Plan of the course

- 1 Integers: 1 lecture
- 2 Groups: 6 lectures
- 3 Rings and fields: 5 lectures
- 4 Review: 1 lecture

Today: Groups-1

- (a) Definition and first examples
- (b) Subgroups
- (c) Cosets and Lagrange's theorem
- (d) Application: Euler's and Fermat's theorems
- (e) Application: RSA

Fermat's theorem

Poll: The following statement is NOT a Fermat's theorem:

- ✓ **A:** There are no nonzero integers a, b, c such that $a^3 + b^3 = c^3$
 - ✓ **B:** $a^3 + b^3 \neq c^3$ for any positive integers a, b, c
 - ✓ **C:** $a^n + b^n \neq c^n$ for natural $n \geq 3$ and any positive integers a, b, c
 - ✓ **D:** There exist nonzero integers a, b, c such that $a^n + b^n = c^n$ for some, but not all natural $n \geq 3$ *False*
 - ✓ **F:** For $a \in \mathbb{Z}_+$ and p a prime that does not divide a , we have $a^{p-1} \equiv 1 \pmod{p}$. *↖ little Fermat's theorem*
- The last Fermat's theorem*

Groups: definition

Definition

A **group** is a set G with a binary operation $\cdot : G \times G \rightarrow G$ satisfying the axioms:

- 1 Associativity: $(a \cdot b) \cdot c = a \cdot (b \cdot c)$ for any $a, b, c \in G$.
- 2 Neutral element: $\exists 1 \in G$ such that $1 \cdot a = a \cdot 1 = a$ for any $a \in G$
- 3 Inverse: For any $a \in G \exists a^{-1} \in G$ such that $a \cdot a^{-1} = a^{-1}a = 1$.

Definition

A group G is called **finite** if $|G| < \infty$. In this case $|G| \in \mathbb{N}$ is called **the order of the group**.

Definition

A group G is called **abelian** if $a \cdot b = b \cdot a$ for any $a, b \in G$.

Groups: first examples

- ① The real numbers $(\mathbb{R}, +, 0)$ form an abelian group with respect to addition. The integers $(\mathbb{Z}, +, 0)$ form an abelian group with respect to addition.

abelian
infinite

- ② For any $n \in \mathbb{N}, n \geq 2$, the equivalence classes of integers modulo n :

abelian
finite

$\mathbb{Z}/n\mathbb{Z} = \{[0], [1], \dots, [n-1]\}$ form an abelian group with respect to addition. In $\mathbb{Z}/6\mathbb{Z}$, we have $[2] + [5] = [1]$ etc. The order $|\mathbb{Z}/n\mathbb{Z}| = n$.

$[0]$ is neutral; $[2] + [4] = [0] \Rightarrow [4]$ is the inverse of $[2]$ in $\mathbb{Z}/6\mathbb{Z}$.

- ③ The group of real invertible $n \times n$ matrices $GL(n, \mathbb{R})$ is a non-abelian infinite group with respect to the matrix multiplication.

infinite
non-abelian

$$A \cdot B \neq B \cdot A; \quad \forall A \exists \underline{A^{-1}} \in GL(n, \mathbb{R}).$$

$$\text{Id} = \begin{pmatrix} 1 & & 0 \\ & 1 & \\ 0 & & \ddots \\ & & & 1 \end{pmatrix}$$

Groups: further examples

Euler's totient function

Multiplicative group modulo n

Let $n \in \mathbb{Z}_{\geq 2}$, $K = \{x \in \mathbb{N} : 1 \leq x \leq n, \gcd(x, n) = 1\}$. Then K is a group with respect to multiplication modulo n , and $|K| = \varphi(n)$.

Notation: $(\mathbb{Z}/n\mathbb{Z}, \cdot)^*$.

$$\begin{aligned} \{1 \leq x \leq n : \gcd(x, n) = 1\} &\Leftrightarrow \exists a, b \in \mathbb{Z} : ax + bn = 1 \Leftrightarrow \\ ax &\equiv 1 \pmod{n} \Leftrightarrow [a] \cdot [x] = [1] \\ &\Rightarrow [x] \text{ is invertible.} \end{aligned}$$

Let $n = 5$. Then $K = \{[1], [2], [3], [4]\}$

$$[1] \cdot [1] = [1], [2] \cdot [3] = [1], [4] \cdot [4] = [1] \Rightarrow$$

$$[2]^{-1} = [3], [3]^{-1} = [2], [4]^{-1} = [4],$$

$[1]$ is the neutral element in K .

Groups: further examples

vertex to midface:

2×4 nontrivial rotations
by $\frac{2\pi}{3}, \frac{4\pi}{3}$

mid-edge to mid-edge:

1×3 nontrivial rotations
by π

1 trivial element

12 rotations at least.

Poll: The order of the group of rotational symmetries of the regular tetrahedron is:

A: 6

B: 8

C: 9

D: 12

Conclusions

- 1 There are groups with respect to addition, multiplication, or another binary operation satisfying the axioms.
- 2 Important example: additive and multiplicative groups of integers modulo n : $(\mathbb{Z}/n\mathbb{Z}, +) \neq (\mathbb{Z}/n\mathbb{Z}, \cdot)^*$.
In particular, $|(\mathbb{Z}/n\mathbb{Z}, +)| = n$ and $|(\mathbb{Z}/n\mathbb{Z}, \cdot)^*| = \varphi(n)$.

of unusual groups
(Appendix A and B are
not a part of the exam).

Subgroups

Definition

A **subgroup** $H \subset G$ is a subset in G such that $1 \in H$ and H is closed with respect to the multiplication and taking inverses.

Example: $\{0, \pm 3, \pm 6, \pm 9, \dots\} \subset (\mathbb{Z}, +, 0)$ is a subgroup of integers with respect to addition.

$$3n + 3k = 3(n+k) \in \{0, \pm 3, \pm 6, \dots\}$$

$$3n + (3(-n)) = 0 \text{ inverse element}$$

Subgroup generated by a single element

Suppose $g \in G$. Consider the subset $\langle g \rangle = \{1, g^{\pm 1}, g^{\pm 2}, g^{\pm 3}, \dots\} \subset G$. Then $g^i \cdot g^k = g^{i+k} \in \langle g \rangle$, and for each g^i the inverse $g^{-i} \in \langle g \rangle$. Therefore $\langle g \rangle \subset G$ is a subgroup by construction. It is called the **subgroup in G generated by the element g** . It is the smallest subgroup of G containing g .

Example: $(\mathbb{Z}, +, 0) = G$, $g = 3 \Rightarrow \langle g \rangle = \{0, \pm 3, \pm 6, \pm 9, \dots\} = 3\mathbb{Z}$
 $3\mathbb{Z} \subset \mathbb{Z}$ is a subgroup with respect to addition,
generated by $3 \in \mathbb{Z}$.

Definition

If there exists $n \in \mathbb{N}_+$ minimal such that $g^n = 1$ in G , then n is called **the order of element g** . In this case $\langle g \rangle = \{1, g, g^2, \dots, g^{n-1}\}$ and $|\langle g \rangle| = n$.

Inverse: $g \cdot g^{n-1} = 1$

Cosets

Definition

Let $H \subset G$ be a subgroup and $g \in G$ an element. The **left coset** gH is the set of group elements of the form $gH = \{gh, h \in H\}$.

Proposition

- 1 Two cosets xH and yH are either equal or disjoint: $xH = yH$ or $xH \cap yH = \emptyset$.
- 2 Any element $g \in G$ belongs to a left H -coset
- 3 If H is finite, then $|xH| = |H|$ for any $x \in G$.

Proof: (1) $xH \cap yH \neq \emptyset \Rightarrow \exists h_1, h_2 \in H : xh_1 = yh_2 \Rightarrow x = yh_2h_1^{-1} = yh_3 \in yH$
Then $\forall h \in H \Rightarrow xh = \underbrace{yh_3}_{\in H}h \in yH \Rightarrow xH \subset yH$, similarly $yH \subset xH \Rightarrow xH = yH$.

(2) Take the coset of g : $gH = \{g, gh_1, gh_2, \dots\}_{h_1, h_2 \in H}$

(3) Let $f: H \rightarrow xH, f(h) = xh$: f is surjective: $xH = \{xh\}_{h \in H}$
 f is injective: if $xh_1 = xh_2 \Rightarrow x^{-1}xh_1 = x^{-1}xh_2 \Rightarrow h_1 = h_2$

Example of cosets $(\mathbb{Z}, +, 0) = G$; $3\mathbb{Z} = H \subset \mathbb{Z}$

Coset 0 wrt $3\mathbb{Z}$ in $\mathbb{Z}$

$$\{0+3k\}_{k \in \mathbb{Z}} = 3\mathbb{Z} = H$$

Coset of 1 wrt $3\mathbb{Z}$ in $\mathbb{Z}$

$$\{1+3k\}_{k \in \mathbb{Z}} = \{1, 4, 7, -2, -5, \dots\}$$

$$\text{Coset of } 10 = \{10+3k\}_{k \in \mathbb{Z}} = \{1, 4, 7, -2, -5, \dots, 10, \dots\} = \{1+3k\}_{k \in \mathbb{Z}}$$

$$\text{Coset of } 2 = \{2+3k\}_{k \in \mathbb{Z}} = \{2, 5, -1, -4, \dots\}$$

$$\text{Note that } \mathbb{Z} = \{0+3k\}_{k \in \mathbb{Z}} \cup \{1+3k\}_{k \in \mathbb{Z}} \cup \{2+3k\}_{k \in \mathbb{Z}}$$

Lagrange's theorem

Theorem

Let G be a finite group and $H \subset G$ a subgroup. Then $|H|$ divides $|G|$.

Proof: Each $g \in G$ belongs to a left H -coset, and $xH = yH$, or $xH \cap yH = \emptyset$
 $\Rightarrow G = \bigcup_{i=1}^r x_i H$ disjoint union of left H -cosets, finitely many

$$\Rightarrow |G| = \sum_{i=1}^r |x_i H|, \text{ but } |x_i H| = |H| \quad \forall x_i$$

$$\Rightarrow |G| = \sum_{i=1}^r |H| = r \cdot |H| \Rightarrow |H| \text{ divides } |G|. \quad \square$$

Definition

The number of left H -cosets in G is called **the index of H in G** . Notation:

$$[G : H] = \frac{|G|}{|H|} \in \mathbb{N}_+.$$

Order of an element divides order of the group

Corollary

- ① Let G be a finite group, and $g \in G$. Then the order of g divides $|G|$.
- ② $g^{|G|} = 1$.

Proof: (1) Let $H = \langle g \rangle = \{1, g, g^2, \dots, g^{k-1}\}$ where k is the order of g in G .
 $\Rightarrow \langle g \rangle = H < G$ subgroup $\Rightarrow$ by Lagrange $\Rightarrow |\langle g \rangle| = k$ divides $|G|$.

(2) We have $g^k = 1 \Rightarrow g^{|G|} = g^{k \cdot t} = (g^k)^t = 1^t = 1$
 $|G| = kt, \quad t \in \mathbb{N}$ ◻

Applications of Lagrange's theorem

Theorem

(Euler's theorem)

Let $a, n \in \mathbb{Z}_+$ such that $\gcd(a, n) = 1$. Then $a^{\varphi(n)} \equiv 1 \pmod{n}$.

Proof: Let $G = (\mathbb{Z}/n\mathbb{Z}, \cdot, 1)^*$, then $|G| = \varphi(n)$
if $\gcd(a, n) = 1 \Rightarrow [a] \in G \Rightarrow$ by Corollary $[a]^{\varphi(n)} = [1] \in G$
 $a^{\varphi(n)} \equiv 1 \pmod{n}$ 

Theorem

(Fermat's little theorem)

Let $a \in \mathbb{Z}_+$ and p a prime that does not divide a . Then $a^{p-1} \equiv 1 \pmod{p}$.

Proof: $\gcd(a, p) = 1$, $\varphi(p) = p-1 \Rightarrow$ by Euler's thm $\Rightarrow a^{\varphi(p)} = a^{p-1} \equiv 1 \pmod{p}$ 

Conclusions

- ① If G is a finite group, and $H \subset G$ a subgroup, then $|H|$ divides $|G|$.
- ② If G is a finite group, and $g \in G$, then the order of the element g divides $|G|$.
- ③ Let $a, n \in \mathbb{Z}_+$ such that $\gcd(a, n) = 1$. Then $a^{\varphi(n)} \equiv 1 \pmod{n}$.

Why do we care?

How RSA Encryption Works

RSA encryption system

Setting

- 1 Choose two large distinct primes p, q .
- 2 Let $m = pq$. Then $\varphi(m) = (p - 1)(q - 1)$.
- 3 Choose $1 < e < m$ such that $\gcd(e, \varphi(m)) = 1$.
- 4 Use the Euclidean algorithm to find $d \in \mathbb{Z}$ such that $ed - k\varphi(m) = 1$ for some $k \in \mathbb{Z}$.
- 5 Publish the encryption key (m, e) .
- 6 Keep secret the decryption key (m, d) .

Send a message

- 1 **A** publishes the encryption key (m, e) .
- 2 **B** wants to send message x , $0 < x < m$ to **A**. Then **B** computes $y \equiv x^e \pmod{m}$ and sends y publicly to **A**.
- 3 **A** computes $y^d = x^{ed} \equiv x \pmod{m}$.

RSA encryption system

Why does it work?

Proposition

Let p, q be two distinct primes and $m = pq$. Let $1 < e < m$ be such that $\gcd(e, \varphi(m)) = 1$, and $d \in \mathbb{Z}$ such that $ed - k\varphi(m) = 1$ for some $k \in \mathbb{Z}$. Then for any $0 < x < m$, $x^{ed} \equiv x \pmod{m}$.

Proof: (1) If $x = pt \Rightarrow x^{ed} \equiv 0 \pmod{p} \Rightarrow (x^{ed} - x) \equiv 0 \pmod{p}$

(2) If x is not divisible by $p \Rightarrow$ Fermat's thm $x^{p-1} \equiv 1 \pmod{p}$

$$x^{ed} = x^{k\varphi(m)+1} = x^{k(p-1)(q-1)+1} = \underbrace{(x^{p-1})^{k(q-1)}}_{\equiv 1 \pmod{p}} x \equiv 1 \cdot x \pmod{p}$$

$$\Rightarrow (x^{ed} - x) \equiv 0 \pmod{p}.$$

The same argument works for $q \Rightarrow (x^{ed} - x)$ divisible by p and q

$$\Rightarrow x^{ed} \equiv x \pmod{\underbrace{pq}_m}$$

RSA encryption system

Why does it work?

Proposition

Let p, q be two distinct primes and $m = pq$. Let $1 < e < m$ be such that $\gcd(e, \varphi(m)) = 1$, and $d \in \mathbb{Z}$ such that $ed - k\varphi(m) = 1$ for some $k \in \mathbb{Z}$. Then for any $0 < x < m$, $x^{ed} \equiv x \pmod{m}$.

Example $p = 3, q = 11 \Rightarrow m = pq = 33, \varphi(m) = (p-1)(q-1) = 20$

Let $e = 7 \Rightarrow \gcd(7, 20) = 1$. Compute d : $ed - k\varphi(m) = 1$

$$\underbrace{7}_{e} \cdot \underbrace{3}_{d} - \underbrace{20}_{\varphi(m)} \cdot \underbrace{1}_{k} = 1 \Rightarrow d = 3$$

$(m, e) = (33, 7)$ encoding key
 $(m, d) = (33, 3)$ decoding key.

Suppose we want to send $x = 20$. Encoding: compute $x^e \pmod{m}$

$$\begin{aligned} 20^7 \pmod{33} &= 2^{14} \cdot 5^7 \pmod{33} = (2^5)^2 \cdot 2^4 \cdot 5^7 \pmod{33} = 2^4 \cdot (-8)^3 \cdot 5 \pmod{33} \\ &= -2^{13} \cdot 5 \pmod{33} = -(2^5)^2 \cdot 8 \cdot 5 \pmod{33} = -7 \pmod{33} \equiv 26 \pmod{33} \end{aligned}$$

RSA encryption system

Why does it work?

Proposition

Let p, q be two distinct primes and $m = pq$. Let $1 < e < m$ be such that $\gcd(e, \varphi(m)) = 1$, and $d \in \mathbb{Z}$ such that $ed - k\varphi(m) = 1$ for some $k \in \mathbb{Z}$. Then for any $0 < x < m$, $x^{ed} \equiv x \pmod{m}$.

$\Rightarrow$ send $y = 26$

$$\begin{aligned} \text{To decode: } y^d \pmod{m} &\equiv 26^3 \pmod{33} \equiv (-7)^3 \pmod{33} \\ &\equiv -49 \cdot 7 \pmod{33} \equiv -16 \cdot 7 \pmod{33} \equiv -13 \pmod{33} \equiv 20 \pmod{33} \end{aligned}$$

$$\Rightarrow y^d \equiv x = 20 \pmod{33}.$$
