

Graded exercise 1

- Graded Exercise 1 will be available on moodle after next week's lecture, and the solutions must be uploaded to moodle before **midnight Thursday, 16th October (so you have 9 days)**
- Submit a single pdf document containing your handwritten work / scanned images
- Each person must submit their own solution, no photocopies, nor one person in a group submitting a single solution for several people
- All questions should be done by hand
- Submit early in case of glitches with the system

Background quiz

Background quiz: go.epfl.ch/turningpoint

Session Id: [julian23](#)

All input is anonymous; data are stored outside CH

Break

Lecture 4 Introduction

- There is only **one** 1D **linear** ODE: $dx/dt = ax$
- 2D *linear* problems are so varied, we need a scheme to classify them.
- 2D *non-linear* problems are reducible to (locally) independent *linear* problems; so solving a 2D linear problem is nearly all you need to solve any non-linear 2D problem.
- Each higher dimension allows new phenomena: in 2D we get new types of fixed point: saddlepoints, spirals, and limit cycles.
- You can visualize phase portraits using a 2D Runge-Kutta integration scheme to create trajectories (see moodle for today)

Classification of Fixed Points

Now you're probably tired of all the examples and ready for a simple scheme. Happily, there is one. We can show the type and stability of fixed points on a single diagram (Figure 5.2.8).

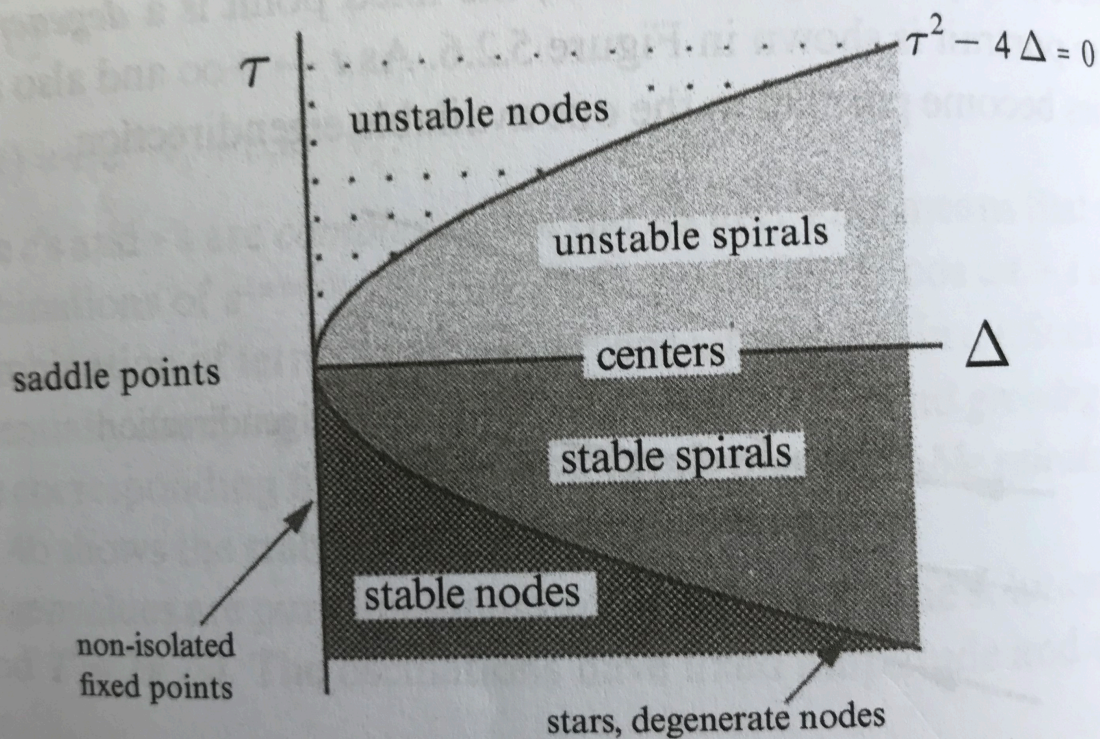

Figure 5.2.8

The axes are the trace τ and the determinant Δ of the matrix A . All information in the diagram is implied by the following formulas:

$$\lambda_{1,2} = \frac{1}{2}(\tau \pm \sqrt{\tau^2 - 4\Delta}), \quad \Delta = \lambda_1 \lambda_2, \quad \tau = \lambda_1 + \lambda_2.$$

Strogatz, ch. 5

Given the 2D linear dynamical system:

$$d\mathbf{X}/dt = \mathbf{M} \mathbf{X}$$

where the matrix $\mathbf{M} = (a, b, c, d)$.

Calculate the trace τ and determinant Δ of \mathbf{M} :

$$\tau = a + c$$

$$\det \mathbf{M} = ad - bc$$

Draw XY axes with Δ as the X axis and τ as the Y axis.

Add the quadratic curve $\tau^2 - 4\Delta = 0$ on rhs.

Locate the point (Δ, τ) on the graph, and read off the type and stability of the fixed point.

NB For fixed points on the curves, linear stability analysis fails for nonlinear 2D systems.

Recipe for solving the general 2D linear dynamical system

- 1) Given $d\mathbf{X}/dt = \mathbf{M} \mathbf{X}$, the type of FP at the origin is determined by the trace (τ) and determinant (Δ) of \mathbf{M} .
- 2) Draw the Δ - τ plot from previous slide, and add the curve $\tau^2 - 4\Delta = 0$ on the right hand side. Locate the fixed point of \mathbf{M} by its (Δ , τ) value, and read off its type and stability.
(if you just want the type/stability of FP, stop here)
- 3) On the phase portrait, draw the nullclines where $dx/dt = 0$ or $dy/dt = 0$. Mark the direction of flow of the other component of the vector field on the nullclines.
- 4) Find the eigenvalues, λ_1 λ_2 , and eigenvectors, \mathbf{V}_1 \mathbf{V}_2 , of the matrix \mathbf{M} .
- 5) Draw the eigenvectors of \mathbf{M} (they are always straight lines in the plane). and fill in the vector field around the fixed point

Trajectories approach (leave) a stable (unstable) node parallel to the slow eigendirection (smallest magnitude eigenvalue) as time goes to plus infinity, and become parallel to the fast eigenvector as time goes to minus (plus for unstable) infinity

Trajectories approach the unstable manifold of a saddlepoint as time goes to infinity, and the stable manifold as time goes to minus infinity.

(if you just want the qualitative solution, stop here)

- 6) Write the general solution as: $\mathbf{X}(t) = c_1 \exp(\lambda_1 t) \mathbf{V}_1 + c_2 \exp(\lambda_2 t) \mathbf{V}_2$
- 7) Given an initial condition (x_0, y_0) solve $\mathbf{X}(0) = c_1 \mathbf{V}_1 + c_2 \mathbf{V}_2$ for c_1, c_2 and draw the trajectory.
(This is the full solution)

Tricky points

- Trajectories **never** cross: don't draw them crossing on a phase portrait, even roughly (they meet at nodes and stars, but not at saddlepoints)
- Nullclines are curves defined by $dx/dt = 0$ or $dy/dt = 0$, they are **not always** a trajectory of the system.
- Nullclines do **not always** coincide with the axes
- Nullclines are straight lines for linear 2D systems (why?), but are usually curves for non-linear systems.
- Be able to distinguish **slow/fast eigenvectors of a node** from **stable/unstable manifolds of a saddlepoint** and **nullclines**
- Know the tau-delta plot. The type of fixed points on the boundaries between regions may not be correctly identified by linear stability analysis for nonlinear systems.
