2.2.1. Comparison between pyrrole and pyridine

5 membered ring electron rich

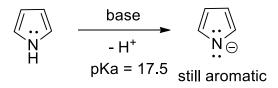

N is not basic (cannot be protonated) lone pair is integral part of the aromatic system

why electron rich?

for benzene: 6 π electrons on 6 atoms

here: 6π electrons on 5 atoms -> higher electron density

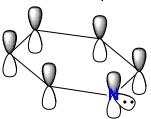

Examples:

Pyrrole can be deprotonated

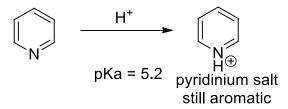

6 membered ring electron poor

N is basic (can be protonated) lone pair available; orthogonal to the aromatic system

why electron poor? 6 π electrons on 6 atoms N has a higher electronegativity than carbon and pulls electrons

Pyridine can be protonated

S_EAr for electron rich heteroaromatics:

- The 2-position is the most activated:

One additionnal mesomeric structure possible by an addition to the 2-position
→ better stabilization

Similar reactivity for furane and thiophene

S_EAr for indole:

- The 3-position is the most activated:

Example: gramine synthesis

$$\begin{array}{c} \text{NHMe}_2 \\ \text{H}_2\text{C=O} \\ \text{EtOH, 20°C} \end{array}$$

$$\begin{array}{c} \text{N} \\ \text{N} \\ \text{H} \end{array}$$

$$\begin{array}{c} \text{Mannich type reaction:} \\ \text{OH} \\ \text{H} \\ \text{H} \end{array}$$

3

N-Alkylation / N-Acylation of indoles or pyrroles:

S_FAr for electron poor heteroaromatics:

Pyridine is electron poor and therefore a very deactivated substrate for S_EAr All positions are deactivated

- The 3 position is the least deactivated one and reacts preferentially:

S_EAr on pyridines require forcing conditions:

Examples:

$$\begin{array}{c|c}
& N_2O_5 \\
\hline
& N_2O_5$$

- Method to address the 2- and 4-position of pyridine with S_FAr
- → oxidation into the more electron rich pyridine N-oxide

PCl₃ selectively reduces the N-Oxyde and regenerate the original pyridine

 Under forcing conditions the nitrogen atom of the pyridine can be alkylated or acylated to give pyridinium salts:

$$\begin{array}{c|c}
 & RX \\
 & \Delta T
\end{array}$$

$$\begin{array}{c}
 & RX \\
 & & \\
 & & \\
 & & \\
 & & \\
\end{array}$$

• Examples:

$$\begin{array}{c|c}
\hline
 & BnI \\
\hline
 & \Delta T
\end{array}$$

$$\begin{array}{c}
\hline
 & O \\
\hline
 & Ph
\end{array}$$

$$\begin{array}{c}
\hline
 & MeO \\
\hline
 & CI
\end{array}$$

$$\begin{array}{c}
\hline
 & MeO \\
\hline
 & O
\end{array}$$

$$\begin{array}{c}
\hline
 & O \\
\hline
 & Ph
\end{array}$$

$$\begin{array}{c}
\hline
 & O \\
 & O \\
\hline
 & O \\
\hline$$

2.2.4. The Tschitschibabin reaction

The Tschitschibabin reaction is equivalent to S_NAr reaction on a pyridine:

• Example for the synthesis of 2-aminopyridine:

$$\begin{array}{c|c}
\hline
 & NaNH_2 \\
\hline
 & \Delta T
\end{array}$$

$$\begin{array}{c|c}
\hline
 & N \oplus NH_2
\end{array}$$

$$\begin{array}{c|c}
\hline
 & -NaH
\end{array}$$

$$\begin{array}{c|c}
\hline
 & NH_2
\end{array}$$

2.3.1. Synthesis of five-membered ring heteroaromatics

Recapitulation of some relevant carbonyl chemistry
