

MSE-441 Exercise-3 Solutions

1. High field approximation (HFA): $|\eta| > 0.1 \text{ V}$

Anodic current; $i = i_o \exp\{(1 - \alpha) \eta F/RT\}$

Cathodic current; $i = -i_o \exp\{-\alpha \eta F/RT\}$

2. Low field approximation (LFA): $|\eta| < 0.01 \text{ V}$

$$i = 2i_o \sin(F\eta/2RT) \approx 2i_o (F\eta/2RT) = i_o (F\eta/RT)$$

3. For $\eta \approx 0.01 \text{ V} - 0.1 \text{ V}$

Use the BV-equation.

4. BV equation can be used as it is under any circumstances.

Exercise 1:

Calculate the ratio of the rates of the reaction: $\text{Ag}^+ + \text{e}^- \rightarrow \text{Ag}$ at:

- a) $\eta = -0.15 \text{ V}$ & $\eta = 0.15 \text{ V}$.
- b) $\eta = -0.2 \text{ V}$ & $\eta = 0.2 \text{ V}$.

Assume room temperature at 25°C .

$$\text{rate} = i/(nF)$$

$$\text{Therefore, } \text{rate}_1 / \text{rate}_2 = i_1 / i_2$$

Since it is a cathodic reaction, we compare the cathodic rate for both η .

$$i_c = i_o \exp\{-\alpha \eta F/RT\}$$

$$\begin{aligned} \text{a) } \frac{i_{c1}}{i_{c2}} &= \frac{e^{-0.5(-0.2)\frac{96500}{8.314(298)}}}{e^{-0.5(0.2)\frac{96500}{8.314(298)}}} = \frac{18.56}{0.054} = \mathbf{344} \\ \text{b) } \frac{i_{c1}}{i_{c2}} &= \frac{e^{-0.5(-0.2)\frac{96500}{8.314(298)}}}{e^{-0.5(0.2)\frac{96500}{8.314(298)}}} = \frac{49}{0.02} = \mathbf{2450} \end{aligned}$$

A small change in potential from -0.2 to $+2 \text{ V}$ increases the rate by 2450 times

Exercise 2:

For an overpotential of $\eta = 10 \text{ mV}$, a current $I = 0.62 \text{ mA}$ is passed through a 2 cm^2 Pt electrode for a H^+/H_2 half reaction given as: $\text{H}^+ + \text{e}^- \rightarrow \frac{1}{2} \text{H}_2$.

What will be the current density i for (a) $\eta = 100 \text{ mV}$? (b) $\eta = -100 \text{ mV}$?

Assume the symmetry factor as 0.5 and a room temperature of 25°C

For $\eta = 10 \text{ mV} = 0.01 \text{ V}$, we have $i = I/A = 0.62/2 = 0.31 \text{ mA.cm}^{-2}$

The exchange current density i_0 is obtained using the BV equation

$$i = i_0 (e^{(1-\alpha) \eta F / RT} - e^{-\alpha \eta F / RT})$$

$$0.31 = i_0 [e^{0.5 \times 0.01 \times F / RT} - e^{-0.5 \times 0.01 \times F / RT}]$$

$$i_0 = 0.79 \text{ mA.cm}^{-2}$$

a) For $\eta = 100 \text{ mV} = 0.1 \text{ V}$

$$i = 0.79 (e^{0.5 \times 0.1 \times 96500 / 8.314 \times 298} - e^{-0.5 \times 0.1 \times 96500 / 8.314 \times 298})$$

$$i = 5.42 \text{ mA.cm}^{-2}$$

b) For $\eta = -100 \text{ mV} = -0.1 \text{ V}$

$$i = 0.79 (e^{0.5 \times -0.1 \times 96500 / 8.314 \times 298} - e^{-0.5 \times -0.1 \times 96500 / 8.314 \times 298})$$

$$i = -5.42 \text{ mA.cm}^{-2}$$

Exercise 3:

The exchange current density of a Pt electrode for the H^+ / H_2 half reaction is $i_0 = 0.79 \text{ mA.cm}^{-2}$ at 25°C.

Calculate the current density across it when the over potential is (a) $\eta = 10 \text{ mV}$ (b) $\eta = -200 \text{ mV}$.

a) For $\eta = 10 \text{ mV} = 0.01 \text{ V}$,

$$i = i_0 \eta F / RT = 0.79 \frac{(0.01) 96500}{8.314 (298)} = 0.308 \text{ mA.cm}^{-2}$$

b) $\eta = -200 \text{ mV} = -0.2 \text{ V}$, negative (net cathodic current)

$$i = i_0 e^{-\alpha \eta F / RT} = 0.79 e^{-0.5 \times 0.2 \times 96,500 / RT} = 38.79 \text{ mA.cm}^{-2}$$

$$i = i_a - i_c = -i_c = -38.79 \text{ mA.cm}^{-2}$$

Exercise 4:

Calculate the effective resistance across 1 cm^2 of

a) Pt, H_2 , H^+ ; $i_0 = 0.79 \text{ mA.cm}^{-2}$

b) Hg, H_2 , H^+ ; $i_0 = 0.79 \times 10^{-12} \text{ A.cm}^{-2}$

What conclusion you can draw from the result?

For $\eta < 0.01 \text{ V}$ and using $I = i_0 \frac{\eta F}{RT}$, the overpotential is obtained as $\eta = I \frac{RT}{i_0 F}$.

With $V = IR$, then area specific resistance $ASR = \frac{RT}{i_0 F}$ and the resistance is $R = ASR \times A$

$$a) ASR = \frac{8.314 (298)}{(0.790 \times 10^{-3}) 96,495} = 32.5 \Omega. \text{cm}^2$$

Less resistance, the electrode can be less polarizable (non-polarizable)

$$b) ASR = \frac{8.314 (298)}{(0.790 \times 10^{-12}) 96,495} = 3.25 \times 10^{10} \Omega. \text{cm}^2$$

Greater resistance, the electrode can be more polarizable

Exercise 5:

In an experiment involving Pt, H₂, H⁺ electrode, the following data were obtained at 298 K. Determine α_{anodic} and i_0

η/mV	50	100	150	200	250
$i / \text{mA}\cdot\text{cm}^{-2}$	3.19	10.69	35.88	120.00	402.00

Answer:

Do the Tafel plot:

η/mV	50	100	150	200	250
$\ln(i) / \text{mA}\cdot\text{cm}^{-2}$	1.16064768	2.369496	3.58018	4.787492	5.996452

The reaction is anodic ($\eta > 0$, and $i > 0$), use B-V equation for anode:

$$i = i_0 \times \exp\left(\frac{z\alpha_{\text{anodic}}F\eta}{RT}\right)$$

$$\ln(i) = \ln(i_0) + \frac{z\alpha_{\text{anodic}}F\eta}{RT}$$

$$\text{slope} = 0.0242 = \frac{z\alpha_{\text{anodic}}F}{RT} = \frac{2 \times \alpha_{\text{anodic}} \times 96485 \text{ A} \cdot \frac{\text{s}}{\text{mol}} \times 0.001 \frac{\text{V}}{\text{mV}}}{8.314 \frac{\text{J}}{\text{mol} \cdot \text{K}} \times 298 \text{ K}}$$

$$\alpha_{\text{anodic}} = 0.689$$

$$\text{intercept} = -0.048 = \ln(i_0)$$

$$i_0 = 0.953 \text{ mA/cm}^2$$

Exercise 6:

For the system Pt /Fe³⁺, Fe²⁺ at 298K the i were measured as shown below:

Determine α_{anodic} , α_{cathodic} and i_0

η/mV	-50	-80	-100	-120	-150	-200
$i / \text{mA}\cdot\text{cm}^{-2}$	-8.01	-16.1	-25.17	-41	-82.4	-264
η/mV	50	80	100	120	150	200
$i / \text{mA}\cdot\text{cm}^{-2}$	5.50	8.78	11.91	16.30	26.00	56.60

Answer:

Do the Tafel plot:

For anodic plot ($\eta > 0$, and $i > 0$):

$$i = i_0 \times \exp\left(\frac{z\alpha_{\text{anodic}}F\eta}{RT}\right)$$

$$\ln(i) = \ln(i_0) + \frac{z\alpha_{\text{anodic}}F\eta}{RT}$$

$$\text{slope} = 0.0155 = \frac{z\alpha_{\text{anodic}}F}{RT}$$

$$\alpha_{\text{anodic}} = 0.398$$

$$\text{intercept} = 0.9261 = \ln(i_0)$$

$$i_0 = 2.52 \text{ mA/cm}^2$$

For cathodic plot ($\eta < 0$, and $i < 0$),

$$|i| = i_0 \times \exp\left(\frac{-z\alpha_{\text{cathodic}}F\eta}{RT}\right)$$

$$\ln(|i|) = \ln(i_0) + \frac{-z\alpha_{cathodic}F\eta}{RT}$$

$$slope = -0.0233 = \frac{-z\alpha_{cathodic}F}{RT}$$

$$\alpha_{cathodic} = 0.598$$

$$intercept = 0.9092 = \ln(i_0)$$

$$i_0 = 2.48 \text{ mA/cm}^2$$

The value of i_0 estimated from anode and cathode plot should be close.

Not that the sum of $\alpha_{cathodic}$ and α_{anodic} is approximately 1.

$$\alpha_{cathodic} + \alpha_{anodic} = 1$$

Exercise 7:

The exchange current density of Pt/Fe³⁺, Fe²⁺ is 2.5 mA·cm⁻². Calculate the current density across the electrode at 25 °C maintained at 1V when [Fe²⁺] = 0.1 M and [Fe³⁺] = 0.2 M (Standard reduction potential = 0.771 V, $\alpha_{cathodic} = 0.58$)

Answer:

Reaction is

First, the thermodynamic potential of the reaction at operation condition is

$$E = E^o - \frac{RT}{nF} \ln \frac{[\text{Fe}^{2+}]}{[\text{Fe}^{3+}]} = 0.771 - \frac{8.314 \times 298}{1 \times 96485} \ln \frac{1}{2} = 0.788 \text{ V}$$

To calculate overpotential:

$$E_{applied} = E + \eta$$

$$\eta = 1 - 0.788 = 0.212 \text{ V}$$

The reaction is anodic, use anodic B-V equation:

$$i = i_0 \times \exp\left(\frac{z\alpha_{anodic}F\eta}{RT}\right)$$

$$\alpha_{anodic} = 1 - \alpha_{cathodic}$$

$$i = 2.5 \times \exp\left(\frac{1 \times (1 - 0.58) \times 96485 \times 0.212}{8.314 \times 298}\right) = 80.3 \text{ mA/cm}^2$$
