2022 Experimental Methods in Physics Marco Cantoni

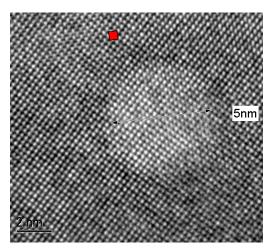

#### High resolution ....?!

#### electron at 300keV:

- $v = 2.33 \cdot 10^{-8} \text{ m/s}$ (0.78 c)
- $\lambda = 0.00197$ nm
- $\theta_{\rm diff}$  = 10<sup>-3</sup> rad

Atomic resolution ...?

Precipitate in a ceramic: PbTiO<sub>3</sub>

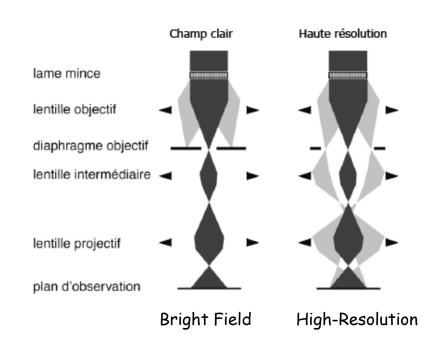

## the TEM in "high-resolution" mode

A high-resolution image is an interference image of the transmitted and the diffracted beams!

Diffracted electrons: coherent elastic scattering (the electrons have seen the crystal lattice)

The quality of the image depends on the optical system that makes the beams interfere

2022

## High-resolution

- The image should resemble the atomic structure!
- Atoms...?
   Thin samples: atom columns: orientation of the sample (incident beam // atom columns)
- The observed contrast varies with thickness and defocalisation...!
- Need to compare with simulations!

## The objective lens

- Field with rotational symmetry
- Lorenz Force: F = -e v ^ B
   e on optical axis: F = 0
   e not on optical axis: deviated
   optical axis: symmetry axis
  - Scherzer 1936:
  - Magnetic lens with rotational symmetry:

Aberration coefficients:

 $C_s$ : spherical

 $C_c$ : chromatical

Always positive !!

$$C_{s} = \frac{1}{16} \int_{z_{s}}^{z_{s}} \left\{ b^{4}h^{4} + 2(hb' + h'b)^{2} h^{2} + 2b^{2}h^{2}h'^{2} \right\} dz$$

$$C_{c} = \frac{1}{4} \int_{z_{s}}^{z} b^{2}h^{2} dz$$

Resolution limit:  $D_{res}=0.66\lambda^{3/4}C_s^{1/4}$ 

Example:

$$\lambda$$
= 0.00197nm, C<sub>s</sub> = 1 mm  
D<sub>res</sub> = 1.8 10<sup>-10</sup> = 1.8Å

### Image formation

Illumination

$$\Psi(\vec{\mathbf{r}}) = \Psi_0 \exp^{2\pi i \vec{\mathbf{k}} \cdot \vec{\mathbf{r}}}$$

Sample

$$\Psi_o(\vec{\mathbf{x}}) = exp\left[-i\sigma V_p(\vec{\mathbf{x}};z)\right] \cong 1 - i\sigma V_p(\vec{\mathbf{x}};z)$$

· objective lens

$$T(\vec{\mathbf{h}}) = \exp[2\pi i \chi(\vec{\mathbf{h}})]$$
 avec  $\chi(\vec{\mathbf{h}}) = 0.25C_s \lambda^3 h^4 + 0.5\Delta z \lambda h^2$ 

$$\Psi_{o}(\vec{\mathbf{x}}) = \Psi_{o}(\vec{\mathbf{x}}) \otimes T(\vec{\mathbf{x}})$$

· Image, contrast

$$I_{i}(\vec{\mathbf{x}}) = \Psi_{i}(\vec{\mathbf{x}})\Psi_{i}^{*}(\vec{\mathbf{x}})$$

### sample = phase objet

Plane wave

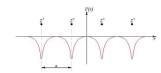

Wave vector in vacuum:

$$k = \sqrt{\frac{2me(E)}{h^2}}$$

Wave vector in a potential:

$$k = \sqrt{\frac{2me(E + V(\vec{r}))/h^2}{h^2}}$$

Cristal potential

Cristal potential = phase object

Phase shift  $\Delta\alpha$  due to the cristal potential  $V_p$ :

$$\Delta \alpha = \frac{\sigma}{2\pi} V_p(\vec{x}, z)$$

$$\sigma = \frac{\pi}{\lambda E}$$

Exit wave function:

$$\Psi_o(\vec{\mathbf{x}}) = exp\left[-i\sigma V_p(\vec{\mathbf{x}};z)\right]$$

2022

Experimental Methods in Physics

Marco Cantoni

#### WPOA

Weak phase object approximation:

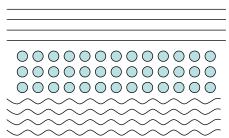

$$\Psi_o(\vec{\mathbf{x}}) = exp\left[-i\sigma V_p(\vec{\mathbf{x}};z)\right] \cong 1 - i\sigma V_p(\vec{\mathbf{x}};z)$$

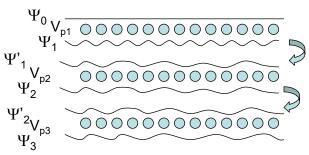

No absorbtion, effect of the object on the outgoing wave: only phase shift

The exit wave function contains the information about the structure of the sample

#### Multi-slice calculation:

Calculation of the exit wave function for complex structures:

The sample is cut into thin slices

#### Transfer Function

 The optical system (lenses) can be described by a convolution with a transfer function T(x):
 Point spread function (PSF): describes how a point on the object side is

transformed into the image.

$$\Psi_i(\underline{x}) = \int_{-\infty}^{\infty} \Psi_o(\underline{u}) T(\underline{x} - \underline{u}) d\underline{u} = \Psi_o(\underline{x}) \otimes T(\underline{x})$$

$$\Psi_i(\underline{h}) = \Psi_o(\underline{h})T(\underline{h})$$

 The image INTENSITY observed on a screen (or a camera / negative plate etc.)

$$I_{i}(\underline{\boldsymbol{x}}) = \Psi_{i}(\underline{\boldsymbol{x}})\Psi_{i}^{*}(\underline{\boldsymbol{x}}) \qquad I_{i}(\underline{\boldsymbol{h}}) = \Psi_{i}(\underline{\boldsymbol{h}}) \otimes \Psi_{i}^{*}(-\underline{\boldsymbol{h}}) = \int \Psi_{i}(\underline{\boldsymbol{h}}')\Psi_{i}^{*}(\underline{\boldsymbol{h}} - \underline{\boldsymbol{h}}')d\underline{\boldsymbol{h}}'$$

$$I_{i}(\underline{\boldsymbol{h}}) = [\Psi_{o}(\underline{\boldsymbol{h}})T(\underline{\boldsymbol{h}})] \otimes [\Psi_{o}^{*}(-\underline{\boldsymbol{h}})T^{*}(-\underline{\boldsymbol{h}})]$$

2022

Experimental Methods in Physics

Marco Cantoni

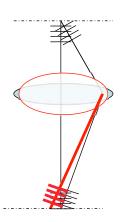

#### Coherent Transfer Function (CTF) of magnetic lens

$$T(\vec{\mathbf{h}}) = \exp[2\pi i \chi(\vec{\mathbf{h}})]$$

$$\chi(\vec{\mathbf{h}}) \neq 0.25C_s \lambda^3 h^4 + 0.5\Delta z \lambda h^2$$

Spherical aberration

defocus

Object plane

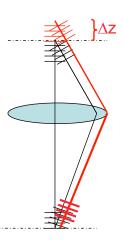

image plane

### The « magic » of image contrast

Objet de Phase Faible (Weak Phase Object)

$$\begin{split} \Psi_o(\underline{\pmb{x}}) &= \exp[-i\sigma V_p(\underline{\pmb{x}};z)] \cong 1 - i\sigma V_p(\underline{\pmb{x}};z) \\ \Psi_o(\underline{\pmb{h}}) &= \delta(\underline{\pmb{h}}) - i\sigma V_p(\underline{\pmb{h}}) \\ \Psi_i(\underline{\pmb{h}}) &= \Psi_o(\underline{\pmb{h}})T(\underline{\pmb{h}}) = \Psi_o(\underline{\pmb{h}})\exp[2\pi i\chi(\underline{\pmb{h}})] \\ \Psi_i(\underline{\pmb{h}}) &= [\delta(\underline{\pmb{h}}) - i\sigma V_p(\underline{\pmb{h}})]\cos 2\pi \chi(\underline{\pmb{h}}) + i\sin 2\pi \chi(\underline{\pmb{h}}) \end{split}$$
 Fourier Space

En choisissant  $\sin[2\pi\chi(\underline{\mathbf{h}})] = -1$  et  $\cos[2\pi\chi(\underline{\mathbf{h}})] = 0$  pour les réflexions  $\underline{\mathbf{h}}$  les plus intenses,  $\Psi_i(\underline{\mathbf{h}})$ 

Fonction d'onde image

$$\Psi_i(\underline{\boldsymbol{h}}) = \delta(\underline{\boldsymbol{h}}) - \sigma V_p(\underline{\boldsymbol{h}})$$

L'intensité de l'image  $(\Psi_i(\underline{x})\ \Psi_i^*(\underline{x}))$  est alors donnée par :

Intensité de l'image de l'objet faible en contraste direct

$$I(\underline{\mathbf{x}}) = (1 - \sigma V_p(\underline{\mathbf{x}}))(1 + \sigma V_p(\underline{\mathbf{x}})) = 1 - 2\sigma V_p(\underline{\mathbf{x}}) + O(\sigma^2 V_p^2(\underline{\mathbf{x}}))$$

2022

Experimental Methods in Physics

Marco Cantoni

#### but....

En choisissant  $\sin[2\pi\chi(\underline{\mathbf{h}})] = 0$  et  $\cos[2\pi\chi(\underline{\mathbf{h}})] = 1$ , l'intensité de l'image  $(\Psi_i(\underline{\mathbf{x}}) \ \Psi_i^*(\underline{\mathbf{x}}))$  est puisque  $\Psi_i(\underline{\mathbf{h}})$  égale:

Fonction d'onde image

$$\Psi_i(\underline{\boldsymbol{h}}) = [\delta(\underline{\boldsymbol{h}}) - i\sigma V_p(\underline{\boldsymbol{h}})]$$

Intensité de l'image de l'objet faible en contrast inverse

$$I(\underline{\mathbf{x}}) = (1 - i\sigma V_p(\underline{\mathbf{x}}))(1 + i\sigma V_p(\underline{\mathbf{x}})) = 1 + \sigma^2 V_p^2(\underline{\mathbf{x}})$$

L'intensité est reliée linéairement au carré du potentiel projeté: l'interprétation en terme de colonnes atomiques et de canaux n'est plus aussi directe.

For a direct and simple interpretation of the image contrast: the imaginary part (sin) of the transfer function  $\exp[2pi\chi(h)]$  should be ~1

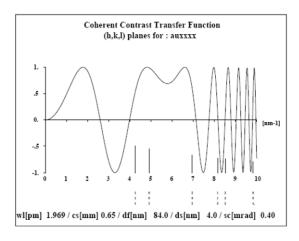

The only free parameter in the microscope is: the defocus  $\Delta z$ 

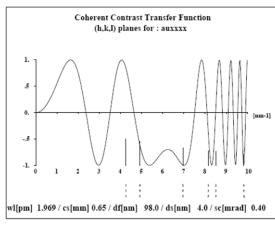

#### CTF

 CTF: contrast transfer function (« useful » = V<sub>p</sub>)

$$CTF(k) = -\sin\left[\frac{\pi}{2}C_s\lambda^3k^4 + \pi\Delta z\lambda k^2\right]$$

2022

Experimental Methods in Physics

Marco Cantoni

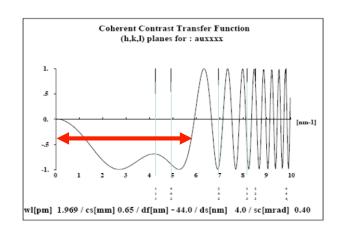

#### Scherzer defocus

With  $\Delta z_{\text{scherzer}}$ 

$$\Delta z = -\sqrt{\frac{4}{3}C_s\lambda}$$

The CTF has a wide pass band

$$D_{scherzer} = 0.66 \lambda^{3/4} C_s^{1/4}$$

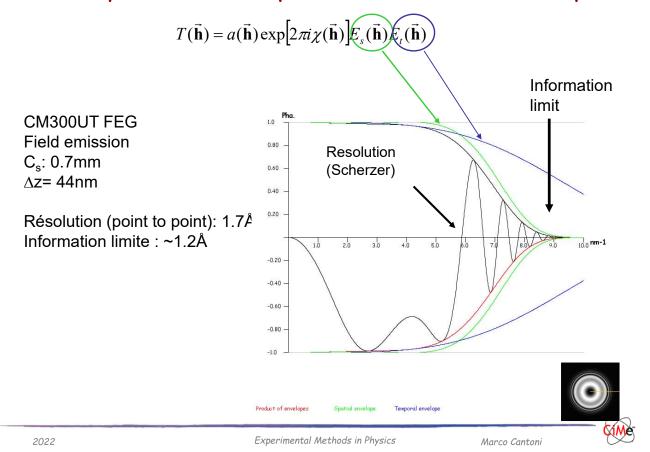

The first zero crossing of the CTF defines the « point-to-point » resolution of an electron microscope

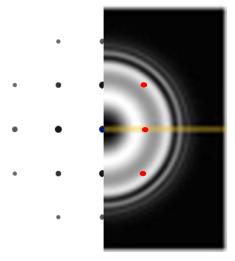

The atom columns appear as dark areas on a bright background

$$I(\underline{\mathbf{x}}) = (1 - \sigma V_p(\underline{\mathbf{x}}))(1 + \sigma V_p(\underline{\mathbf{x}})) = 1 - 2\sigma V_p(\underline{\mathbf{x}}) + O(\sigma^2 V_p^2(\underline{\mathbf{x}}))$$

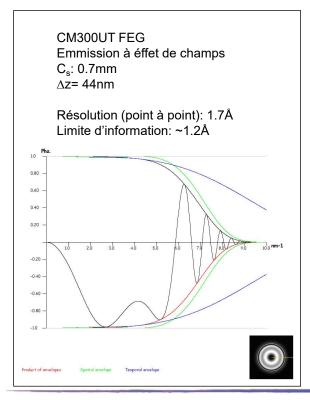

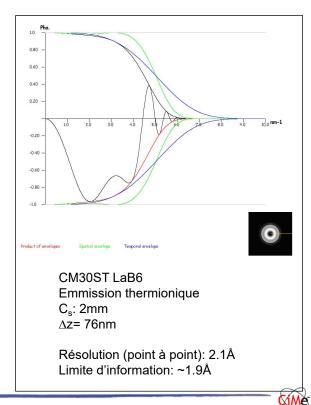

#### CTF & spatial and temporal coherence « envelopes »
