Le fichier *.sta

Exo9: charge/décharge élastique d'une poutre encastrée

Les degrés de liberté (dof)

Degrees of freedom

5

6

Except for axisymmetric elements, fluid continuum elements, and electromagnetic elements, the degrees of freedom are always referred to as follows:

- 1 u1 = ux, u2 = uy et u3 = uz
- y-displacement magnitude = $\sqrt{\vec{u}.\vec{u}}$
- ³ z-displacement 11 = node temperature (temp pour les éléments)
- 4 Rotation about the *x*-axis, in radians

 Les dof 4 à 6 sont réservés aux coques (shells)
 - Rotation about the *z*-axis, in radians et poutres (beams)
- 7 Warping amplitude (for open-section beam elements)
- 8 Pore pressure, hydrostatic fluid pressure, or acoustic pressure
- 9 Electric potential
- 10 Connector material flow (units of length)

Rotation about the y-axis, in radians

11 Temperature (or normalized concentration in mass diffusion analysis)

Axisymmetric elements

The displacement and rotation degrees of freedom in axisymmetric elements are referred to as follows:

- 1 r-displacement !!!!! en axisymétrique (cylindrique):
- 2 z-displacement u1= ur et u2= uz

Les symétries

Un modèle EF a une symétrie si et seulement si la géométrie, les conditions aux limites et les matériaux présentent tout trois cette même symétrie.

Utiliser les symétries permet de diminuer les temps de calcul et de visualisation, la taille des fichiers et de simplifier les conditions isostatiques.

La symétrie plane se fait en imposant le déplacement selon la normale au plan à zéro.

Exemple avec un plan de normale e_v : u2 = uy = 0.

*boundary

ou *boundary

Nsym,2,2,0.

Nsym, ysymm

YSYMM

Symmetry about a plane Y = constant (degrees of freedom 2, 4, 6 = 0).

Modèle EF axisymétrique (géométrie, C.L. et matériaux)

L'axe de symétrie cylindrique est z (u1=ur et u2=uz). Les tenseurs contraintes et déformations n'ont alors que 4 composantes, 11 = rr, $33 = \theta\theta$, 22 = zz et 12 = rz.

Etude de la friction dans l'étirage de tubes sur olives: échauffement des outils dû à la friction sur les outils et aux déformations de l'acier inox 316 LVM.

Modèle EF axisymétrique (géométrie, C.L. et matériaux)

L'axe de symétrie est z (u1=ur et u2=uz).

Miniaturized tube fixed plug drawing: Determination of the friction coefficients and drawing limit of 316 LVM stainless steel

N. Chobaut^a, J-M. Drezet^{b,*}, S. Mischler^b, V. Nguyen^b, B. De Marco^c, S. Dobler^c, E. Rosset^a

^a University of Applied Sciences and Arts Western Switzerland (HES-SO), Hepia, 1202 Geneva, Switzerland

^b Swiss Federal Institute of Technology (EPFL), Tribology and Interfacial Chemistry Group, 1015 Lausanne, Switzerland

^c Swiss-Tube LN Industries SA, 1424 Champagne, Switzerland

Modèle EF avec symétrie cyclique (géométrie, C.L. et matériaux)

La pièce n'est pas axisymétrique mais il y a invariance par secteurs autour d'un axe. On ne modélise alors qu'un secteur (1/8 de la pièce) et on applique les bonnes C.L. sur les bords du secteur.

MPC type CYCLSYM imposes the cyclic symmetry by equating radial, circumferential, and axial displacement components (and rotations, if active) at the two nodes (a and b). The symmetry axis can be defined by the original coordinates of two additional nodes (c and d) that do not need to be connected to any element in the structure. Scalar degrees of freedom (such as temperature) are made equal.

Aube avec 8 secteurs

Modèle EF avec symétrie cyclique (géométrie, C.L. et matériaux)

On utilise *mpc (multipoint constraints) pour les C.L sur les 2 bords du secteur. Dans notre cas, l'axe de symétrie cyclique est z donc on réalise un maillage concordant nœud à nœud sur les 2 faces pour utiliser cyclsym (sinon, on utilise des surfaces ...).

****** mpc with rotation around z axis *mpc cyclsym,Na,Nb

Le nième nœud du node set Na a le même vecteur déplacement et la même température que le nième nœud du node set Nb.

Modèle EF: conditions isostatiques

Conditions isostatiques: retirer les possibles translations et rotations du corps rigide pour en étudier seulement les déformations (dans ce cas, le tenseur des déformations vaut gradu).

Il convient de bloquer ux, ou uy ou uz sur au moins 3 points différents (sinon pb de convergence).

*boundary,type=displacement (default)

```
****** Nomenclature Abaqus
*boundary
node, i, j, val
***** signifie que les dof i à j sont imposés à la valeur val

Exemple:
```

```
*boundary
```

```
3256,2,2,0. (dof 2 = 0.)
1250,1,1,0.1 (dof 1 = 0.1)
325,3 (dof 3 à 3 = 0.)
nfix,1,3,0. (dof 1 à 3 sont nuls sur nfix)
```

*BOUNDARY

EDGE, 1

indicates that all nodes in node set EDGE are constrained in degree of freedom 1 (u_x), while the data line

EDGE, 1, 4

indicates that all nodes in node set EDGE are constrained in degrees of freedom 1-4 (u_x , u_y , u_z , ϕ_x).

*boundary,type=displacement (default)

TYPE

This parameter cannot be used with the FIXED parameter.

This parameter is used in a stress/displacement analysis to specify whether the magnitude is in the form of a displacement history, a velocity history, or an acceleration history. In an Abaqus/Standard analysis TYPE=VELOCITY should normally be used to specify finite rotations.

Set TYPE=DISPLACEMENT (default) to give a displacement history. Abaqus/Explicit does not admit jumps in displacement. If no amplitude is specified, Abaqus/Explicit will ignore the user-supplied displacement value and enforce a zero displacement boundary condition. See "Boundary conditions in Abaqus/Standard and Abaqus/Explicit," Section 34.3.1 of the Abaqus Analysis User's Guide, for details. In Abaqus/CFD this type is used to prescribe mesh displacements.

Set TYPE=VELOCITY to give a velocity history. Velocity histories can be specified in static analyses in Abaqus/Standard, as discussed in "Prescribing large rotations" in "Boundary conditions in Abaqus/Standard and Abaqus/Explicit," Section 34.3.1 of the Abaqus Analysis User's Guide. In this case the default variation is STEP. Velocity histories are not used in Abaqus/CFD.

Set TYPE=ACCELERATION to give an acceleration history. Acceleration histories should not be used in Abaqus/CFD or in static analysis steps in Abaqus/Standard.

$$\dot{\mathbf{u}}_1 = \frac{\partial \mathbf{u}_1}{\partial \mathbf{t}} = \frac{\partial \mathbf{u}_x}{\partial \mathbf{t}} = 0.5 \text{ (L/T eg mm/s)}$$

*boundary, op = mod (default)

Permet de modifier les C.L. dans les différents steps donc lors des différents chargements.

!!!! Op=new annule toutes les C.L. préexistantes.

OP

Set OP=MOD (default) to modify existing boundary conditions or to add boundary conditions to degrees of freedom that were previously unconstrained.

Set OP=NEW if all boundary conditions that are currently in effect should be removed. To remove only selected boundary conditions, use OP=NEW and respecify all boundary conditions that are to be retained.

If a boundary condition is removed in a stress/displacement analysis in Abaqus/Standard, it will be replaced by a concentrated force equal to the reaction force calculated at the restrained degree of freedom at the end of the previous step. If the step is a general nonlinear analysis step, this concentrated force will then be removed according to the AMPLITUDE parameter on the *STEP option. Therefore, if the default amplitudes are used, the concentrated force will be reduced linearly to zero over the period of the step in a static analysis and immediately in a dynamic analysis.

Les chargements mécaniques locaux et surfaciques

• Pressure:

- Units: force / area
- Is always **NORMAL** to the surface
- Positive towards the Inside
- *dsload

top,p,0.2

Surface tractions:

- Units: force / area
- Define intensity and stress vector e*dsload

Surf, TRVEC, 0.1, 0., 0., -1.

Imposed shear:

- Special case: type « TRSHR » for surface shear
- vector e is parallel to the surface
- The shear tractions will be // to surface
- *Dsload Surf, TRSHR, 0.32, 0., 0., -1.

Les chargements mécaniques volumiques

• Gravity (or any other linear acceleration):

- Units: L/T²
- Defines the accelaration vector g of gravity loads.
- You must define a density in material properties
- *dload
- eall,grav,10.,0.,0.,-1.

Body force (linear volumic force):

- Units: Force/volume
- Defines the volumic force fv (force per unit volume) as 3 components in X,Y,Z.
- *dload
- eall,bx,-1.e-2
- eall, by, 1.e-3

Centrifugal loads (rotationnal body force)

- Type « centrifuge » : centrifuge acceleration around a rotation axis
- Define rotation speed ω
- Define rotation axis by 2 separate points and possibly $d\omega/dt$

fv dv

Les chargements mécaniques, forces, moments et déplacements

Concentrated force (on point)

- Units: force, only available on a point
- *cload
- 9945,1,200.
- 9945,2,-30.

• Moment:

- Units: force * length !!
- Only on concentrated points linked to a shell, beam or reference point
- *cload

• Imposed displacement:

- Units: length
- Defines selected components of displacement on each node of a region.
- Rotation UR can only be imposed on shell, beams or reference points.

Else it is ignored.

*boundary

Nfix, 1, 3, 0.

Symmetry, Encastre :

- These are just **presets** (eg. zsymm) for imposed displacement = 0

*elastic, type =isotropic (default value)

Data lines to define isotropic elasticity (TYPE=ISOTROPIC):

First line:

- 1. Young's modulus, E.
- 2. Poisson's ratio, ν .
- 3. Temperature, θ .
- 4. First field variable.
- 5. Second field variable.

****Aluminium, N, mm, s

**** unit for E: MPa

**** E, nu, temp

*elastic

71.e3,0.31,20.

53.e3,0.33,200.

39.e3,0.37,500.

*elastic, type =engineering constants for non isotropic behaviour (laminas, fibers, ...)

- *step, inc = \dots , name = \dots , nlgeom = \dots
- est suivi d'une procédure (*static, *heat transfer, *coupled temperature-displacement, *dynamic, etc)
- et se termine par *end step

Optional parameters: inc =, name =, nlgeom = no (default) nlgeom = yes or no: non linéarité géométrique : la matrice de rigidité est recalculée à chaque incrément sur le maillage déformé

Set this parameter equal to the maximum number of increments in a step (or in a single loading cycle for direct cyclic analysis). This value is only an upper bound. The default value is 100.

The INC parameter has no effect in procedures where automatic incrementation cannot be used (for example, *BUCKLE, *STEADY STATE DYNAMICS, and *MODAL DYNAMIC).

NAME

Set this parameter equal to a label that will be used to refer to the step on the output database. Step names in the same input file must be unique. Step names from the original input file can be reused in a restart input file.

NLGEOM

Omit this parameter or set NLGEOM=NO to perform a geometrically linear analysis during the current step. Include this parameter or set NLGEOM=YES to indicate that geometric nonlinearity should be accounted for during the step (stress analysis, fully coupled thermal-stress analysis, and coupled thermal-electrical-stress analysis only). Once the NLGEOM option has been switched on, it will be active during all subsequent steps in the analysis.

INC

Amplitude du chargement: *step, amp =

This parameter defines the default amplitude variation for loading magnitudes during the step.

Set AMPLITUDE=STEP if the load is to be applied instantaneously at the start of the step and remain constant throughout the step.

Set AMPLITUDE=RAMP if the load magnitude is to vary linearly over the step, from the value at the end of the previous step (or zero, at the start of the analysis) to the value given on the loading option.

If this parameter is omitted, the default amplitude choice depends on the procedure chosen, as shown in "Defining an analysis," Section 6.1.2 of the Abaqus Analysis User's Guide. The default amplitude variation can be overwritten for individual loadings by using the AMPLITUDE parameter on the loading options ("Amplitude curves," Section 34.1.2 of the Abaqus Analysis User's Guide).

This parameter is rarely needed, and changing the defaults may cause problems. For example, the automatic load incrementation scheme in procedures without a real time scale (such as the *STATIC option) applies the loads gradually by incrementing the normalized time scale. The use of AMPLITUDE=STEP specifies that the entire load will be applied immediately, so Abaqus/Standard may not be able to choose suitable small increments if the loading causes strongly nonlinear response.

plusieurs *step dans abaqus

Un step = une étape de chargement (mécanique, thermique, changement de conditions aux limites,). Exemple sur la poutre encastrée:

Step 1 = chargement à 12 kPa sur la surface supérieure :

```
*STEP ,amp=ramp,nlgeom=yes loading 12 kPa
```

*static

THE ANALYSIS HAS COMPLETED SUCCESSFULLY

Exemple: calcul du fléchissement (ou déflection) d'une poutre élastique sous pression uniforme

La mathématique du pb: calcul du champ de déplacement u, des déformations élastiques et des contraintes dans la poutre encastrée.

3 équations aux dérivées partielles (EDP) linéaires et couplées à résoudre par la méthode des éléments finis: les coefficients C (tenseur d'élasticité) sont des fonctions de E et v uniquement pour comportement isotrope.

$$\begin{split} & \rho g_X + \frac{\partial}{\partial x} \Bigg[C_{11} \frac{\partial u_X}{\partial x} + C_{12} \frac{\partial u_Y}{\partial y} + C_{12} \frac{\partial u_Z}{\partial z} \Bigg] + \frac{\partial}{\partial y} \Bigg[C_{44} \left(\frac{\partial u_X}{\partial y} + \frac{\partial u_Y}{\partial x} \right) \Bigg] + \frac{\partial}{\partial z} \Bigg[C_{44} \left(\frac{\partial u_X}{\partial z} + \frac{\partial u_Z}{\partial x} \right) \Bigg] = 0 \\ & \rho g_Y + \frac{\partial}{\partial y} \Bigg[C_{12} \frac{\partial u_X}{\partial x} + C_{11} \frac{\partial u_Y}{\partial y} + C_{12} \frac{\partial u_Z}{\partial z} \Bigg] + \frac{\partial}{\partial x} \Bigg[C_{44} \left(\frac{\partial u_X}{\partial y} + \frac{\partial u_Y}{\partial x} \right) \Bigg] + \frac{\partial}{\partial z} \Bigg[C_{44} \left(\frac{\partial u_Y}{\partial z} + \frac{\partial u_Z}{\partial y} \right) \Bigg] = 0 \\ & \rho g_Z + \frac{\partial}{\partial z} \Bigg[C_{12} \frac{\partial u_X}{\partial x} + C_{12} \frac{\partial u_Y}{\partial y} + C_{11} \frac{\partial u_Z}{\partial z} \Bigg] + \frac{\partial}{\partial x} \Bigg[C_{44} \left(\frac{\partial u_X}{\partial z} + \frac{\partial u_Z}{\partial x} \right) \Bigg] + \frac{\partial}{\partial y} \Bigg[C_{44} \left(\frac{\partial u_Y}{\partial z} + \frac{\partial u_Z}{\partial y} \right) \Bigg] = 0 \end{split}$$

On peut donc:

- 1- comparer la solution EF avec la solution analytique venant de la théorie des poutres
- 2- et étudier la dépendance des résultats EF avec la finesse du maillage et la nature des éléments (linéaires ou quadratique).

pour une poutre encastrée sous charge linéique
$$q$$
, on a $\delta = \frac{qL^4}{8EI}$.

| variable | valeur | unités SI |
