## General nonsmooth problems

- We will show that the restricted template captures the familiar composite minimization:

$$\min_{\mathbf{x} \in \mathbb{R}^p} f(\mathbf{x}) + g(\mathbf{Ax}).$$

- ▶  $f, g$  are convex, nonsmooth functions; and  $\mathbf{A}$  is a linear operator.

### Examples

- ▶  $g(\mathbf{Ax}) = \|\mathbf{Ax} - \mathbf{b}\|_1$  or  $g(\mathbf{Ax}) = \|\mathbf{Ax} - \mathbf{b}\|_2^2$ .
- ▶  $g(\mathbf{Ax}) = \delta_{\{\mathbf{b}\}}(\mathbf{Ax})$ , where  $\delta_{\{\mathbf{b}\}}(\mathbf{Ax}) = \begin{cases} 0, & \text{if } \mathbf{Ax} = \mathbf{b}, \\ +\infty, & \text{if } \mathbf{Ax} \neq \mathbf{b}. \end{cases}$

- Observations:**
- The indicator example covers constrained problems, such as  $\min_{\mathbf{x} \in \mathcal{X}} \{f(\mathbf{x}) : \mathbf{Ax} = \mathbf{b}\}$ .
  - We need a tool, called Fenchel conjugation, to reveal the underlying minimax problem.

# Conjugation of functions

- Idea: Represent a convex function in max-form:

## Definition

Let  $\mathcal{Q}$  be a Euclidean space and  $\mathcal{Q}^*$  be its dual space. Given a proper, closed and convex function  $f : \mathcal{Q} \rightarrow \mathbb{R} \cup \{+\infty\}$ , the function  $f^* : \mathcal{Q}^* \rightarrow \mathbb{R} \cup \{+\infty\}$  such that

$$f^*(\mathbf{y}) = \sup_{\mathbf{x} \in \text{dom}(f)} \{ \mathbf{y}^T \mathbf{x} - f(\mathbf{x}) \}$$

is called the Fenchel conjugate (or conjugate) of  $f$ .

- Observations:**
- $\mathbf{y}$  : slope of the hyperplane
  - $-f^*(\mathbf{y})$  : intercept of the hyperplane

**Figure:** The conjugate function  $f^*(\mathbf{y})$  is the maximum gap between the linear function  $\mathbf{x}^T \mathbf{y}$  (red line) and  $f(\mathbf{x})$ .

# Conjugation of functions

## Definition

Given a **proper, closed and convex function**  $f : \mathcal{Q} \rightarrow \mathbb{R} \cup \{+\infty\}$ , the function  $f^* : \mathcal{Q}^* \rightarrow \mathbb{R} \cup \{+\infty\}$  such that

$$f^*(\mathbf{y}) = \sup_{\mathbf{x} \in \text{dom}(f)} \left\{ \mathbf{y}^T \mathbf{x} - f(\mathbf{x}) \right\}$$

is called the **Fenchel conjugate** (or conjugate) of  $f$ .

# Conjugation of functions

## Definition

Given a **proper, closed and convex function**  $f : \mathcal{Q} \rightarrow \mathbb{R} \cup \{+\infty\}$ , the function  $f^* : \mathcal{Q}^* \rightarrow \mathbb{R} \cup \{+\infty\}$  such that

$$f^*(\mathbf{y}) = \sup_{\mathbf{x} \in \text{dom}(f)} \{ \mathbf{y}^T \mathbf{x} - f(\mathbf{x}) \}$$

is called the **Fenchel conjugate** (or conjugate) of  $f$ .

## Properties

- $f^*$  is a **convex** and lower semicontinuous function by construction as the supremum of affine functions of  $\mathbf{y}$ .
- The **conjugate** of the **conjugate** of a convex function  $f$  is the same function  $f$ ; i.e.,  $f^{**} = f$  for  $f \in \mathcal{F}(\mathcal{Q})$ .
- The **conjugate** of the **conjugate** of a non-convex function  $f$  is its lower convex envelope when  $\mathcal{Q}$  is compact:
  - ▶  $f^{**}(\mathbf{x}) = \sup \{ g(\mathbf{x}) : g \text{ is convex and } g \leq f, \forall \mathbf{x} \in \mathcal{Q} \}$ .
- For closed convex  $f$ ,  $\mu$ -strong convexity w.r.t.  $\|\cdot\|$  is equivalent to  $\frac{1}{\mu}$  smoothness of  $f^*$  w.r.t.  $\|\cdot\|_*$ .
  - ▶ Recall dual norm:  $\|\mathbf{y}\|_* = \sup_{\mathbf{x}} \{ \langle \mathbf{x}, \mathbf{y} \rangle : \|\mathbf{x}\| \leq 1 \}$ .
  - ▶ See for example Theorem 3 in [12].

## Examples

### $\ell_2$ -norm-squared

$$f(\mathbf{x}) = \frac{\lambda}{2} \|\mathbf{x}\|^2 \Rightarrow f^*(\mathbf{y}) = \max_{\mathbf{x}} \langle \mathbf{y}, \mathbf{x} \rangle - \frac{\lambda}{2} \|\mathbf{x}\|^2.$$

○ Take the derivative and equate to 0:  $0 = \mathbf{y} - \lambda \mathbf{x} \iff \mathbf{x}^* = \frac{1}{\lambda} \mathbf{y} \iff f^*(\mathbf{y}) = \frac{1}{\lambda} \|\mathbf{y}\|^2 - \frac{1}{2\lambda} \|\mathbf{y}\|^2 = \frac{1}{2\lambda} \|\mathbf{y}\|^2.$

### $\ell_1$ -norm

$$f(\mathbf{x}) = \lambda \|\mathbf{x}\|_1 \Rightarrow f^*(\mathbf{y}) = \max_{\mathbf{x}} \langle \mathbf{y}, \mathbf{x} \rangle - \lambda \|\mathbf{x}\|_1.$$

○ By definition of the  $\ell_1$ -norm:  $f^*(\mathbf{y}) = \max_{\mathbf{x}} \sum_{i=1}^n y_i x_i - \lambda |x_i| = \max_{\mathbf{x}} \sum_{i=1}^n y_i \text{sign}(x_i) |x_i| - \lambda |x_i|.$

○ By inspection:

► If all  $|y_i| \leq \lambda$ , then  $\forall i, (y_i \text{sign}(x_i) - \lambda) |x_i| \leq 0$ . Taking  $\mathbf{x} = 0$  gives the maximum value:  $f^*(\mathbf{y}) = 0$ .

► If for at least one  $i, |y_i| > \lambda$ ,  $(y_i \text{sign}(x_i) - \lambda) |x_i| \rightarrow +\infty$  as  $|x_i| \rightarrow +\infty$ .

○  $f^*(\mathbf{y}) = \delta_{\mathbf{y}: \|\cdot\|_\infty \leq \lambda}(\mathbf{y}) = \begin{cases} 0, & \text{if } \|\mathbf{y}\|_\infty \leq \lambda \\ +\infty, & \text{if } \|\mathbf{y}\|_\infty > \lambda \end{cases}$

**Remark:**

○ See advanced material at the end for non-convex examples, such as  $f(\mathbf{x}) = \|\mathbf{x}\|_0$ .

## General nonsmooth problems

$$\min_{\mathbf{x} \in \mathbb{R}^p} f(\mathbf{x}) + g(\mathbf{Ax})$$

- By Fenchel-conjugation, we have  $g(\mathbf{Ax}) = \max_{\mathbf{y}} \langle \mathbf{Ax}, \mathbf{y} \rangle - g^*(\mathbf{y})$ , where  $g^*$  is the conjugate of  $g$ .
- Min-max formulation:

$$\min_{\mathbf{x} \in \mathbb{R}^p} f(\mathbf{x}) + g(\mathbf{Ax}) = \min_{\mathbf{x} \in \mathbb{R}^p} \max_{\mathbf{y}} \{ \Phi(\mathbf{x}, \mathbf{y}) := f(\mathbf{x}) + \langle \mathbf{Ax}, \mathbf{y} \rangle - g^*(\mathbf{y}) \}$$

### An example with linear constraints

$$\circ \text{ If } g(\mathbf{Ax}) = \delta_{\{\mathbf{b}\}}(\mathbf{Ax}) = \begin{cases} 0, & \text{if } \mathbf{Ax} = \mathbf{b}, \\ +\infty, & \text{if } \mathbf{Ax} \neq \mathbf{b}, \end{cases}$$

$$\Rightarrow g^*(\mathbf{y}) = \max_{\mathbf{x}} \langle \mathbf{y}, \mathbf{x} \rangle - \delta_{\{\mathbf{b}\}}(\mathbf{x}) = \max_{\mathbf{x}: \mathbf{x}=\mathbf{b}} \langle \mathbf{y}, \mathbf{x} \rangle = \langle \mathbf{y}, \mathbf{b} \rangle.$$

- We reach the minimax formulation (or the so-called “Lagrangian”) via conjugation:

$$\min_{\mathbf{x}} \{ f(\mathbf{x}) : \mathbf{Ax} = \mathbf{b} \} = \min_{\mathbf{x}} f(\mathbf{x}) + g(\mathbf{Ax}) = \min_{\mathbf{x}} \max_{\mathbf{y}} f(\mathbf{x}) + \langle \mathbf{Ax} - \mathbf{b}, \mathbf{y} \rangle.$$

## A special case in minimax optimization

### Bilinear min-max template

$$\min_{\mathbf{x} \in \mathcal{X}} \max_{\mathbf{y} \in \mathcal{Y}} f(\mathbf{x}) + \langle \mathbf{A}\mathbf{x}, \mathbf{y} \rangle - h(\mathbf{y}),$$

where  $\mathcal{X} \subseteq \mathbb{R}^p$  and  $\mathcal{Y} \subseteq \mathbb{R}^n$ .

- ▶  $f: \mathcal{X} \rightarrow \mathbb{R}$  is convex.
- ▶  $h: \mathcal{Y} \rightarrow \mathbb{R}$  is convex.

## Example: Sparse recovery

An example from sparseland  $\mathbf{b} = \mathbf{A}\mathbf{x}^\dagger + \mathbf{w}$ : constrained formulation

The basis pursuit denoising (BPDN) formulation is given by

$$\mathbf{x}^\star \in \arg \min_{\mathbf{x} \in \mathbb{R}^p} \{ \|\mathbf{x}\|_1 : \|\mathbf{A}\mathbf{x} - \mathbf{b}\|_2 \leq \|\mathbf{w}\|_2, \|\mathbf{x}\|_\infty \leq 1 \}. \quad (\text{BPDN})$$

A primal problem prototype

$$f^\star := \min_{\mathbf{x} \in \mathbb{R}^p} \left\{ f(\mathbf{x}) : \mathbf{A}\mathbf{x} - \mathbf{b} \in \mathcal{K}, \mathbf{x} \in \mathcal{X} \right\},$$

The above template captures BPDN formulation with

- ▶  $f(\mathbf{x}) = \|\mathbf{x}\|_1$ .
- ▶  $\mathcal{K} = \{\|\mathbf{u}\| \in \mathbb{R}^n : \|\mathbf{u}\| \leq \|\mathbf{w}\|_2\}$ .
- ▶  $\mathcal{X} = \{\mathbf{x} \in \mathbb{R}^p : \|\mathbf{x}\|_\infty \leq 1\}$ .

## An alternative formulation

### A primal problem prototype

$$f^* := \min_{\mathbf{x} \in \mathbb{R}^p} \left\{ f(\mathbf{x}) : \mathbf{Ax} - \mathbf{b} \in \mathcal{K}, \mathbf{x} \in \mathcal{X} \right\}, \quad (1)$$

- ▶  $f$  is a proper, closed and **convex** function
- ▶  $\mathcal{X}$  and  $\mathcal{K}$  are nonempty, closed **convex** sets
- ▶  $\mathbf{A} \in \mathbb{R}^{n \times p}$  and  $\mathbf{b} \in \mathbb{R}^n$  are known
- ▶ An optimal solution  $\mathbf{x}^*$  to (1) satisfies  $f(\mathbf{x}^*) = f^*$ ,  $\mathbf{Ax}^* - \mathbf{b} \in \mathcal{K}$  and  $\mathbf{x}^* \in \mathcal{X}$

### A simplified template without loss of generality

$$f^* := \min_{\mathbf{x} \in \mathbb{R}^p} \left\{ f(\mathbf{x}) : \mathbf{Ax} = \mathbf{b} \right\}, \quad (2)$$

- ▶  $f$  is a proper, closed and **convex** function
- ▶  $\mathbf{A} \in \mathbb{R}^{n \times p}$  and  $\mathbf{b} \in \mathbb{R}^n$  are known
- ▶ An optimal solution  $\mathbf{x}^*$  to (2) satisfies  $f(\mathbf{x}^*) = f^*$ ,  $\mathbf{Ax}^* = \mathbf{b}$

## Reformulation between templates

### A primal problem template

$$\min_{\mathbf{x} \in \mathbb{R}^p} \left\{ f(\mathbf{x}) : \mathbf{Ax} - \mathbf{b} \in \mathcal{K}, \mathbf{x} \in \mathcal{X} \right\}.$$

First step: Let  $\mathbf{r}_1 = \mathbf{Ax} - \mathbf{b} \in \mathbb{R}^n$  and  $\mathbf{r}_2 = \mathbf{x} \in \mathbb{R}^p$ .

$$\min_{\mathbf{x}, \mathbf{r}_1, \mathbf{r}_2} \left\{ f(\mathbf{x}) : \mathbf{r}_1 \in \mathcal{K}, \mathbf{r}_2 \in \mathcal{X}, \mathbf{Ax} - \mathbf{b} = \mathbf{r}_1, \mathbf{x} = \mathbf{r}_2 \right\}.$$

- Define  $\mathbf{z} = \begin{bmatrix} \mathbf{x} \\ \mathbf{r}_1 \\ \mathbf{r}_2 \end{bmatrix} \in \mathbb{R}^{2p+n}$ ,  $\bar{\mathbf{A}} = \begin{bmatrix} \mathbf{A} & -\mathbf{I}_{n \times n} & \mathbf{0}_{n \times p} \\ \mathbf{I}_{p \times p} & \mathbf{0}_{p \times n} & -\mathbf{I}_{p \times p} \end{bmatrix}$ ,  $\bar{\mathbf{b}} = \begin{bmatrix} \mathbf{b} \\ \mathbf{0} \end{bmatrix}$ ,  $\bar{f}(\mathbf{z}) = f(\mathbf{x}) + \delta_{\mathcal{K}}(\mathbf{r}_1) + \delta_{\mathcal{X}}(\mathbf{r}_2)$ ,  
where  $\delta_{\mathcal{X}}(\mathbf{x}) = 0$ , if  $\mathbf{x} \in \mathcal{X}$ , and  $\delta_{\mathcal{X}}(\mathbf{x}) = +\infty$ , o/w.

### The simplified template

$$\min_{\mathbf{z} \in \mathbb{R}^{2p+n}} \left\{ \bar{f}(\mathbf{z}) : \bar{\mathbf{A}}\mathbf{z} = \bar{\mathbf{b}} \right\}.$$

## From constrained formulation back to minimax

### A general template

$$\min_{\mathbf{x} \in \mathbb{R}^p} \{f(\mathbf{x}) : \mathbf{Ax} = \mathbf{b}\}.$$

Other examples:

- ▶ **Standard convex optimization** formulations: *linear programming, convex quadratic programming, second order cone programming, semidefinite programming and geometric programming.*
- ▶ **Reformulations** of existing unconstrained problems via **convex splitting**: *composite convex minimization, consensus optimization, ...*

### Formulating as min-max

$$\max_{\mathbf{y} \in \mathbb{R}^n} \langle \mathbf{y}, \mathbf{Ax} - \mathbf{b} \rangle = \begin{cases} 0, & \text{if } \mathbf{Ax} = \mathbf{b}, \\ +\infty, & \text{if } \mathbf{Ax} \neq \mathbf{b}. \end{cases}$$

$$\min_{\mathbf{x} \in \mathbb{R}^p} \{f(\mathbf{x}) : \mathbf{Ax} = \mathbf{b}\} = \min_{\mathbf{x} \in \mathbb{R}^p} \max_{\mathbf{y} \in \mathbb{R}^n} \{ \Phi(\mathbf{x}, \mathbf{y}) := f(\mathbf{x}) + \langle \mathbf{y}, \mathbf{Ax} - \mathbf{b} \rangle \}$$

## Dual problem

$$\min_{\mathbf{x} \in \mathbb{R}^p} \{f(\mathbf{x}) : \mathbf{Ax} = \mathbf{b}\} = \min_{\mathbf{x} \in \mathbb{R}^p} \max_{\mathbf{y} \in \mathbb{R}^n} \{ \Phi(\mathbf{x}, \mathbf{y}) := f(\mathbf{x}) + \langle \mathbf{y}, \mathbf{Ax} - \mathbf{b} \rangle \}$$

- We define the dual problem

$$\max_{\mathbf{y} \in \mathbb{R}^n} d(\mathbf{y}) := \max_{\mathbf{y} \in \mathbb{R}^n} \underbrace{\left\{ \min_{\mathbf{x} \in \mathbb{R}^p} f(\mathbf{x}) + \langle \mathbf{y}, \mathbf{Ax} - \mathbf{b} \rangle \right\}}_{d(\mathbf{y})}.$$

### Concavity of dual problem

Even if  $f(\mathbf{x})$  is not convex,  $d(\mathbf{y})$  is concave:

- ▶ For each  $\mathbf{x}$ ,  $d(\mathbf{y})$  is linear; i.e., it is both convex and concave.
- ▶ Pointwise minimum of concave functions is still concave.

**Remark:**

- If we can exchange min and max, we obtain a **concave** maximization problem.

## Example: Nonsmoothness of the dual function

- Consider a constrained convex problem:

$$\begin{aligned} \min_{\mathbf{x} \in \mathbb{R}^3} \quad & \{f(\mathbf{x}) := x_1^2 + 2x_2\}, \\ \text{s.t.} \quad & 2x_3 - x_1 - x_2 = 1, \\ & \mathbf{x} \in \mathcal{X} := [-2, 2] \times [-2, 2] \times [0, 2]. \end{aligned}$$

- The **dual function** is **concave** and **nonsmooth** as written and then illustrated below.

$$d(\lambda) := \min_{\mathbf{x} \in \mathcal{X}} \{x_1^2 + 2x_2 + \lambda(2x_3 - x_1 - x_2 - 1)\}$$

## Exchanging min and max: A dangerous proposal

- Weak duality:

$$\underbrace{\max_{\mathbf{y} \in \mathbb{R}^n} d(\mathbf{y})}_{\text{Dual problem}} =: \boxed{\max_{\mathbf{y} \in \mathbb{R}^n} \min_{\mathbf{x} \in \mathbb{R}^p} \Phi(\mathbf{x}, \mathbf{y}) \leq \min_{\mathbf{x} \in \mathbb{R}^p} \max_{\mathbf{y} \in \mathbb{R}^n} \Phi(\mathbf{x}, \mathbf{y})} = \underbrace{\min_{\mathbf{x} \in \mathbb{R}^p} \{f(\mathbf{x}) : \mathbf{Ax} = \mathbf{b}\}}_{\text{Primal problem}} = \begin{cases} f^*, & \text{if } \mathbf{Ax} = \mathbf{b} \\ +\infty, & \text{if } \mathbf{Ax} \neq \mathbf{b} \end{cases}$$

## A proof of weak duality

$$f^* := \min_{\mathbf{x} \in \mathbb{R}^p} \left\{ f(\mathbf{x}) : \mathbf{Ax} = \mathbf{b} \right\} = \min_{\mathbf{x} \in \mathbb{R}^p} \max_{\mathbf{y} \in \mathbb{R}^n} \left\{ \Phi(\mathbf{x}, \mathbf{y}) := f(\mathbf{x}) + \langle \mathbf{y}, \mathbf{Ax} - \mathbf{b} \rangle \right\}$$

- Since  $\mathbf{Ax}^* = \mathbf{b}$ , it holds for any  $\mathbf{y}$

$$\begin{aligned} \Phi(\mathbf{x}^*, \mathbf{y}) &= f^* = f(\mathbf{x}^*) + \langle \mathbf{y}, \mathbf{Ax}^* - \mathbf{b} \rangle \\ &\geq \min_{\mathbf{x} \in \mathbb{R}^p} \left\{ f(\mathbf{x}) + \langle \mathbf{y}, \mathbf{Ax} - \mathbf{b} \rangle \right\} \\ &= \min_{\mathbf{x} \in \mathbb{R}^p} \Phi(\mathbf{x}, \mathbf{y}). \end{aligned}$$

- Take maximum of both sides in  $\mathbf{y}$  and note that  $f^*$  is independent of  $\mathbf{y}$ :

$$f^* = \min_{\mathbf{x} \in \mathbb{R}^p} \max_{\mathbf{y} \in \mathbb{R}^n} \Phi(\mathbf{x}, \mathbf{y}) \geq \max_{\mathbf{y} \in \mathbb{R}^n} \min_{\mathbf{x} \in \mathbb{R}^p} \Phi(\mathbf{x}, \mathbf{y}) =: \max_{\mathbf{y} \in \mathbb{R}^n} d(\mathbf{y}) = d^*.$$

# Strong duality and saddle points

## Strong duality

$$f^* = f(\mathbf{x}^*) = \min_{\mathbf{x} \in \mathbb{R}^p} \max_{\mathbf{y} \in \mathbb{R}^n} \Phi(\mathbf{x}, \mathbf{y}) = \max_{\mathbf{y} \in \mathbb{R}^n} \min_{\mathbf{x} \in \mathbb{R}^p} \Phi(\mathbf{x}, \mathbf{y}) =: \max_{\mathbf{y} \in \mathbb{R}^n} d(\mathbf{y}) = d^*.$$

Under strong duality and assuming existence of  $\mathbf{x}^*$ ,  $\Phi(\mathbf{x}, \mathbf{y})$  has a saddle point. We have primal and dual optimal values coincide, i.e.,  $f^* = d^*$ .

# Strong duality and saddle points

## Strong duality

$$f^* = f(\mathbf{x}^*) = \min_{\mathbf{x} \in \mathbb{R}^p} \max_{\mathbf{y} \in \mathbb{R}^n} \Phi(\mathbf{x}, \mathbf{y}) = \max_{\mathbf{y} \in \mathbb{R}^n} \min_{\mathbf{x} \in \mathbb{R}^p} \Phi(\mathbf{x}, \mathbf{y}) =: \max_{\mathbf{y} \in \mathbb{R}^n} d(\mathbf{y}) = d^*.$$

Under strong duality and assuming existence of  $\mathbf{x}^*$ ,  $\Phi(\mathbf{x}, \mathbf{y})$  has a saddle point. We have primal and dual optimal values coincide, i.e.,  $f^* = d^*$ .

## Recall saddle point / LNE

A point  $(\mathbf{x}^*, \mathbf{y}^*) \in \mathbb{R}^p \times \mathbb{R}^n$  is called a **saddle point** of  $\Phi$  if

$$\Phi(\mathbf{x}^*, \mathbf{y}) \leq \Phi(\mathbf{x}^*, \mathbf{y}^*) \leq \Phi(\mathbf{x}, \mathbf{y}^*), \quad \forall \mathbf{x} \in \mathbb{R}^p, \mathbf{y} \in \mathbb{R}^n.$$

## Toy example: Strong duality

### Primal problem

- Consider the following primal minimization problem:  $\min_{\mathbf{x}} P(\mathbf{x}) := f(\mathbf{x}) + g(\mathbf{x}) := \frac{1}{2}\|\mathbf{x}\|^2 + \|\mathbf{x}\|_1$
- Using conjugation and strong duality

$$\begin{aligned} P(\mathbf{x}^*) &= \min_{\mathbf{x}} P(\mathbf{x}) = \min_{\mathbf{x}} \max_{\mathbf{y}} f(\mathbf{x}) + \langle \mathbf{x}, \mathbf{y} \rangle - g^*(\mathbf{y}), && \text{by conjugation} \\ &= \max_{\mathbf{y}} -g^*(\mathbf{y}) + \min_{\mathbf{x}} f(\mathbf{x}) + \langle \mathbf{x}, \mathbf{y} \rangle, && \text{by changing min-max} \\ &= \max_{\mathbf{y}} -g^*(\mathbf{y}) - \max_{\mathbf{x}} \langle \mathbf{x}, -\mathbf{y} \rangle - f(\mathbf{x}), && \text{by } \min f = -\max -f \\ &= \max_{\mathbf{y}} -g^*(\mathbf{y}) - f^*(-\mathbf{y}), && \text{by conjugation.} \end{aligned}$$

### Dual problem

- Dual problem:  $d^* = \max_{\mathbf{y}} d(\mathbf{y}) = -g^*(\mathbf{y}) - f^*(-\mathbf{y})$
- Recall  $f^*(-\mathbf{y}) = \frac{1}{2}\|\mathbf{y}\|^2$  and  $g^*(\mathbf{y}) = \delta_{\mathbf{y}: \|\mathbf{y}\|_\infty \leq 1}(\mathbf{y})$ .

## Toy example: Strong duality

$$\text{Primal problem: } \min_{\mathbf{x}} P(\mathbf{x}) = \frac{1}{2} \|\mathbf{x}\|^2 + \|\mathbf{x}\|_1$$

$$\text{Dual problem: } \max_{\mathbf{y}} -\frac{1}{2} \|\mathbf{y}\|^2 - \delta_{\mathbf{y}: \|\mathbf{y}\|_\infty \leq 1}(\mathbf{y})$$

$$d(\mathbf{y}) = \begin{cases} -\frac{1}{2} \|\mathbf{y}\|^2, & \text{if } \|\mathbf{y}\|_\infty \leq 1 \\ -\infty, & \text{if } \|\mathbf{y}\|_\infty > 1 \end{cases}$$

## Back to convex-concave: Necessary and sufficient condition for strong duality

- Existence of a saddle point is not automatic even in convex-concave setting!
- Recall the minimax template:

$$\min_{\mathbf{x} \in \mathbb{R}^p} \max_{\mathbf{y} \in \mathbb{R}^n} \{ \Phi(\mathbf{x}, \mathbf{y}) := f(\mathbf{x}) + \langle \mathbf{y}, \mathbf{Ax} - \mathbf{b} \rangle \}$$

### Theorem (Necessary and sufficient optimality condition)

Under the **Slater's condition**:  $\text{relint}(\text{dom } f) \cap \{ \mathbf{x} : \mathbf{Ax} = \mathbf{b} \} \neq \emptyset$ , strong duality holds, where the primal and dual problems are given by

$$f^* := \begin{cases} \min_{\mathbf{x} \in \mathbb{R}^p} & f(\mathbf{x}) \\ \text{s.t.} & \mathbf{Ax} = \mathbf{b}, \end{cases} \quad \text{and} \quad d^* := \max_{\mathbf{y} \in \mathbb{R}^n} d(\mathbf{y}).$$

Remarks:

- By definition of  $f^*$  and  $d^*$ , we always have  $d^* \leq f^*$  (**weak duality**).
- If a primal solution exists and the Slater's condition holds, we have  $d^* = f^*$  (**strong duality**).

## Slater's qualification condition

- Denote  $\text{relint}(\text{dom } f)$  the **relative interior** of the domain.
- The **Slater condition** requires

$$\text{relint}(\text{dom } f) \cap \{\mathbf{x} : \mathbf{Ax} = \mathbf{b}\} \neq \emptyset. \quad (3)$$

### Special cases

- ▶ If  $\text{dom } f = \mathbb{R}^p$ , then  $(3) \Leftrightarrow \boxed{\exists \bar{\mathbf{x}} : \mathbf{A}\bar{\mathbf{x}} = \mathbf{b}}$ .
- ▶ If  $\text{dom } f = \mathbb{R}^p$  and instead of  $\mathbf{Ax} = \mathbf{b}$ , we have the feasible set  $\{\mathbf{x} : h(\mathbf{x}) \leq 0\}$ , where  $h$  is  $\mathbb{R}^p \rightarrow \mathbb{R}^q$  is convex, then

$$(3) \Leftrightarrow \boxed{\exists \bar{\mathbf{x}} : h(\bar{\mathbf{x}}) < 0.}$$

## Example: Slater's condition

### Example

Let us consider solving  $\min_{\mathbf{x} \in \mathcal{D}_\alpha} f(\mathbf{x})$  and so the feasible set is  $\mathcal{D}_\alpha := \mathcal{X} \cap \mathcal{A}_\alpha$ , where

$$\mathcal{X} := \{\mathbf{x} \in \mathbb{R}^2 : x_1^2 + x_2^2 \leq 1\}, \quad \mathcal{A}_\alpha := \{\mathbf{x} \in \mathbb{R}^2 : x_1 + x_2 = \alpha\},$$

where  $\alpha \in \mathbb{R}$ .

## Example: Slater's condition

### Example

Let us consider solving  $\min_{\mathbf{x} \in \mathcal{D}_\alpha} f(\mathbf{x})$  and so the feasible set is  $\mathcal{D}_\alpha := \mathcal{X} \cap \mathcal{A}_\alpha$ , where

$$\mathcal{X} := \{\mathbf{x} \in \mathbb{R}^2 : x_1^2 + x_2^2 \leq 1\}, \quad \mathcal{A}_\alpha := \{\mathbf{x} \in \mathbb{R}^2 : x_1 + x_2 = \alpha\},$$

where  $\alpha \in \mathbb{R}$ .

### Two cases where Slater's condition holds and does not hold

$\mathcal{D}_{1/\sqrt{2}}$  satisfies Slater's condition –  $\mathcal{D}_{\sqrt{2}}$  does not satisfy Slater's condition

## Performance of optimization algorithms

$$f^* := \min_{\mathbf{x} \in \mathbb{R}^p} \left\{ f(\mathbf{x}) : \mathbf{Ax} = \mathbf{b}, \right\}, \quad (\text{Affine-Constrained})$$

### Exact vs. approximate solutions

- ▶ Computing an **exact solution**  $\mathbf{x}^*$  to (Affine-Constrained) is **impracticable**
- ▶ Algorithms seek  $\mathbf{x}_\epsilon^*$  that **approximates**  $\mathbf{x}^*$  up to  $\epsilon$  in some sense

### A performance metric: Time-to-reach $\epsilon$

time-to-reach  $\epsilon$  = number of iterations to reach  $\epsilon$   $\times$  per iteration time

A key issue: Number of iterations to reach  $\epsilon$

**The notion of  $\epsilon$ -accuracy is elusive in constrained optimization!**

## Numerical $\epsilon$ -accuracy

- **Unconstrained case:** All iterates are feasible (no advantage from infeasibility)!

$$f(\mathbf{x}_\epsilon^*) - f^* \leq \epsilon$$

$$f^* = \min_{\mathbf{x} \in \mathbb{R}^p} f(\mathbf{x})$$

- **Constrained case:** We need to also measure the infeasibility of the iterates!

$$f^* - f(\mathbf{x}_\epsilon^*) \leq \epsilon \quad !!!$$

$$f^* = \min_{\mathbf{x} \in \mathbb{R}^p} \left\{ f(\mathbf{x}) : \mathbf{Ax} = \mathbf{b} \right\}$$

(4)

### Our definition of $\epsilon$ -accurate solutions [16]

Given a numerical tolerance  $\epsilon \geq 0$ , a point  $\mathbf{x}_\epsilon^* \in \mathbb{R}^p$  is called an  $\epsilon$ -solution of (4) if

$$\begin{cases} f(\mathbf{x}_\epsilon^*) - f^* & \leq \epsilon \text{ (objective residual),} \\ \|\mathbf{Ax}_\epsilon^* - \mathbf{b}\| & \leq \epsilon \text{ (feasibility gap),} \end{cases}$$

- When  $\mathbf{x}^*$  is unique, we can also obtain  $\|\mathbf{x}_\epsilon^* - \mathbf{x}^*\| \leq \epsilon$  (iterate residual).

## Numerical $\epsilon$ -accuracy

### Constrained problems

Given a numerical tolerance  $\epsilon \geq 0$ , a point  $\mathbf{x}_\epsilon^* \in \mathbb{R}^p$  is called an  $\epsilon$ -solution of (4) if

$$\begin{cases} f(\mathbf{x}_\epsilon^*) - f^* & \leq \epsilon \text{ (objective residual),} \\ \|\mathbf{A}\mathbf{x}_\epsilon^* - \mathbf{b}\| & \leq \epsilon \text{ (feasibility gap),} \end{cases}$$

► When  $\mathbf{x}^*$  is unique, we can also obtain  $\|\mathbf{x}_\epsilon^* - \mathbf{x}^*\| \leq \epsilon$  (iterate residual).

### General minimax problems

Since duality gap is 0 at the solution, we measure the primal-dual gap

$$\text{Gap}(\bar{\mathbf{x}}, \bar{\mathbf{y}}) = \max_{\mathbf{y} \in \mathcal{Y}} \Phi(\bar{\mathbf{x}}, \mathbf{y}) - \min_{\mathbf{x} \in \mathcal{X}} \Phi(\mathbf{x}, \bar{\mathbf{y}}) \leq \epsilon. \quad (5)$$

#### Remarks:

- $\epsilon$  can be different for the objective, feasibility gap, or the iterate residual.
- It is easy to show  $\text{Gap}(\mathbf{x}, \mathbf{y}) \geq 0$  and  $\text{Gap}(\bar{\mathbf{x}}, \bar{\mathbf{y}}) = 0$  iff  $(\bar{\mathbf{x}}, \bar{\mathbf{y}})$  is a saddle point.

## Primal-dual gap function for nonsmooth minimization

$$\min_{\mathbf{x} \in \mathcal{X}} f(\mathbf{x}) + g(\mathbf{Ax}) = \min_{\mathbf{x} \in \mathcal{X}} \max_{\mathbf{y} \in \mathcal{Y}} \underbrace{f(\mathbf{x}) + \langle \mathbf{Ax}, \mathbf{y} \rangle - g^*(\mathbf{y})}_{\Phi(\mathbf{x}, \mathbf{y})} = \max_{\mathbf{y} \in \mathcal{Y}} \min_{\mathbf{x} \in \mathcal{X}} f(\mathbf{x}) + \langle \mathbf{Ax}, \mathbf{y} \rangle - g^*(\mathbf{y})$$

- Primal problem:  $\min_{\mathbf{x} \in \mathcal{X}} P(\mathbf{x})$  where

$$P(\mathbf{x}) = \max_{\mathbf{y} \in \mathcal{Y}} \Phi(\mathbf{x}, \mathbf{y}).$$

- Dual problem:  $\max_{\mathbf{y} \in \mathcal{Y}} d(\mathbf{y})$  where

$$d(\mathbf{y}) = \min_{\mathbf{x} \in \mathcal{X}} \Phi(\mathbf{x}, \mathbf{y}).$$

- The primal-dual gap, i.e.,  $\text{Gap}(\bar{\mathbf{x}}, \bar{\mathbf{y}})$ , is literally (primal value at  $\bar{\mathbf{x}}$ ) – (dual value at  $\bar{\mathbf{y}}$ ):

$$\text{Gap}(\bar{\mathbf{x}}, \bar{\mathbf{y}}) = P(\bar{\mathbf{x}}) - d(\bar{\mathbf{y}}) = \max_{\mathbf{y} \in \mathcal{Y}} \Phi(\bar{\mathbf{x}}, \mathbf{y}) - \min_{\mathbf{x} \in \mathcal{X}} \Phi(\mathbf{x}, \bar{\mathbf{y}}).$$

## Toy example for nonnegativity of gap

- $P(\mathbf{x}) = \frac{1}{2}\|\mathbf{x}\|^2 + \|\mathbf{x}\|_1$

- $d(\mathbf{y}) = -\frac{1}{2}\|\mathbf{y}\|^2 - \delta_{\mathbf{y}: \|\mathbf{y}\|_\infty \leq 1}(\mathbf{y})$

Recall the indicator function

$$\delta_{\mathbf{y}: \|\mathbf{y}\|_\infty \leq 1}(\mathbf{y}) = \begin{cases} 0, & \text{if } \|\mathbf{y}\|_\infty \leq 1 \\ +\infty, & \text{if } \|\mathbf{y}\|_\infty > 1 \end{cases}$$

## Primal-dual gap function in the general case

$$\min_{\mathbf{x} \in \mathcal{X}} \max_{\mathbf{y} \in \mathcal{Y}} \Phi(\mathbf{x}, \mathbf{y}) = \max_{\mathbf{y} \in \mathcal{Y}} \min_{\mathbf{x} \in \mathcal{X}} \Phi(\mathbf{x}, \mathbf{y})$$

- Saddle point  $(\mathbf{x}^*, \mathbf{y}^*)$  is such that  $\forall \mathbf{x} \in \mathbb{R}^p, \forall \mathbf{y} \in \mathbb{R}^n$ :

$$\Phi(\mathbf{x}^*, \mathbf{y}) \stackrel{(*)}{\leq} \Phi(\mathbf{x}^*, \mathbf{y}^*) \stackrel{(**)}{\leq} \Phi(\mathbf{x}, \mathbf{y}^*).$$

- Nonnegativity of Gap:

$$\begin{aligned} \text{Gap}(\bar{\mathbf{x}}, \bar{\mathbf{y}}) &= \max_{\mathbf{y} \in \mathcal{Y}} \Phi(\bar{\mathbf{x}}, \mathbf{y}) - \min_{\mathbf{x} \in \mathcal{X}} \Phi(\mathbf{x}, \bar{\mathbf{y}}) \\ &\geq \Phi(\bar{\mathbf{x}}, \mathbf{y}^*) - \min_{\mathbf{x} \in \mathcal{X}} \Phi(\mathbf{x}, \bar{\mathbf{y}}), \quad \text{by the definition of maximization} \\ &\geq \Phi(\mathbf{x}^*, \mathbf{y}^*) - \min_{\mathbf{x} \in \mathcal{X}} \Phi(\mathbf{x}, \bar{\mathbf{y}}), \quad \text{by the inequality (**)} \\ &\geq \Phi(\mathbf{x}^*, \bar{\mathbf{y}}) - \min_{\mathbf{x} \in \mathcal{X}} \Phi(\mathbf{x}, \bar{\mathbf{y}}), \quad \text{by the inequality (*)} \\ &\geq 0, \quad \text{by the definition of minimization.} \end{aligned}$$

- If  $(\bar{\mathbf{x}}, \bar{\mathbf{y}}) = (\mathbf{x}^*, \mathbf{y}^*)$ , then all the inequalities will be equalities and  $\text{Gap}(\bar{\mathbf{x}}, \bar{\mathbf{y}}) = 0$ .

## Optimality conditions for minimax

### Saddle point

We say  $(\mathbf{x}^*, \mathbf{y}^*)$  is a primal-dual solution corresponding to primal and dual problems

$$f^* := \begin{cases} \min_{\mathbf{x} \in \mathbb{R}^p} & f(\mathbf{x}) \\ \text{s.t.} & \mathbf{Ax} = \mathbf{b}, \end{cases} \quad \text{and} \quad d^* := \max_{\mathbf{y} \in \mathbb{R}^n} d(\mathbf{y}) = \max_{\mathbf{y} \in \mathbb{R}^n} \min_{\mathbf{x}} \Phi(\mathbf{x}, \mathbf{y}).$$

if it is a saddle point of  $\Phi(\mathbf{x}, \mathbf{y}) = f(\mathbf{x}) + \langle \mathbf{y}, \mathbf{Ax} - \mathbf{b} \rangle$ :

$$\Phi(\mathbf{x}^*, \mathbf{y}) \leq \Phi(\mathbf{x}^*, \mathbf{y}^*) \leq \Phi(\mathbf{x}, \mathbf{y}^*), \quad \forall \mathbf{x} \in \mathbb{R}^p, \mathbf{y} \in \mathbb{R}^n.$$

### Karush-Khun-Tucker (KKT) conditions

Under our assumptions, an equivalent characterization of  $(\mathbf{x}^*, \mathbf{y}^*)$  is via the KKT conditions of the problem

$$\min_{\mathbf{x} \in \mathbb{R}^p} f(\mathbf{x}) : \mathbf{Ax} = \mathbf{b},$$

which reads

$$\begin{cases} 0 & \in \partial_{\mathbf{x}} \Phi(\mathbf{x}^*, \mathbf{y}^*) = \mathbf{A}^T \mathbf{y}^* + \partial f(\mathbf{x}^*), \\ 0 & = \nabla_{\mathbf{y}} \Phi(\mathbf{x}^*, \mathbf{y}^*) = \mathbf{Ax}^* - \mathbf{b}. \end{cases}$$

## Primal approach: The Penalty Method

$$\min_{\mathbf{x} \in \mathbb{R}^p} \left\{ f(\mathbf{x}) : \mathbf{Ax} = \mathbf{b} \right\}$$

### Penalty methods

- Convert constrained problem (**difficult**) to unconstrained (**easy**).
- Penalized function with penalty parameter  $\mu > 0$ :

$$F_\mu(\mathbf{x}) := \left\{ f(\mathbf{x}) + \frac{\mu}{2} \|\mathbf{Ax} - \mathbf{b}\|^2 \right\} \quad \xLeftrightarrow{\mu \rightarrow \infty} \quad \min_{\mathbf{x} \in \mathbb{R}^p} \left\{ f(\mathbf{x}) : \mathbf{Ax} = \mathbf{b} \right\}.$$

- **Observations:**

- ▶ Minimize a weighted combination of  $f(\mathbf{x})$  and  $\|\mathbf{Ax} - \mathbf{b}\|^2$  at the same time.
- ▶  $\mu$  determines the weight of  $\|\mathbf{Ax} - \mathbf{b}\|^2$ .
- ▶ As  $\mu \rightarrow \infty$ , we enforce  $\mathbf{Ax} = \mathbf{b}$ .
- ▶ Other functions than the **quadratic**  $\frac{1}{2} \|\cdot\|^2$  are also possible e.g., exact nonsmooth penalty functions:
  - ▶  $\mu \|\mathbf{Ax} - \mathbf{b}\|_2$  or  $\mu \|\mathbf{Ax} - \mathbf{b}\|_1$
  - ▶ They work with finite  $\mu$ , but they are difficult to solve [13, Section 17.2], [4]

## Quadratic penalty: Intuition

## Quadratic penalty: Conceptual algorithm

### Quadratic penalty method (QP):

1. Choose  $\mathbf{x}_0 \in \mathbb{R}^p$  and  $\mu_0 > 0$ .
2. For  $k = 0, 1, \dots$ , perform:
  - 2.a.  $\mathbf{x}_k := \arg \min_{\mathbf{x} \in \mathbb{R}^p} \left\{ f(\mathbf{x}) + \frac{\mu_k}{2} \|\mathbf{A}\mathbf{x} - \mathbf{b}\|^2 \right\}$ .
  - 2.b. Update  $\mu_{k+1} > \mu_k$ .

### Theorem [13, Theorem 17.1]

Assume that  $f$  is smooth and  $\mu_k \rightarrow \infty$ . Then, every limit point  $\bar{\mathbf{x}}$  of the sequence  $\{\mathbf{x}_k\}$  is a solution of the constrained problem

$$\mathbf{x}^* \in \arg \min_{\mathbf{x} \in \mathbb{R}^p} \left\{ f(\mathbf{x}) : \mathbf{A}\mathbf{x} = \mathbf{b} \right\}.$$

### Limitation

- The minimization problems of step 2.a. of the algorithm become ill-conditioned as  $\mu_k \rightarrow \infty$ .
- Common improvements:
  - ▶ Solve the subproblem inexactly, *i.e.*, up to  $\epsilon$  accuracy.
  - ▶ **Linearization** to simplify subproblems (**up next**).

## Quadratic penalty: Linearization

### Generalized quadratic penalty method:

1. Choose  $\mathbf{x}_0 \in \mathbb{R}^p$ ,  $\mu_0 > 0$  and positive semidefinite matrix  $\mathbf{Q}_k$ .

2. For  $k = 0, 1, \dots$ , perform:

2.a.  $\mathbf{x}_k := \arg \min_{\mathbf{x} \in \mathbb{R}^p} \left\{ f(\mathbf{x}) + \frac{\mu_k}{2} \|\mathbf{A}\mathbf{x} - \mathbf{b}\|^2 + \frac{1}{2} \|\mathbf{x} - \mathbf{x}_{k-1}\|_{\mathbf{Q}_k}^2 \right\}.$

2.b. Update  $\mu_{k+1} > \mu_k$ .

### Ideas

- Minimize a **majorizer** of  $F_\mu(\mathbf{x})$ , parametrized by  $\mathbf{Q}_k$  in step 2.a..
- $\mathbf{Q}_k = \mathbf{0}$  gives the standard QP;  $\mathbf{Q}_k = \mathbf{I}$  gives strongly convex subproblems.
- $\mathbf{Q}_k = \alpha_k \mathbf{I} - \mu_k \mathbf{A}^\top \mathbf{A}$ , with  $\alpha_k \geq \mu_k \|\mathbf{A}\|^2$  gives

$$\mathbf{x}_k = \text{prox}_{\frac{1}{\alpha_k} f} \left( \mathbf{x}_{k-1} - \frac{\mu_k}{\alpha_k} \mathbf{A}^\top (\mathbf{A}\mathbf{x}_{k-1} - \mathbf{b}) \right) \quad \text{Only one proximal operator!}$$

and picking  $\alpha_k = \mu_k \|\mathbf{A}\|^2$  gives

$$\mathbf{x}_k = \text{prox}_{\frac{1}{\mu_k \|\mathbf{A}\|^2} f} \left( \mathbf{x}_{k-1} - \frac{1}{\|\mathbf{A}\|^2} \mathbf{A}^\top (\mathbf{A}\mathbf{x}_{k-1} - \mathbf{b}) \right).$$

## Per-iteration time: The key role of the prox-operator

### Recall: Prox-operator

$$\text{prox}_f(\mathbf{x}) := \arg \min_{\mathbf{z} \in \mathbb{R}^p} \left\{ f(\mathbf{z}) + \frac{1}{2} \|\mathbf{z} - \mathbf{x}\|^2 \right\}.$$

Key properties:

- ▶ single valued & non-expansive since  $f$  is a proper convex function.
- ▶ distributes when the primal problem has decomposable structure:

$$f(\mathbf{x}) := \sum_{i=1}^m f_i(\mathbf{x}_i), \quad \text{and} \quad \mathcal{X} := \mathcal{X}_1 \times \cdots \times \mathcal{X}_m.$$

where  $m \geq 1$  is the number of components.

- ▶ often efficient & has closed form expression. For instance, if  $f(\mathbf{z}) = \|\mathbf{z}\|_1$ , then the prox-operator performs coordinate-wise soft-thresholding by 1.

## Quadratic penalty: Linearized methods

| Linearized QP method (LQP)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Accelerated linearized QP method (ALQP)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### Theorem (Convergence [17])

#### o LQP:

$$|f(\mathbf{x}_k) - f(\mathbf{x}^*)| \leq \mathcal{O}(\mu_0 k^{-1/2} + \mu_0^{-1} k^{-1/2})$$

$$\|\mathbf{A} \mathbf{x}_k - \mathbf{b}\| \leq \mathcal{O}(\mu_0^{-1} k^{-1/2})$$

#### o ALQP:

$$|f(\mathbf{x}_k) - f(\mathbf{x}^*)| \leq \mathcal{O}(\mu_0 k^{-1} + \mu_0^{-1} k^{-1})$$

$$\|\mathbf{A} \mathbf{x}_k - \mathbf{b}\| \leq \mathcal{O}(\mu_0^{-1} k^{-1})$$

## In practice: **poor (worst case) performance**

- A nonsmooth problem: Sqrt Lasso

$$\min_{\mathbf{x} \in \mathbb{R}^p} \|\mathbf{Ax} - \mathbf{b}\|_2 + \lambda \|\mathbf{x}\|_1.$$

## Wrap up!

- Try to finish Homework #2...

## A **convex** proto-problem for **structured** sparsity

A combinatorial approach for estimating  $\mathbf{x}^\natural$  from  $\mathbf{b} = \mathbf{A}\mathbf{x}^\natural + \mathbf{w}$

We may consider the sparsest estimator or its surrogate with a valid sparsity pattern:

$$\hat{\mathbf{x}} \in \arg \min_{\mathbf{x} \in \mathbb{R}^p} \{ \|\mathbf{x}\|_s : \|\mathbf{b} - \mathbf{A}\mathbf{x}\|_2 \leq \kappa, \|\mathbf{x}\|_\infty \leq 1 \} \quad (\mathcal{P}_s)$$

with some  $\kappa \geq 0$ . If  $\kappa = \|\mathbf{w}\|_2$ , then the structured sparse  $\mathbf{x}^\natural$  is a feasible solution.

### Sparsity and structure together [6]

Given some weights  $\mathbf{d} \in \mathbb{R}^d, \mathbf{e} \in \mathbb{R}^p$  and an integer input  $c \in \mathbb{Z}^l$ , we define

$$\|\mathbf{x}\|_s := \min_{\omega} \{ \mathbf{d}^T \omega + \mathbf{e}^T \mathbf{s} : M \begin{bmatrix} \omega \\ \mathbf{s} \end{bmatrix} \leq \mathbf{c}, \mathbb{1}_{\text{supp}(\mathbf{x})} = \mathbf{s}, \omega \in \{0, 1\}^d \}$$

for all feasible  $\mathbf{x}$ ,  $\infty$  otherwise. The parameter  $\omega$  is useful for latent modeling.

## A **convex** proto-problem for **structured** sparsity

A combinatorial approach for estimating  $\mathbf{x}^\natural$  from  $\mathbf{b} = \mathbf{A}\mathbf{x}^\natural + \mathbf{w}$

We may consider the sparsest estimator or its surrogate with a valid sparsity pattern:

$$\hat{\mathbf{x}} \in \arg \min_{\mathbf{x} \in \mathbb{R}^p} \{ \|\mathbf{x}\|_s : \|\mathbf{b} - \mathbf{A}\mathbf{x}\|_2 \leq \kappa, \|\mathbf{x}\|_\infty \leq 1 \} \quad (\mathcal{P}_s)$$

with some  $\kappa \geq 0$ . If  $\kappa = \|\mathbf{w}\|_2$ , then the structured sparse  $\mathbf{x}^\natural$  is a feasible solution.

### Sparsity and structure together [6]

Given some weights  $\mathbf{d} \in \mathbb{R}^d, \mathbf{e} \in \mathbb{R}^p$  and an integer input  $c \in \mathbb{Z}^l$ , we define

$$\|\mathbf{x}\|_s := \min_{\boldsymbol{\omega}} \{ \mathbf{d}^T \boldsymbol{\omega} + \mathbf{e}^T \mathbf{s} : M \begin{bmatrix} \boldsymbol{\omega} \\ \mathbf{s} \end{bmatrix} \leq \mathbf{c}, \mathbb{1}_{\text{supp}(\mathbf{x})} = \mathbf{s}, \boldsymbol{\omega} \in \{0, 1\}^d \}$$

for all feasible  $\mathbf{x}$ ,  $\infty$  otherwise. The parameter  $\boldsymbol{\omega}$  is useful for **latent** modeling.

A convex candidate solution for  $\mathbf{b} = \mathbf{A}\mathbf{x}^\natural + \mathbf{w}$

We use the **convex** estimator based on the **tightest** convex relaxation of  $\|\mathbf{x}\|_s$ :

$\hat{\mathbf{x}} \in \arg \min_{\mathbf{x} \in \text{dom}(\|\cdot\|_s)} \{ \|\mathbf{x}\|_s^{**} : \|\mathbf{b} - \mathbf{A}\mathbf{x}\|_2 \leq \kappa \}$  with some  $\kappa \geq 0$ ,  $\text{dom}(\|\cdot\|_s) := \{ \mathbf{x} : \|\mathbf{x}\|_s < \infty \}$ .

# Tractability & tightness of biconjugation

## Proposition (Hardness of conjugation)

Let  $F(s) : 2^{\mathbb{P}} \rightarrow \mathbb{R} \cup \{+\infty\}$  be a set function defined on the support  $s = \text{supp}(\mathbf{x})$ . Conjugate of  $F$  over the unit infinity ball  $\|\mathbf{x}\|_{\infty} \leq 1$  is given by

$$g^*(\mathbf{y}) = \sup_{s \in \{0,1\}^{\mathbb{P}}} |\mathbf{y}|^T s - F(s).$$

### Observations:

- ▶  $F(s)$  is general set function

**Computation:** NP-Hard

- ▶  $F(s) = \|\mathbf{x}\|_s$

**Computation:** Integer Linear Program (ILP) in general. However, if

- ▶  $M$  is Totally Unimodular **TU**
- ▶  $(M, \mathbf{c})$  is Total Dual Integral **TDI**

then tight convex relaxations with a linear program (LP, which is “usually” tractable)

Otherwise, relax to LP anyway!

- ▶  $F(s)$  is submodular

**Computation:** Polynomial-time

## Tree sparsity [11, 5, 3, 18]

Wavelet coefficients

Wavelet tree

Valid selection of nodes

Invalid selection of nodes

**Structure:** *We seek the sparsest signal with a rooted connected subtree support.*

**Linear description:** A **valid** support satisfy  $s_{\text{parent}} \geq s_{\text{child}}$  over tree  $\mathcal{T}$

$$T\mathbf{1}_{\text{supp}(\mathbf{x})} := T\mathbf{s} \geq 0$$

where  $T$  is the directed edge-node incidence matrix, which is **TU**.

Invalid selection of nodes

**Structure:** *We seek the sparsest signal with a rooted connected subtree support.*

**Linear description:** A **valid** support satisfy  $s_{\text{parent}} \geq s_{\text{child}}$  over tree  $\mathcal{T}$

$$T\mathbf{1}_{\text{supp}(\mathbf{x})} := T\mathbf{s} \geq 0$$

where  $T$  is the directed edge-node incidence matrix, which is **TU**.

**Biconjugate:**  $\|\mathbf{x}\|_s^{**} = \min_{\mathbf{s} \in [0,1]^p} \{\mathbf{1}^T \mathbf{s} : T\mathbf{s} \geq 0, |\mathbf{x}| \leq \mathbf{s}\}$

for  $\mathbf{x} \in [-1, 1]^p$ ,  $\infty$  otherwise.

## Tree sparsity [11, 5, 3, 18]

$$\mathfrak{G}_H = \{\{1, 2, 3\}, \{2\}, \{3\}\} \quad \text{valid selection of nodes}$$

**Structure:** *We seek the sparsest signal with a rooted connected subtree support.*

**Linear description:** A **valid** support satisfy  $s_{\text{parent}} \geq s_{\text{child}}$  over tree  $\mathcal{T}$

$$T\mathbf{1}_{\text{supp}(\mathbf{x})} := T\mathbf{s} \geq 0$$

where  $T$  is the directed edge-node incidence matrix, which is **TU**.

**Biconjugate:**  $\|\mathbf{x}\|_s^{**} = \min_{\mathbf{s} \in [0, 1]^p} \{\mathbf{1}^T \mathbf{s} : T\mathbf{s} \geq 0, |\mathbf{x}| \leq \mathbf{s}\} \stackrel{*}{=} \sum_{\mathcal{G} \in \mathfrak{G}_H} \|x_{\mathcal{G}}\|_{\infty}$

for  $\mathbf{x} \in [-1, 1]^p$ ,  $\infty$  otherwise.

The set  $\mathcal{G} \in \mathfrak{G}_H$  are defined as each node and all its descendants.

# Group knapsack sparsity [20, 8, 7]

**Structure:** *We seek the sparsest signal with group allocation constraints.*

**Linear description:** A **valid** support obeys budget constraints over  $\mathcal{G}$

$$\mathcal{B}^T \mathbf{s} \leq \mathbf{c}_u$$

where  $\mathcal{B}$  is the biadjacency matrix of  $\mathcal{G}$ , i.e.,  $\mathcal{B}_{ij} = 1$  iff  $i$ -th coefficient is in  $\mathcal{G}_j$ .

When  $\mathcal{B}$  is an interval matrix or  $\mathcal{G}$  has a **loopless** group intersection graph, it is **TU**.

**Remark:** We can also budget a lowerbound  $\mathbf{c}_\ell \leq \mathcal{B}^T \mathbf{s} \leq \mathbf{c}_u$ .

## Group knapsack sparsity [20, 8, 7]

$$\mathfrak{B}^T = \begin{bmatrix} 1 & 1 & \cdots & 1 & 1 & 0 & 0 & \cdots & 0 \\ 0 & 1 & 1 & \cdots & 1 & 1 & 0 & \cdots & 0 \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ & & & & & & & & \\ 0 & \cdots & 0 & 0 & 1 & 1 & \cdots & 1 & 1 \end{bmatrix}_{(p-\Delta+1) \times p}$$

**Structure:** *We seek the sparsest signal with group allocation constraints.*

**Linear description:** A **valid** support obeys budget constraints over  $\mathfrak{G}$

$$\mathfrak{B}^T \mathbf{s} \leq \mathbf{c}_u$$

where  $\mathfrak{B}$  is the biadjacency matrix of  $\mathfrak{G}$ , i.e.,  $\mathfrak{B}_{ij} = 1$  iff  $i$ -th coefficient is in  $\mathcal{G}_j$ .

When  $\mathfrak{B}$  is an interval matrix or  $\mathfrak{G}$  has a **loopless** group intersection graph, it is **TU**.

**Remark:** We can also budget a lowerbound  $\mathbf{c}_\ell \leq \mathfrak{B}^T \mathbf{s} \leq \mathbf{c}_u$ .

**Biconjugate:** 
$$\|\mathbf{x}\|_{\mathbf{s}}^{**} = \begin{cases} \|\mathbf{x}\|_1 & \text{if } \mathbf{x} \in [-1, 1]^p, \mathfrak{B}^T |\mathbf{x}| \leq \mathbf{c}_u, \\ \infty & \text{otherwise} \end{cases}$$

For the neuronal spike example, we have  $\mathbf{c}_u = \mathbf{1}$ .

## Group knapsack sparsity [20, 8, 7]

(left)  $\|\mathbf{x}\|_s^{**} \leq 1$  (middle)  $\|\mathbf{x}\|_s^{**} \leq 1.5$  (right)  $\|\mathbf{x}\|_s^{**} \leq 2$  for  $\mathfrak{G} = \{\{1, 2\}, \{2, 3\}\}$

**Structure:** *We seek the sparsest signal with group allocation constraints.*

**Linear description:** A **valid** support obeys budget constraints over  $\mathfrak{G}$

$$\mathfrak{B}^T \mathbf{s} \leq c_u$$

where  $\mathfrak{B}$  is the biadjacency matrix of  $\mathfrak{G}$ , i.e.,  $\mathfrak{B}_{ij} = 1$  iff  $i$ -th coefficient is in  $\mathcal{G}_j$ .

When  $\mathfrak{B}$  is an interval matrix or  $\mathfrak{G}$  has a **loopless** group intersection graph, it is **TU**.

**Remark:** We can also budget a lowerbound  $c_\ell \leq \mathfrak{B}^T \mathbf{s} \leq c_u$ .

**Biconjugate:**  $\|\mathbf{x}\|_s^{**} = \begin{cases} \|\mathbf{x}\|_1 & \text{if } \mathbf{x} \in [-1, 1]^p, \mathfrak{B}^T |\mathbf{x}| \leq c_u, \\ \infty & \text{otherwise} \end{cases}$

For the neuronal spike example, we have  $c_u = 1$ .

# Group knapsack sparsity example: A stylized spike train

- ▶ Basis pursuit (BP):  $\|\mathbf{x}\|_1$
- ▶ TU-relax (TU):

$$\|\mathbf{x}\|_s^{**} = \begin{cases} \|\mathbf{x}\|_1 & \text{if } \mathbf{x} \in [-1, 1]^p, \mathfrak{B}^T |\mathbf{x}| \leq \mathbf{c}_u, \\ \infty & \text{otherwise} \end{cases}$$

Figure: Recovery for  $n = 0.18p$ .

## Group knapsack sparsity: A simple variation

**Structure:** We seek the signal with the minimal overall group allocation.

$$\text{Objective: } \mathbb{1}^T s \rightarrow \|\mathbf{x}\|_{\omega} = \begin{cases} \min_{\omega \in \mathbb{Z}_{++}} \omega & \text{if } \mathbf{x} \in [-1, 1]^p, \mathfrak{B}^T s \leq \omega \mathbb{1}, \\ \infty & \text{otherwise} \end{cases}$$

**Linear description:** A valid support obeys budget constraints over  $\mathfrak{G}$

$$\mathfrak{B}^T s \leq \omega \mathbb{1}$$

where  $\mathfrak{B}$  is the biadjacency matrix of  $\mathfrak{G}$ , i.e.,  $\mathfrak{B}_{ij} = 1$  iff  $i$ -th coefficient is in  $\mathcal{G}_j$ .

When  $\mathfrak{B}$  is an interval matrix or  $\mathfrak{G}$  has a *loopless* group intersection graph, it is **TU**.

$$\text{Biconjugate: } \|\mathbf{x}\|_s^{**} = \begin{cases} \max_{\mathcal{G} \in \mathfrak{G}} \|\mathbf{x}^{\mathcal{G}}\|_1 & \text{if } \mathbf{x} \in [-1, 1]^p, \\ \infty & \text{otherwise} \end{cases}$$

**Remark:** The regularizer is known as *exclusive Lasso* [20, 15].

## Group cover sparsity: **Minimal group cover** [2, 14, 9]

**Structure:** *We seek the signal covered by a minimal number of groups.*

$$\text{Objective: } \mathbf{1}^T \mathbf{s} \rightarrow \mathbf{d}^T \omega$$

**Linear description:** *At least one* group containing a sparse coefficient is selected

$$\mathcal{B}\omega \geq \mathbf{s}$$

where  $\mathcal{B}$  is the biadjacency matrix of  $\mathcal{G}$ , i.e.,  $\mathcal{B}_{ij} = 1$  iff  $i$ -th coefficient is in  $\mathcal{G}_j$ .

When  $\mathcal{B}$  is an interval matrix, or  $\mathcal{G}$  has a *loopless* group intersection graph it is **TU**.

## Group cover sparsity: **Minimal group cover** [2, 14, 9]

Figure:  $\mathbb{G} = \{\{1, 2\}, \{2, 3\}\}$ , unit group weights  $\mathbf{d} = \mathbf{1}$ .

**Structure:** *We seek the signal covered by a minimal number of groups.*

**Objective:**  $\mathbf{1}^T \mathbf{s} \rightarrow \mathbf{d}^T \boldsymbol{\omega}$

**Linear description:** *At least one* group containing a sparse coefficient is selected

$$\mathbb{B}\boldsymbol{\omega} \geq \mathbf{s}$$

where  $\mathbb{B}$  is the biadjacency matrix of  $\mathbb{G}$ , i.e.,  $\mathbb{B}_{ij} = 1$  iff  $i$ -th coefficient is in  $\mathcal{G}_j$ .

When  $\mathbb{B}$  is an interval matrix, or  $\mathbb{G}$  has a *loopless* group intersection graph it is **TU**.

**Biconjugate:**  $\|\mathbf{x}\|_{\boldsymbol{\omega}^*}^{**} = \min_{\boldsymbol{\omega} \in [0,1]^M} \{\mathbf{d}^T \boldsymbol{\omega} : \mathbb{B}\boldsymbol{\omega} \geq |\mathbf{x}|\}$  for  $\mathbf{x} \in [-1, 1]^p$ ,  $\infty$  otherwise

## Group cover sparsity: **Minimal group cover** [2, 14, 9]

Figure:  $\mathbb{G} = \{\{1, 2\}, \{2, 3\}\}$ , unit group weights  $\mathbf{d} = \mathbf{1}$ .

**Structure:** *We seek the signal covered by a minimal number of groups.*

$$\text{Objective: } \mathbf{1}^T \mathbf{s} \rightarrow \mathbf{d}^T \boldsymbol{\omega}$$

**Linear description:** *At least one* group containing a sparse coefficient is selected

$$\mathbb{B}\boldsymbol{\omega} \geq \mathbf{s}$$

where  $\mathbb{B}$  is the biadjacency matrix of  $\mathbb{G}$ , i.e.,  $\mathbb{B}_{ij} = 1$  iff  $i$ -th coefficient is in  $\mathcal{G}_j$ .

When  $\mathbb{B}$  is an interval matrix, or  $\mathbb{G}$  has a *loopless* group intersection graph it is **TU**.

$$\begin{aligned} \text{Biconjugate: } \|\mathbf{x}\|_{\boldsymbol{\omega}}^{**} &= \min_{\boldsymbol{\omega} \in [0,1]^M} \{\mathbf{d}^T \boldsymbol{\omega} : \mathbb{B}\boldsymbol{\omega} \geq |\mathbf{x}|\} \text{ for } \mathbf{x} \in [-1, 1]^p, \infty \text{ otherwise} \\ &\stackrel{*}{=} \min_{\mathbf{v}_i \in \mathbb{R}^p} \left\{ \sum_{i=1}^M d_i \|\mathbf{v}_i\|_{\infty} : \mathbf{x} = \sum_{i=1}^M \mathbf{v}_i, \forall \text{supp}(\mathbf{v}_i) \subseteq \mathcal{G}_i \right\}, \end{aligned}$$

## Group cover sparsity: **Minimal group cover** [2, 14, 9]

Figure:  $\mathbb{G} = \{\{1, 2\}, \{2, 3\}\}$ , unit group weights  $\mathbf{d} = \mathbf{1}$ .

**Structure:** *We seek the signal covered by a minimal number of groups.*

$$\text{Objective: } \mathbf{1}^T \mathbf{s} \rightarrow \mathbf{d}^T \boldsymbol{\omega}$$

**Linear description:** *At least one* group containing a sparse coefficient is selected

$$\mathbb{B}\boldsymbol{\omega} \geq \mathbf{s}$$

where  $\mathbb{B}$  is the biadjacency matrix of  $\mathbb{G}$ , i.e.,  $\mathbb{B}_{ij} = 1$  iff  $i$ -th coefficient is in  $\mathcal{G}_j$ .

When  $\mathbb{B}$  is an interval matrix, or  $\mathbb{G}$  has a *loopless* group intersection graph it is **TU**.

**Biconjugate:**  $\|\mathbf{x}\|_{\boldsymbol{\omega}}^{**} = \min_{\boldsymbol{\omega} \in [0,1]^M} \{\mathbf{d}^T \boldsymbol{\omega} : \mathbb{B}\boldsymbol{\omega} \geq |\mathbf{x}|\}$  for  $\mathbf{x} \in [-1, 1]^p$ ,  $\infty$  otherwise

$$\stackrel{*}{=} \min_{\mathbf{v}_i \in \mathbb{R}^p} \left\{ \sum_{i=1}^M d_i \|\mathbf{v}_i\|_{\infty} : \mathbf{x} = \sum_{i=1}^M \mathbf{v}_i, \forall \text{supp}(\mathbf{v}_i) \subseteq \mathcal{G}_i \right\},$$

**Remark:** Weights  $\mathbf{d}$  can depend on the **sparsity** within each groups (**not TU**) [6].

## Budgeted group cover sparsity

**Structure:** We seek the sparsest signal covered by  $G$  groups.

$$\text{Objective: } d^T \omega \rightarrow \mathbb{1}^T s$$

**Linear description:** At least one of the  $G$  selected groups cover each sparse coefficient.

$$\mathfrak{B} \omega \geq s, \mathbb{1}^T \omega \leq G$$

where  $\mathfrak{B}$  is the biadjacency matrix of  $\mathfrak{G}$ , i.e.,  $\mathfrak{B}_{ij} = 1$  iff  $i$ -th coefficient is in  $\mathcal{G}_j$ .

When  $\begin{bmatrix} \mathfrak{B} \\ \mathbb{1} \end{bmatrix}$  is an interval matrix, it is **TU**.

## Budgeted group cover sparsity

**Structure:** We seek the sparsest signal covered by  $G$  groups.

**Objective:**  $d^T \omega \rightarrow \mathbb{1}^T s$

**Linear description:** At least one of the  $G$  selected groups cover each sparse coefficient.

$$\mathcal{B}\omega \geq s, \mathbb{1}^T \omega \leq G$$

where  $\mathcal{B}$  is the biadjacency matrix of  $\mathcal{G}$ , i.e.,  $\mathcal{B}_{ij} = 1$  iff  $i$ -th coefficient is in  $\mathcal{G}_j$ .

When  $\begin{bmatrix} \mathcal{B} \\ \mathbb{1} \end{bmatrix}$  is an interval matrix, it is **TU**.

**Biconjugate:**  $\|\mathbf{x}\|_{\omega}^* = \min_{\omega \in [0,1]^M} \{\|\mathbf{x}\|_1 : \mathcal{B}\omega \geq |\mathbf{x}|, \mathbb{1}^T \omega \leq G\}$   
for  $\mathbf{x} \in [-1, 1]^p, \infty$  otherwise.

## Budgeted group cover example: Interval overlapping groups

- ▶ Basis pursuit (BP):  $\|\mathbf{x}\|_1$
- ▶ Sparse group Lasso (SGL<sub>q</sub>):

$$(1 - \alpha) \sum_{\mathcal{G} \in \mathbb{G}} \sqrt{|\mathcal{G}|} \|\mathbf{x}^{\mathcal{G}}\|_q + \alpha \|\mathbf{x}^{\mathcal{G}}\|_1$$

- ▶ TU-relax (TU):

$$\|\mathbf{x}\|_{\omega}^{**} = \min_{\omega \in [0,1]^M} \{ \|\mathbf{x}\|_1 : \mathfrak{B}\omega \geq |\mathbf{x}|, \mathbf{1}^T \omega \leq G \}$$

for  $\mathbf{x} \in [-1, 1]^p, \infty$  otherwise.

Figure: Recovery for  $n = 0.25p, s = 15, p = 200, G = 5$  out of  $M = 29$  groups.

## Group intersection sparsity [10, 19, 1]

**Structure:** We seek the signal intersecting with minimal number of groups.

**Objective:**  $\mathbf{1}^T \mathbf{s} \rightarrow d^T \boldsymbol{\omega}$

**Linear description:** All groups containing a sparse coefficient are selected

$$\mathbf{H}_k \mathbf{s} \leq \boldsymbol{\omega}, \forall k \in \mathfrak{P}$$

where  $\mathbf{H}_k(i, j) = \begin{cases} 1 & \text{if } j = k, j \in \mathcal{G}_i \\ 0 & \text{otherwise} \end{cases}$ , which is TU.

## Group intersection sparsity [10, 19, 1]

$\mathbb{G} = \{\{1, 2\}, \{2, 3\}\}$ , unit group weights  $d = \mathbb{1}$   
(left) intersection (right) cover.

**Structure:** *We seek the signal intersecting with minimal number of groups.*

**Objective:**  $\mathbb{1}^T s \rightarrow d^T \omega$

**Linear description:** All groups containing a sparse coefficient are selected

$$H_k s \leq \omega, \forall k \in \mathfrak{P}$$

where  $H_k(i, j) = \begin{cases} 1 & \text{if } j = k, j \in \mathcal{G}_i \\ 0 & \text{otherwise} \end{cases}$ , which is **TU**.

**Biconjugate:**  $\|x\|_{\omega}^{**} = \min_{\omega \in [0, 1]^M} \{d^T \omega : H_k |x| \leq \omega, \forall k \in \mathfrak{P}\}$   
for  $x \in [-1, 1]^p$ ,  $\infty$  otherwise.

## Group intersection sparsity [10, 19, 1]

$\mathfrak{G} = \{\{1, 2\}, \{2, 3\}\}$ , unit group weights  $d = \mathbb{1}$   
(left) intersection (right) cover.

**Structure:** *We seek the signal intersecting with minimal number of groups.*

**Objective:**  $\mathbb{1}^T s \rightarrow d^T \omega$  (*submodular*)

**Linear description:** All groups containing a sparse coefficient are selected

$$H_k s \leq \omega, \forall k \in \mathfrak{P}$$

where  $H_k(i, j) = \begin{cases} 1 & \text{if } j = k, j \in \mathcal{G}_i \\ 0 & \text{otherwise} \end{cases}$ , which is **TU**.

**Biconjugate:**  $\|x\|_{\omega}^{**} = \min_{\omega \in [0, 1]^M} \{d^T \omega : H_k |x| \leq \omega, \forall k \in \mathfrak{P}\}^* = \sum_{g \in \mathfrak{G}} \|x_g\|_{\infty}$   
for  $x \in [-1, 1]^p$ ,  $\infty$  otherwise.

## Group intersection sparsity [10, 19, 1]

$$\mathfrak{G} = \{\{1, 2, 3\}, \{2\}, \{3\}\}, \text{ unit group weights } d = \mathbb{1}.$$

**Structure:** *We seek the signal intersecting with minimal number of groups.*

$$\text{Objective: } \mathbb{1}^T s \rightarrow d^T \omega \quad (\text{submodular})$$

**Linear description:** All groups containing a sparse coefficient are selected

$$H_k s \leq \omega, \forall k \in \mathfrak{P}$$

where  $H_k(i, j) = \begin{cases} 1 & \text{if } j = k, j \in \mathcal{G}_i \\ 0 & \text{otherwise} \end{cases}$ , which is TU.

**Biconjugate:**  $\|\mathbf{x}\|_{\omega}^{**} = \min_{\omega \in [0, 1]^M} \{d^T \omega : H_k |\mathbf{x}| \leq \omega, \forall k \in \mathfrak{P}\}^* = \sum_{\mathcal{G} \in \mathfrak{G}} \|x_{\mathcal{G}}\|_{\infty}$   
for  $\mathbf{x} \in [-1, 1]^p$ ,  $\infty$  otherwise.

**Remark:** For hierarchical  $\mathfrak{G}_H$ , group intersection and tree sparsity models coincide.

## Beyond linear costs: Graph dispersiveness

Figure: (left)  $\|\mathbf{x}\|_s^{**} = 0$  (right)  $\|\mathbf{x}\|_s^{**} \leq 1$  for  $\mathcal{E} = \{\{1, 2\}, \{2, 3\}\}$  (chain graph)

**Structure:** *We seek a signal dispersive over a given graph  $\mathcal{G}(\mathfrak{V}, \mathcal{E})$*

**Objective:**  $\mathbb{1}^T s \rightarrow \sum_{(i,j) \in \mathcal{E}} s_i s_j$  (non-linear, supermodular function)

**Linearization:**

$$\|\mathbf{x}\|_s = \min_{\mathbf{z} \in \{0,1\}^{|\mathcal{E}|}} \left\{ \sum_{(i,j) \in \mathcal{E}} z_{ij} : z_{ij} \geq s_i + s_j - 1 \right\}$$

When edge-node incidence matrix of  $\mathcal{G}(\mathfrak{V}, \mathcal{E})$  is TU (e.g., bipartite graphs), it is **TU**.

## Beyond linear costs: Graph dispersiveness

Figure: (left)  $\|\mathbf{x}\|_s^{**} = 0$  (right)  $\|\mathbf{x}\|_s^{**} \leq 1$  for  $\mathcal{E} = \{\{1, 2\}, \{2, 3\}\}$  (chain graph)

**Structure:** *We seek a signal dispersive over a given graph  $\mathcal{G}(\mathfrak{V}, \mathcal{E})$*

**Objective:**  $\mathbf{1}^T \mathbf{s} \rightarrow \sum_{(i,j) \in \mathcal{E}} s_i s_j$  (non-linear, supermodular function)

**Linearization:**

$$\|\mathbf{x}\|_s = \min_{\mathbf{z} \in \{0,1\}^{|\mathcal{E}|}} \left\{ \sum_{(i,j) \in \mathcal{E}} z_{ij} : z_{ij} \geq s_i + s_j - 1 \right\}$$

When edge-node incidence matrix of  $\mathcal{G}(\mathfrak{V}, \mathcal{E})$  is TU (e.g., bipartite graphs), it is **TU**.

**Biconjugate:**  $\|\mathbf{x}\|_s^{**} = \sum_{(i,j) \in \mathcal{E}} (|x_i| + |x_j| - 1)_+$  for  $\mathbf{x} \in [-1, 1]^p$ ,  $\infty$  otherwise.
