbenium ion, R=H,alkyl)
- Friedel-Crafts acylation: E<sup>+</sup> = RCO<sup>+</sup> (acylium cation, R=alkyl,aryl)

## 1.2.4.1. Friedel-Crafts alkylation

$$\begin{array}{c|c}
& & \\
\hline
& &$$

- Practical methods to generate the electrophile:
  - From protonation of alkenes: the selectivities of the carbenium ion apply

From alcohols and acid:

From alkyl halides and a Lewis acid:

$$R \leftarrow \frac{X}{-LAX} \rightarrow R$$
 $X = -Br, -I, -CI$ 
 $X =$ 

**Caution**: all aspects of carbenium ions apply:

Stability: Benzylic > allylic > tertiary > secondary > primary methyl

#### First issue:

Wagner-Meerwein type rearrangements prone to isomerization It is difficult to make primary alkyl chains under Wagner-Meerwein

## For example:

**Second issue**: alkyl groups are  $\sigma$ -donors which means:

→ The product is more reactive than the starting material and therefore the reaction is difficult to stop at the mono-alkylation stage

## 1.2.4.2. Friedel-Crafts acylation

$$\frac{R-C=O}{Friedel\ Crafts}$$
Acylation

 Practical methods to generate the electrophile: from acid halogenide (acid chloride or anhydride) and a catalytic amount of a Lewis acid (AlCl<sub>3</sub>)

$$\begin{array}{ccc}
O & AICI_3 & R-C=O \\
R & X & R-C=O
\end{array}$$

$$\begin{array}{cccc}
AICI_3 & R-C=O \\
R-C=O & AICI_2
\end{array}$$

$$\begin{array}{cccc}
X = -F, -CI, -Br, & & \oplus \\
-I, -RCOO & acylium cation
\end{array}$$

11

## Typical examples:

$$Ac_2O$$

$$cat. AlCl_3$$

$$Ac_2O = O$$

$$acetophenone$$

$$Ac_2O = O$$

$$AlCl_3$$

$$AlCl_3$$

$$intramolecular$$

- Important characteristics compared to Friedel-Crafts alkylation:
- → The introduction of a carbonyl group (EWG) decreases the reactivity
- → It prevents the risk of double acylation (however possible for intramolecular

reactions)

alternative 2 steps procedure:

## 1.2.2.4. Sulfonation

$$\begin{array}{c|c}
& & \\
& & \\
\hline
& & \\$$

- Electrophile = SO<sub>3</sub>H<sup>+</sup>, sulfonium ion
- Preparative Methods for Electrophile SO<sub>3</sub>H<sup>+</sup> preparation:
- Autoprotolysis of sulfuric acid

$$2 H_2 SO_4$$
  $\longrightarrow$   $H_2 SO_4$ .  $SO_3 + H_2 O$   $\longrightarrow$   $SO_3 + HSO_4^- + H_3 O^+$ 

More forcing condition: Oleum (mixture of H<sub>2</sub>SO<sub>4</sub>(100%) and SO<sub>3</sub> (up to 30%))

## Representative examples:

B) Historical purification of benzene by removal of thiophene after distillation of crude oil

Electron-rich reacts faster then benzene

Washed out by water

Thiophene-free benzene

# 1.2.2.5. Chlorosulfonation

$$\begin{array}{c}
 & \overset{\oplus}{\text{SO}_2\text{CI}} \\
 & & & \\
\hline
 & & & \\
\hline
 & & & \\
\hline
 & & & \\
\hline
 & & & \\
\hline
 & & & &$$

Reagent: Chlorosulfonic acid CISO<sub>3</sub>H

Representative example: sulfochlorides are synthetically very versatiles

14

# 1.2.2.6. Deuteration by ipso-substitution

## Selective method to introduce a <sup>2</sup>H (D) deuterium label
