

# **Randomness and information in biological data**

## **BIO-369**

**Prof. Anne-Florence Bitbol**

**EPFL**

Lecture 5

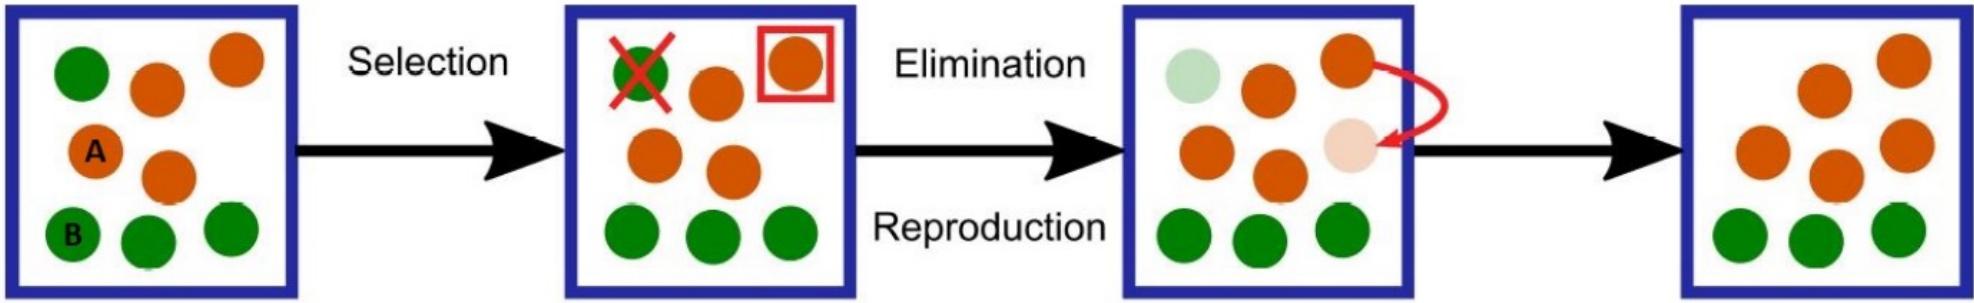

# Outline of the course

## I Randomness in biological processes and biological data

- 1 Randomness and random variables
  - 1.1 Coins and dice: discrete random variables
  - 1.2 Medical testing and conditional probabilities
  - 1.3 Luria-Delbrück experiment: Poisson distribution vs. jackpot distribution
- 2 Importance of thermal fluctuations at the cellular scale
  - 2.1 Thermal fluctuations and associated energy scale
  - 2.2 Strength of various chemical bonds
  - 2.3 Flexibility of biopolymers and biomembranes
- 3 Random walks
  - 3.1 Population genetics
  - 3.2 Protein abundances in single cells
  - 3.3 Importance of random walks in biological systems

# Random walks – Reminder

- The Moran model in population genetics

Schematic of one step of the Moran process

The population comprises two types of individuals, type A (orange) and type B (green)

# Outline of the course

## I Randomness in biological processes and biological data

- 1 Randomness and random variables
  - 1.1 Coins and dice: discrete random variables
  - 1.2 Medical testing and conditional probabilities
  - 1.3 Luria-Delbrück experiment: Poisson distribution vs. jackpot distribution
- 2 Importance of thermal fluctuations at the cellular scale
  - 2.1 Thermal fluctuations and associated energy scale
  - 2.2 Strength of various chemical bonds
  - 2.3 Flexibility of biopolymers and biomembranes
- 3 Random walks
  - 3.1 Population genetics
  - 3.2 Protein abundances in single cells
  - 3.3 Importance of random walks in biological systems

What is the average number of copies of a given protein per cell in bacteria?

0%

A. A few copies

0%

B. A few dozens of copies

0%

C. A few hundreds of copies

0%

D. A few thousands of copies

0%

E. A few tens of thousands of copies

0%

F. A few hundreds of thousands of copies

- Select your answer

# Motivation

- Protein abundances are heterogeneous across cells

Expression of fluorescently labeled chemotaxis proteins with inducible promoters under two conditions

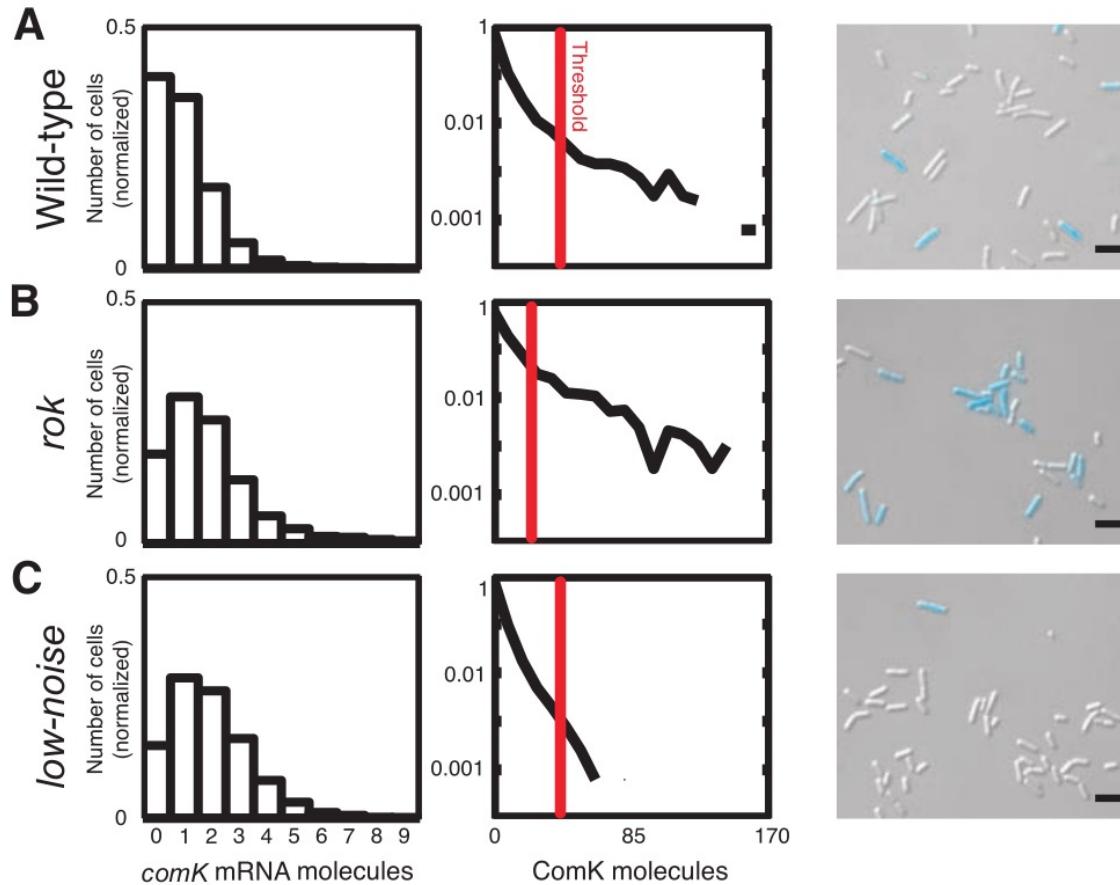

Dufour et al 2016

# Motivation

## Protein abundances can have major consequences

Noise in the expression of the gene *comK* determines the transition to competence for DNA uptake in *Bacillus subtilis* as it enters the stationary growth phase (left and middle: model; right: scale bars 4  $\mu$ m)

Maamar et al 2007

*rok* strain: higher abundance of ComK (no Rok = transcriptional repressor of *comK*)

Low-noise strain: *rok* + reduced translational efficiency (in prokaryotes, translation is noisier than transcription)

During dt, how can the number n of protein copies vary?

- 0% A. It stays constant
- 0% B. It increases by 1
- 0% C. It decreases by 1
- 0% D. A, B and C are all possible
- 0% E. B and C are possible, but not A

To answer, please:

- Select your answer

After a long time, what will happen to the number of protein copies?

0%

- A. It will either go to 0 or reach a maximum value and stay there forever
- B. It will stabilize at a steady-state value
- C. It will fluctuate around a steady-state mean value
- D. It depends

0%

0%

# Protein abundances in single cells

- Protein abundance as a random walk

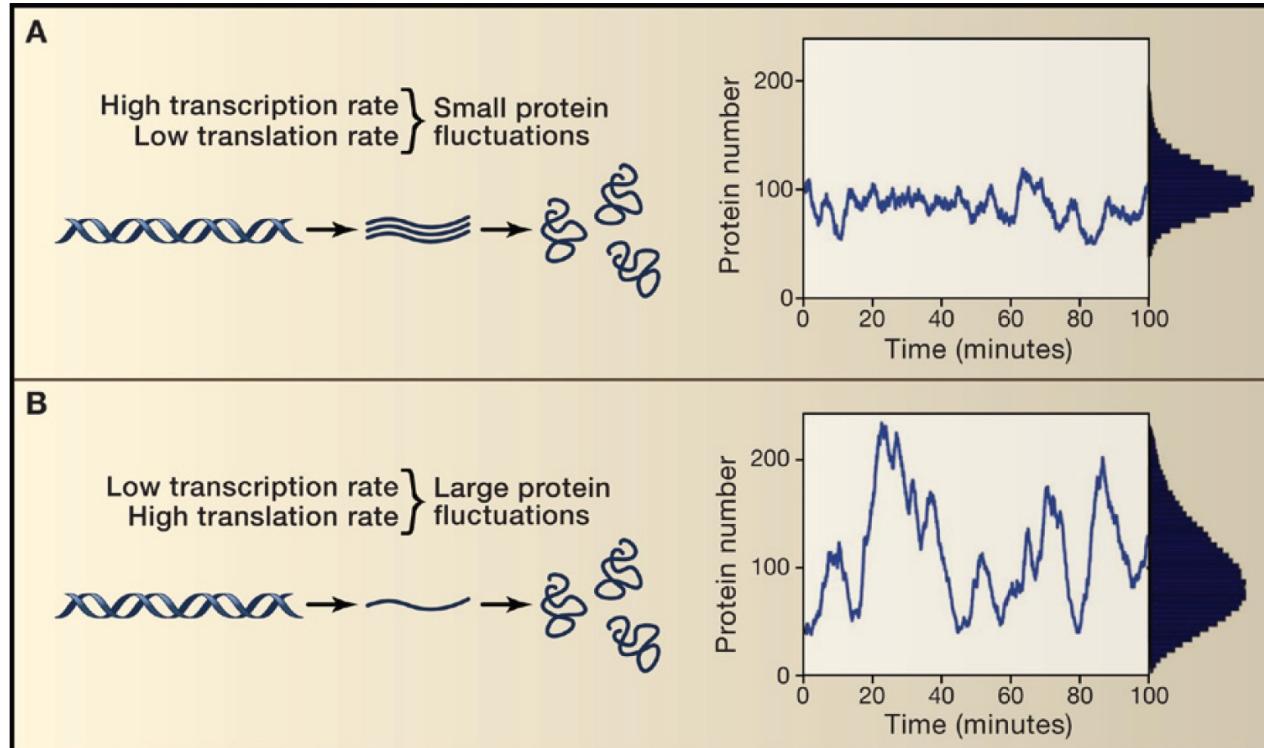

Simulation of a simple model for the abundance of a protein expressed in small copy numbers  
Orange / blue: number of proteins versus time in individual realizations  $\ell$  starting from 0 protein  
Green: mean over 200 such replicates; Black: deterministic approximation

# Gene expression and protein abundances

## Transcription and translation

Raj & van Oudenaarden 2008

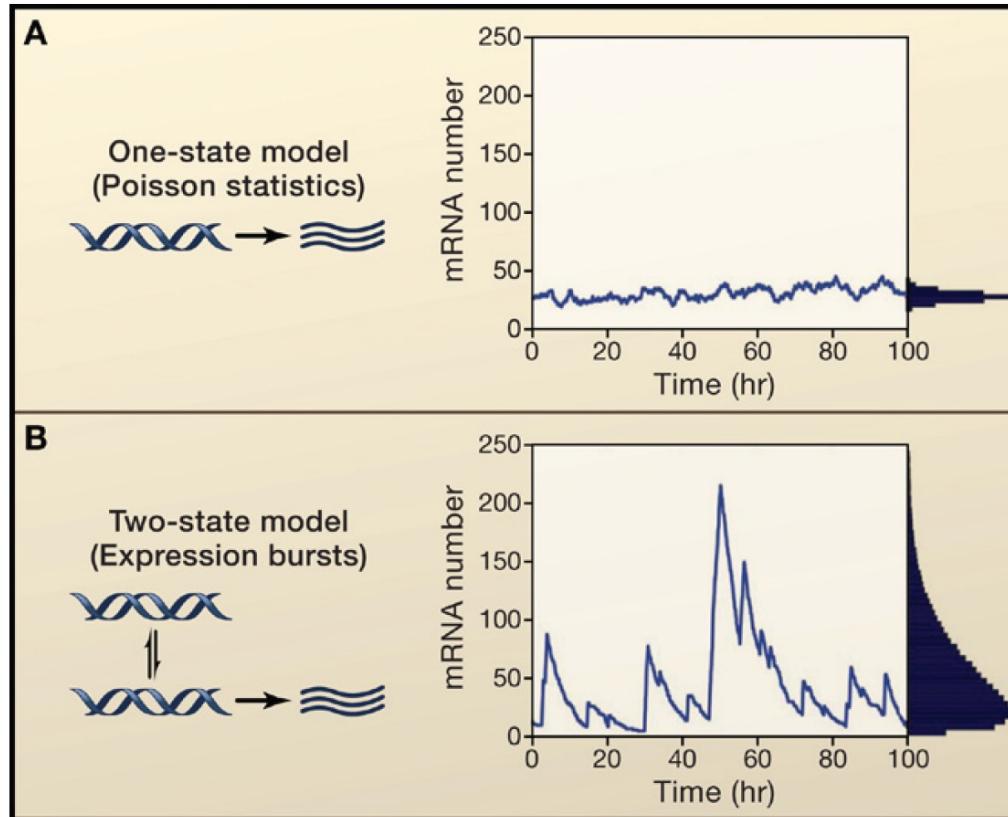

Noise in prokaryotic gene expression depends on the rates of transcription and translation  
Translation is bursty

# Gene expression and protein abundances

- Gene regulation: expressed and repressed gene states

Raj & van Oudenaarden 2008

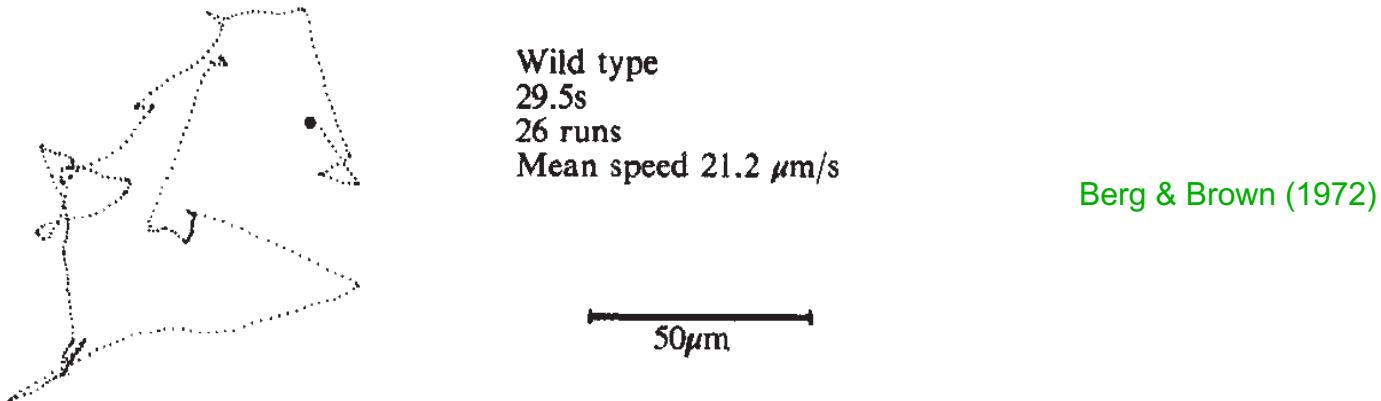

In eukaryotes, genes can be in ON (expressed) or OFF (repressed) states, i.e. be transcribed or not. Transcription is bursty because of the existence of these two states (→ problem class)

# Random walks

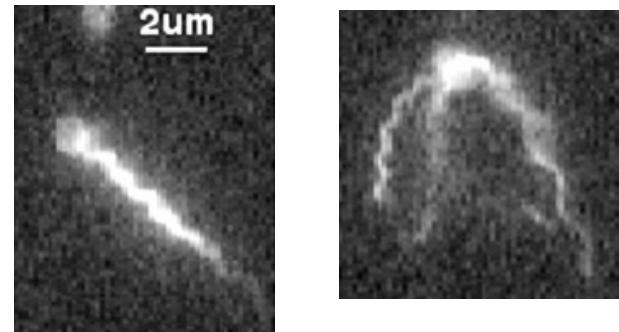

## ■ Bacterial chemotaxis

- Motion of swimming, flagellated bacteria: 3D random walk with “runs” and “tumbles”

Berg & Brown (1972)

- Runs → CCW rotation of the flagella
- Tumbles → CW rotation of the flagella

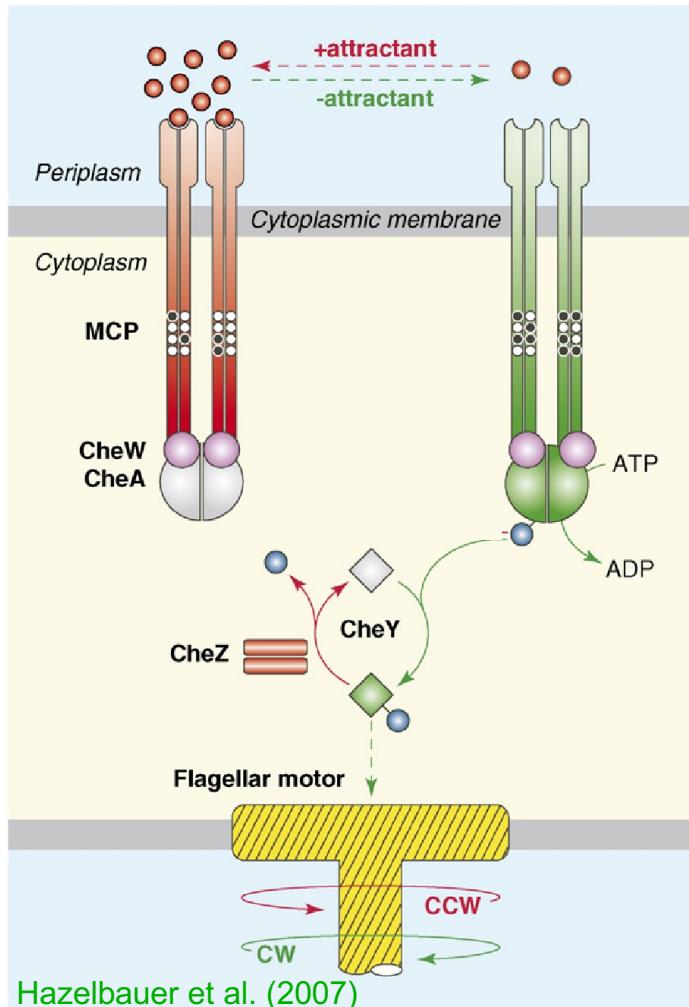

Turner et al. (2000)

- Gradients of chemicals can induce a change of tumbling frequency & CW bias  
→ Chemotaxis: bacteria are attracted or repelled by various chemicals

# Random walks

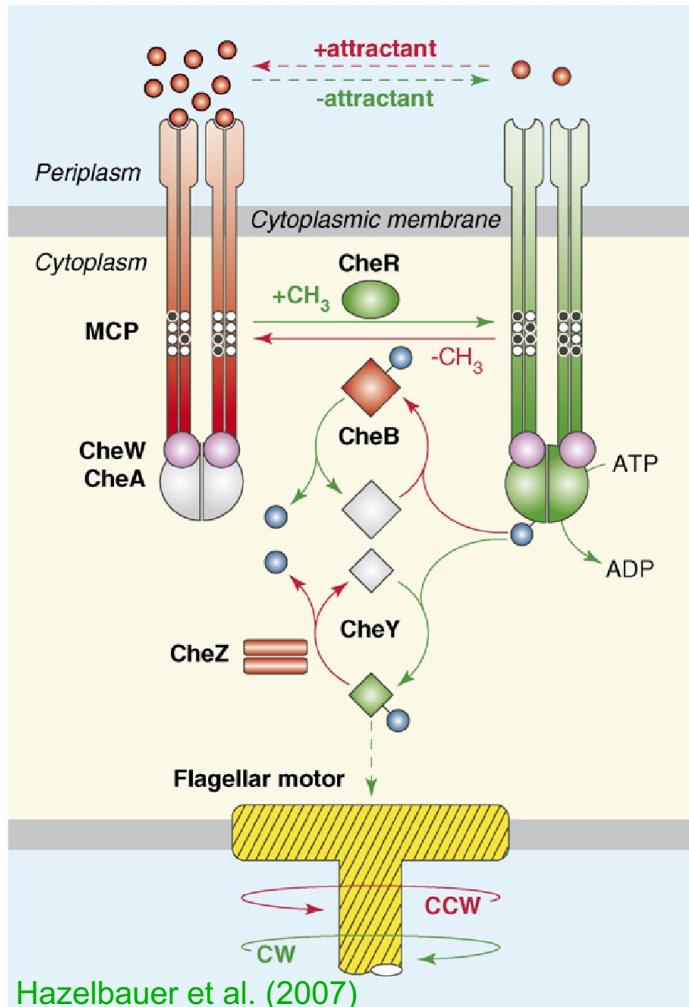

## Chemotaxis transduction pathway in *Escherichia coli*

- If fewer attractant molecules bind to MCP chemoreceptors (transmembrane proteins):
  - The autophosphorylation activity of the histidine kinase CheA (bound to receptors) increases
  - CheA-P phosphorylates CheY, a cytoplasmic protein (response regulator)
  - CheY-P binds to FliM protein of flagellar motor  
→ switching to CW rotation: tumbling
- If more attractants bind to chemoreceptors:
  - The activity of CheA decreases  
CheY-P is dephosphorylated by CheZ (phosphatase)
  - The motor reverts to its default state, CCW  
→ running

# Random walks

## Chemotaxis transduction pathway in *Escherichia coli*

- If fewer attractant molecules bind to MCP chemoreceptors (transmembrane proteins):
  - The autophosphorylation activity of the histidine kinase CheA (bound to receptors) increases
  - CheA-P phosphorylates CheY, a cytoplasmic protein (response regulator)
  - CheY-P binds to FliM protein of flagellar motor  
→ switching to CW rotation: tumbling
- If more attractants bind to chemoreceptors:
  - The activity of CheA decreases  
CheY-P is dephosphorylated by CheZ (phosphatase)
  - The motor reverts to its default state, CCW  
→ running

# Outline of the course

## II Extracting information from biological data

- 1 Quantifying randomness and information in data: entropy
  - 1.1 Notion of entropy
  - 1.2 Interpretation of entropy
  - 1.3 Entropy in neuroscience data: response of a neuron to a sensory input
- 2 Quantifying statistical dependence
  - 2.1 Covariance and correlation
  - 2.2 Mutual information
  - 2.3 Identifying coevolving sites in interacting proteins using sequence data
- 3 Inferring probability distributions from data
  - 3.1 Model selection and parameter estimation: maximum likelihood
  - 3.2 Introduction to maximum entropy inference
  - 3.3 Predicting protein structure from sequence data
- 4 Finding relevant dimensions in data: dimension reduction
  - 4.1 Principal component analysis
  - 4.2 Beyond principal component analysis
- 5 Introduction to Bayesian inference
