**Exercise 1.** The design peak luminosity of the LHC is $L = 10^{34}\,\mathrm{cm}^{-2}\mathrm{s}^{-1}$.

1. Knowing that at $E_{\text{c.o.m.}} = 14\,\text{TeV}$ and that the total event rate is $\frac{dN}{dt} = 1.115 \times 10^{9}\,\mathrm{s}^{-1}$, calculate the total cross section $\sigma_{\text{tot}}$ in barn ($1\,\mathrm{b} = 10^{-28}\,\mathrm{m}^2$).
2. At the same $E_{\text{c.o.m.}}$, the Higgs cross section is about $\sigma_{\text{Higgs}} \approx 57\,\text{pb}$. How many Higgs bosons are produced per second?

**Exercise 2.** The LHC collides 7 TeV proton beams. Calculate the center-of-mass energy relation for two beams:

$$E_{\text{C.O.M.}} = \sqrt{(E_1 + E_2)^2 - (\vec{p}_1 + \vec{p}_2)^2},$$

for the following cases:

1. Two colliding proton beams in the LHC.
2. An LHC proton beam hitting a fixed target.

What is the required proton beam energy hitting a fixed target to have the same $E_{\text{C.O.M.}}$ as the LHC?

**Exercise 3.** There are many future proposals for large particle accelerators. An interesting 10 TeV muon collider proposal is presented in *"10 TeV Center of Mass Energy Muon Collider"* K. Skoufaris [1]. Although the LHC tunnel could be potentially used for this collider, it would be expensive to change all the magnets — not to mention the muon beam cooling system...

Instead, as an intellectual exercise, let's inject some single muons from this proposed collider beam in the present LHC lattice for protons, neglecting any lifetime issues. Performing a Twiss command with the MAD-X simulation code results in the optics functions shown in Figure 1.

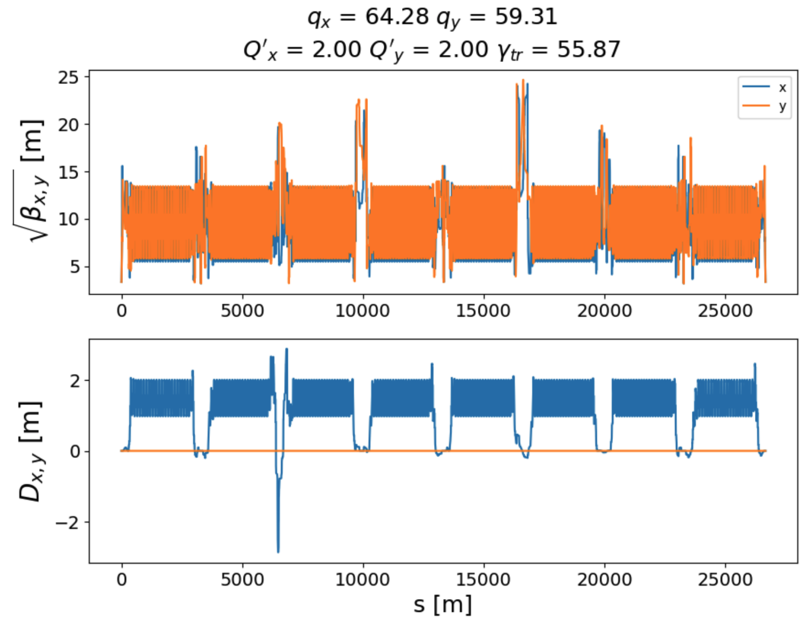

Figure 1: $\beta_{x,y}$ functions (top) and dispersion functions $D_{x,y}$ (bottom) for the muon collider in the LHC.

The $5\sigma_{x,y}$ beam envelope in the horizontal and vertical planes over the whole LHC can be seen in Figure 2. Recall the equation for the one-sigma ($n\sigma_x$, where $n = 1$) horizontal beam size:

$$\sigma_x(s) = \sqrt{\beta_x(s)\epsilon_x + \left(D_x(s)\frac{\Delta p}{p}\right)^2}. \tag{1}$$

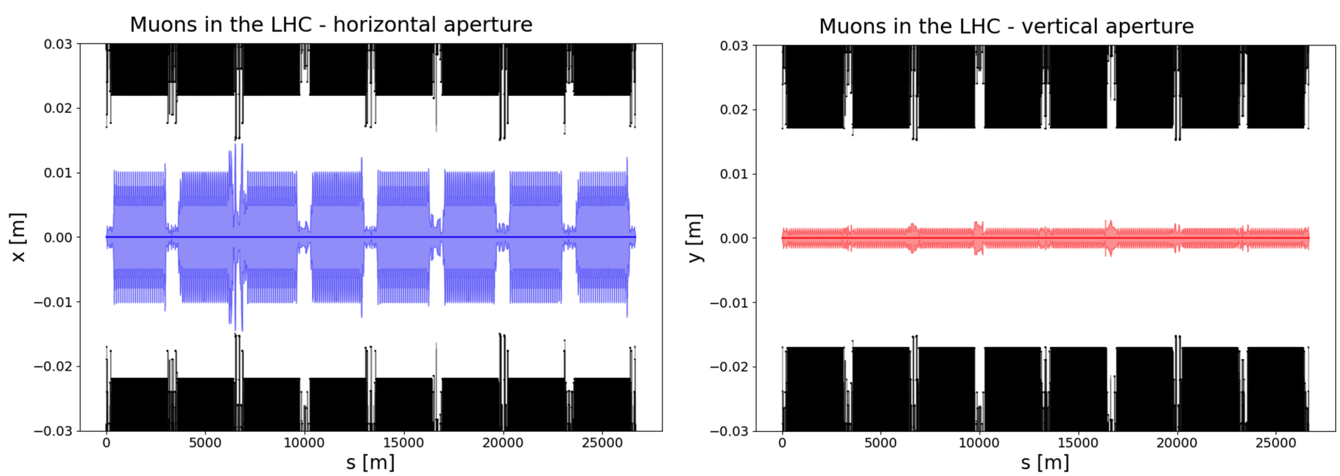

Figure 2: Horizontal and vertical beam envelope for the muon beam.

$D_x$ is the horizontal dispersion, $\beta_{x,y}$ is the beta function, $\epsilon_{x,y}$ is the emittance, and $\frac{\Delta p}{p}$ is the momentum spread, which we assume to be 0.05%. Let us see what can be deduced from these plots and the provided information:

1. What is the muon beam energy for this collider?

2. What is (very) approximately the horizontal emittance $\epsilon_x$ of this beam? (Hint: check the max values of the plots at an easy location, such as $s = 1500$ m.)
3. How would Equation (1) look like in the vertical plane? Why is the blue envelope so much bigger than the red one?
4. What is approximately the vertical beam size at the same location where you checked horizontally?
5. What is the main advantage of using muons instead of electrons in a circular collider?
