Table of Contents

1. Introduction

- 1.1. Examples, History, and Polymer Science at EPFL
- 1.2. Definition and Basic Properties

2. Single Chain Properties

- 2.1. The Ideal Polymer Chain
- 2.2. Real Polymer Chains

3. Structures of Polymers in the Condensed State

- 3.1. The Cohesive Energy
- 3.2. The Amorphous State
- 3.3. The Crystalline State

4. Mechanical Properties

- 4.1. Elastic Deformation
- 4.2. Viscoelasticity
- 4.3. Yield and Crazing

5. Polymer Mixtures

- 5.1. Polymer Blends
- 5.2. Block Copolymers

6. Polymer Technology

- 6.1. Polymer Synthesis
- 6.2. Major Polymer Classes
- 6.3. Polymers as Materials
- 6.4. Processing Techniques

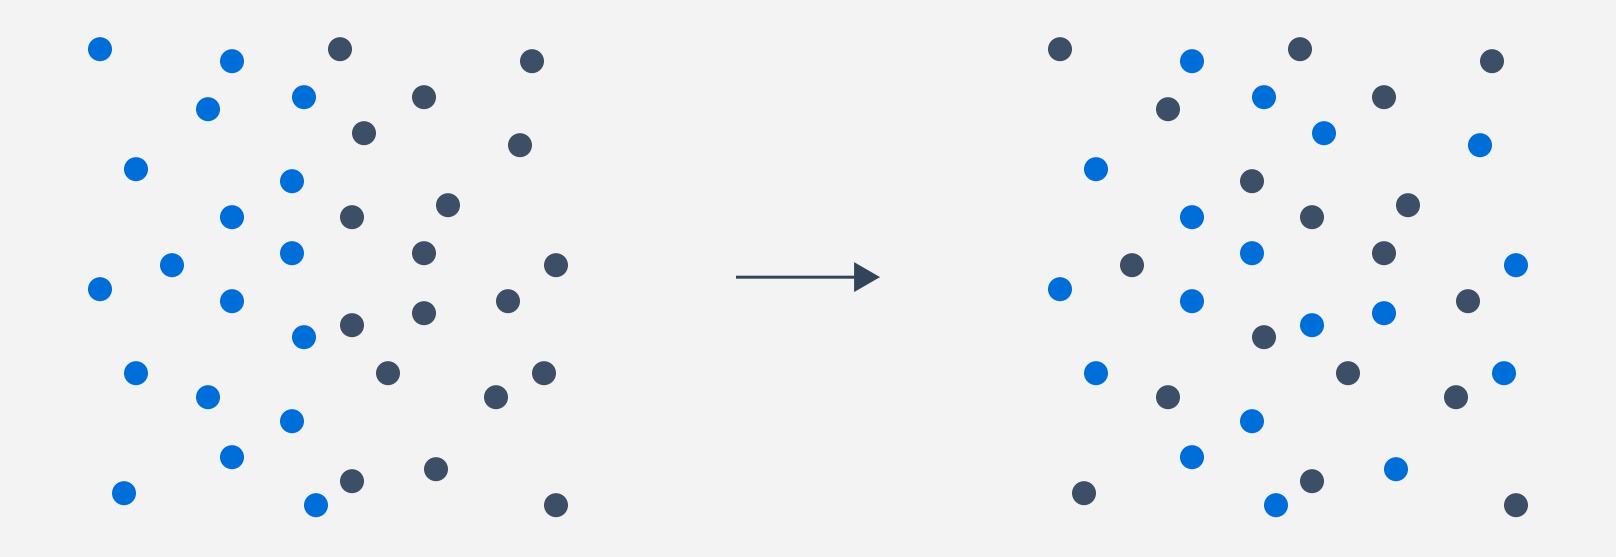

Polymer Mixtures

5.1 Polymer Blends

Thermodynamics of Molecular Mixtures

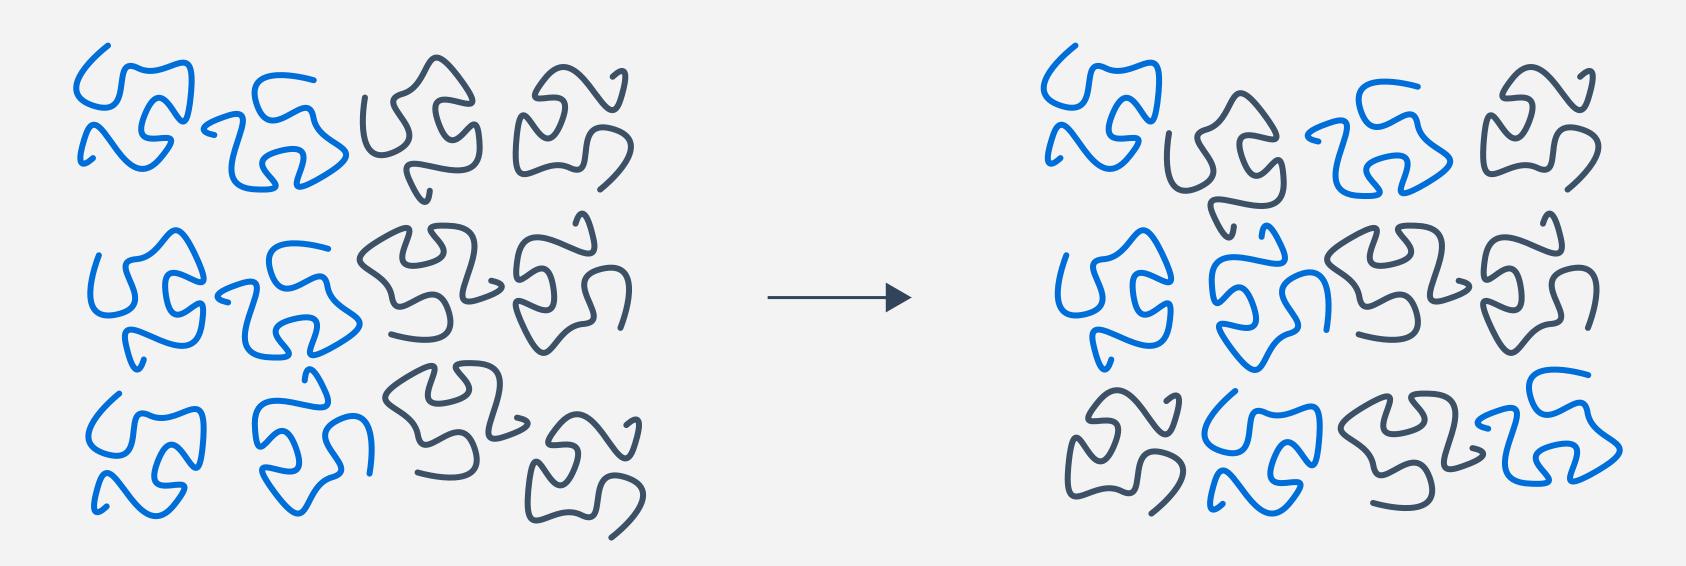

$$\Delta G_{mix} = \Delta H_{mix} - T\Delta S_{mix}$$

- ullet ΔH_{mix} depends on intermolecular interactions between same/different molecules
- ullet ΔH_{mix} is often small and positive, slightly favours demixing
- ΔS_{mix} is typically large and positive, strongly favours mixing

Thermodynamics of Polymer Mixtures

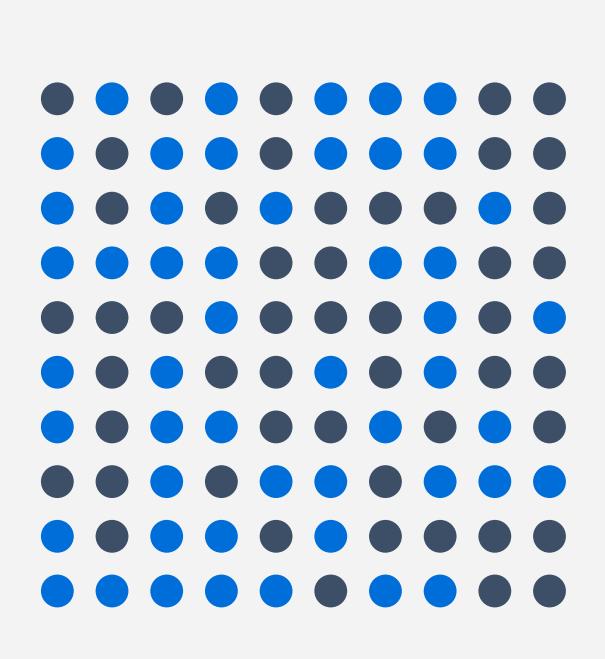

$$\Delta G_{mix} = \Delta H_{mix} - T\Delta S_{mix}$$

- ullet ΔH_{mix} depends on intermolecular interactions between same/different molecules
- ullet ΔH_{mix} is often small and positive, slightly favors demixing
- ullet ΔS_{mix} depends on polymer unfolding (unfavorable) and statistics (slightly favorable)
- ullet ΔS_{mix} is typically small and negative, slightly favours demixing

Mixing Entropy for Regular Solutions

- regular solutions are mixtures of low molar mass species
- here: n_A blue molecules and n_B grey molecules of identical size distributed in a lattice with n sites

number of states before mixing, Ω_A :

$$\Omega_A = n\phi_A$$
 ϕ_A : volume fraction of A

the entropy change of mixing for species A:

$$\Delta S_A = k \ln \Omega_{AB} - k \ln \Omega_A = k \ln \left(\frac{\Omega_{AB}}{\Omega_A}\right)$$
$$= k \ln \left(\frac{n}{n\phi_A}\right) = -k \ln \phi_A$$

the entropy of mixing:

$$\Delta S_{mix} = n_A \Delta S_A + n_B \Delta S_B = -k(n_A \ln \phi_A + n_B \ln \phi_B)$$

the entropy of mixing per lattice site:

$$\Delta \overline{S}_{mix} = -k(\frac{\phi_A}{N_A} \ln \phi_A + \frac{\phi_B}{N_B} \ln \phi_B)$$

ullet for a regular solution the number of lattice sites occupied per molecule $N_A=N_B=1$

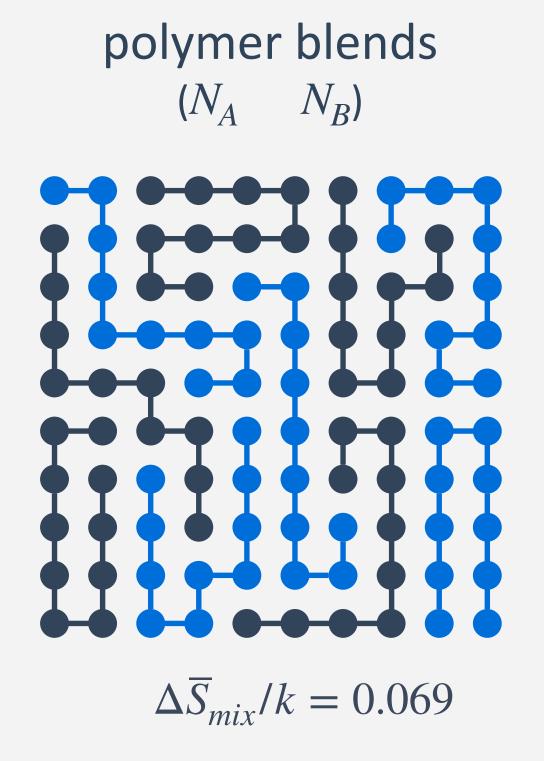

Mixing Entropy of Binary Mixtures

$$\Delta \overline{S}_{mix} = -k(\frac{\phi_A}{N_A} \ln \phi_A + \frac{\phi_B}{N_B} \ln \phi_B)$$

regular solution
$$(N_A = N_B = 1)$$

polymer solution
$$(N_A = N \quad N_B = 1)$$

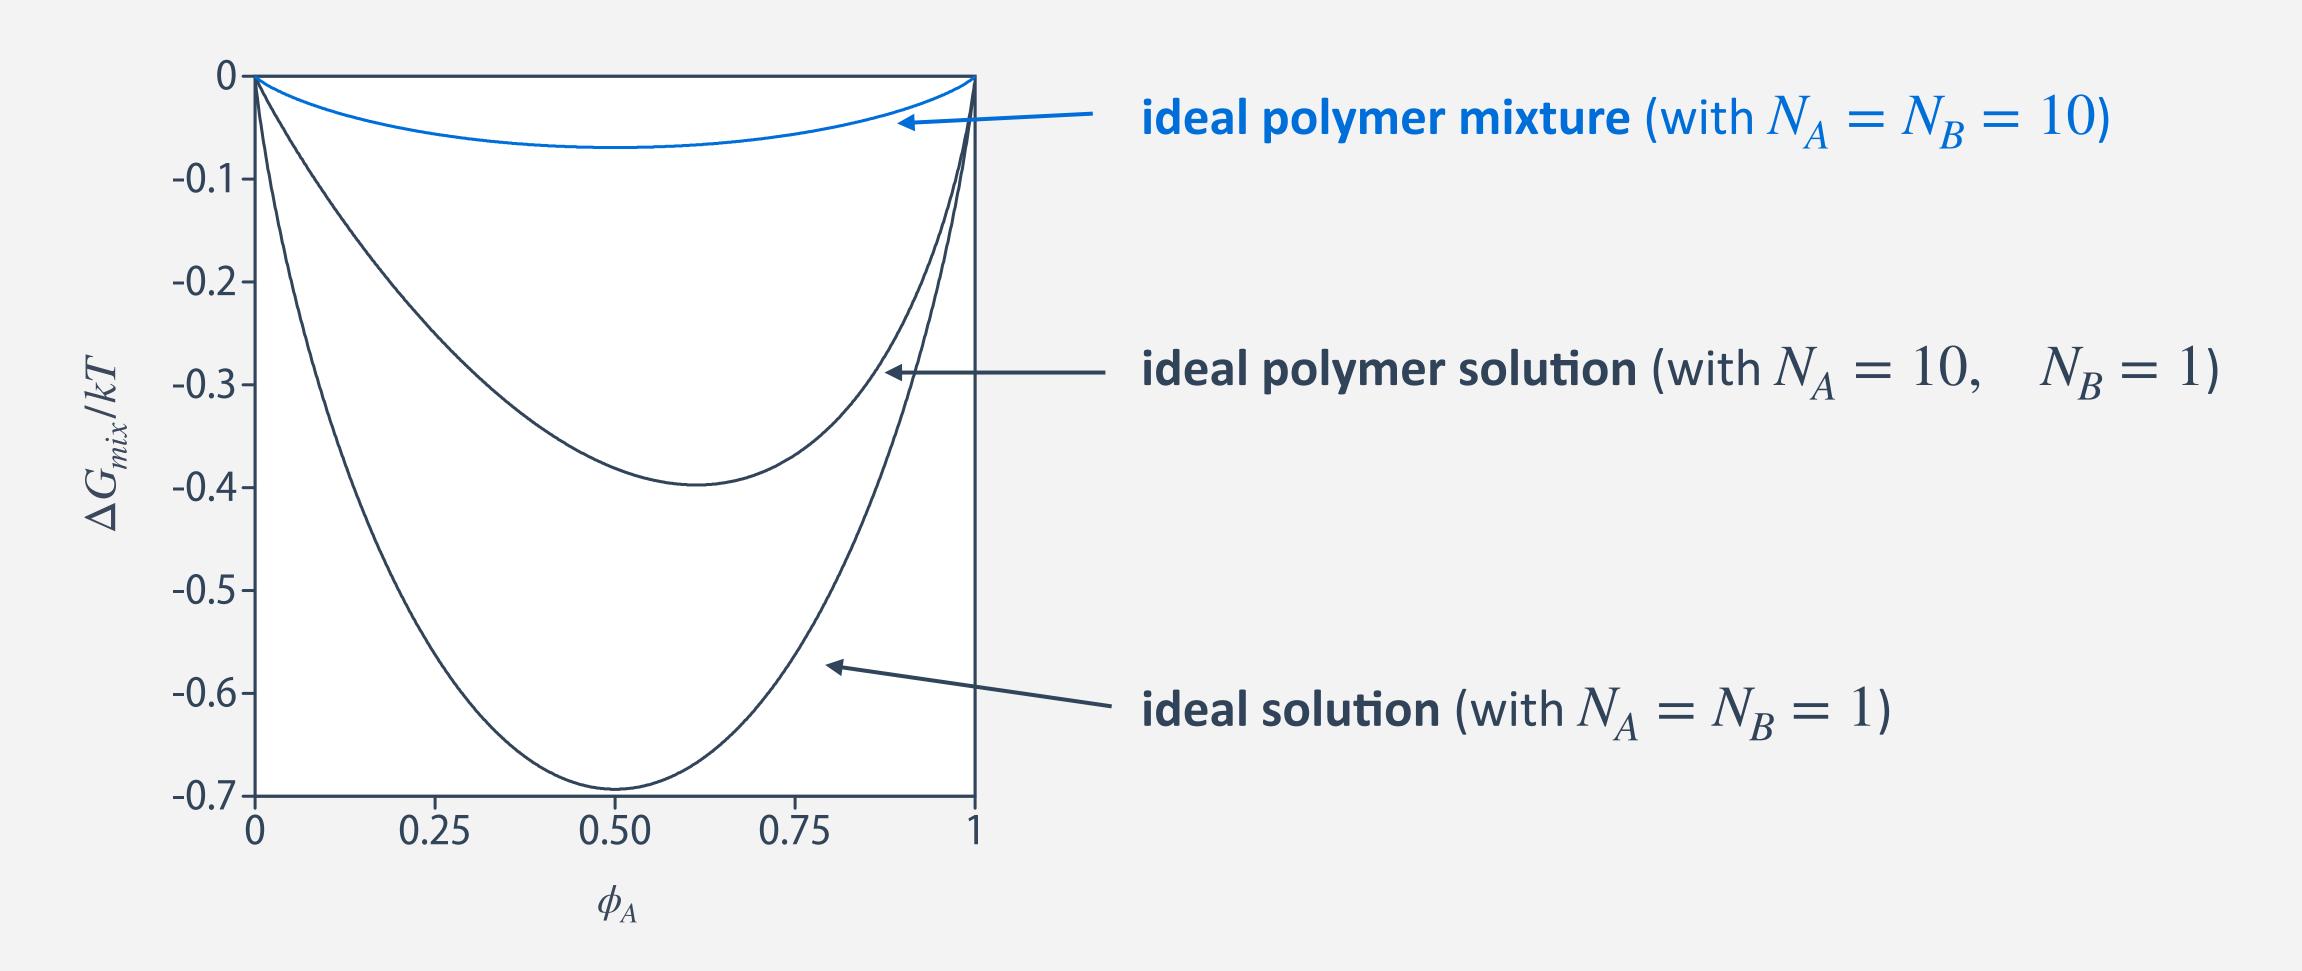

$$\Delta \overline{S}_{mix}/k = 0.38$$

- enormous differences between mixing entropies of regular solutions, polymer solutions, polymer blends
- for polymer blends, the mixing entropy is very small

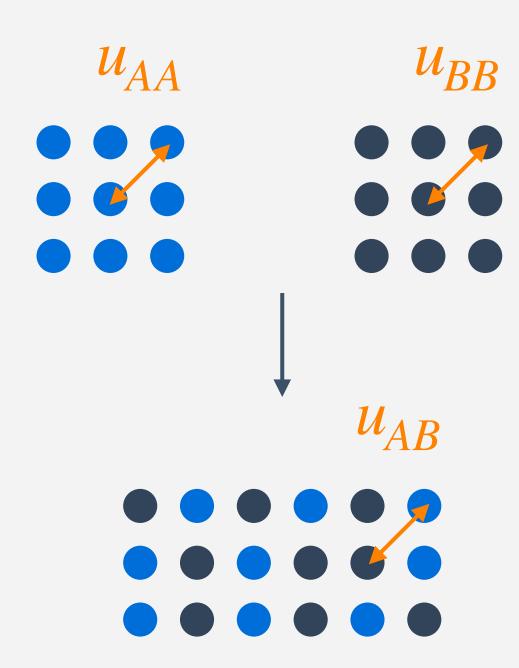

Ideal Mixtures

• for ideal mixtures, the free energy of mixing is purely entropic (translational entropy)

• ideal mixtures are homogenous as a result of an always positive mixing entropy

Mixing Enthalpy in Polymers

 u_{AA} , u_{BB} , u_{AB} : pairwise interaction energies

average pairwise interaction energy:

$$U_A = u_{AA}\phi_A + u_{AB}\phi_B = u_{AA}\phi_A + u_{AB}(1 - \phi_A)$$

total interaction energy of the mixture:

$$U = \frac{z}{2} \left(U_A n \phi_A + U_B n \phi_B \right)$$

= $\frac{zn}{2} \left(u_{AA} \phi^2 + 2u_{AB} \phi (1 - \phi) + u_{BB} (1 - \phi)^2 \right)$

total interaction energy before mixing:

$$U_0 = \frac{zn}{2} \left(u_{AA} \phi + u_{BB} (1 - \phi) \right)$$

the energy change on mixing per lattice site:

$$\Delta \overline{U}_{mix} = \frac{U - U_0}{n} = \frac{z}{2} \phi_A \phi_B (2u_{AB} - u_{AA} - u_{BB})$$

• Flory interaction parameter, χ : describes the differences in the strength of pairwise interaction energies between species in a mixture

$$\Delta \overline{U}_{mix} = \chi \phi_A \phi_B kT \qquad \qquad \chi = \frac{z}{2} \frac{2u_{AB} - u_{AA} - u_{BB}}{kT} = \frac{\left(\sqrt{E_{coh}^{III}} - \sqrt{E_{coh}^{IB}}\right)}{RT} = \frac{V_0(\delta_A - \delta_B)^2}{RT}$$

Free Energy of Mixing

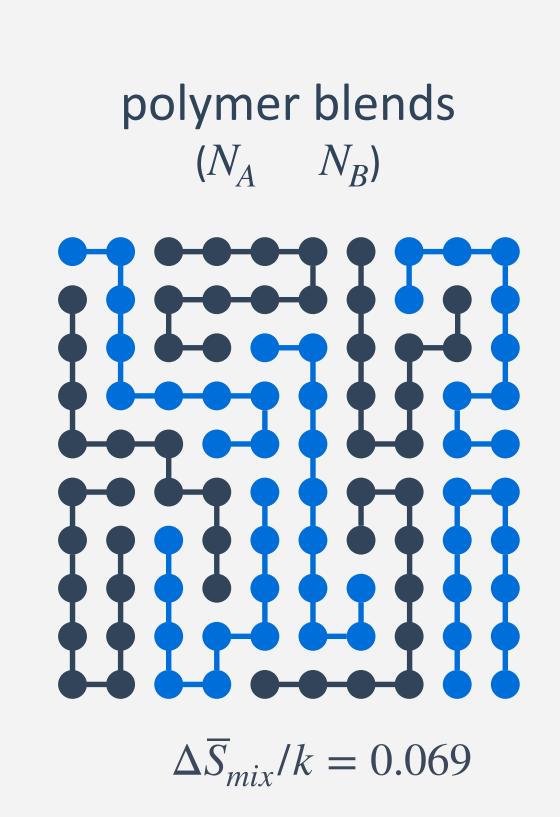

• Flory-Huggins equation:

$$\Delta \overline{G}_{mix} = kT \left(\frac{\phi_A}{N_A} \ln \phi_A + \frac{\phi_B}{N_B} \ln \phi_B + \chi \phi_A \phi_B \right)$$

regular solution
$$(N_A=N_B=1)$$

polymer solution
$$(N_A = N \quad N_B = 1)$$

$$\Delta \overline{S}_{mix}/k = 0.38$$

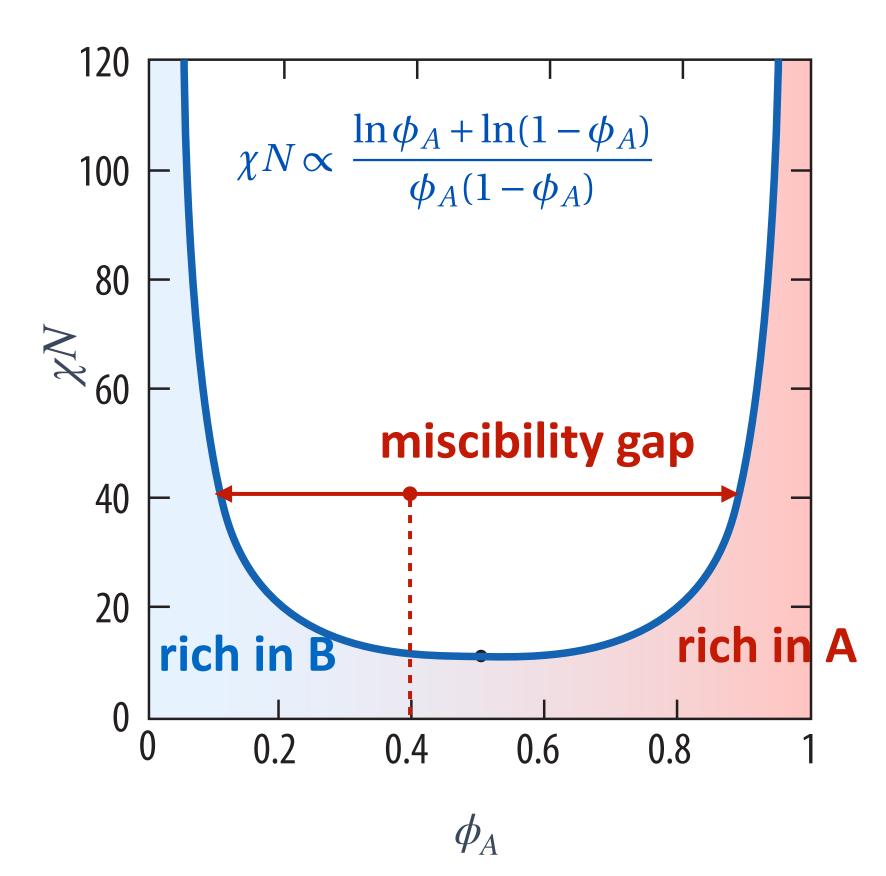

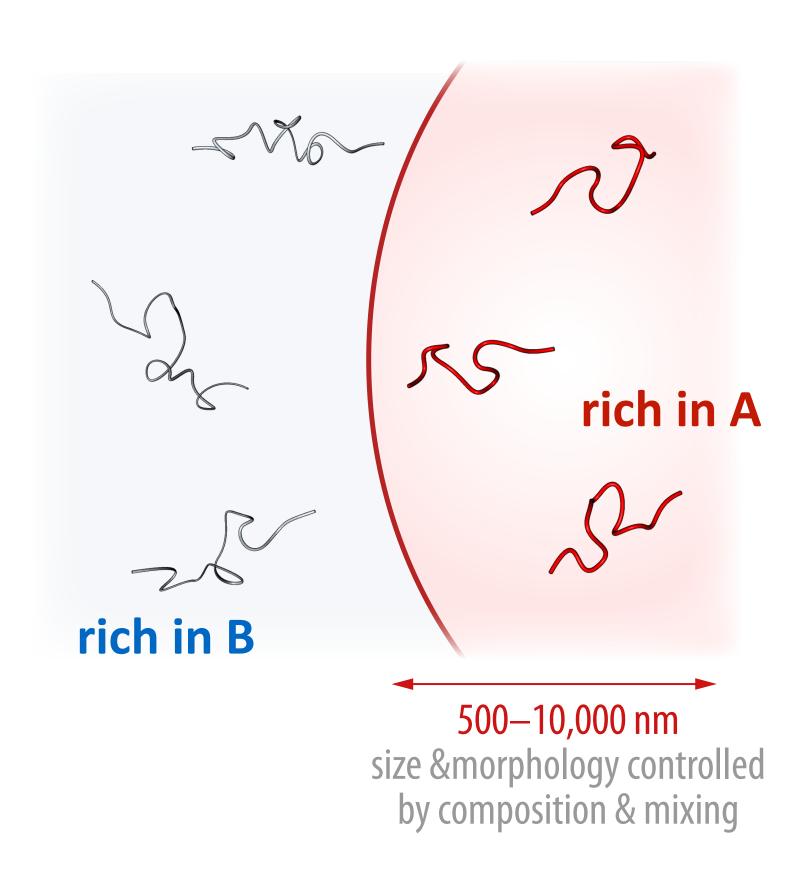

- ullet entropic contribution becomes negligible for high molar masses (large N_A and N_B)
- since χ is positive (in case of no specific intermolecular interactions), a homogenous mixture of two polymers is thermodynamically unstable with respect to macroscopic phase segregation

Macroscopic Phase Segregation in Immiscible Polymer Blends

$$\phi_A \phi_B \chi + \frac{\phi_A \ln \phi_A}{N_A} + \frac{\phi_B \ln \phi_B}{N_B} = 0$$

phase behavior of a symmetric blend: $N_A = N_B = N$

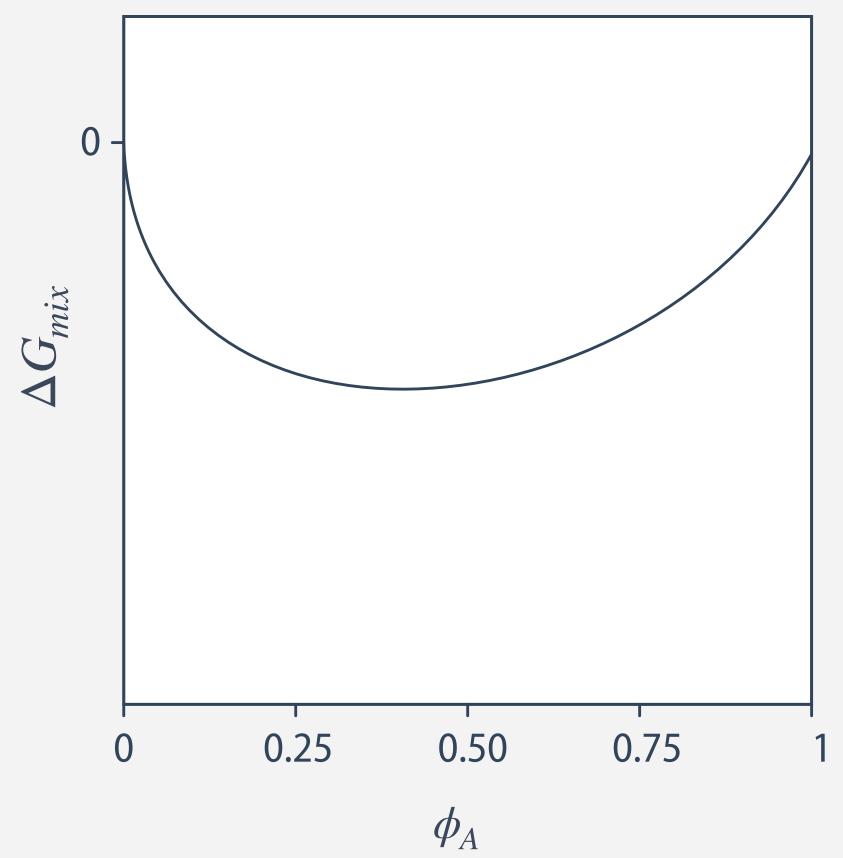

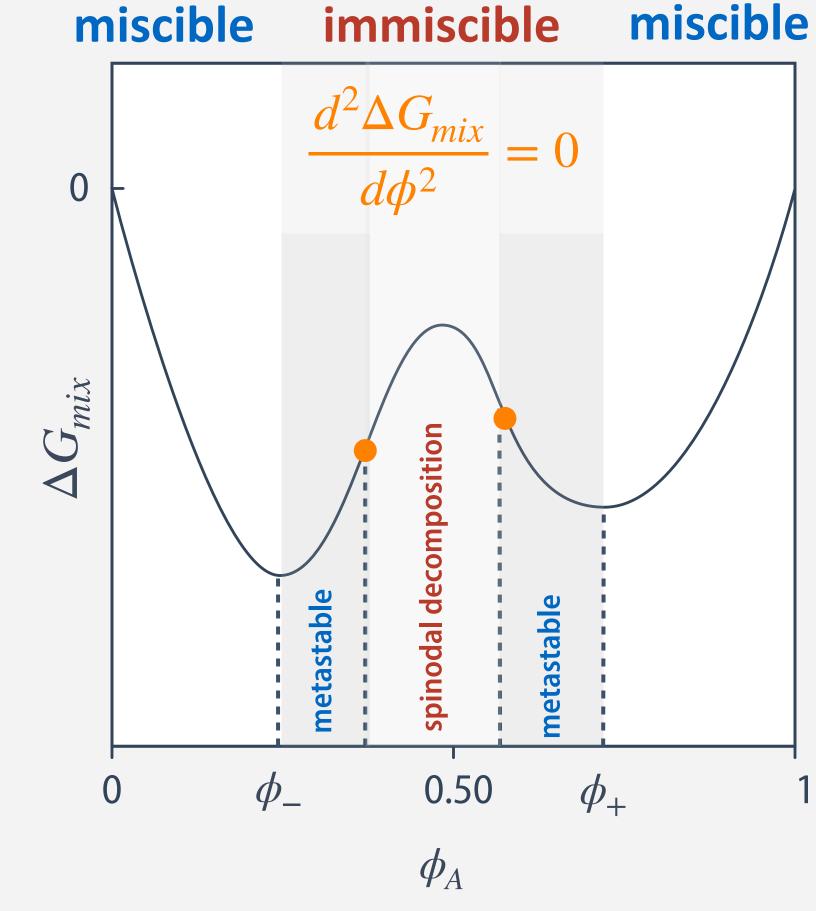

• compositions corresponding to a state with two phases typically show macroscopically phase segregated domains, which often is not desired for mechanical properties.

Phase Diagrams for Binary Mixtures

miscible at any composition

• Lever rule:

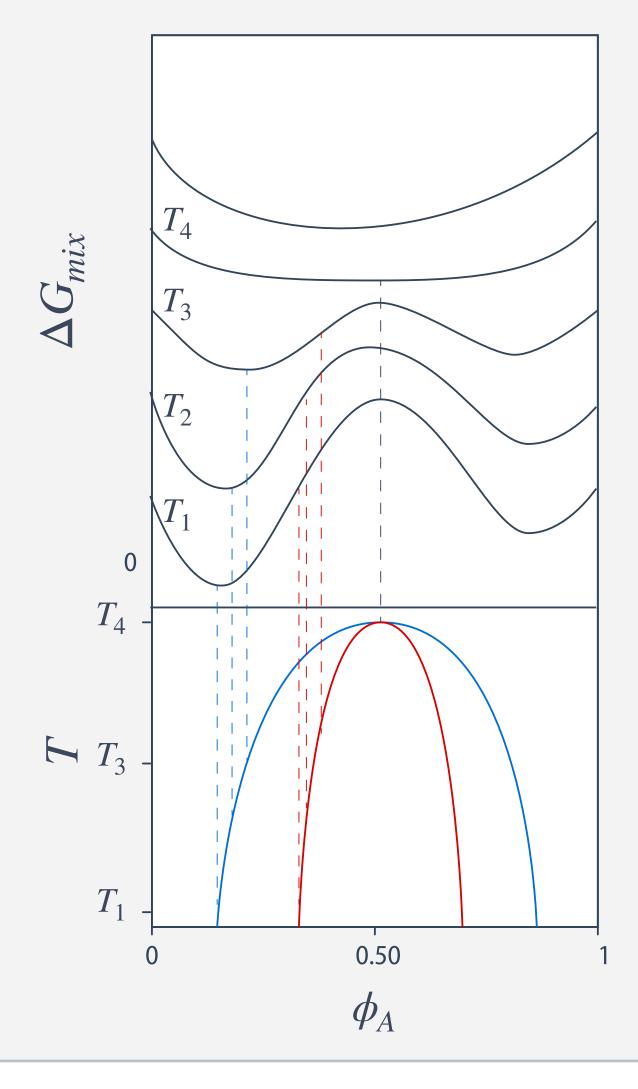

- $\phi = f_-\phi_- + f_+\phi_+ = f_-\phi_- + (1 f_-)\phi_+$
- for certain combinations of χ , N_A , N_B two inflection points indicate the transition from binodal (nucleation-growth) to spinodal (instantaneous) decomposition

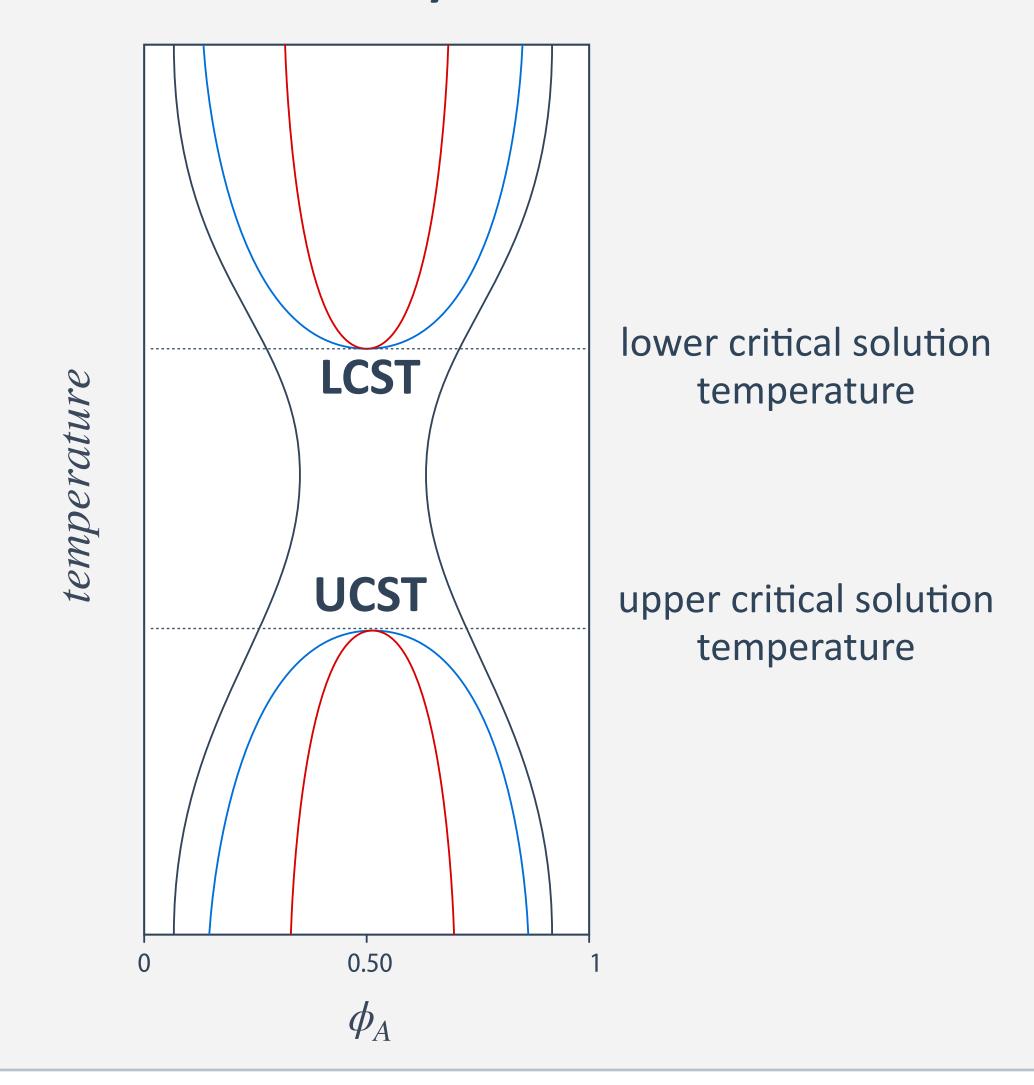

Phase Diagrams for Binary Mixtures

Construction of Phase Diagrams

- ullet construction of phase diagrams from the free energy curves versus χ at different T
- schematic representation of the binodal and spinodal curve for a binary mixture

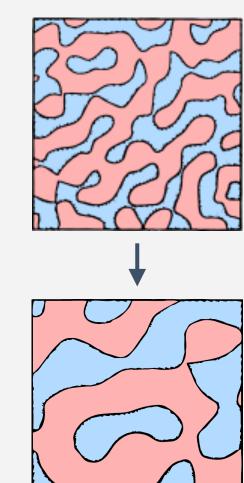

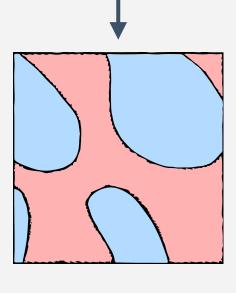

Spinodal Decomposition versus Nucleation & Growth

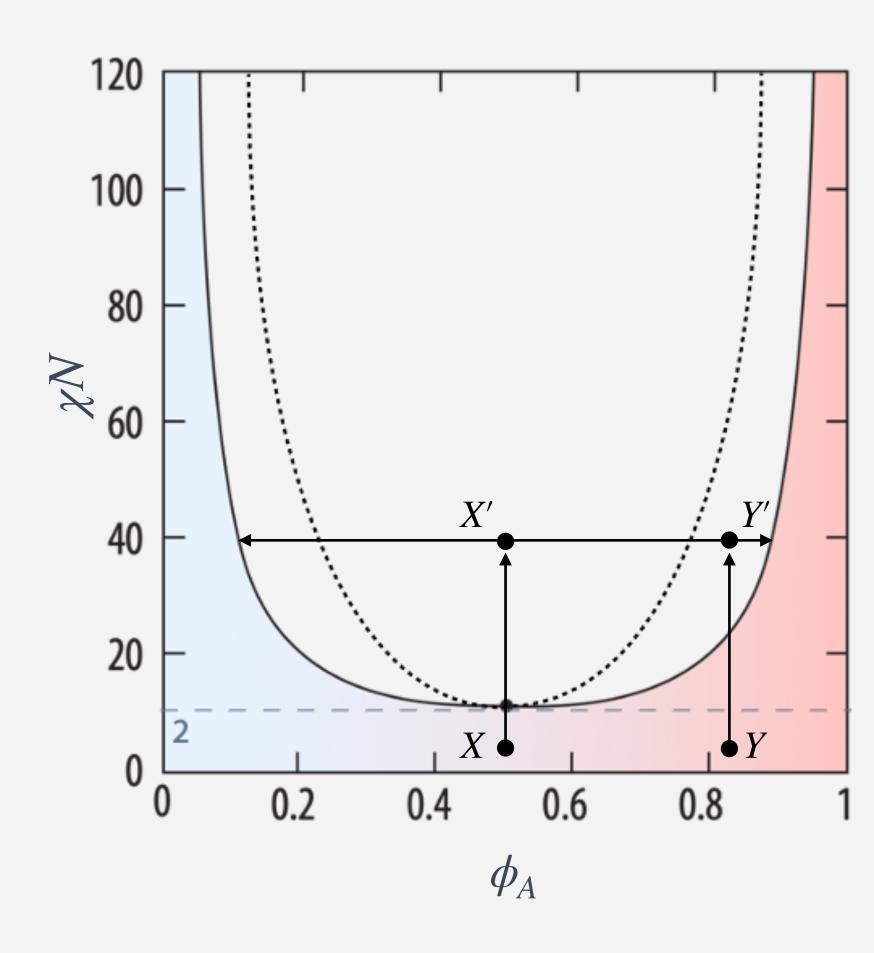

- small fluctuations in composition cause immediate phase separation in the spinodal regime
- nucleation in the metastable zone requires comparably large fluctuations and requires time

spinodal decomposition

$$X \to X'$$

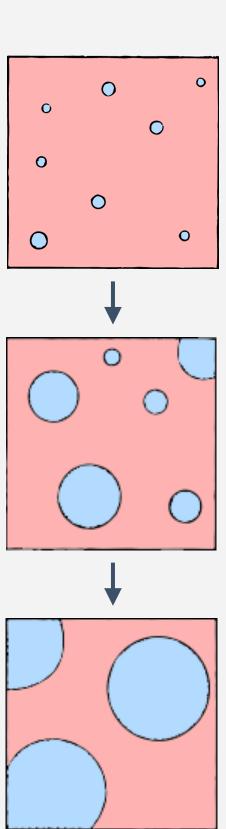

nucleation and growth

$$Y \rightarrow Y'$$

Effect of Flow on Mixing

• in general, immiscible polymers are exerted strong shear forces in an extruder

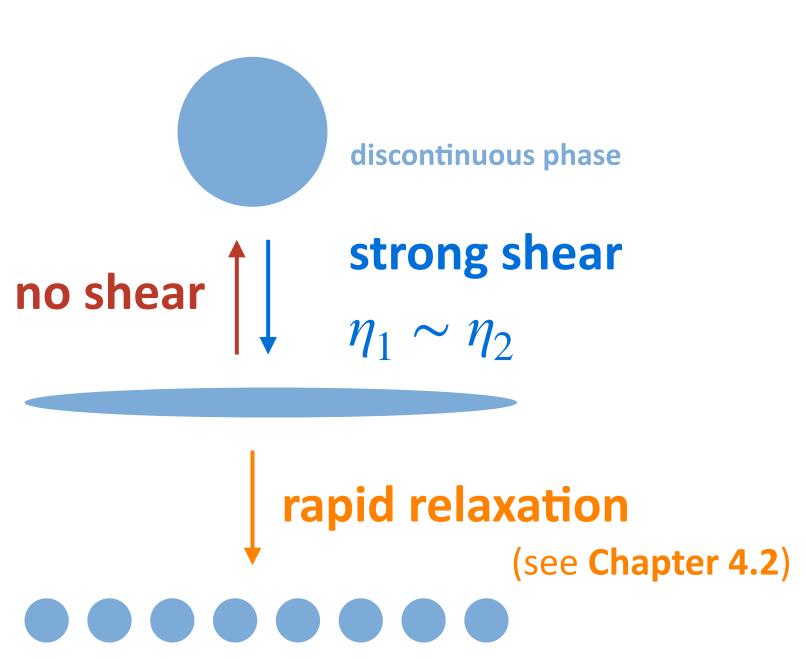

extrusion and injection molding

control parameters

viscosities η_1 , η_2 viscosity ratio $\Lambda = \eta_1/\eta_2$ interfacial tension $\gamma_{1,2}$ capillarity index $\kappa = d\sigma/\gamma_{1,2}$ stress σ initial domain size d

- for $\Lambda < 3.8$, $\kappa > 0.1$: general deformation of the domains of the minor phase
- for $\Lambda < 3.8$, $\kappa > 4$: fibrillar structures may transform into small spherical domains.

Other Ways of Producing Phase-Separated Mixtures

interpenetrating networks

emulsion polymerisation

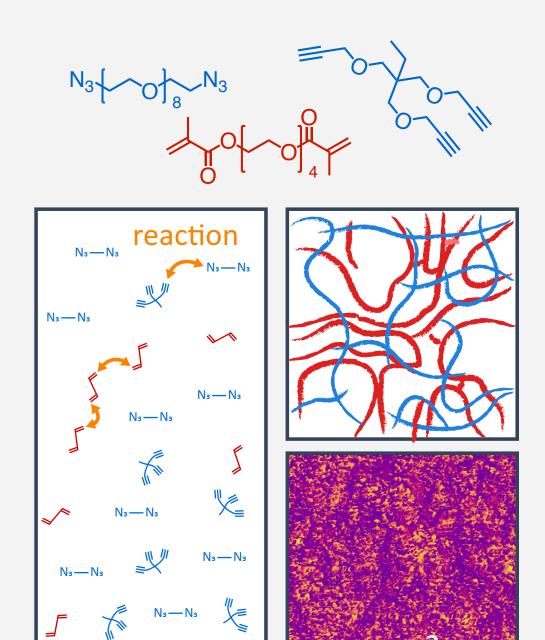

reactive blends preformed & cross-linked particles

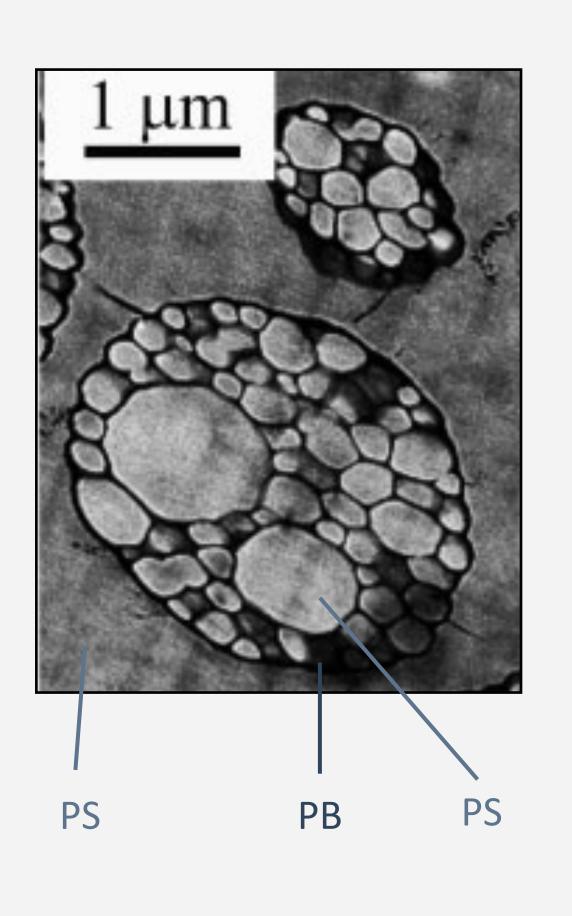

highly cross-linked

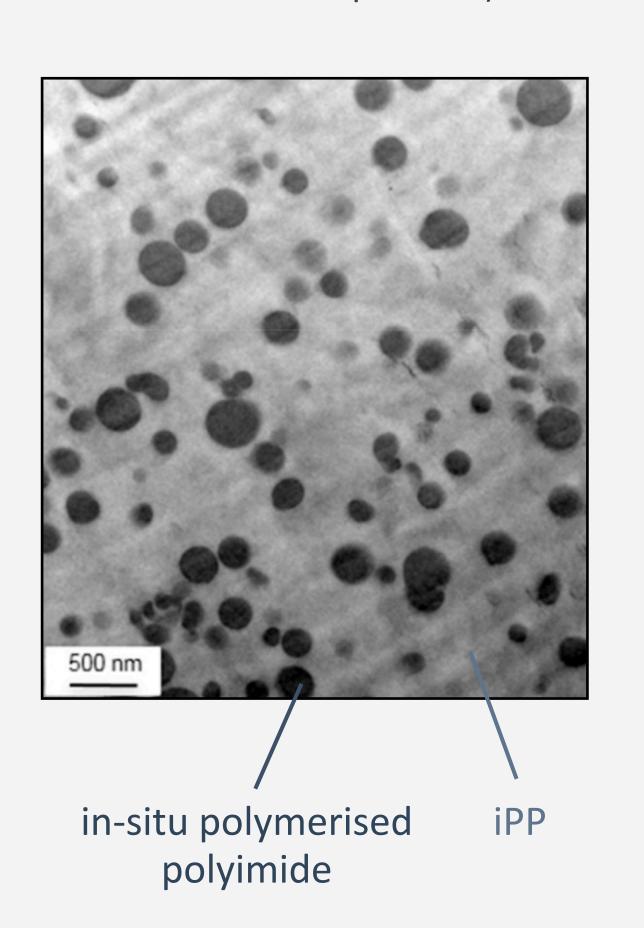

e.g. high impact polystyrene HIPS

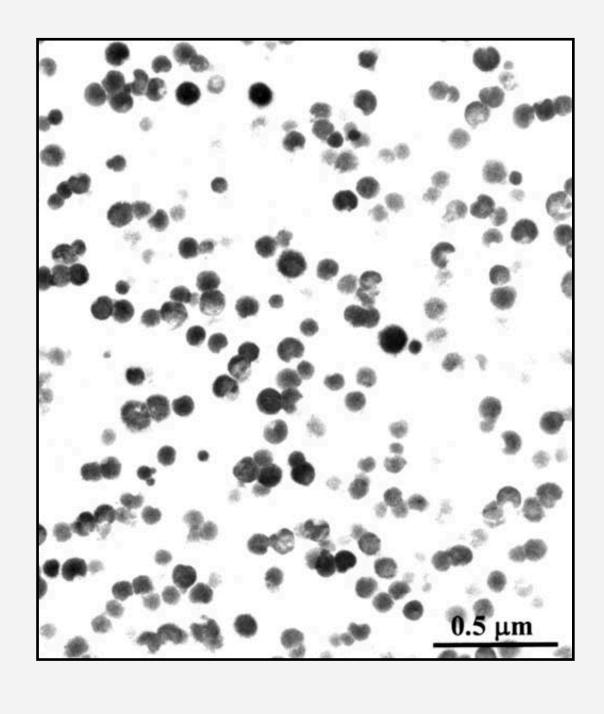

(in-situ synthesis of the different components)

(rubber-toughened PMMA)

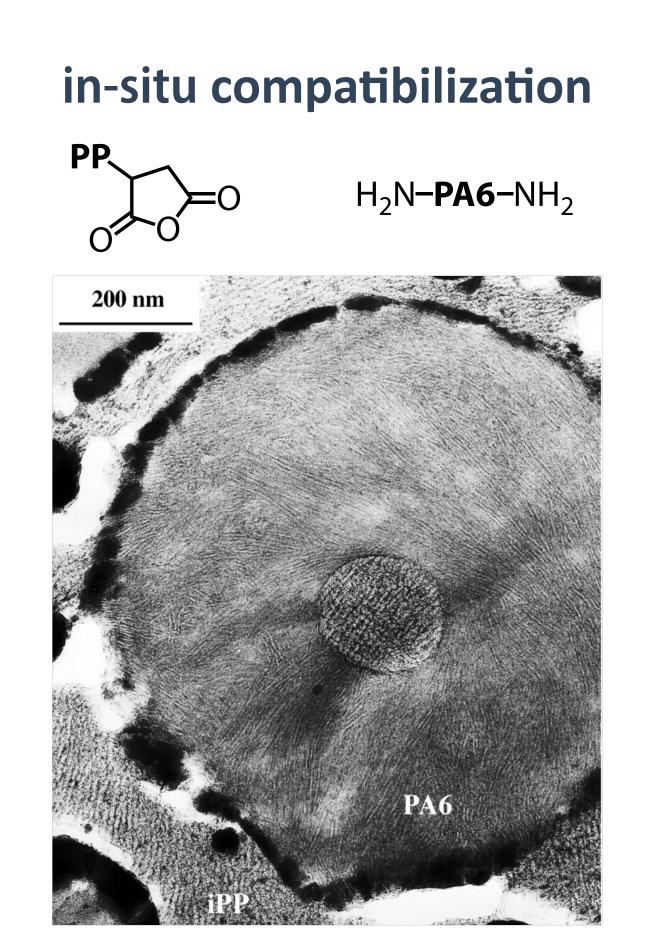

see Chapter 4.3

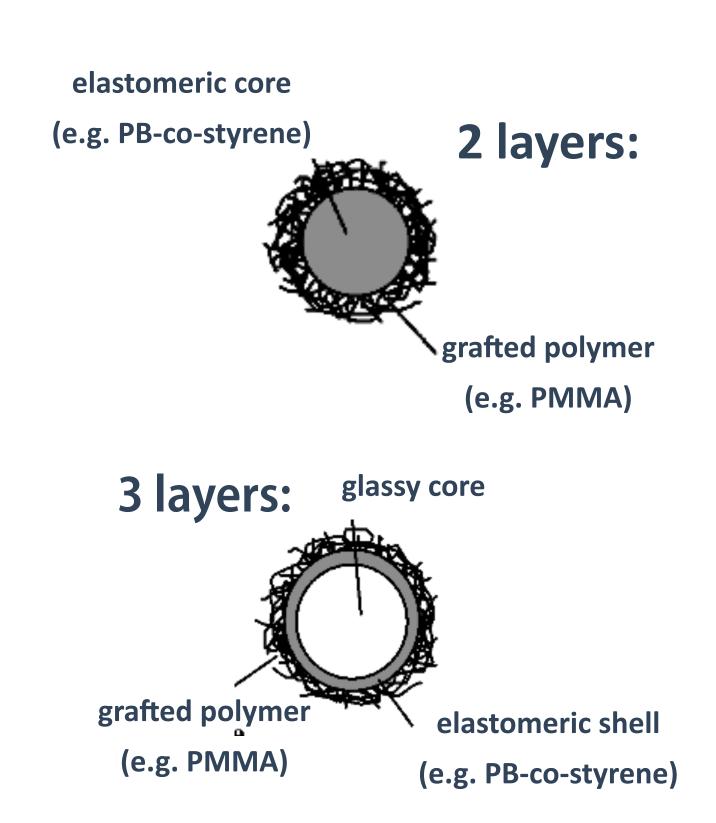

Compatibilization Strategies

• immiscible polymers are compatibilized to stabilize blend morphologies

emulsification

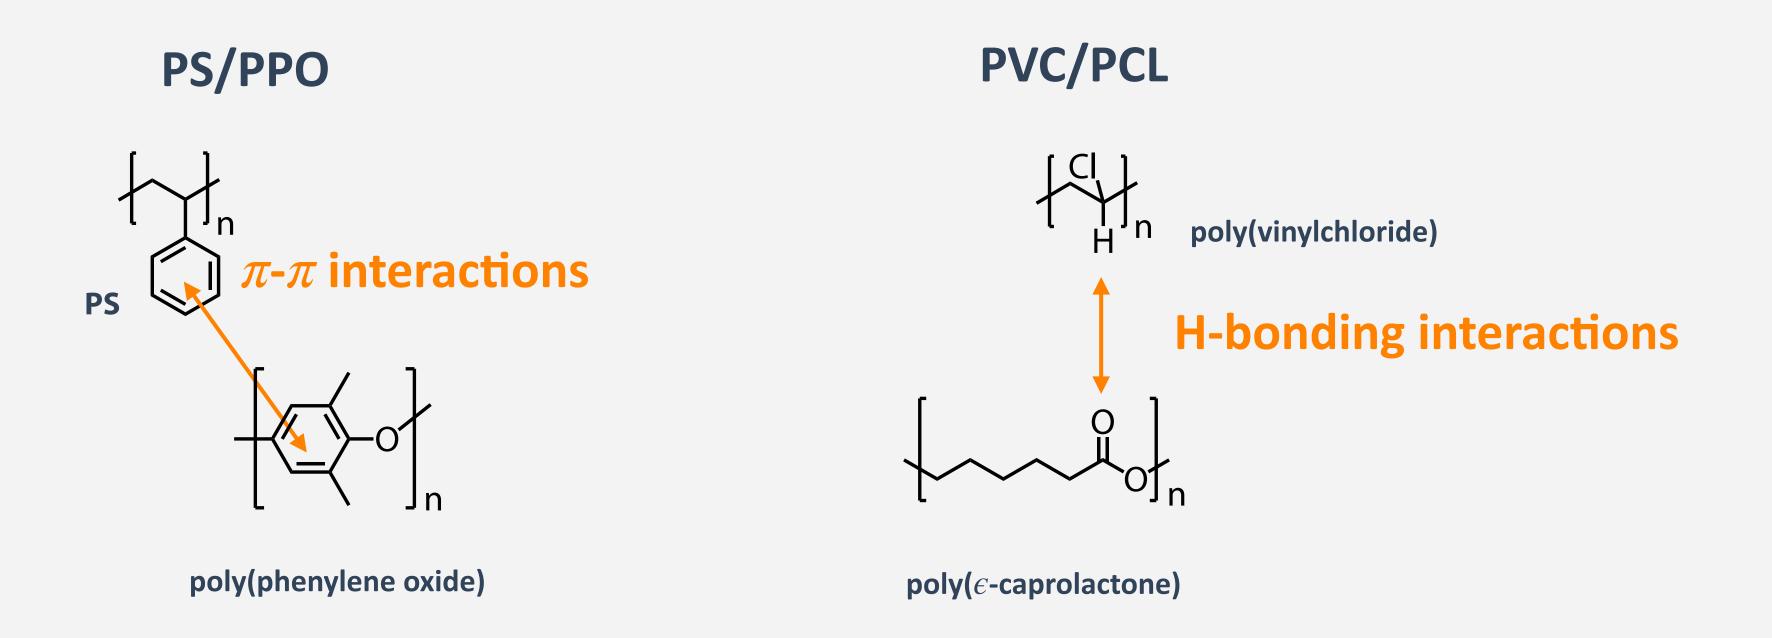

• stabilization by improved interphase adhesion and/or lowered interfacial tension

Miscible Polymer Blends

- Flory-Huggins theory is based on simplifications (ideal chains, constant volume, pure enthalpic origin of the interaction parameter, no specific intermolecular interactions)
- though Flory-Huggins theory predicts general immiscibility of two polymers ($\Delta S \propto 1/N$, $\chi \propto 1/T$), more than 400 miscible systems are known:

ullet miscibility can be favoured by π - π interactions, H-bonding, ionic interactions,...

Applications of Miscible Polymer Blends

• miscibility is particularly favoured, if the specific interaction are only encountered in the mixture

PS + PPO

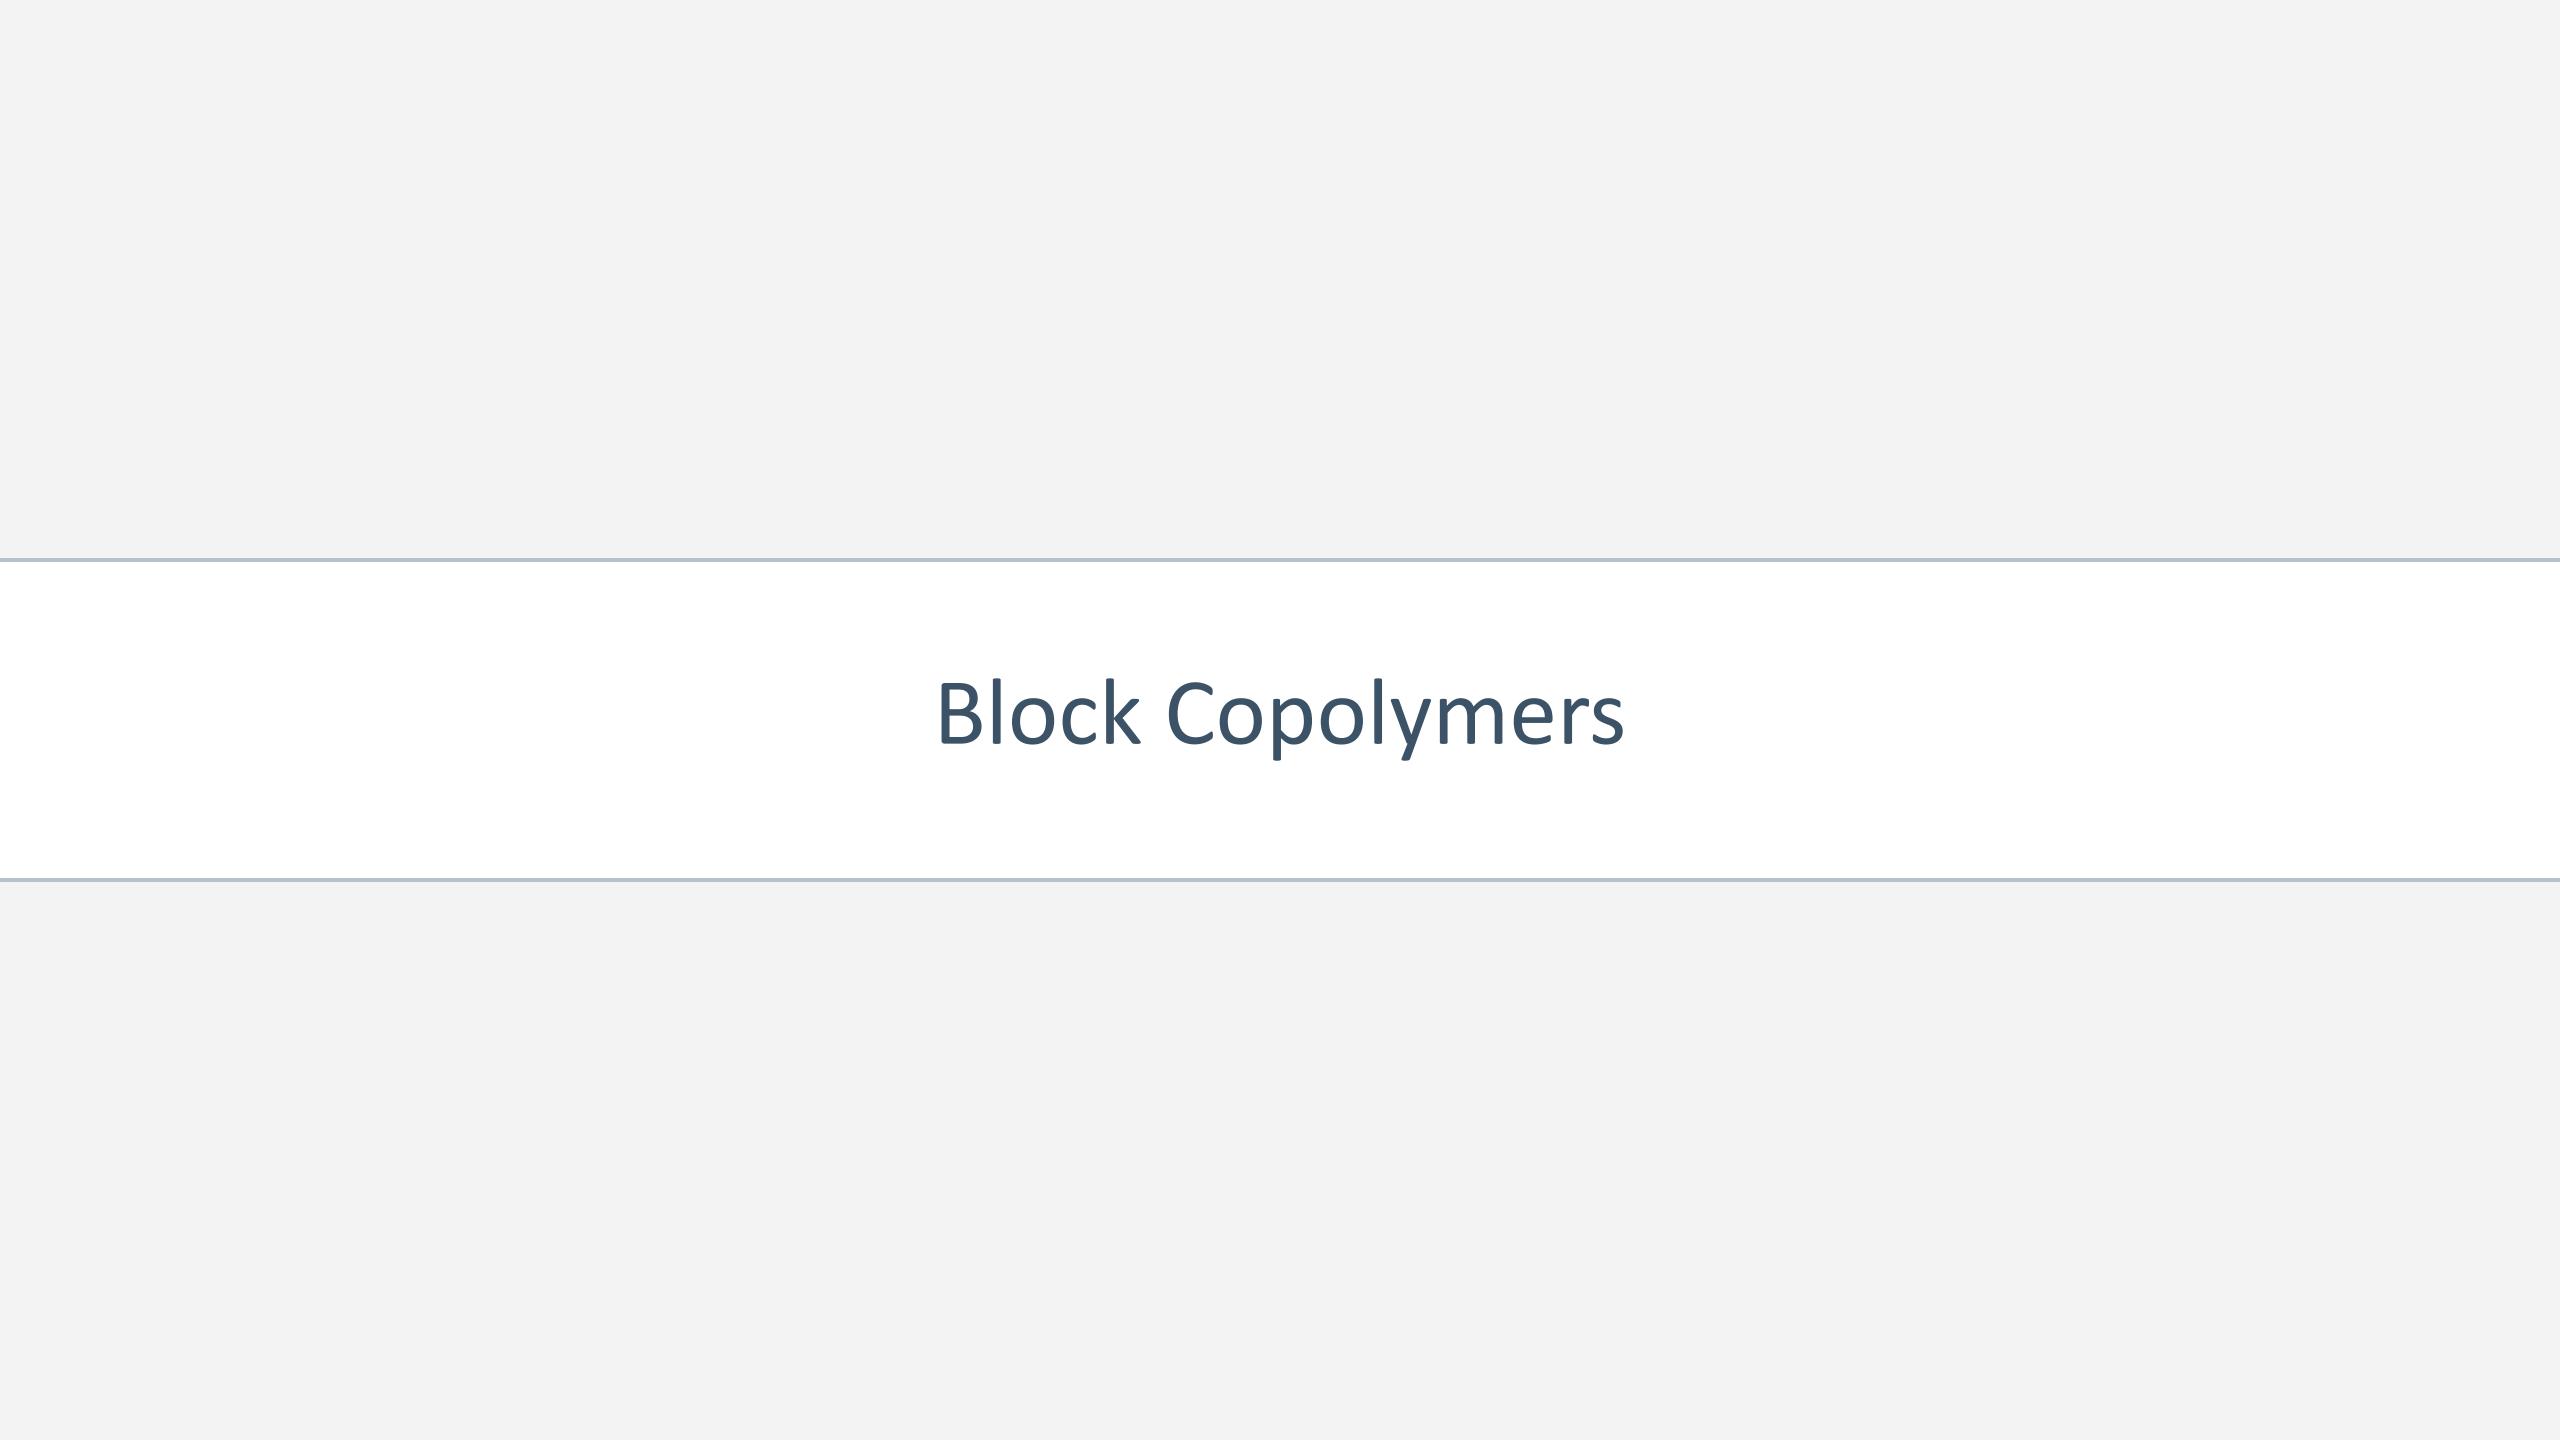

improved ductility increased $T_{\it g}$

PVC + PEC (perchlorinated PE)

improved ductility decreased $T_{
m g}$

- modification of glass transitions without compromising transparency
- synergistic combination of advantageous properties of the respective homopolymers

Two Types of Copolymers

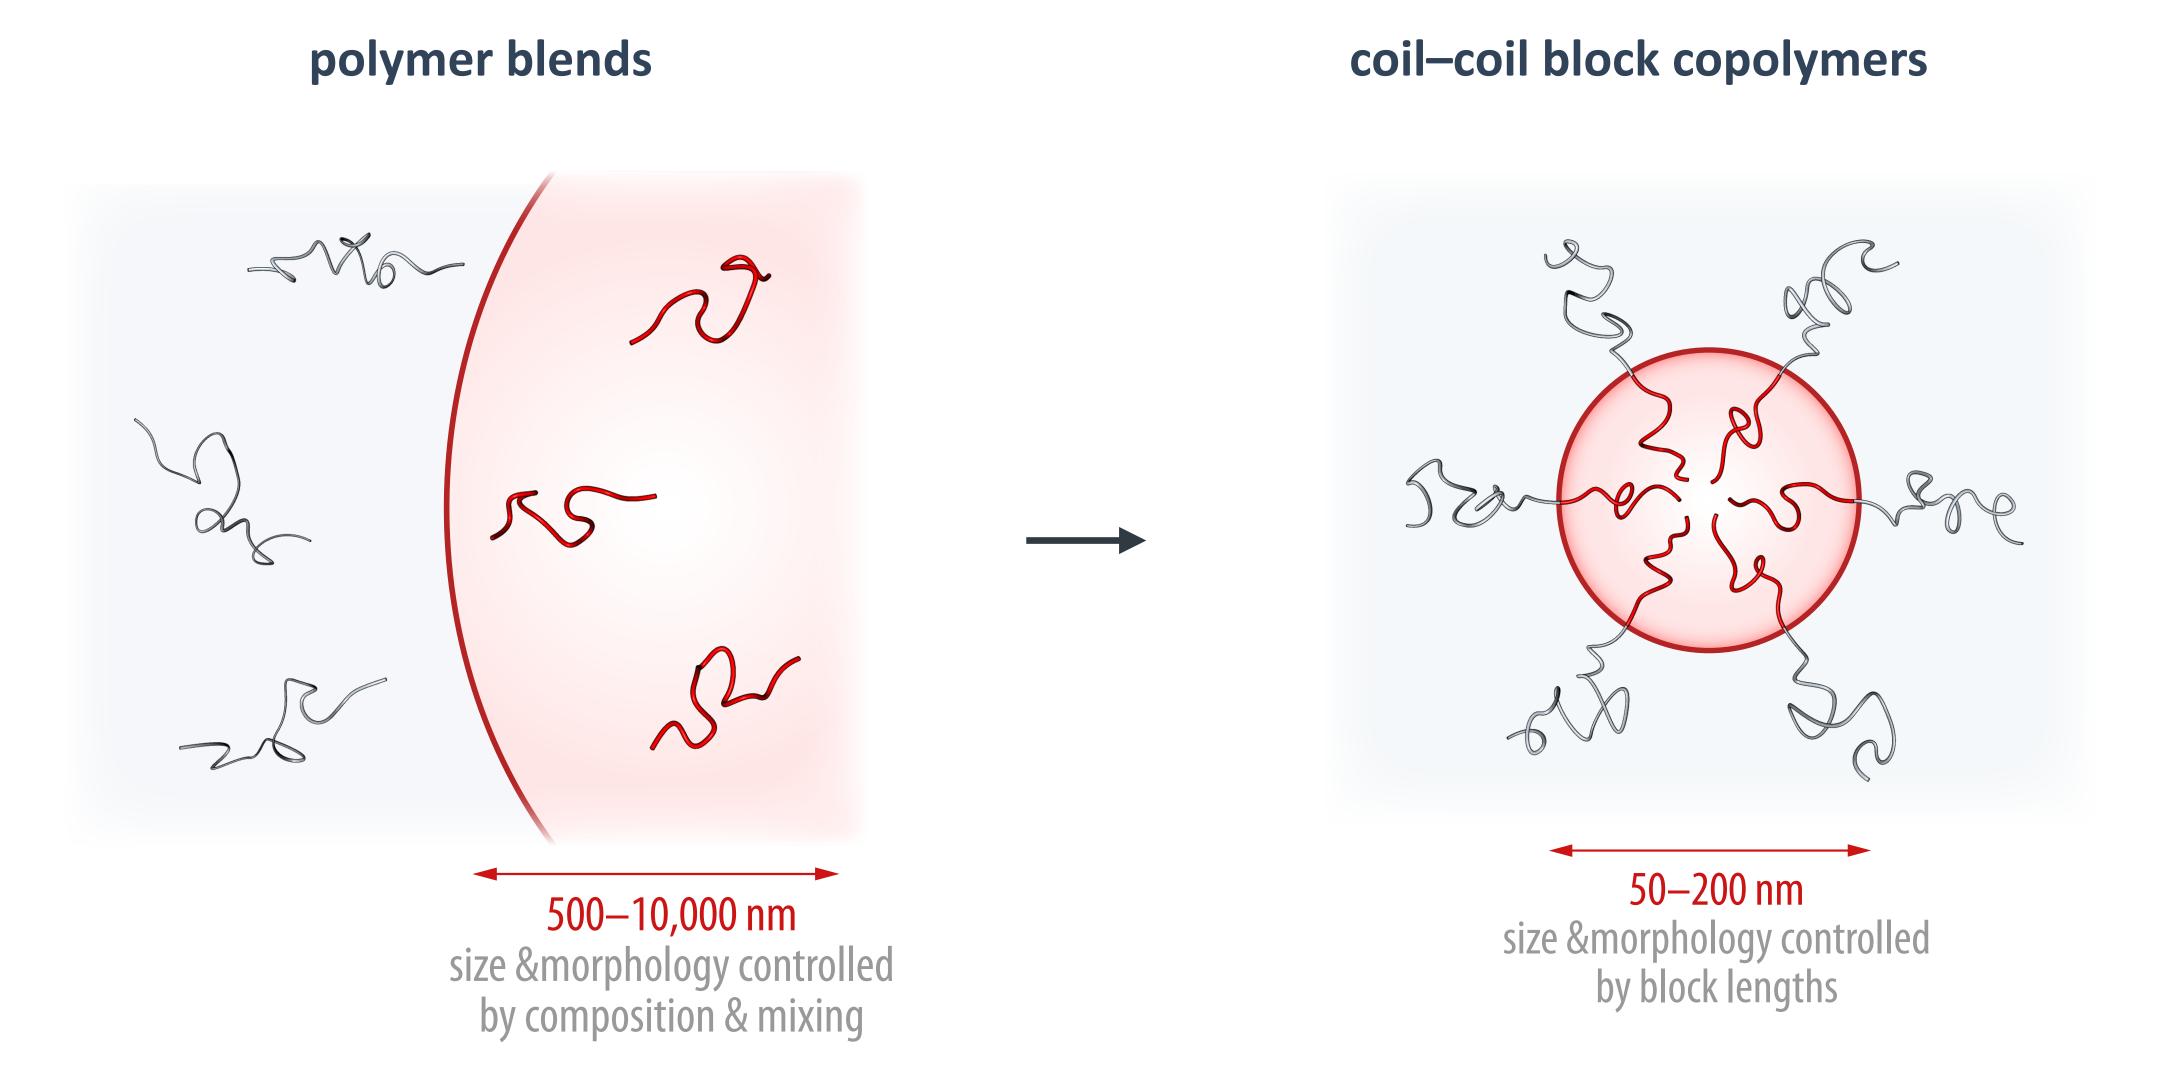

1. Random Copolymers

- ullet T_g is roughly an average of the constitutional components; T_m is either low or not existent
- allows to combine incompatible monomers
- example 1: Poly(ethylene-co-propylene) (EPR): a rubber
- example 2: Poly(styrene-co-acrylonitrile) (PSAN): a glassy polymer, easier to process than PAN)

2. Block Copolymers

- typically two glass transition temperatures and at least one melting point
- allows to combine different properties (i.e. elastomer + glassy polymer) at reduced domain sizes (on the order of R_g) and stabilized interfaces
- total free energy depends on surface tension, entropic forces, and is a function of block length and stiffness as well as curvature of the interfaces, ...
- for mono disperse blocks: well defined block length give rise to periodic structures with constant curvature at the interface (at least for diblock copolymers)

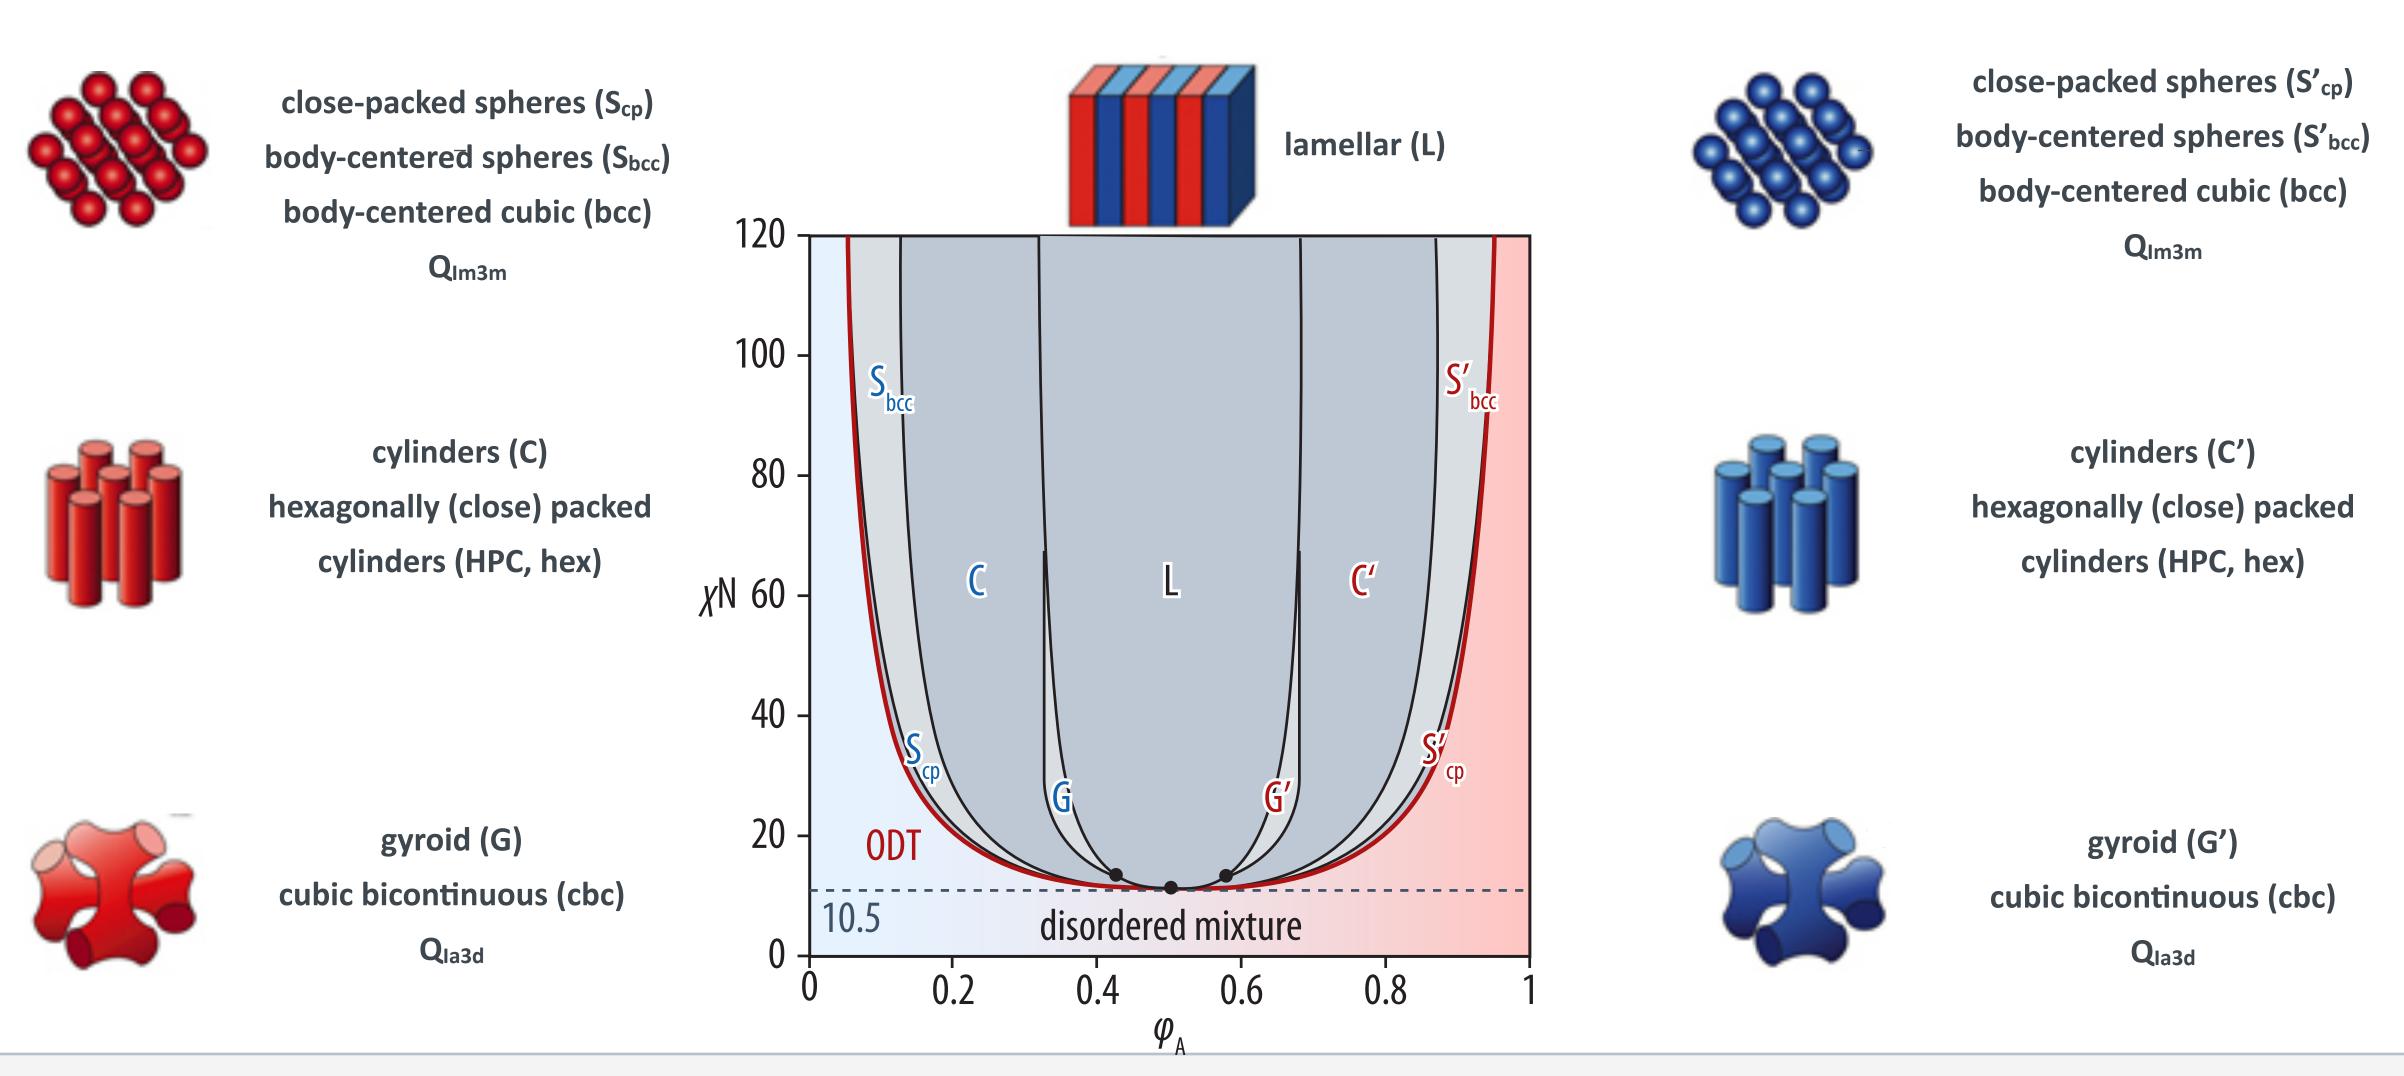

Polymer Blends versus Block Copolymers

phase segregation occurs at smaller length scales and is controlled by block lengths

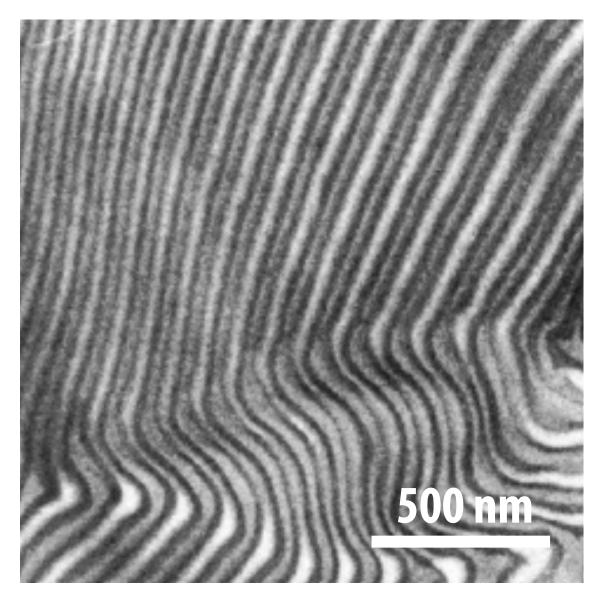

Phase Diagrams

• very characteristic periodic morphologies for monodisperse blocks according to (i) the ratio of block lengths $l_{\rm A}/l_{\rm B}$ and (ii) temperature

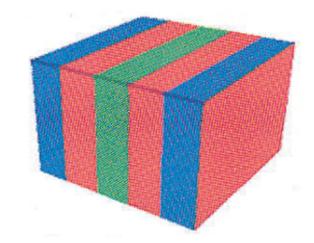

Triblock Copolymers

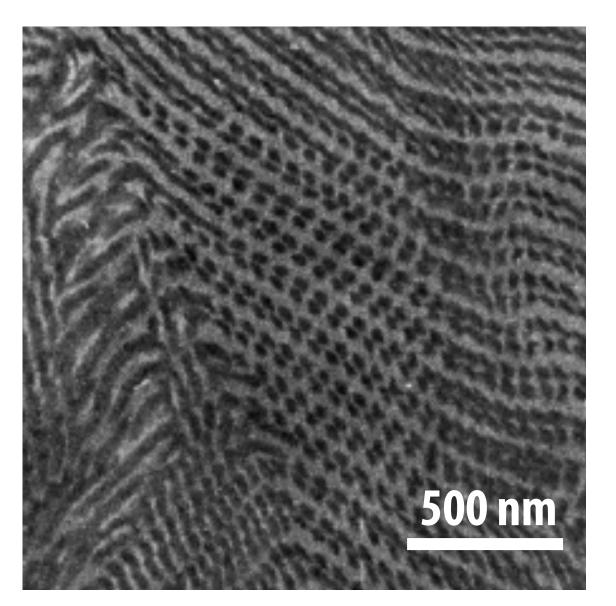

transmission electron microscopy (stained with OsO₄)

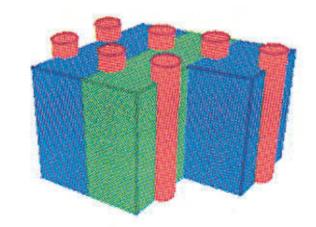

SBM 38 lamellae

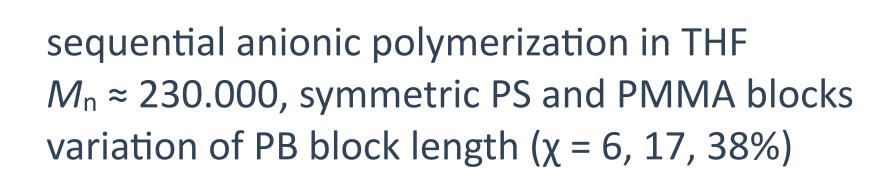

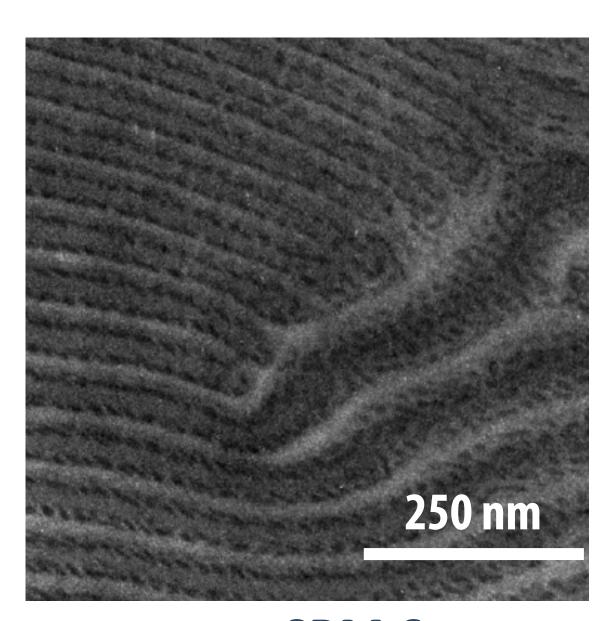

The second secon

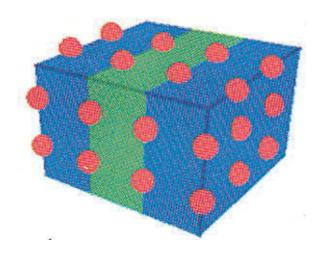

SBM 17 cylinders-at-lamellae

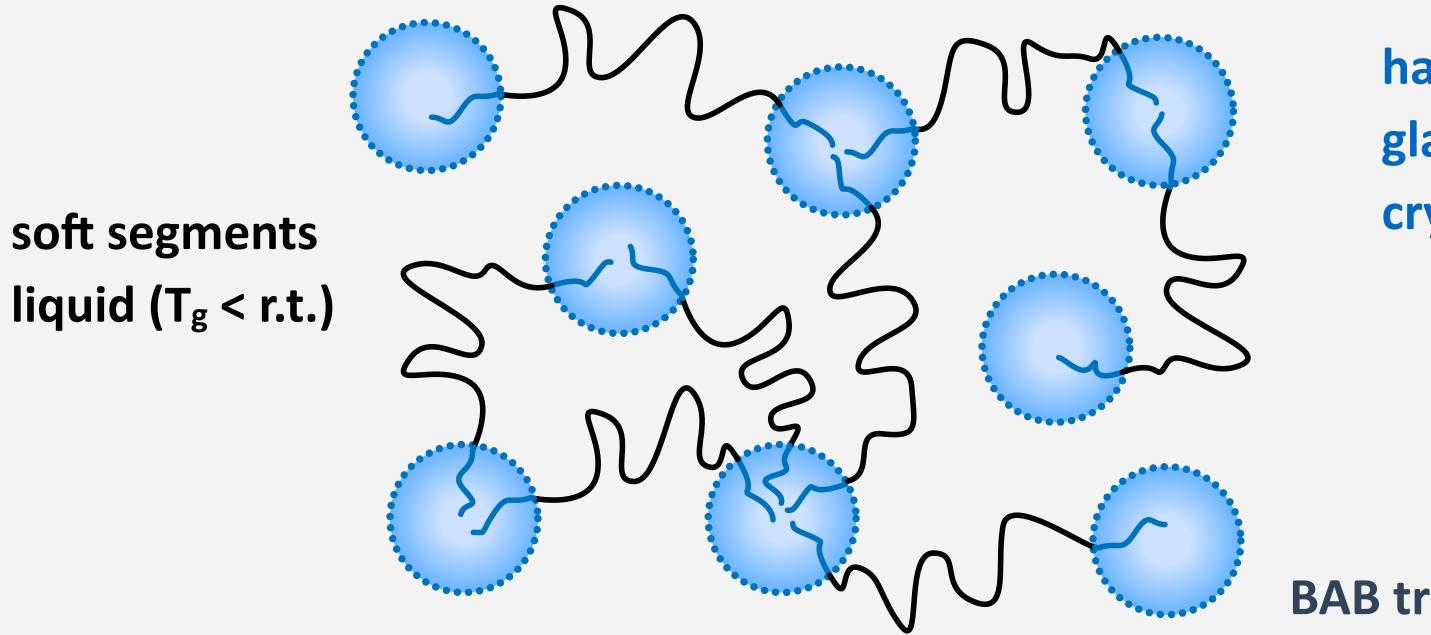

SBM 6 spheres-at-lamellae

BAB Triblock Copolymers - Thermoplastic Elastomers

• hard segments serve as "physical" cross-links, all chains fixed into a network structure

hard segments glassy ($T_g > r.t.$) or crystalline ($T_m > r.t.$)

BAB triblock copolymers

- ullet below T_m or T_g of the hard segments, the result is a rubber (elastomer)
- ullet above T_m or T_g of the hard segments, processable (extrusion, molding)
- thermoplastic elastomers are considered to be recyclable

Applications

1. Thermoplastic Elastomers

2. Emulsifiers

3. Nanotechnology

• self-organised structures as precursors in the manufacturing of periodic arrangements of inorganic nanoparticles (quantum dots

4. Compatibilization/Additive

- PS-b-PBD \rightarrow PS-b-PE: compatibilization of PS/PE mixtures
- PP + acrylic acid → improved adhesion with wood, CaCO3, cellulose (paper, cotton, ...)
- cellulose (paper, cotton,...) + fluorinated monomers: stain-resistant, hydrophobic, non-sticky materials.
- cellulose (paper, cotton,...) + UV absorbing monomers: anti-UV textiles (T-shirts in New Zealand)
- cellulose, polyesters + vinylphosphonates: flame retardant textiles
- any non-harmful support + biocompatible monomers: biocompatible materials
- etc., etc., etc.,...

Learning Outcome

- thermodynamics of binary polymer mixtures can be mapped within the framework of a lattice model. According to Flory-Huggins, polymer blends have very little mixing entropy, and mixing is determined by energetic factors. Most polymers are indeed immiscible with each other, but there are many exceptions to this rule of thumb because pairwise interaction energy differences are not always repulsive.
- by considering the temperature-dependence of the free energy of mixing, a phase diagram can be constructed to summarise the phase behavior of the mixture, showing regions of stability, instability, and metastability.
- block copolymers do not macroscopically phase separate but form domains on the scale of tens of nanometers. For monodisperse architectures, phase segregation (order-disorder transition) is accompanied by formation of well-defined periodic structures.
