

# Computer Security (COM-301)

## Malware

### Introduction

Slides created by Carmela Troncoso

Some slides/ideas adapted from: Gianluca Stringhini / Emiliano de Cristofaro / George Danezis

# Previous attacks: the adversary actively exploits model/ design/ implementation errors

## Insecure interactions between components

Usually enabled by lack of checks when processing input

### 'OS Command Injection'

```
$username = $_POST['user'];  
$command = 'ls -l /home/' . $username;  
system($command);
```

Problem if \$username='; rm -rf'

### 'Cross-site scripting'

```
$username = $_GET['userName'];  
echo '<div class="header"> Welcome, ' . $username . '</div>;
```

Problem if \$username='<script>...</script>'

### 'Cross-site Request Forgery'

```
<form action='http://epflHR.ch/paystudent.php' id='form' method='post'>  
<input type='hidden' name='firstname' value='Ugo'>  
<input type='hidden' name='lastname' value='Damiano'>  
<input type='hidden' name='amount' value='1000 CHF'>
```

Problem if on the server side a user is logged in  
(the server-side code will process the form with THAT user's privileges)

## Risky Resource Management

Enabled by lack of checks or careless programming

### 'Uncontrolled Format String'

```
#include<stdio.h>  
int main(int argc, char** argv) {  
    char buffer[100];  
    strncpy(buffer, argv[1], 100);  
    printf(buffer);  
    return 0;  
}
```

Problem if argv[1]='%d %d %d %d'  
(the program will read from the stack)

### Memory safety ('buffer overflow')

```
void vulnerable(char *buf) {  
    free(buf);  
    buf[12] = 42;  
}
```

Accessing a freed memory region

#### Code Injection

Inject arbitrary code in the stack and execute it

#### Control Flow Hijack

Inject arbitrary return pointers to execute desired existing instructions

## Network attacks

Lack of security mechanisms in network protocols

### 'ARP/DNS/BGP Hijacking'

Change association of high-level and low-level addresses, names, routes

### 'Denial of Service'

Capability of adversaries to exhaust the resources of a victim by using flaws at the network or application layers

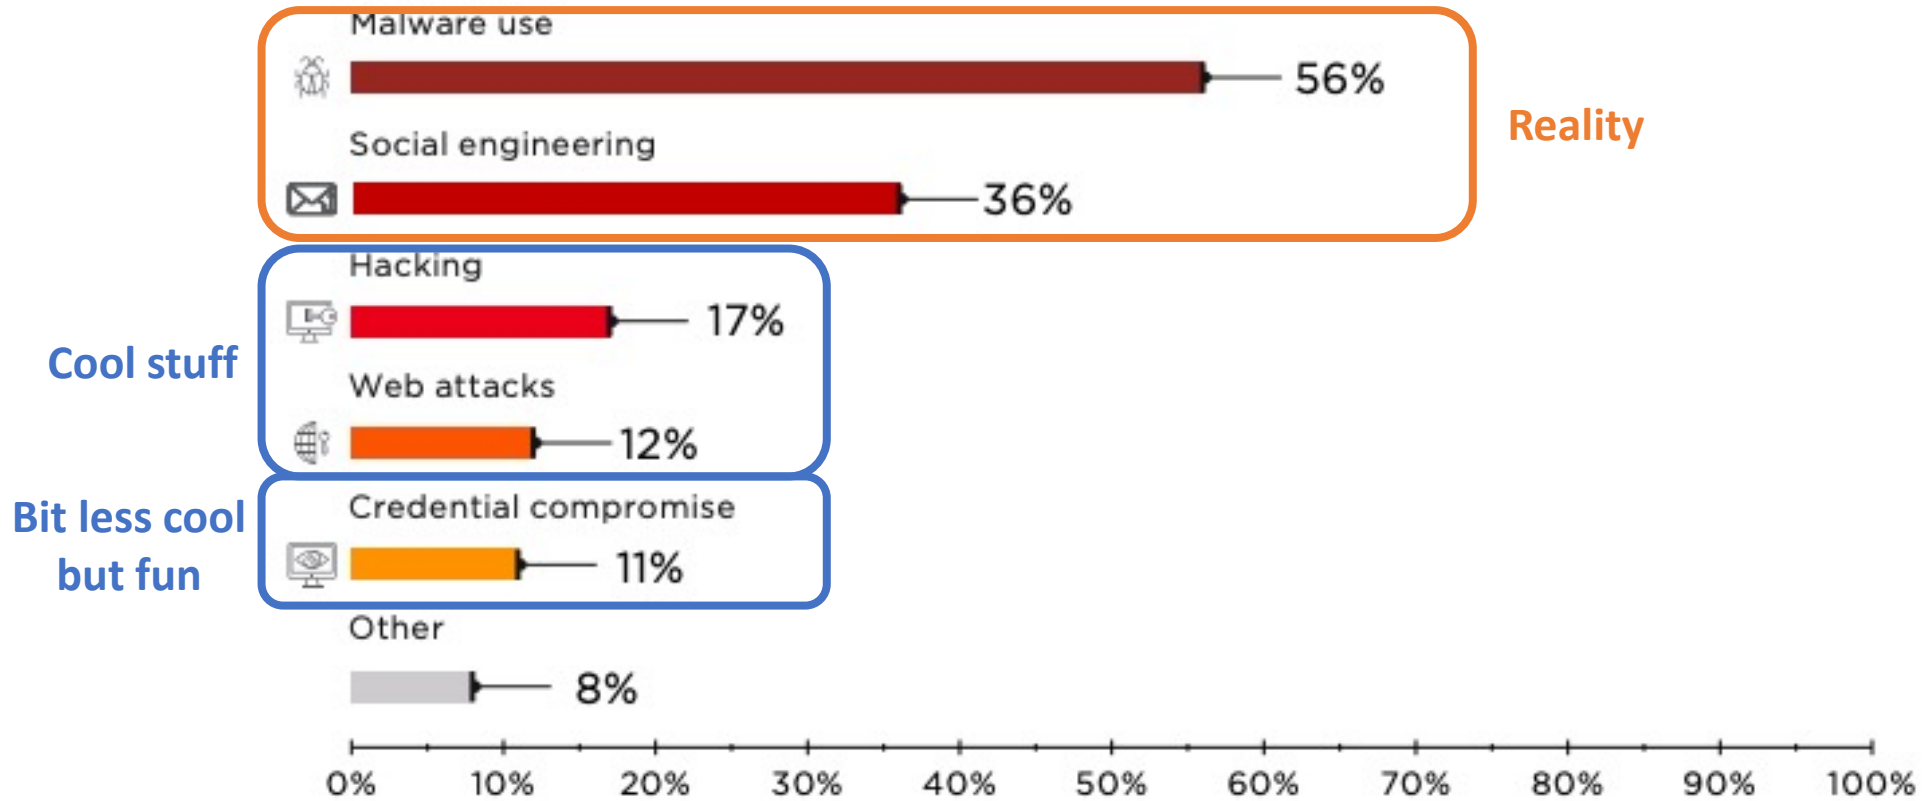

## Expert adversary

requires deep understanding of computer systems and networks

## "Manual" adversary

requires manual coding and testing to find the vulnerabilities and exploit them

# Malware

## Short for “Malicious Software”

Software that **fulfills the author’s malicious intent**

**Intentionally** written to cause adverse effects

Many flavors with a common characteristic: **perform some unwanted activity**

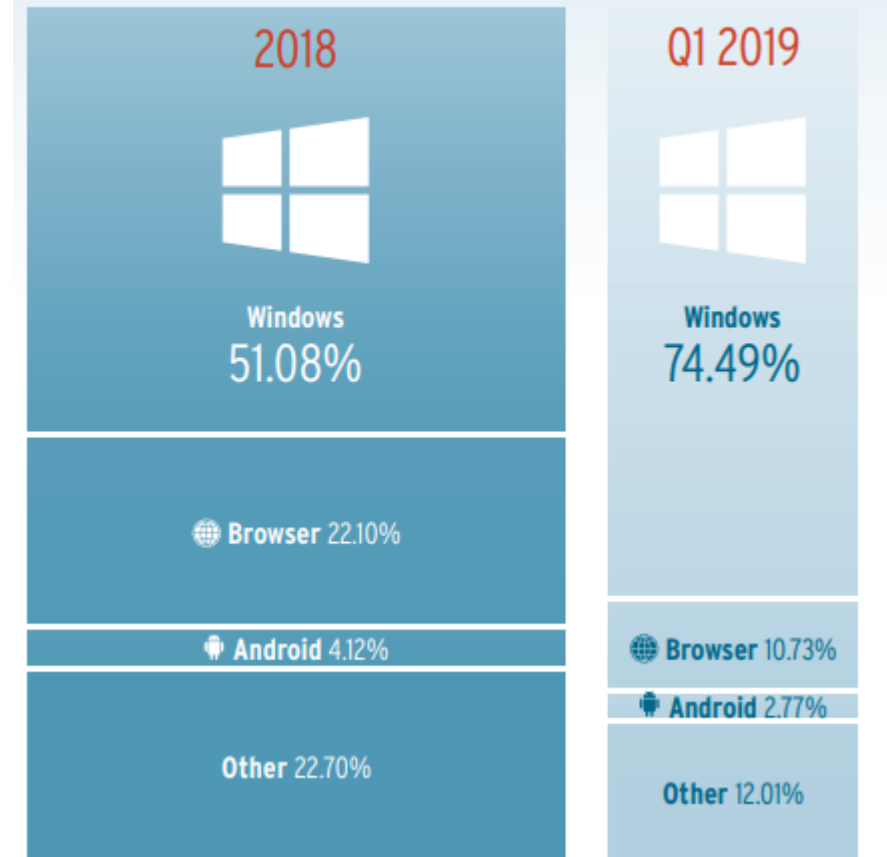

**Malware != virus**

**Virus is a kind of Malware**

## Distribution of malware under Windows in 2018

## Distribution of malware

# Malware – why the rise?

## **Homogeneous computing base**

Windows/Android make very tempting targets

## **Clueless user base**

Many targets available

## **Unprecedented connectivity**

Deploying remote / distributed attacks is increasingly easier

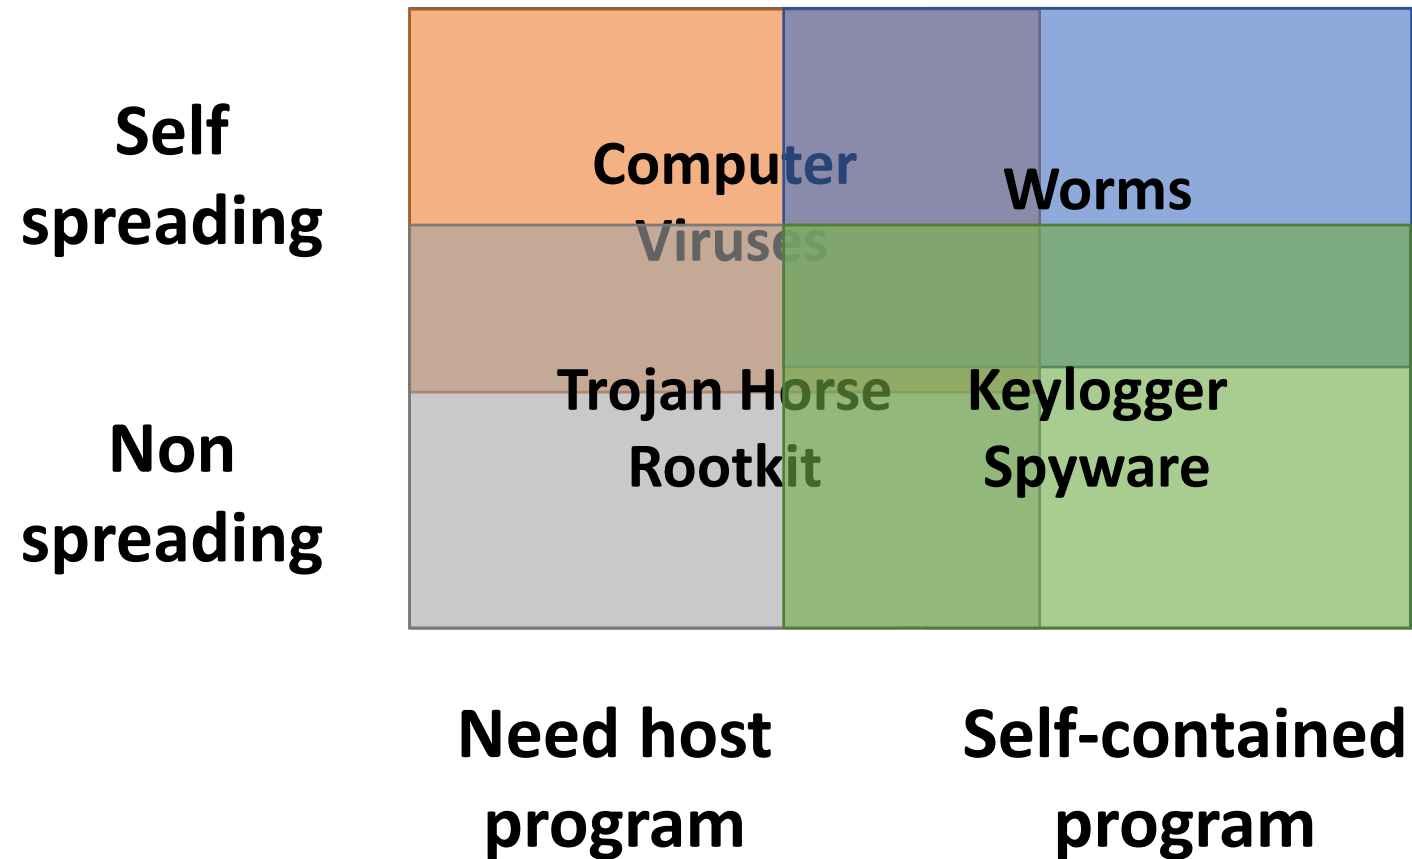

## **Malicious code has become profitable!**

Compromised computers can be sold and/or used to make money (and Bitcoins)

### **ATTACKER ENGINEERING PROCESS**

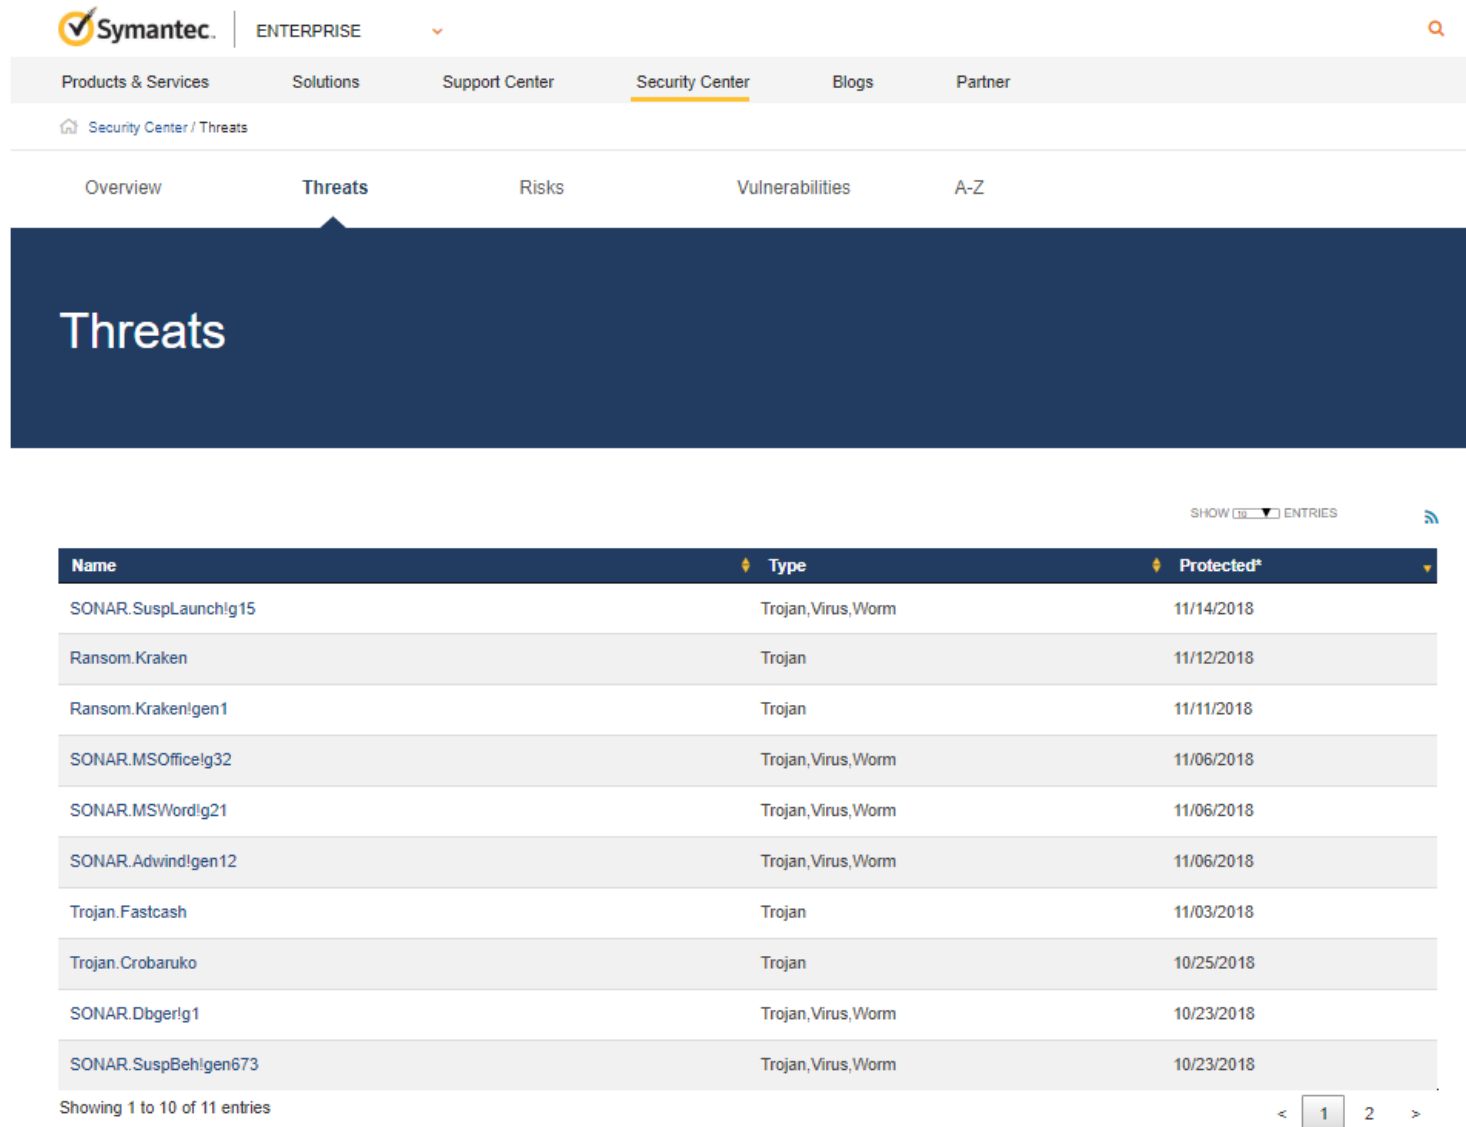

- Exploit new capabilities
- Exploit new entities (that are less prepared than expected in the design phase!)

# Malware – taxonomy

# Malware – taxonomy

Modern malware tends to combine “the best” of the categories to achieve its purpose

The screenshot shows the Symantec Enterprise Security Center interface. The top navigation bar includes 'Products & Services', 'Solutions', 'Support Center', 'Security Center' (highlighted), 'Blogs', and 'Partner'. Below this is a breadcrumb trail 'Security Center / Threats'. A secondary navigation bar has 'Overview', 'Threats' (selected), 'Risks', 'Vulnerabilities', and 'A-Z'. A large dark blue banner with the word 'Threats' is displayed. Below the banner is a table of threats with columns for Name, Type, and Protected\*. The table lists 11 entries, with the first 10 visible. A pagination bar at the bottom shows 'Showing 1 to 10 of 11 entries' and page numbers 1 and 2.

Name	Type	Protected*
SONAR.SuspLaunchlg15	Trojan,Virus,Worm	11/14/2018
Ransom.Kraken	Trojan	11/12/2018
Ransom.Kraken!gen1	Trojan	11/11/2018
SONAR.MSOffice!g32	Trojan,Virus,Worm	11/06/2018
SONAR.MSWord!g21	Trojan,Virus,Worm	11/06/2018
SONAR.Adwind!gen12	Trojan,Virus,Worm	11/06/2018
Trojan.Fastcash	Trojan	11/03/2018
Trojan.Crobaruko	Trojan	10/25/2018
SONAR.Dbger!g1	Trojan,Virus,Worm	10/23/2018
SONAR.SuspBeh!gen673	Trojan,Virus,Worm	10/23/2018

[DEPRECATED]

Lists of:

- Threats
- Vulnerabilities
- Risks

## Reflections on Trusting Trust

*To what extent should one trust a statement that a program is free of Trojan horses? Perhaps it is more important to trust the people who wrote the software.*

# Computer Security (COM-301)

## Malware

### Types of Malware

# Virus (1)

**RANSOMWARE: malware that threatens to destroy a system unless the owner pays money to receive the “antidote”**

Piece of software that **infects** programs to monitor / steal / **destroy**

Viruses modify programs to include a (possibly modified) copy of themselves

Viruses **cannot** survive without the host

What are the permissions of a virus?

The same permissions as the host!

virus can do anything that the host program is permitted to do

virus **executes** secretly when the host program is run

The host program would be acting as... ?

Yes! The confused deputy again!

Recurring problem in security!

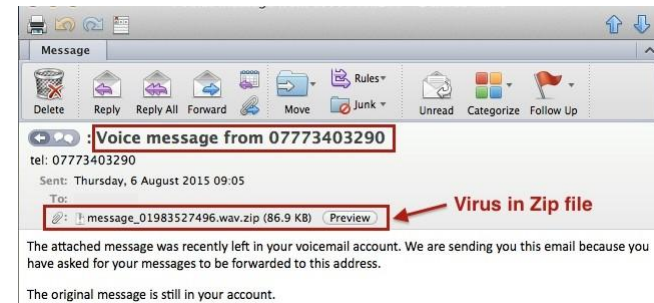

Mitigation: follow the **least privilege principle!**

Specific to operating system and hardware

take advantage of their details and weaknesses

# Virus (2)

**Replicates** to infect other content or machine  
(host spreads through network or hardware)

**Half of people plug in USB drives they find in the parking lot**

Why do we even bother with security software?

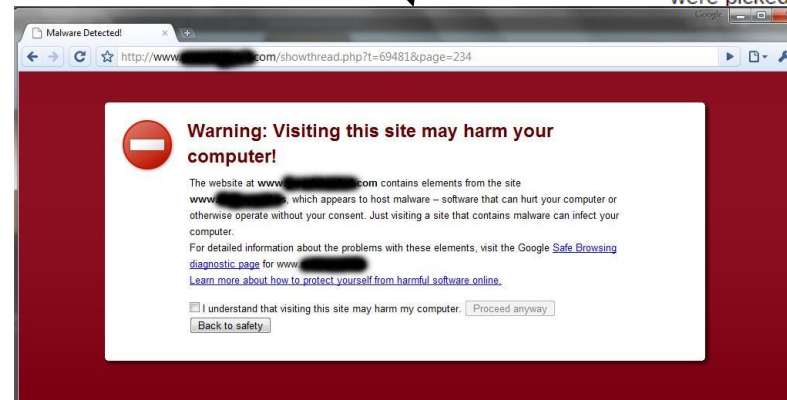

By Shaun Nichols in San Francisco 11 Apr 2016 at 21:09 115 SHARE

A new study has found that almost half the people who pick up a USB stick they happen across in a parking lot plug said drives into their PCs.

Researchers from Google, the University of Illinois Urbana-Champaign, and the University of Michigan, spread 297 USB drives around the Urbana-Champaign campus. They found that 48 percent of the drives were picked up and plugged into a computer, some within minutes of

community has long held the belief that users can be deterred into picking up and plugging in seemingly lost USB drives they find," the researchers reported this month.

whether driven by altruistic motives or human curiosity.

# Virus – where can they act

## **File infection**

*Overwrite* (substitute the original program), *Parasitic* (append and modify)

## **Macro infection**

Overwrite macro executed on program load (MS Excel, Word)

Need to find an exploit to insert the macro

## **Boot infection**

**Most difficult! ...and most dangerous**

Infect booting partition

# Melissa (1999) - Slide Quadrant: Self-spreading / Need host program.

## The host:

It infects Microsoft Word documents (.doc) using a "Macro" (a small script inside the document designed to automate tasks)

A user receives an email titled "Important Message from [Name]" and opens the attached Word file named list.doc.

## First payload:

Once opened, the macro executes, modifies global settings in Word to reattach itself to any other word document opened.

Secretly accesses the user's Microsoft Outlook address book to send infected doc file ...

## Second payload:

When the current minute matches the day when it is being launched, it inserts the quote "Twenty-two points, plus triple-word-score, plus 50 points for using all my letters. Game's over. I'm outta here." (Bart Simpson)

# Virus – defenses

## Antivirus Software

### *Signature-based detection*

sequence of bytes/instructions that are known to be part of the virus

Database of byte-level or instruction-level **signatures** that match virus  
Wildcards and regular expression can be used  
Hash of known malicious programs

*Heuristics* (check for signs of infection / anomalies) and  
incorrect header sizes, suspicious code section name  
Behavioral signatures – detect series of changes done by a virus

## Sandboxing

Run untrusted applications in restricted environment (e.g., use a VM)

# Worm

Self-replicating computer program that uses a network to send copies of itself to other nodes

**Does not** need a host program to execute

**Autonomous spread** over the network

Email harvesting (address book, inbox, browser cache)

Network enumeration

Scanning (at random or targeted)

Email: requires human interaction (fake `from`, hidden attachments)

Network: automated!

# Worm example - WannaCry (2017)

A case of **Ransomware**

↳ **Require money to recover system**

Exploits a vulnerability revealed in a NSA hacking toolkit leak

- Mishandled packets for the Microsoft Server Message Block (protocol for shared access) enable arbitrary code execution
- The leak contained vulnerabilities in systems from e.g., Cisco Systems and Fortinet Inc

Encrypted data and asked for ransom in Bitcoins

- 300\$ in 3 days or 600\$ in 7 days or **DELETE**

>200,000 victims

\$130,634 obtained in ransom

billions of dollars in damage, UK Hospitals affected

# Worm example - WannaCry (2017)

A case of **Ransomware**

↳ **Require money to recover system**

## How did it end?

The worm “kill switch” was found

Upon installation, the malware checked the existence of a web. If yes, it stopped.

A researcher registered the website and the worm stopped

Why have a kill switch?

Avoid worm study if hijacked, or if in sandbox

# Worm – defenses

## Host-level

Protecting software from remote exploitation → **Attacks & Software security lecture!**

Stack protection techniques → **Software security lecture!**

Achieve **diversity** to increase protection → require more sophisticated worms

Antivirus (email-based Worms)

**Heterogeneous systems**

Different OS

Different programs

Different interfaces...

It could clash with  
economy of mechanism  
(and functionality)

## Network-level

Limit the number of outgoing connections: limit worm spreading

Personal firewall

e.g., block outgoing SMTP connections from unknown applications

Intrusion detection systems

# Intrusion detection systems – what they do

## Host-based vs. Network-based

**Host:** process running on a host. Detects local malware

**Network:** network appliance monitoring all traffic

## Signature based vs. Anomaly-based detection

**Signature:** identifies known patterns

+ low false alarms

- expensive (need up-to-date signatures), can't find new attacks

**Anomaly:** attempts to identify behavior different than legitimate

+ adapt to new attacks (legitimate does not change!)

- high number of false alarms

# Trojan Horse

Malware that *appears to perform a desirable function* but it also performs **undisclosed malicious activities**

Requires users to **explicitly** run the program

**Cannot replicate** but can do **any** malicious activity

Spy on sensitive user data (spyware)

Allow remote access (backdoor)

Base for further attacks → act as mail relay (for spammers)

Damage routines (corrupting files)

Defense: Sign programs?  
Train users?

and follow least  
privilege principle!

# Trojan Horse examples:

Zeus (2007 ...)

Tiny Banker Trojan (2012)

**Goal:** steal users sensitive data, such as account login information and banking codes.

## **Mode of Operation 1**

1. Sniff packets to learn when a user visits a **banking website**
2. Steal credentials before they are sent → send to malware server  
Reads keystrokes before encryption!!

## **Mode of Operation 2**

1. Sniff packets to learn when a user visits a **banking website**
2. Steal appearance from website
3. Ask questions to user on a pop-up → send answer to malware server

# Example Worm+Virus+Trojan – I Love You (2000)

**Target:** Windows 9X/2000

"LOVE-LETTER-FOR-YOU.txt.vbs" sent as email attachment

Known extension to Windows, hidden from users!  
Users think they open a text file, not an executable

## Operation:

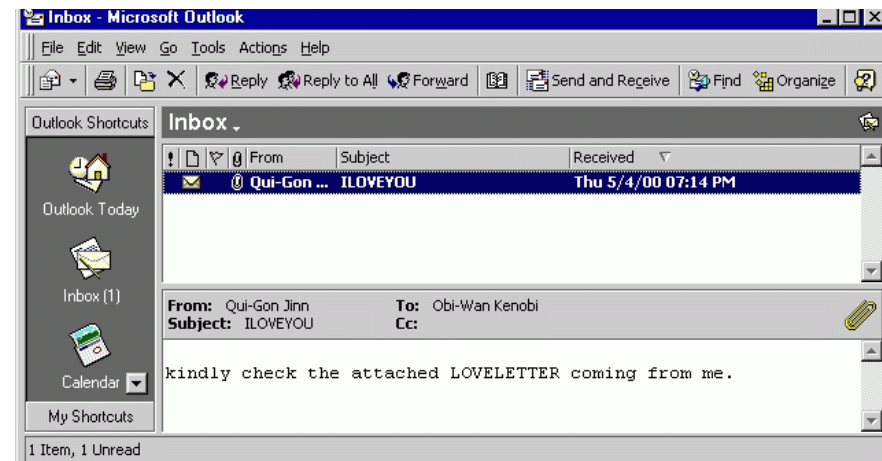

Replaced files with extensions JPG, JPEG, VBS, JS, DOC, ... by itself

The script adds Windows Registry data for automatic startup on system boot

Downloaded a Trojan part "Barok": "WIN-BUGSFIX.EXE" (steal passwords)

*(also: virus-like because, it sent itself to each entry Outlook address book, sometimes changing subject)*

**Damage: \$10 billion**

# Rootkit

Adversary controlled code that takes residence **deep within the TCB** of a system  
Hides his presence by modifying the OS

Installed by an attacker **after** a system has been compromised

Difficult to detect

**Replace system programs** with trojaned versions

**Modify kernel data structures** to hide processes, files, and network activities

Allows the adversary **to return on a later time**

**Defense (difficult!): Integrity checkers user/kernel level**

# Rootkit+Worm example: Stuxnet (2010)

**Goal:** Attack SCADA (Control systems) of Iran's nuclear power plants

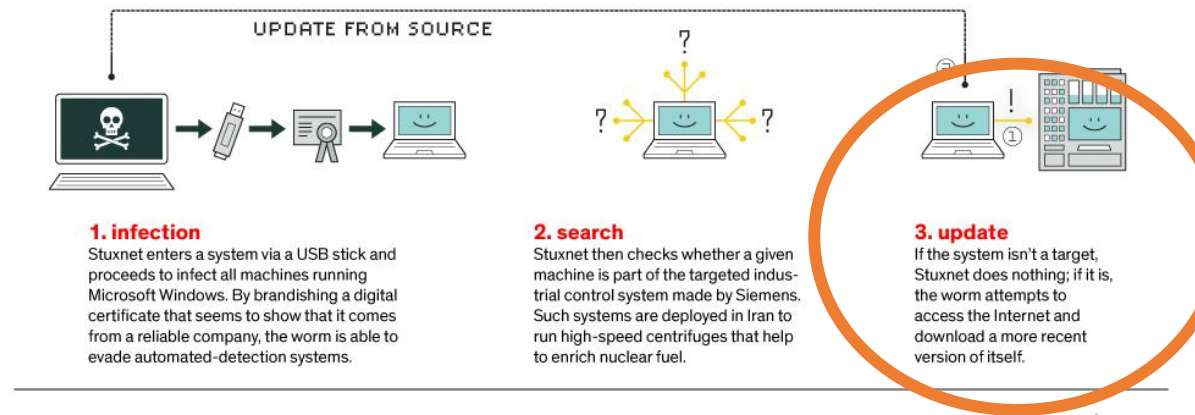

## Three modules:

**Worm:** spread Stuxnet's payload

**Link file:** executed malicious code

**Rootkit:** hide the presence of malicious file to avoid detection

Stuxnet needs to be in the network, but the network is closed and disconnected  
→ Entered via infected USB

### 1. infection

Stuxnet enters a system via a USB stick and proceeds to infect all machines running Microsoft Windows. By brandishing a digital certificate that seems to show that it comes from a reliable company, the worm is able to evade automated-detection systems.

### 2. search

Stuxnet then checks whether a given machine is part of the targeted industrial control system made by Siemens. Such systems are deployed in Iran to run high-speed centrifuges that help to enrich nuclear fuel.

### 3. update

If the system isn't a target, Stuxnet does nothing; if it is, the worm attempts to access the Internet and download a more recent version of itself.

Very targeted attack. If the system infected is not a target, the malware stays dormant.

### 4. compromise

The worm then compromises the target system's logic controllers, exploiting "zero day" vulnerabilities-software weaknesses that haven't been identified by security experts.

### 5. control

In the beginning, Stuxnet spies on the operations of the targeted system. Then it uses the information it has gathered to take control of the centrifuges, making them spin themselves to failure.

### 6. deceive and destroy

Meanwhile, it provides false feedback to outside controllers, ensuring that they won't know what's going wrong until it's too late to do anything about it.

## Authorship?

**Alleged Israel/US Cyberweapon**

# Backdoor

A **hidden** functionality that allows the adversary to bypass some security mechanism

Why not “audit” the program?

We can audit the program source

what if the compiler is malicious and introduces backdoors?

Chain of reasoning leads us to **suspect all programs down to the very first compiler!**

*Key paper: Thompson, Ken. "Reflections on trusting trust." Communications of the ACM (1984)*

**More readable summary:** [https://www.schneier.com/blog/archives/2006/01/countering\\_trus.html](https://www.schneier.com/blog/archives/2006/01/countering_trus.html) 29

# Computer Security (COM-301)

Malware

Botnets

Slides created by Carmela Troncoso

Some slides/ideas adapted from: Gianluca Stringhini / Emiliano de Cristofaro / George Danezis

# Botnets

## Attacks at scale!!

Multiple (millions) compromised **hosts** under the control of a **single entity**

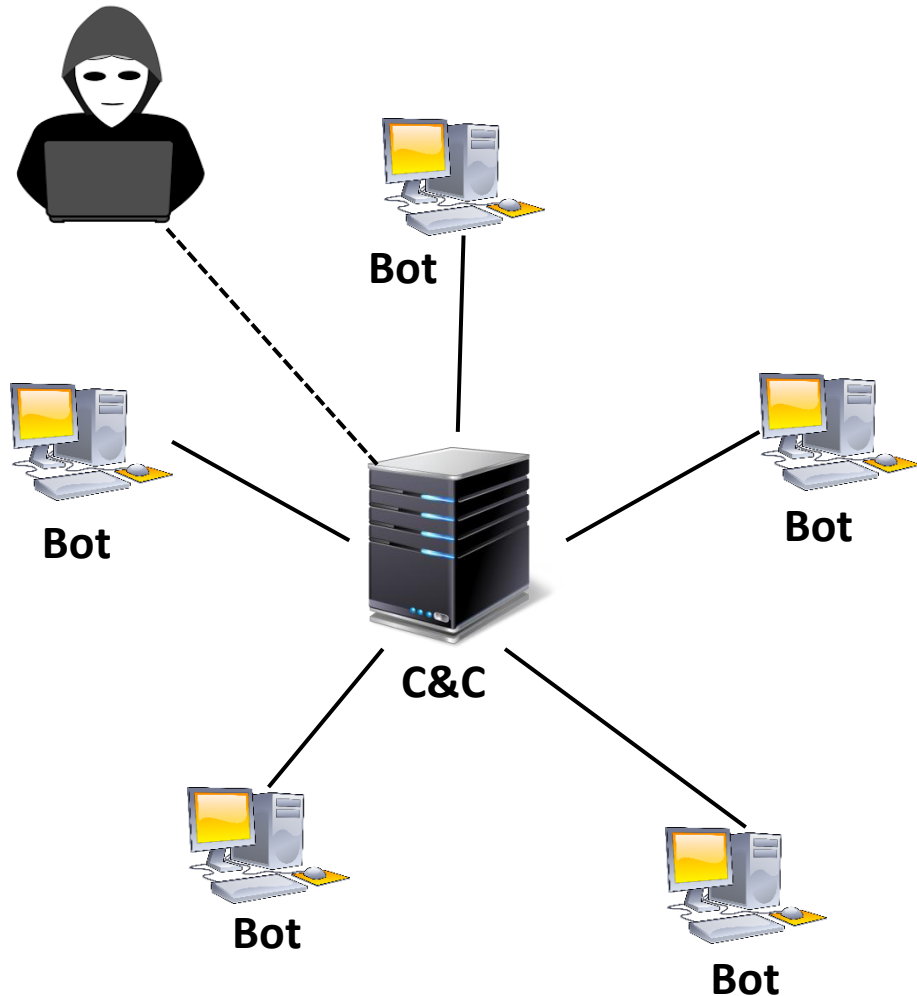

“zombies” or “bots”

uses

Bot-net command & control (C&C)

System to keep track of bots and send commands to them

# Botnets - Star Topology

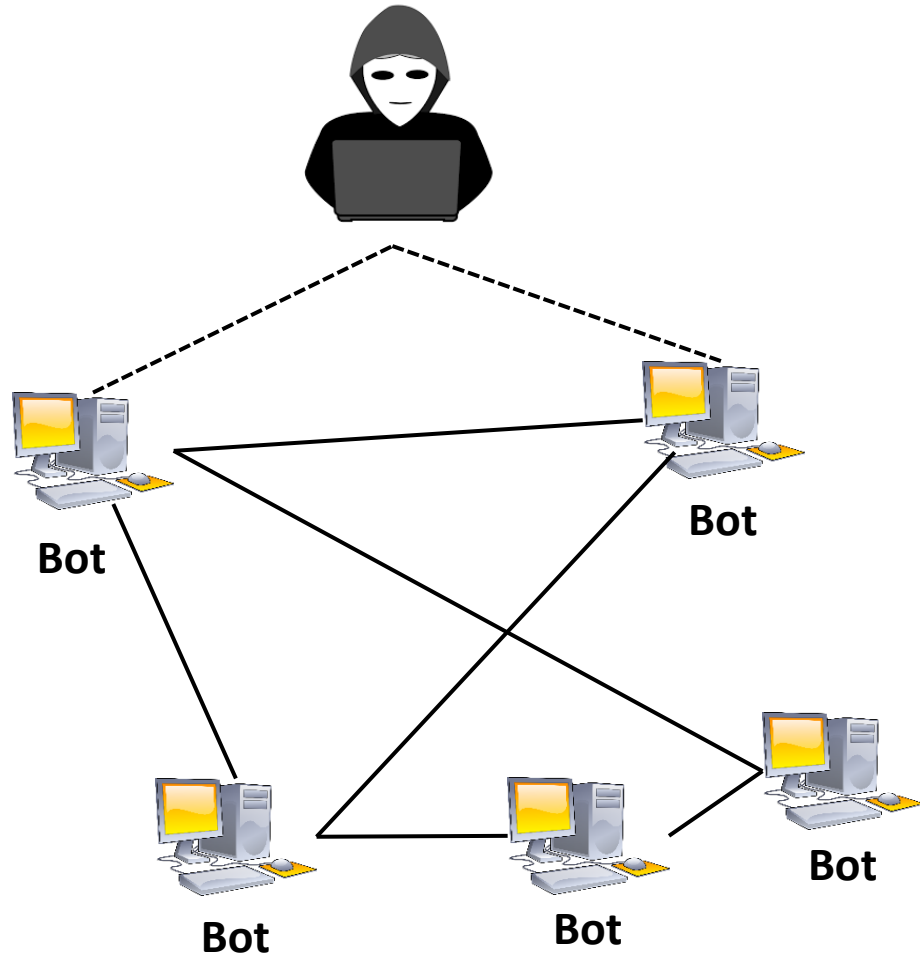

**What is the problem here?**

**C&C single point of failure**

the botnet violates the *least common mechanism* principle!

# Botnets – P2P Topology

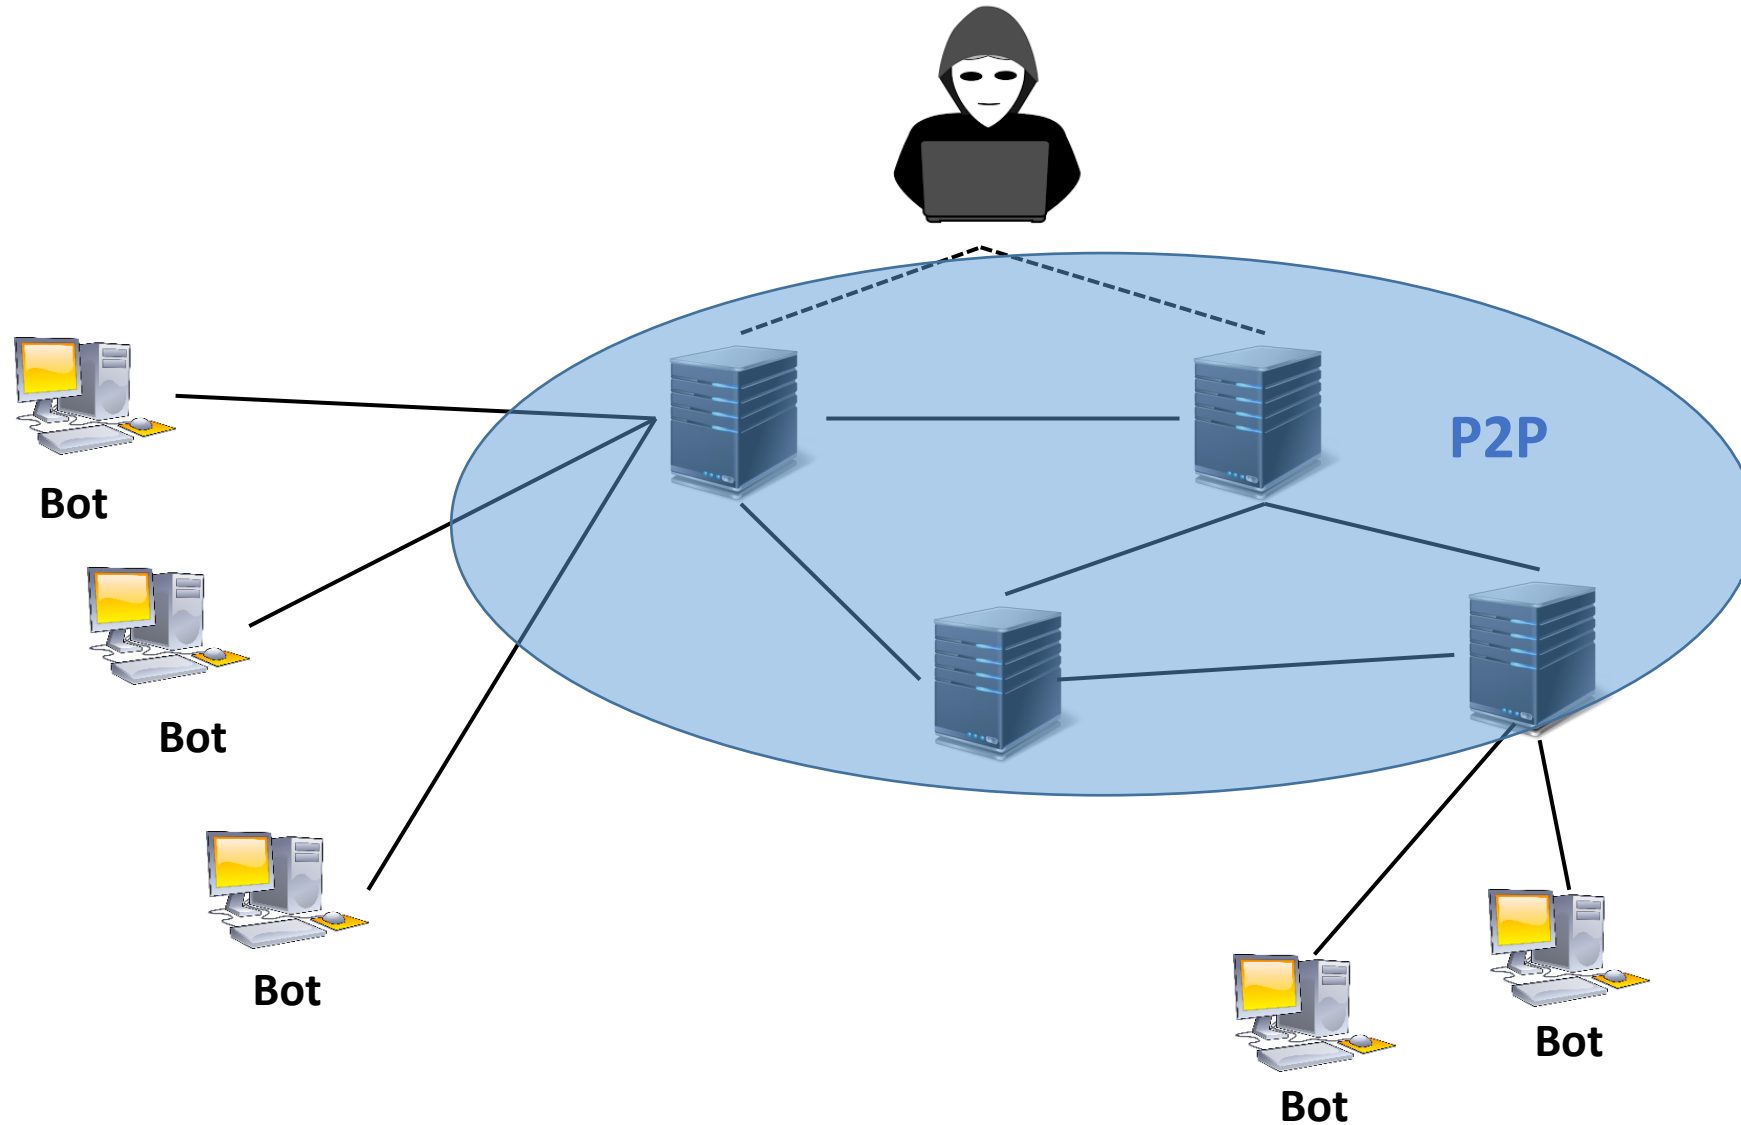

**No Command and Control!!**

Difficult management (join? leave?)

Vulnerable to attacks in which too many bots are taken over (these are called Sybil attacks)

# Botnets – Hybrid

# Monetizing Botnets

**Rental** – “Pay me money, and I’ll let you use my botnet...”

**DDoS extortion** – “Pay me or I take down your legitimate business”

**Bulk traffic selling** – “Pay me to boost visit counts on your website”

**Click fraud** – “Simulate clicks on advertised links to generate revenue”

**Distribute Ransomware** – “I’ve encrypted your hard drive, pay!”

**Advertise products** – “Pay me, I will leave comments all around the web”

**Bitcoin mining!!**

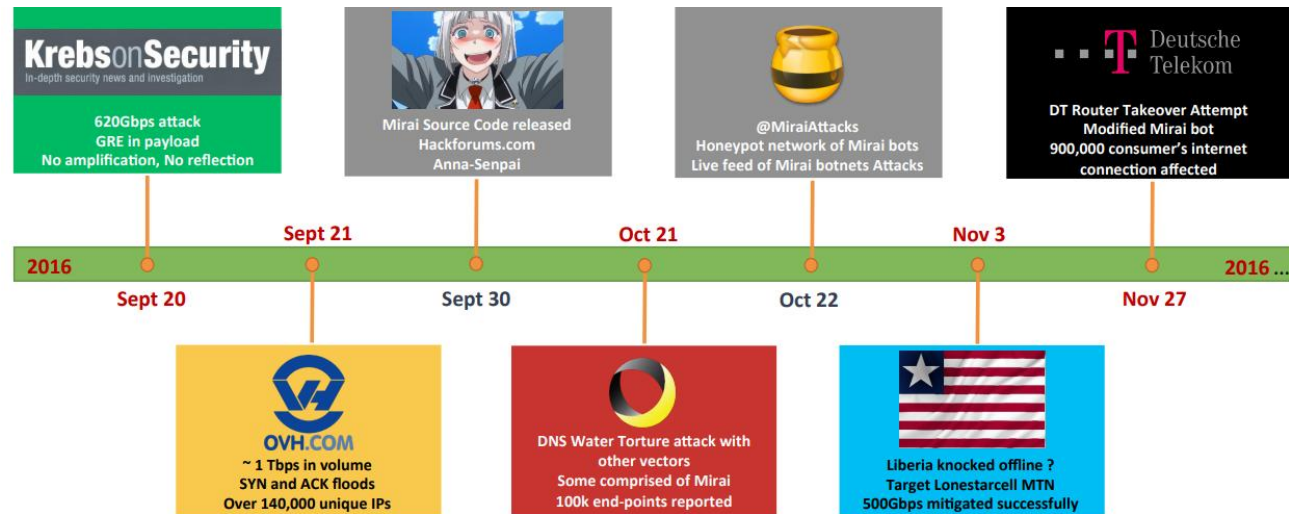

...

# Example Botnet – Mirai (2016)

**Target:** IoT devices

scanning of Telnet ports, attempted to log in using 61 username/password combos

Open source code – variants appear all the time

Wicked (2018): scans ports 8080, 8443, 80, and 81 and attempts to locate vulnerable, unpatched IoT devices running on those ports.

# Botnets: defense

## **Attack C&C infrastructure**

- Take communication channel off-line

- Hijack/poison DNS to route traffic to black hole

## **Honeypots**

- Vulnerable computer that serves no purpose other than to attract attackers and study their behavior in controlled environments

- Study botnet behavior to find defense (or study ecosystem)

# Summary

**Malware = software intentionally malicious**

**Can be exploited by non-experienced adversaries**

**Many types depending on  
(auto) replication, need for a host**

**Botnets – attacks at scale!**
