

# Welcome to BIO-210

Applied software engineering for life sciences

October 28th 2024 – Lecture 6

Prof. Alexander MATHIS

EPFL

# Announcements I

- Congrats on your excellent quiz results: Quiz 1: class average 9.7/10;
- For Quiz 2 we have: 8.6/12. Let's keep studying Python!

# Announcements II

- Today is the *second* in person quiz: please come *in time*, there will be no extra time. Submission closes at 13:35. To start, you'll need to sign in. Bring your Camipro. No notes are allowed. If you switch to a different tab from Moodle's quiz or communicate with somebody, you'll receive 0 points.
- Monday 15:15 - 16: my office hours at SV 2811

# Announcements III

- Final room assignment [here](#). NOTE: you need your EPFL login to see it!
- v2 of your project was due at 10am today (not graded/checked), check out [release guide](#).
  - try to do the majority in the exercise session (we share [the problem set](#) at least by Friday, so you can prepare better)
  - what if you get stuck? -> discuss with your teammates, ask on ED, ... and *release* your best version on Monday at 10am
  - make sure you get feedback about your latest version on Monday from the SA/TAs! You can release a bugfix/patch/update, e.g. `v2.1`, see [details on releases](#)
- We will provide code review for your v2!

# Quiz

You have a dataset representing the expression levels of 5 genes across 4 tissue samples. Each row corresponds to a gene, and each column corresponds to a tissue sample.

```
1 import numpy as np
2 expression_levels = np.array([
3     [5.1, 2.3, 3.4, 6.5],  # Gene 1
4     [1.5, 3.5, 2.4, 4.6],  # Gene 2
5     [3.2, 5.1, 1.6, 3.8],  # Gene 3
6     [4.1, 3.2, 4.5, 2.2],  # Gene 4
7     [2.8, 1.5, 3.1, 5.0],  # Gene 5
8 ])
9
```

Write a program to calculate the standard deviation of the expression levels of each gene.

```
1 In [1]: np.std(expression_levels, axis=1)
2 Out[1]: array([1.60370664, 1.16404467, 1.25772612, 0.88600226, 1.2509996 ])
3
4 In [2]: np.sqrt(np.var(expression_levels, axis=1)) #if you don't know the std command
5 Out[2]: array([1.60370664, 1.16404467, 1.25772612, 0.88600226, 1.2509996 ])
```

# Useful conventions for developing a project

New feature development:

- for new features make branches. Give the branch a good name, e.g. *your\_name/novel\_featurename*
- once you're ready you make a pull request and assign your collaborators for review (e.g., see this example PR)  
-----
- here is an example for the demo project  
-----

# Recommended project workflow:

1. Develop a feature (on a branch)
2. Merge main/master into it [when you're done]
3. Test it, again after you merge: `git push`
4. create a pull request and assign your teammates as reviewers

Alternative workflow: sometimes 2) and 3) are done by the reviewer. i.e. they merge!

# Comments in Python code

We already learned that "#" allows to put comments in code.

```
1  # Hello world <--- this will not be interpreted!
2  # "#" also allows multi-line comments
3
4  # we have also seen inline comments...
5  a=3          # you can also make inline comments!
6  b=4          # assigning b to 4.
7
8  ''' single quotes
9  You can also make long comments ... everything is "ignored" by python!
10 a=f2d123ee1505
11 b=123
12 '''
13 c=a+b
14
15 """ quotation marks
16 Alternative,
17 multiline comment
18 """
19
```

# Some guidelines (not rules)

From [pep 8 = Style Guide for Python Code](#)

- Comments should be complete sentences. The first word should be capitalized, unless it is an identifier that begins with a lower case letter (never alter the case of identifiers, aka keywords, module names, etc.).
- Ensure that your comments are clear and easily understandable to other speakers of the language you are writing in.
- You can look for typos by using the pip-package [codespell](#).
- **Comments that contradict the code** are worse than no comments. Always make a priority of keeping the comments up-to-date when the code changes!

P.S.: PEP stands for Python Enhancement Proposal. A PEP is a design document providing information to the Python community, or describing a new feature for Python or its processes or environment. The PEP should provide a concise technical specification of the feature and a rationale for the feature – from [PEP 1](#).

# Quiz: How do you create a np.array ...

... starting at 12, ending at 176 containing every third number?

```
1 In [1]: import numpy as np
2 In [2]: np.arange(12,177,3)
3 Out[2]:
4 array([ 12,  15,  18,  21,  24,  27,  30,  33,  36,  39,  42,  45,  48,
5         51,  54,  57,  60,  63,  66,  69,  72,  75,  78,  81,  84,  87,
6         90,  93,  96,  99, 102, 105, 108, 111, 114, 117, 120, 123, 126,
7        129, 132, 135, 138, 141, 144, 147, 150, 153, 156, 159, 162, 165,
8        168, 171, 174])
```

But what if you forgot how to use `np.arange`?

```
1 help(np.arange)
2 np.arange?
```

# The displayed help is actually the `docstring`

```
1 In [3]: help(np.arange)
2
3 Help on built-in function arange in module numpy:
4
5 arange(...)
6     arange([start[, stop[, step[, dtype=None, *, like=None]]])
7
8     Return evenly spaced values within a given interval.
9
10    Values are generated within the half-open interval ``[start, stop)``
11    (in other words, the interval including 'start' but excluding 'stop'). For
12    integer arguments the function is equivalent to the Python built-in
13    'range' function, but returns an ndarray rather than a list.
14
15    When using a non-integer step, such as 0.1, the results will often not
16    be consistent. It is better to use 'numpy.linspace' for these cases.
17
18    Parameters
19    -----
20    start : integer or real, optional
21        Start of interval. The interval includes this value. The default
22        start value is 0.
23    stop : integer or real
24        End of interval. The interval does not include this value, except
```

# Essential documentation: Docstrings

A docstring is a string literal that occurs as the first statement in a module, function, class, or method definition. Such a docstring becomes the `__doc__` special attribute of that object.

- Docstrings provide help for your code (so you (and others) can re-use it in the future!)

```
1 In [4]: def myfun(x):
2     ''' identity function '''          # Docstrings are defined like comments!
3     return x
4
5     ....: print(myfun.__doc__)        # Docstrings are assinged to the attribute '__doc__'
6     ....:
7     identity function
8
9 In [5]: help(myfun)                  # They become accessible via help!
10 Help on function myfun in module __main__:
11
12 myfun(x)
13     identity function
```

# Python's recommendations for docstrings

- Write docstrings for all public modules, functions, classes, and methods.
- Docstrings are not necessary for non-public methods, but you should have a comment that describes what the method does. This comment should appear after the def line.
- PEP 257 immortalizes Python's docstring conventions
- For mathematical functions (like in our projects) the detailed numpy style guide is excellent to follow

# What should be contained in a docstring?

- A **Short summary** (for basic, simple functions)

```
1  def add(a, b):  
2      """The sum of two numbers.  
3  
4      """
```

- **Extended summary** contains among others:

- a simple description (clarify functionality, not implementation details those belong to Notes)
- parameters
- returns
- examples
- notes
- references

Details are available in the [Numpy doc style guide](#)

# Example (*shortened from np.arange*)

```
1 In [13]: np.arange?  
2 Return evenly spaced values within a given interval.  
3 ! !OMMITTED for space reasons!!  
4 Parameters  
5 -----  
6 start : integer or real, optional  
7     Start of interval. The interval includes this value. The default  
8     start value is 0.  
9 stop : integer or real  
10 ! !OMMITTED for space reasons!!  
11  
12 Returns  
13 -----  
14 arange : ndarray  
15     Array of evenly spaced values.  
16 ! !OMMITTED for space reasons!!  
17  
18 Examples  
19 -----  
20 >>> np.arange(3)  
21 array([0, 1, 2])  
22 Type:    builtin_function_or_method
```

# Documentation

- Note that the (numpy) docstrings are also (html-rendered) on the web, e.g., for `np.arange`
- this is all automatically generated with `Sphinx`, see <https://github.com/numpy/doc>

# Docstrings in action

- Today you will work on docstrings for your functions!
- Compare to the demo-project

# Quiz: How do you define a function that can offset the output by a specific parameter with default 2?

```
1 In [1]: def f(x,offset = 2):  
2     ...:     return x+offset  
3     ...:  
4  
5 # Testing our function:  
6 In [2]: f(0)  
7 Out[2]: 2  
8  
9 In [3]: f(3)  
10 Out[3]: 5  
11  
12 In [4]: f(2,5)  
13 Out[4]: 7
```

# Quiz: How do you write docstrings for this function?

```
1 def offsetter(x,offset = 2):          # use a good name!
2     """ Function that offsets input by default value (offset)
3     Parameters
4     -----
5         x      : array or float
6         offset : float, optional
7                 default 2
8     Returns
9     -----
10    numpy array or float
11    x + offset
12    Examples
13    -----
14    >>> offsetter(2)
15    4
16    >>> offsetter(2,3)
17    5
18    """
19    return x+offset
```

# Questions?

# Visualization

- is crucial in science and beyond ("a picture is worth 1000 words...")
- python has strong support for plotting with matplotlib (our focus), seaborn (neat interface on top), Majavi (esp. 3D visualization), Plotly (esp. web), Bokeh (esp. web), Pandas, gnuplot, ...

P.S. A formula is worth a thousand pictures... (by Edsger W. Dijkstra)

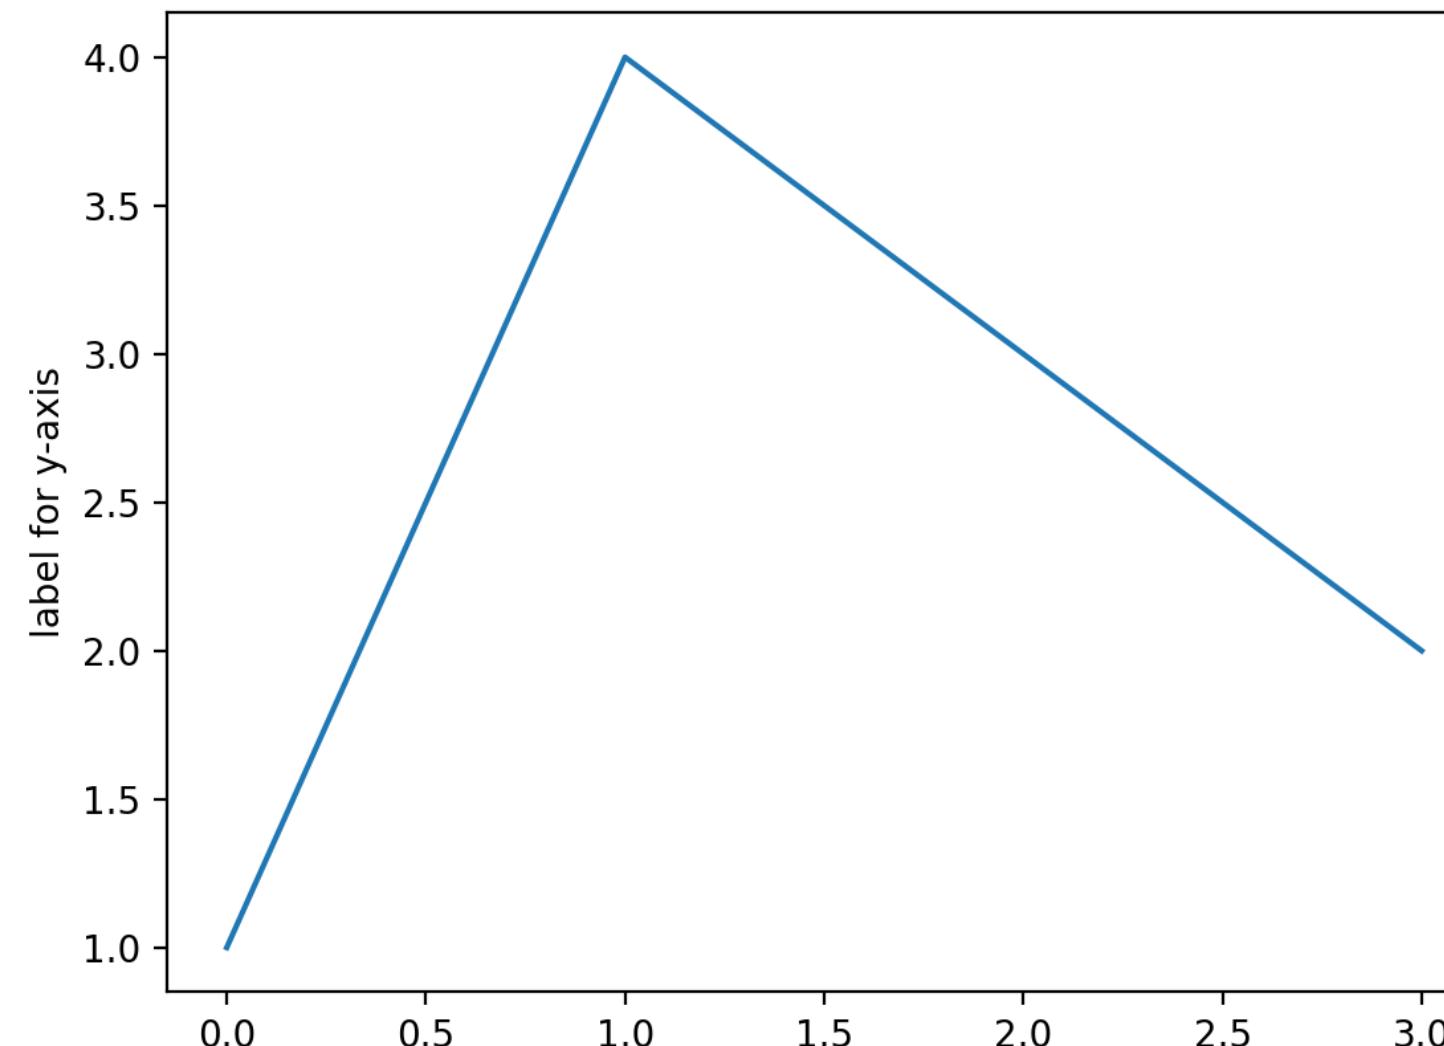

P.P.S. Just like Numpy, matplotlib is a library you need to install --> `pip install matplotlib`

# Pyplot: simple plotting in matplotlib

```
1 import matplotlib.pyplot as plt      # Importing matplotlib.pyplot
2 # Note: we use all functions from this library with plt.XYZ
3 plt.plot([1, 4, 3, 2])            # Plotting x vs. y data
4 plt.ylabel('label for y-axis')    # Making a label for y
5 plt.show()                      # Display all open figures
```

# Pyplot: simple plotting in matplotlib

```
1 import matplotlib.pyplot as plt      # Importing matplotlib.pyplot
2 # Note: we use all functions from this library with plt.XYZ
3 plt.plot([1, 4, 3, 2])            # Plotting x vs. y data
4 plt.ylabel('label for y-axis')    # Making a label for y
5 plt.show()                      # Display all open figures
```

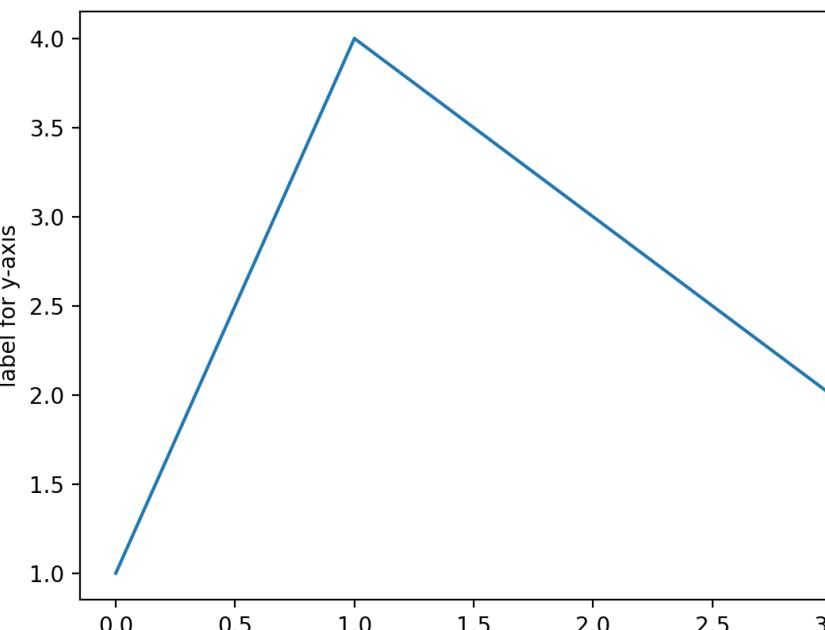

# Quiz: Why does the plot look like this?

```
1 import matplotlib.pyplot as plt      # Importing matplotlib.pyplot
2 # Note: we use all functions from this library with plt.XYZ
3 plt.plot([1, 4, 3, 2])            # Plotting x vs. y data
4 plt.ylabel('label for y-axis')    # Making a label for y
5 plt.show()                      # Display all open figures
```

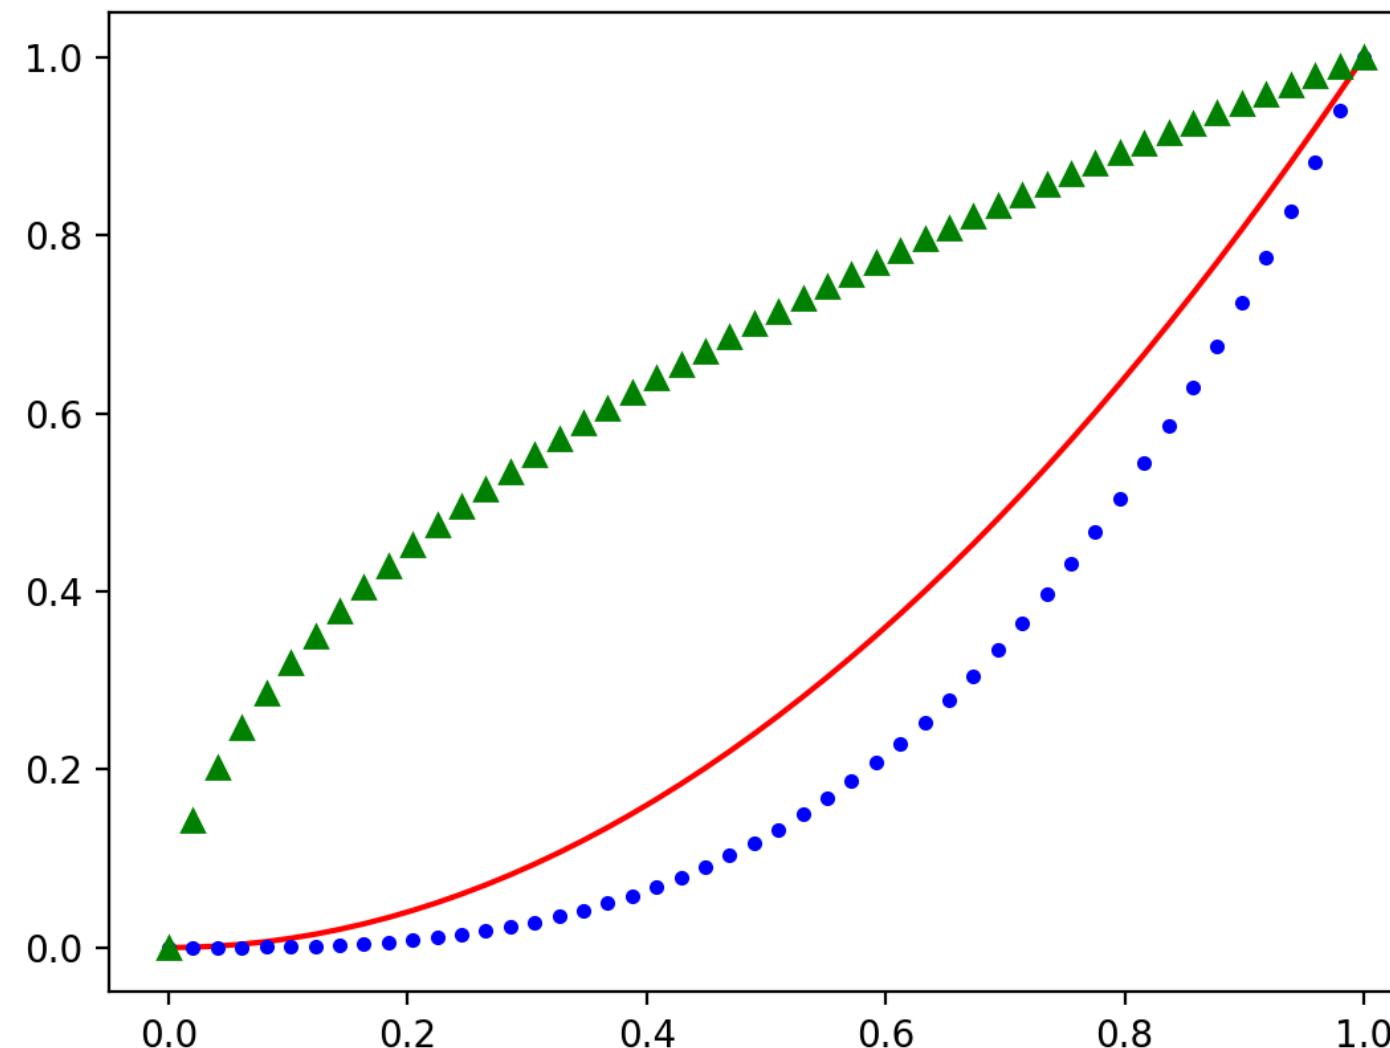

Quiz: Why does the plot look like this?

If one gives just one array `a`, this array is interpreted as y-axis values. By default the x-values are just enumerated 0 to `len(a)-1`. All those points are connected by line segments.

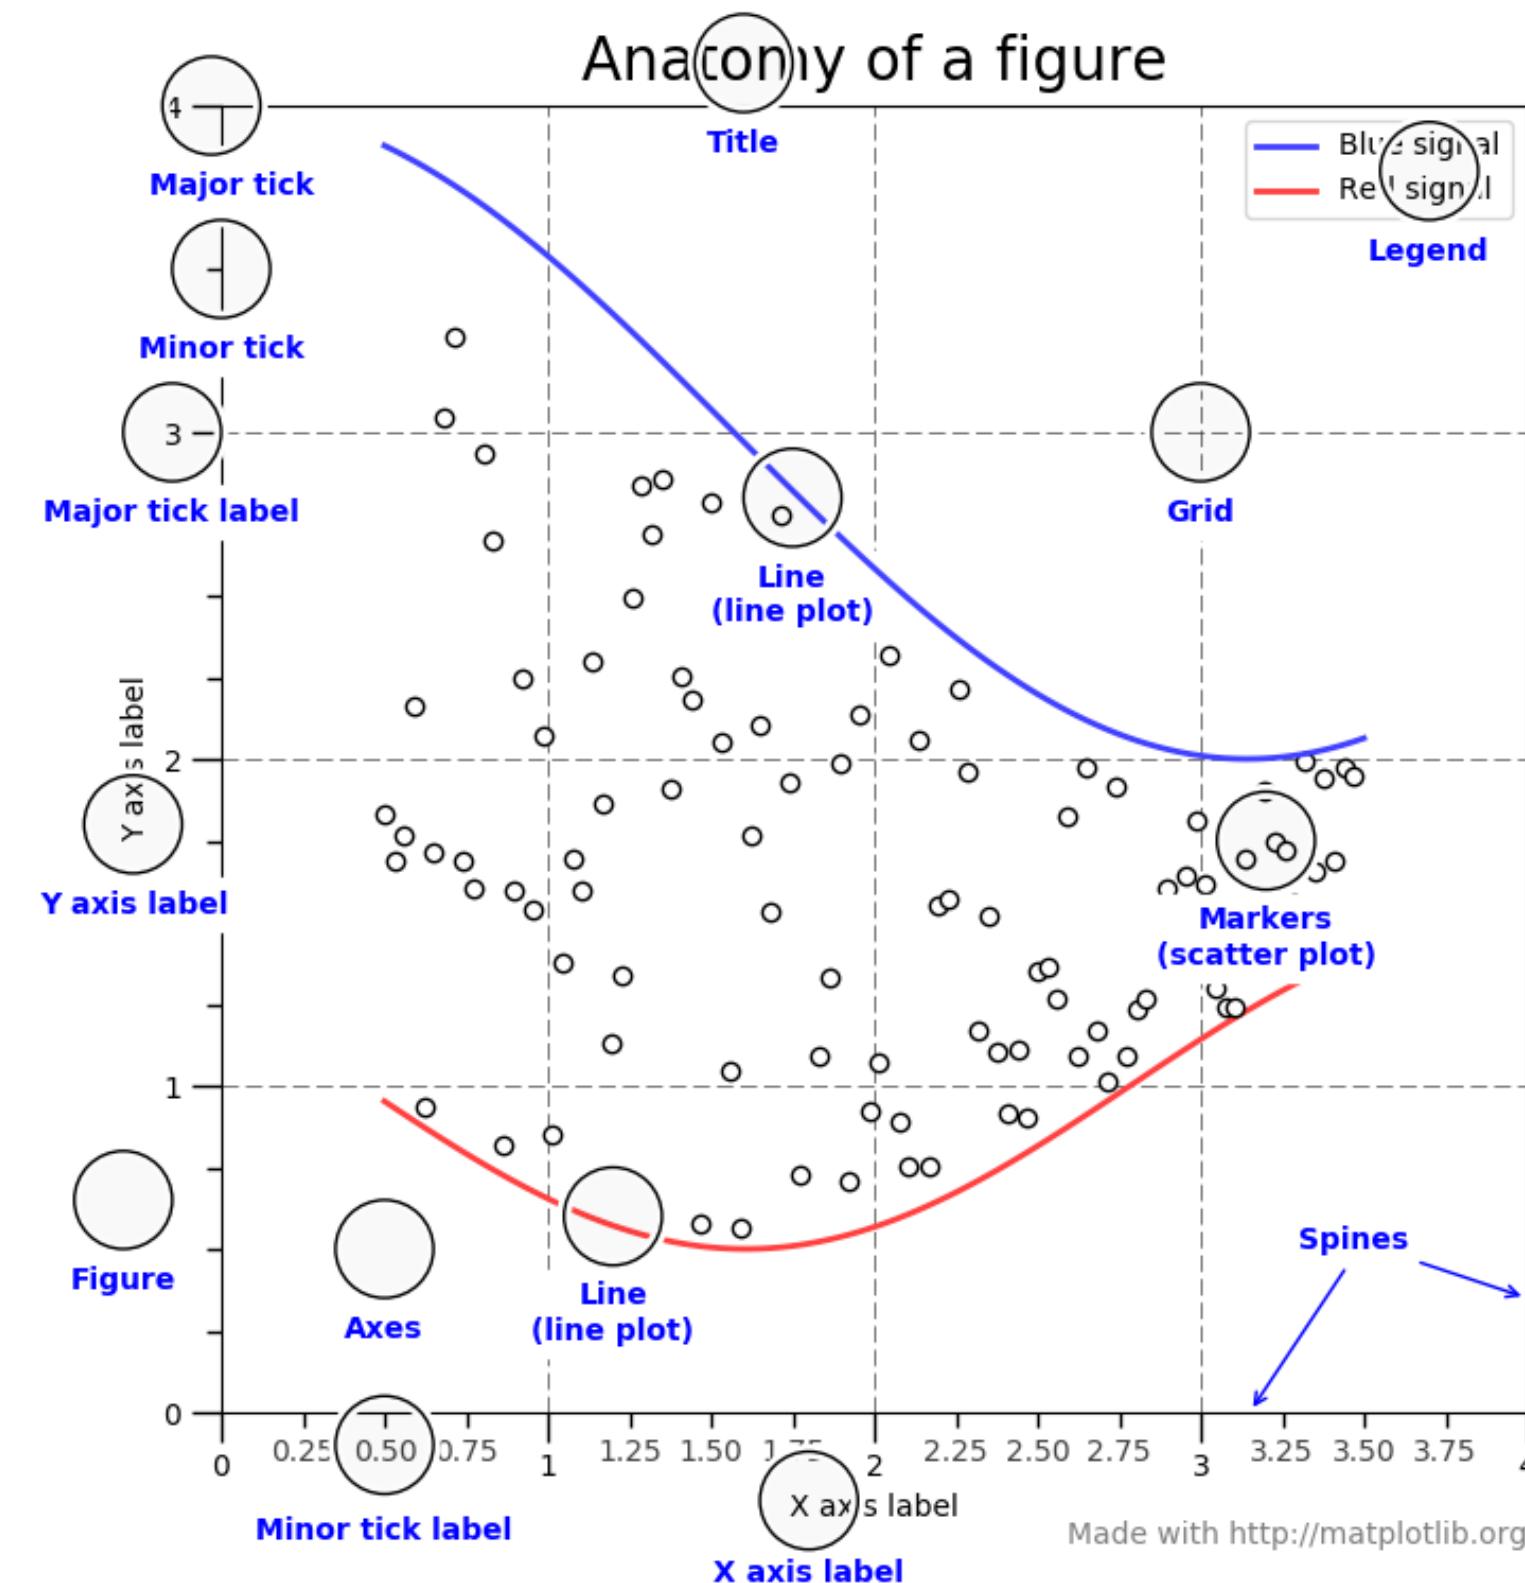

# Example 2: formatting the style of plot

```
1 import numpy as np
2 x = np.linspace(0,1,50)
3 # Plotting x vs. y data (for multiple functions/ x-y pairs with their own style)
4 plt.plot(x,x**2,'r',x,x**3,'b.',x,np.sqrt(x),'g^')
5 plt.show()
```

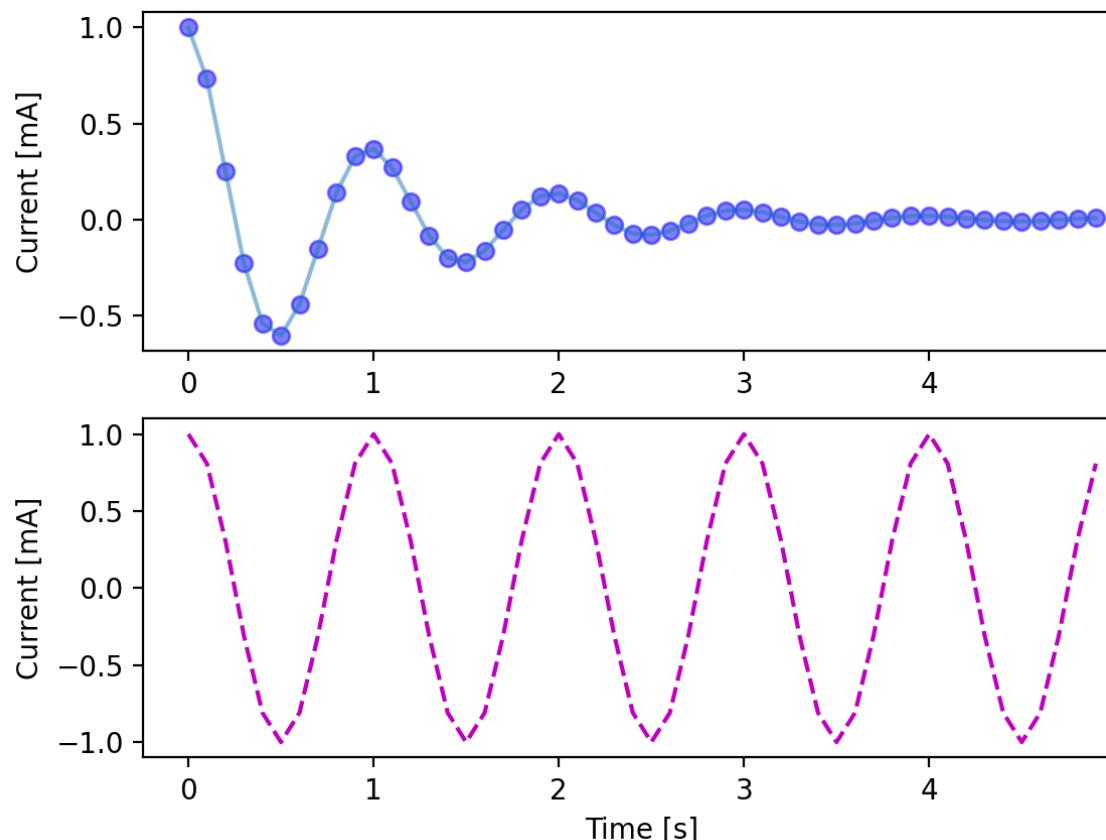

# Anatomy of a matplotlib figure

```

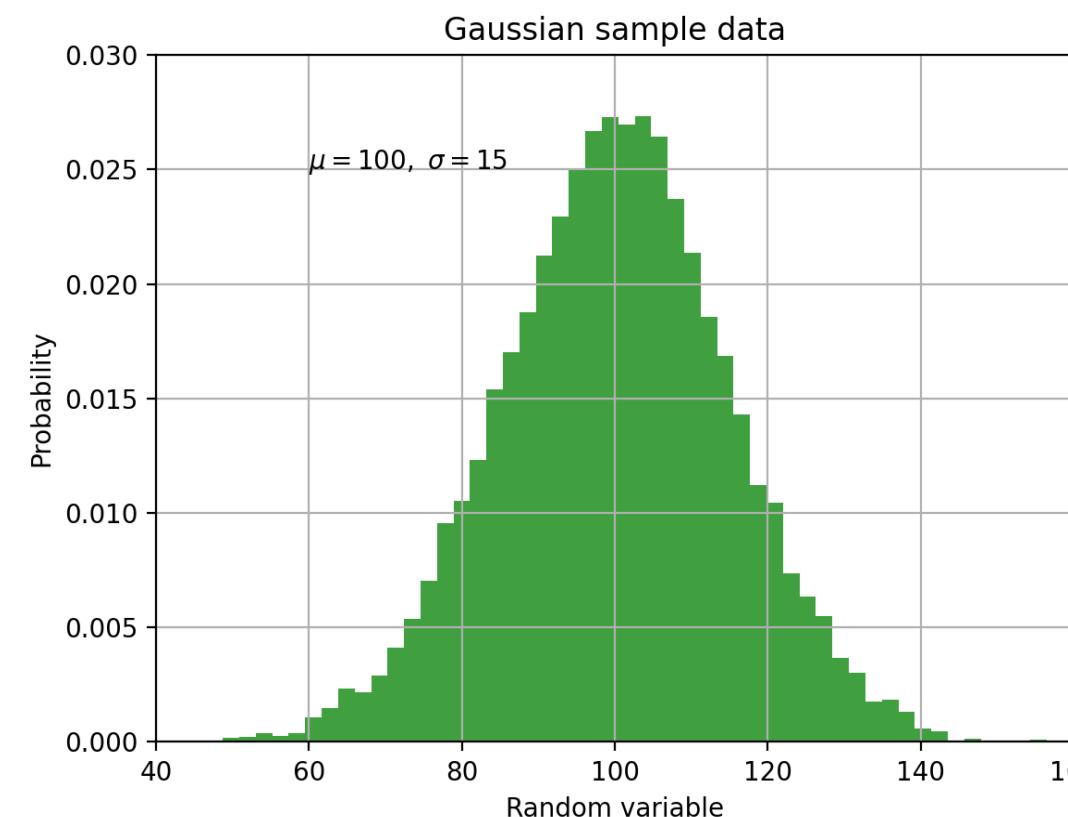

1 # Creating figures with subplots (here nrows = 2, ncols = 1)
2 T = np.arange(0.0, 5.0, 0.1)
3 Y = np.exp(-T) * np.cos(2*np.pi*T)      # Vectorized computation!
4 plt.figure()                          # Creating a new figure (or activate existing)
5 plt.subplot(211)                      # subplot(nrows, ncols, index)
6 plt.plot(T, Y, 'bo', T, Y, 'r-' ,alpha=.5)
7 plt.ylabel("Current [mA]")           # y-label
8 plt.subplot(212)                      # creating index = 2
9 plt.plot(T, np.cos(2*np.pi*T), 'm--')
10 plt.xlabel("Time [s]")
11 plt.ylabel("Current [mA]")
12 plt.show()

```

# Histograms and working with text

```
1 mu, sigma = 100, 15
2 x = mu + sigma * np.random.randn(10000)      # creating 10k samples with mu 100 and std 15
3 # Creating histogram of the data
4 n, bins, patches = plt.hist(x, 50, density=1, facecolor='g', alpha=0.75)
5 plt.xlabel('Random variable')
6 plt.ylabel('Probability')
7 plt.title('Gaussian sample data')
8 plt.text(60, .025, r'$\mu=100, \ \sigma=15$')      # putting text at location (60,0.025)
9 plt.axis([40, 160, 0, 0.03])                      # setting the axis limits
10 plt.grid(True)                                    # making grid
```

# Remember, use docstrings to get help!

```
1 In [15]: plt.axis?
2 Signature: plt.axis(*args, emit=True, **kwargs)
3 Docstring:
4 Convenience method to get or set some axis properties.
5
6 Call signatures::
7
8     xmin, xmax, ymin, ymax = axis()
9     xmin, xmax, ymin, ymax = axis([xmin, xmax, ymin, ymax])
10    xmin, xmax, ymin, ymax = axis(option)
11    xmin, xmax, ymin, ymax = axis(**kwargs)
12
13 Parameters
14 -----
15 xmin, xmax, ymin, ymax : float, optional
16     The axis limits to be set. This can also be achieved using :::
17
18     ax.set(xlim=(xmin, xmax), ylim=(ymin, ymax))
19
20 option : bool or str
21     If a bool, turns axis lines and labels on or off. If a string,
22     possible values are:
23
24 =====
```

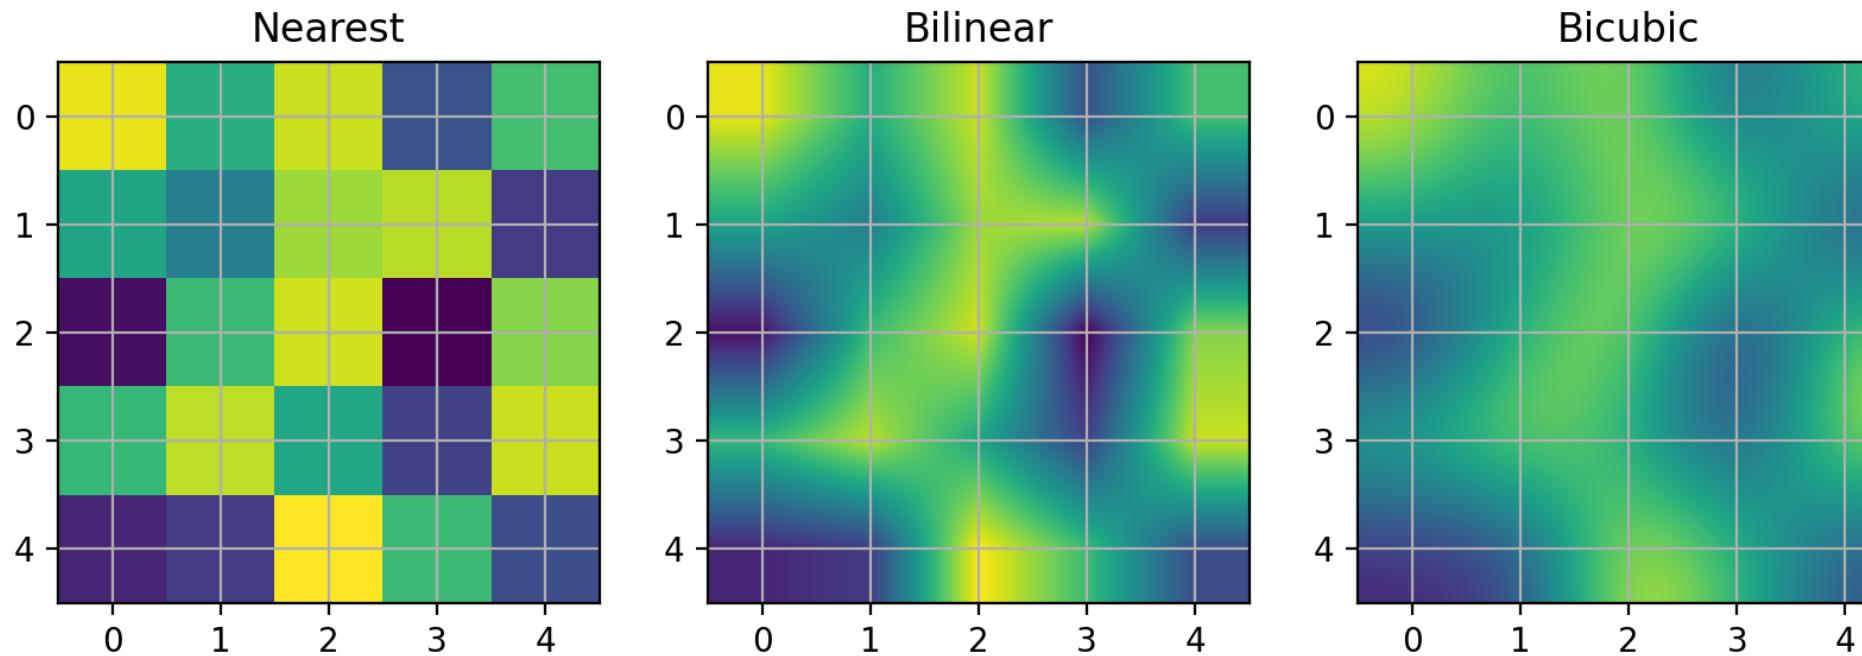

# Questions?

# Matplotlib has two interfaces

- `'matplotlib.pyplot'` is a state-based interface to matplotlib
  - this is what we saw so far
  - [Pyplot tutorial](#)
- it also has an object-oriented (OO) interface. In this case, we utilize an instance of `'axes.Axes'` in order to render visualizations on an instance of `'figure.Figure'`.
  - [more details what that means](#) with a nice example plotting financial data
  - all plots we saw so far, you can all also do this way
  - [lots of examples](#)

# Plotting images `imshow`

```
1 A = np.random.rand(5, 5)                  # creating a random 5 x 5 array (uniform)
2 fig, axs = plt.subplots(1, 3, figsize=(10, 3))      # creating a figure object
3 for ax, interp in zip(axs, ['nearest', 'bilinear', 'bicubic']):
4     ax.imshow(A, interpolation=interp)           # plotting `image` A
5     ax.set_title(interp.capitalize())
6     ax.grid(True)
7
8 plt.show()
```

Source / also works for images (loaded as arrays)

# Check out the Matplotlib gallery

---

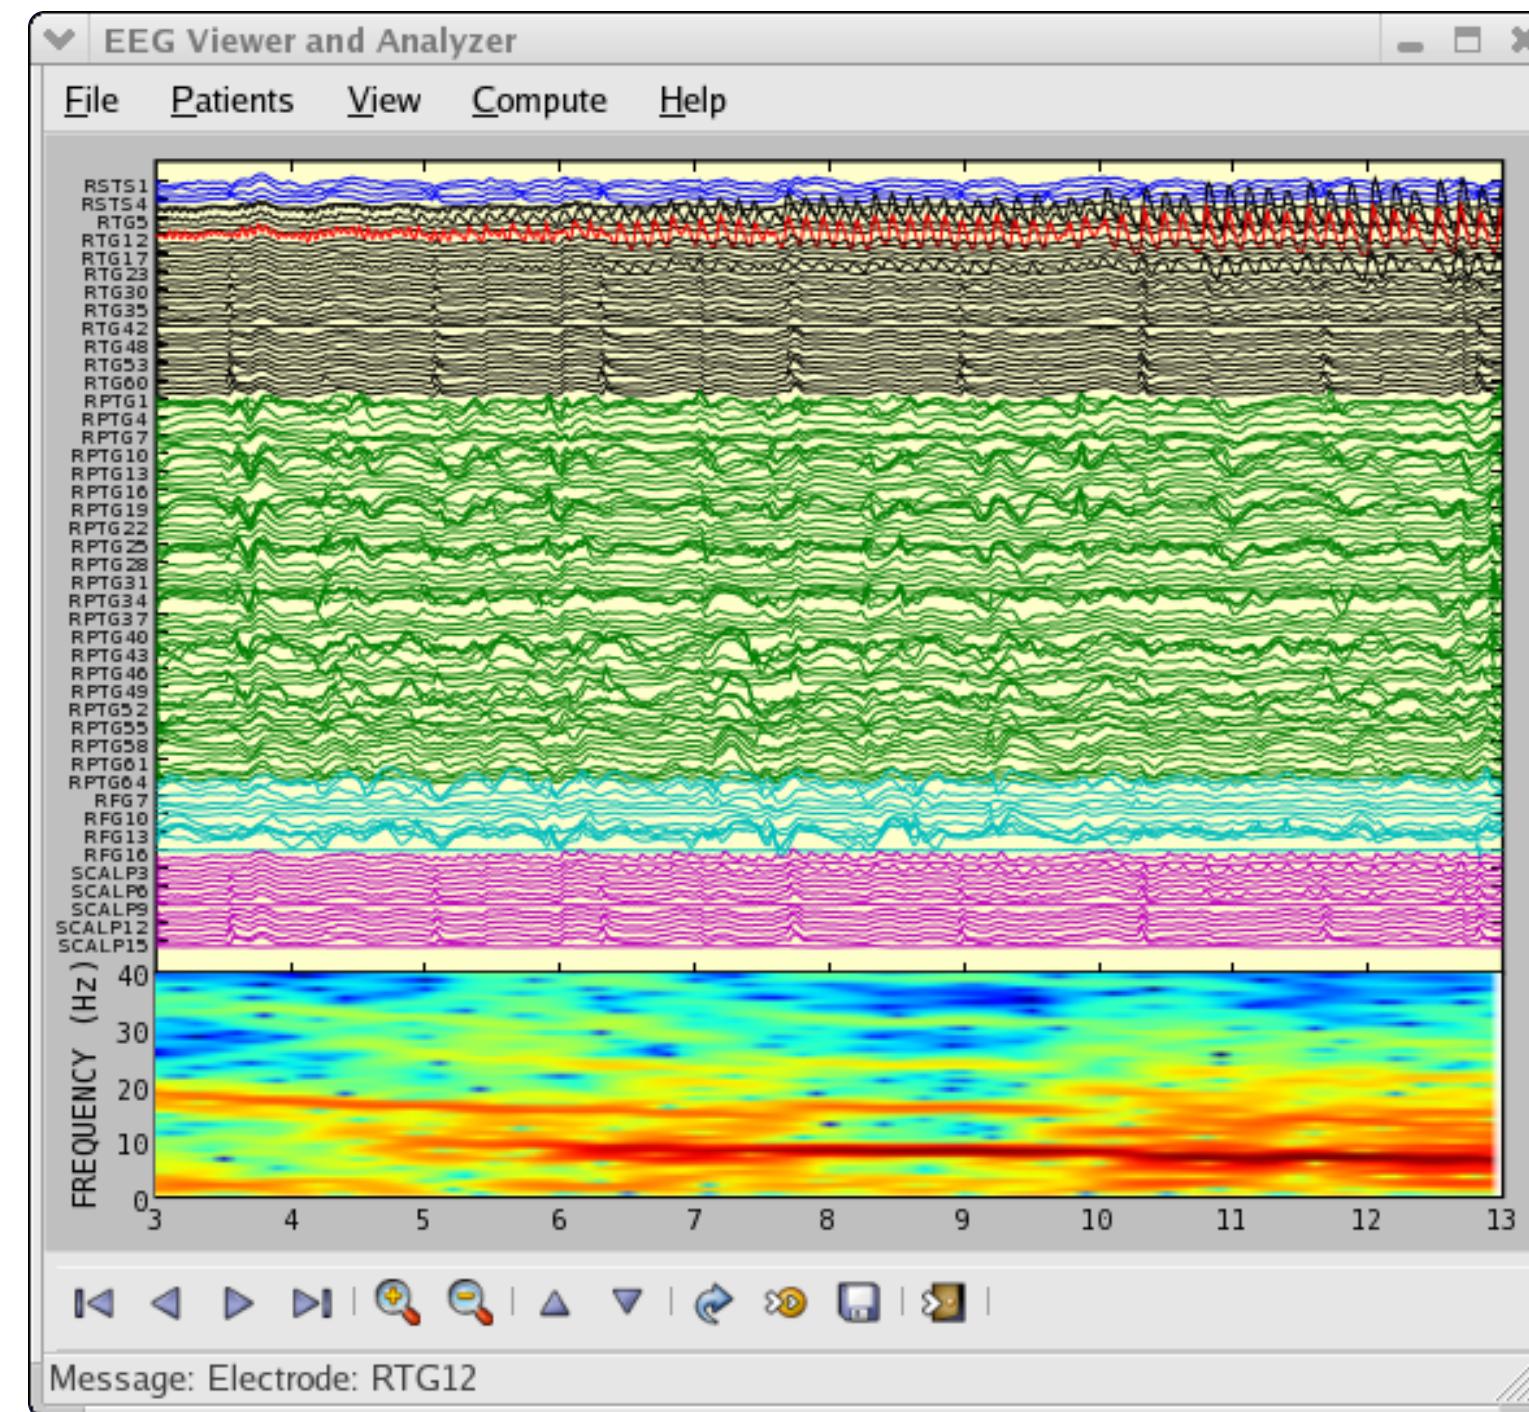

Tons of visual examples with code, e.g. [matlab-unchained](#)

---

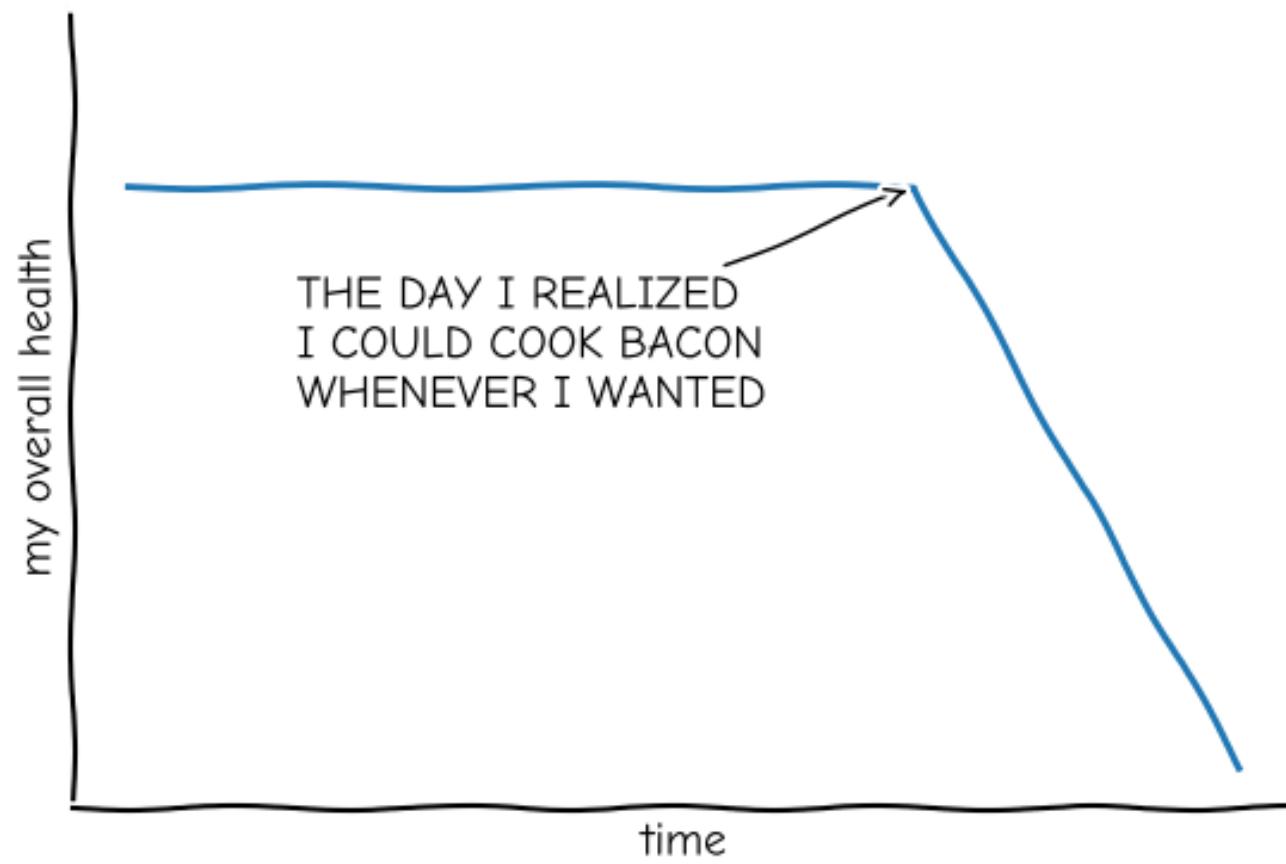

# Fun stuff I:

Matplotlib can be integrated in GUIs and make complex figures, e.g., here is a screenshot from pbrain

## Fun stuff II:

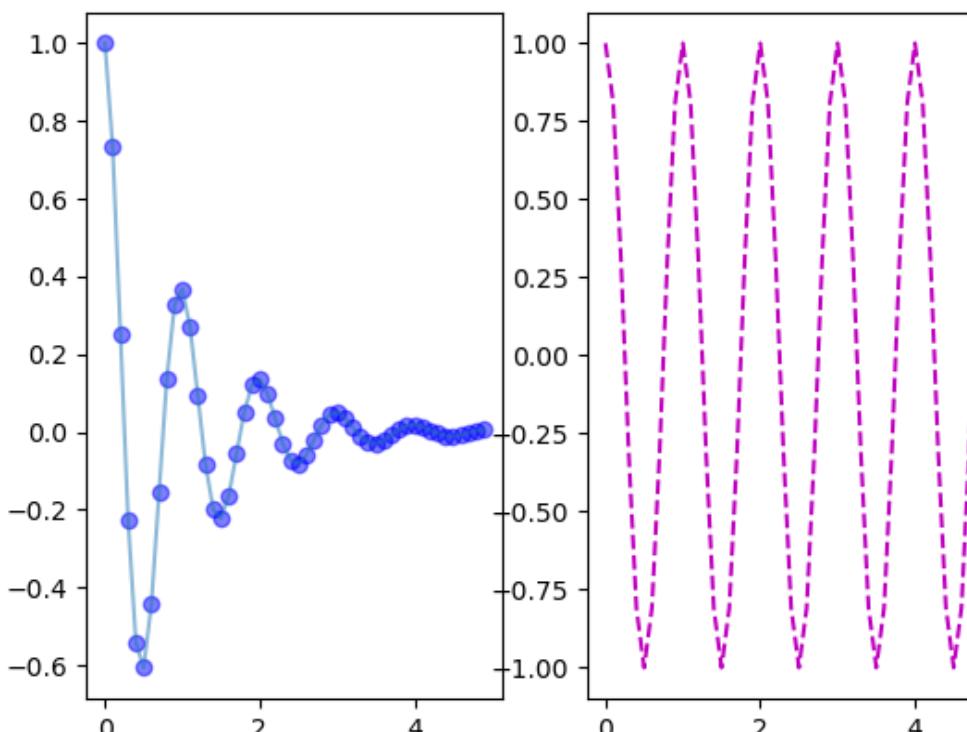

You can plot xkcd-comic style...

"Stove Ownership" from xkcd by Randall Munroe

# Quiz: How do you make a plot with 2 columns and 1 row?

```
1  T = np.arange(0.0, 5.0, 0.1)
2  Y = np.exp(-T) * np.cos(2*np.pi*T)      # Vectorized computation!
3  plt.figure()                                # Creating a new figure (or activate existing)
4  plt.subplot(121)                            # subplot(nrows, ncols, index)
5  plt.plot(T, Y, 'bo', T, Y, '-.', alpha=.5)
6  plt.subplot(122)                            # creating index = 2
7  plt.plot(T, np.cos(2*np.pi*T), 'm--')
8  plt.show()
```

# Questions?

# Today's summary

- docstrings
- visualization with matplotlib

As always, try out the commands in the python shell/notebooks!

In the exercises you will add docstrings and visualizations to your project.

# After lunch:

- Arrive early for the quiz (so you can start at 13:15)
- This week we will add visualizations and docstrings.
- Stay tuned for your code review, release v3 by Monday at 10 am
- Monday 15:15 - 16: my office hours at SV 2811
