

# Basics of Unsaturated Soil Mechanics

## **SLOPE STABILITY COURSE**

Dr. Alessio Ferrari

EPFL / ENAC / GC section – Master semester 2 and 4 – 2024-2025

# Outline

- Basic concepts
  - Introduction
  - The definition of suction
- Hydraulic properties of soils under unsaturated conditions
  - The water retention curve and its hysteretic feature
  - The permeability
- Mechanical behavior of unsaturated soils
  - Net stress and generalized effective stress
  - Possible stress paths
  - Volumetric behavior
  - Shear strength

# Outline

- Basic concepts
  - Introduction
  - The definition of suction
- Hydraulic properties of soils under unsaturated conditions
  - The water retention curve and its hysteretic feature
  - The permeability
- Mechanical behavior of unsaturated soils
  - Net stress and generalized effective stress
  - Possible stress paths
  - Volumetric behavior
  - Shear strength

Three-phase description

- Volume of voids  $V_v = V_a + V_w$
- Total volume  $V = V_v + V_s$
- Porosity  $n = V_v/V$
- Void ratio  $e = V_v/V_s$

The amount of water in the soil can be quantified in different ways:

- Gravimetric Water content  $w = W_w/W_s$
- Degree of saturation  $S_r = V_w/V_v$
- Volumetric water content  $\theta = V_w/V$
- Water ratio  $e_w = V_w/V_s$

**Unsaturated soils** are soils whose voids are occupied by water and air.

## Capillary systems

- **Adhesion** is the attraction force between molecules of different type.
- **Cohesion** is the attraction force between molecules of the same type.

Adhesion > Cohesion

The liquid “wets” the surface

Adhesion < Cohesion

The liquid does not wet the surface

- When in contact with a solid surface, the interface will curve near that surface to form a **meniscus**
- The contact angle  $\theta$ , which is measured through the liquid, lower than  $90^\circ$  is typical for soil water on soil minerals

- Equilibrium of the interphase in the vertical direction :

$$u_a \pi \frac{d^2}{4} = u_w \pi \frac{d^2}{4} + 2\pi \frac{d}{2} T \cos \theta$$

$$u_a - u_w = \frac{4T \cos(\theta)}{d} = \frac{2T}{R}$$

$u_a$  = air pressure [F/L<sup>2</sup>]

$u_w$  = water pressure [F/L<sup>2</sup>]

$\theta$  = contact angle

$T$  = surface tension [F/L]

$d$  = diameter of capillary tube [L]

$R$  = radius of curvature of spherical cup [L]

The difference between pore air pressure and pore water pressure is named **matric suction**

$$s = u_a - u_w$$

In a capillary tube, suction depends on the size of the pore ( $d$ ) and the curvature of the interface ( $\theta$ )

$$s = u_a - u_w = \frac{4T \cos(\theta)}{d}$$

## Capillary systems

Values of suction we can expect in soils

$$s = u_a - u_w = \frac{4T \cos(\theta)}{d}$$

$$\mathcal{G} = 0$$

$$T = 0.073 \text{ N} / \text{m} \text{ (20}^\circ \text{ C)}$$

	Sand	Silt	Clay
d grain (mm)	2	0.075	0.002
d pore (mm)	0.2	0.0075	0.0002
$u_a - u_w$ (kPa)	1.4	38	1440

Relative pore water pressure are negative

Pore water pressure can be negative in absolute values (!)

# The water retention curve

## SATURATED STATE

An initially saturated soil is subjected to evaporation

- **Menisci** at the surface start to appear
- The pore water pressure decreases and the suction becomes higher than 0,  **$s > 0$**
- The soil is still saturated,  **$S_r = 1$**

# The water retention curve

## QUASI - SATURATED STATE

Indicative values of the degree of saturation  
 $0.85-0.90 < S_r < 1$

- More menisci appear, air cavities in the larger pores expand
- The pore water pressure continues decreasing and the suction continue increasing,  $s > 0$
- **Gas** phase is **discontinuous**, **liquid** phase is **continuous**
- The degree of saturation decreases,  $S_r < 1$

# The water retention curve

## PARTIALLY SATURATED STATE

Indicative values of the degree of saturation  
 $0.1 < S_r < 0.85-0.90$

- More menisci appear, also the smaller pores start to desaturate; at the interface the maximum curvature of the menisci is reached and the air enters
- The pore water pressure continues decreasing and the suction continues increasing,  $s > 0$
- **Gas** phase is **continuous**, **liquid** phase is **continuous**
- The degree of saturation decreases,  $S_r < 1$

# The water retention curve

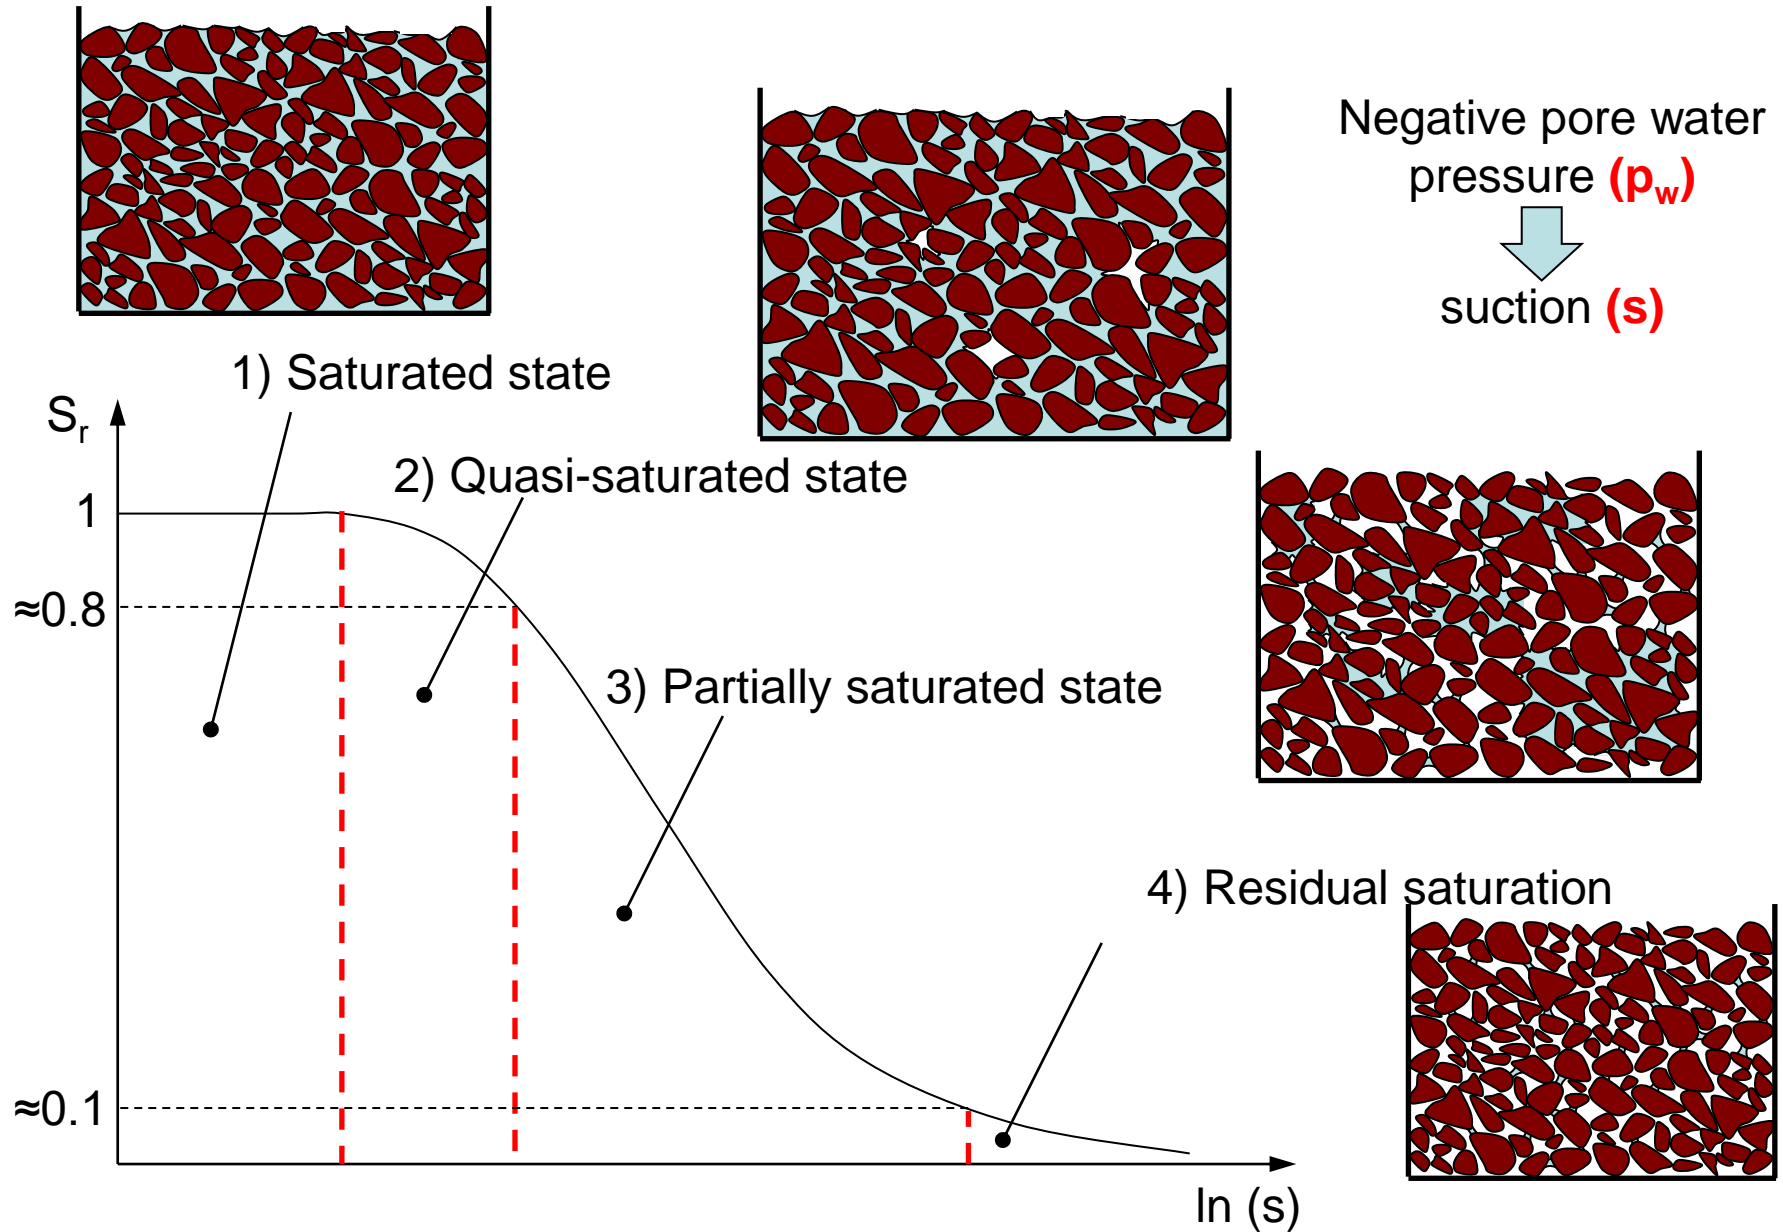

## RESIDUAL STATE

Indicative values of the  
degree of saturation  
 $S_r < 0.1$

- There is water in some isolated pores
- The pore water pressure continues decreasing and the suction continues increasing,  $s > 0$
- **Gas** phase is **continuous**, **liquid** phase is **discontinuous**
- The degree of saturation does not decrease significantly,  $S_r < 1$

# The water retention curve

# The water retention curve

The relationship between the degree of saturation and the suction is called “water retention curve”. It expresses the capacity of the soil to retain water.

# The water retention curve

## THE AIR ENTRY VALUE

- The air entry value ( $s_{AEV}$ ) is the approximate value of suction starting from which the soil starts to desaturate.
- The order of magnitude of  $s_{AEV}$  is a function of the pores size: the larger the pores the lower is the suction needed for desaturating the specimen.
- $s_{AEV}$  can be computed by using the Young-Laplace equation

D: pore diameter for different  
geomaterials

Young-Laplace equation

$$s = u_a - u_w = \frac{4T \cos \theta}{d}$$

Values assumed for the other  
parameters

$$T = 0.072 \text{ N/m}$$

$$\theta = 0^\circ$$

**Order of magnitude of the air entry value depending on the characteristic pore size:**

<b>sand</b> <b>(<math>d_{\max}=30 \mu\text{m}</math>)</b>	<b>silt</b> <b>(<math>d_{\max}=3 \mu\text{m}</math>)</b>	<b>clay</b> <b>(<math>d_{\max}=0.3 \mu\text{m}</math>)</b>
<b>9.6 kPa</b>	<b>96 kPa</b>	<b>960 kPa</b>

# The soil water retention curve

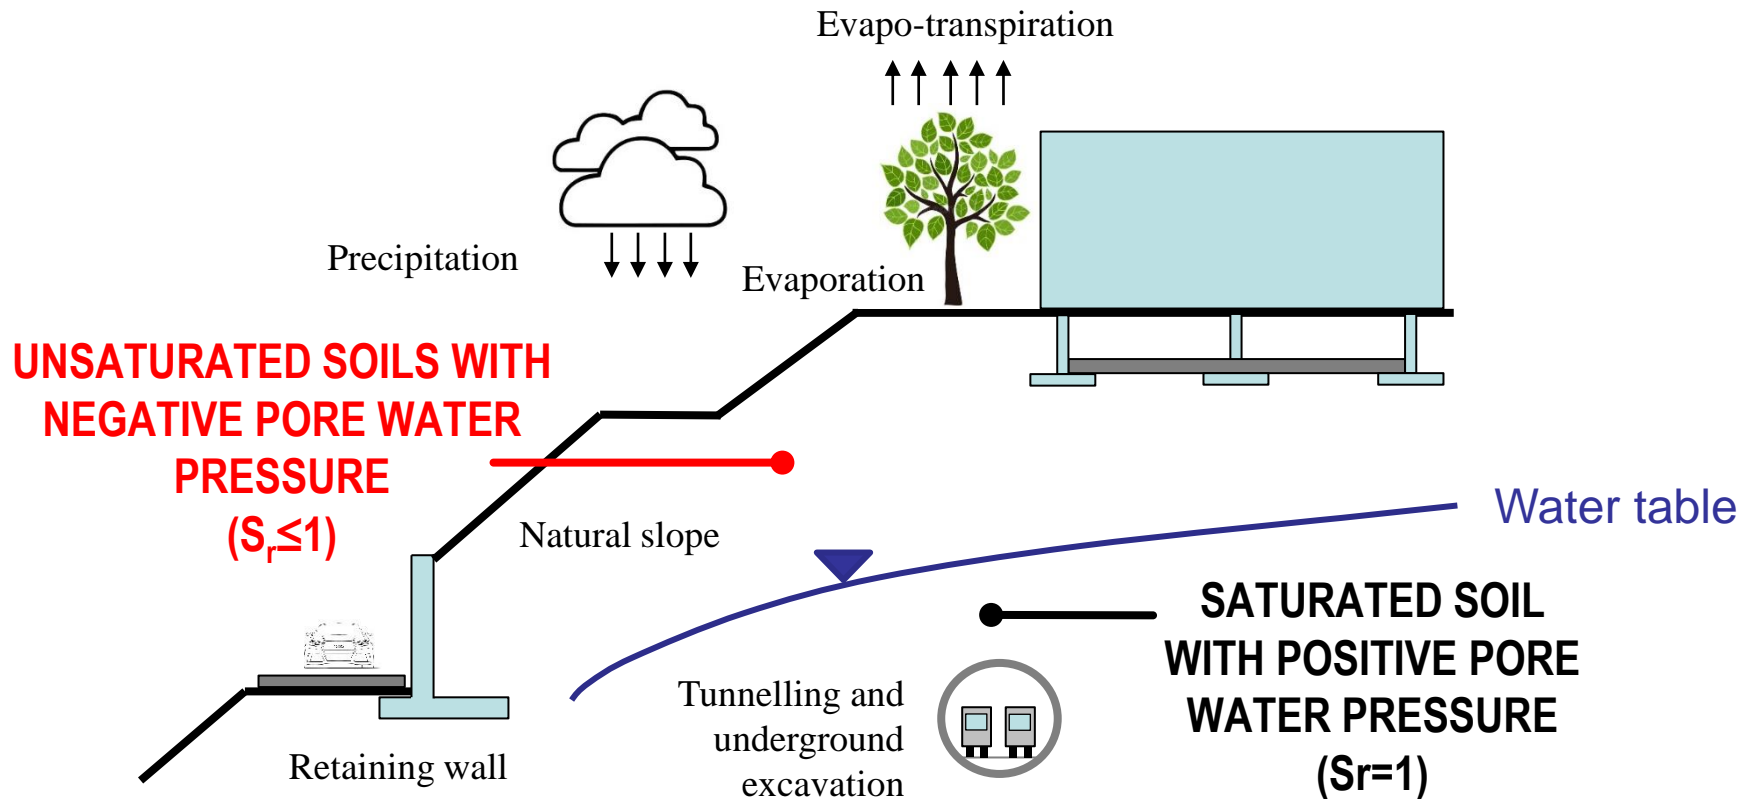

## DRYING AND WETTING PROCESSES – AN HYSTERETIC BEHAVIOR

- A process characterized by an increase in suction is called “drying process”
- A process characterized by a decrease in suction is called “wetting process”
- The relationship between suction and degree of saturation changes depending on the alternation of these processes

Above the water table the pore water pressure is negative and the soil can be unsaturated. Rainfall and evaporation phenomena are example of processes affecting pore water pressure and degree of saturation.

# Permeability

The **coefficient of permeability** is the coefficient of proportionality between the flow rate and the hydraulic head gradient.

$$v_{w,x} = -k_w \frac{\partial h_w}{\partial x}$$

**Darcy's law** (example for the x-direction)

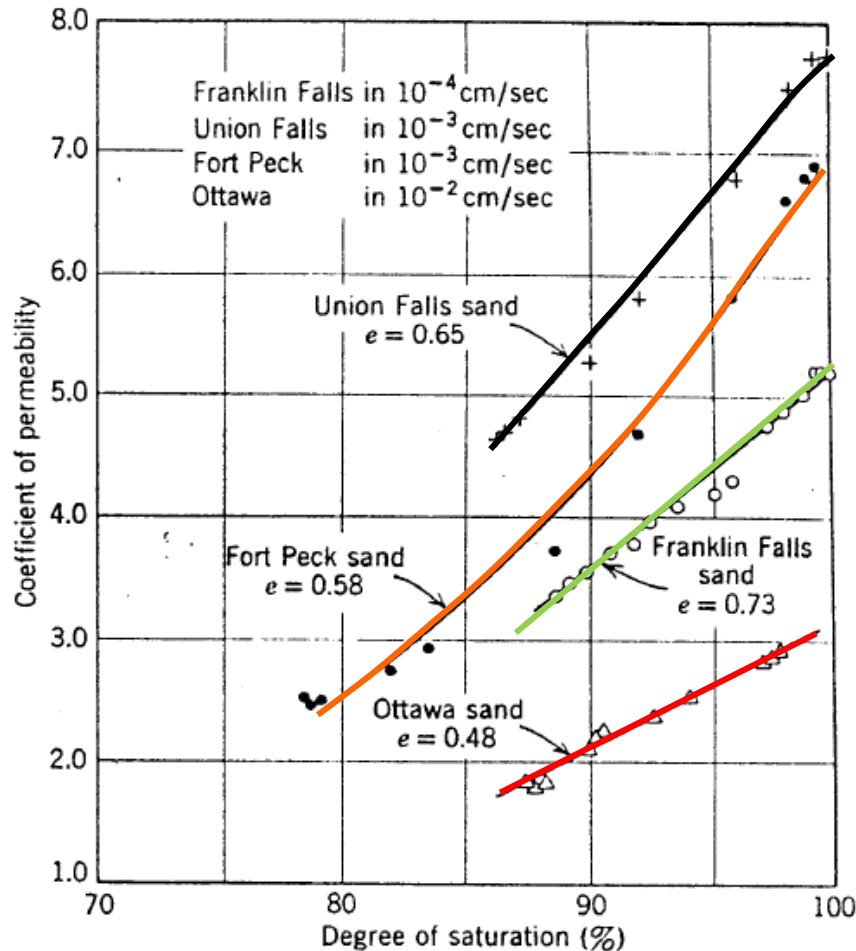

For a given **saturated soil**, the coefficient of permeability mainly depends on the void ratio.

The higher the void ratio, the higher is the permeability coefficient.

Example of test results  
from Lambe and Whitman, 1969

# Permeability

For an **unsaturated soil**, the **Darcy's law is still valid** but the coefficient of permeability depends on both the water content (or degree of saturation) and the void ratio.

The more water is available in the soil, the more there are connected pores filled with water that the water can use for flowing.

For a given void ratio, the higher the degree of saturation the higher is the permeability coefficient.

Example of test results  
from Lambe and Whitman, 1969

# Water retention and permeability

Van Genuchten, M., 1980

$$S_r = \left\{ \frac{1}{1 + [\alpha(p_a - p_w)]^n} \right\}^m$$

$\alpha$ ,  $n$ ,  $m$  calibration parameters

The evolution of the coefficient of permeability with suction can be described for example by using the Gardner's model (1958).

Gardner's model

$$k = k_s e^{-\alpha(p_a - p_w)}$$

$\alpha$  fitting parameter

## Capillary effect in soils

The contact angle of water with the particle surface is less than  $90^\circ$

The meniscus is concave toward the air side and pore water pressure is **negative**

Particles are stuck together by surface tension and negative pressure

The Daytona Beach race (Florida, United States)

The sand castle and the possibility of having races in the beach are example of how the negative pore water pressure affect the mechanical properties of soils.

# Suction, net stress and eff. stress

In the case of saturated specimens with incompressible water and solid grains the effective stress is

# Suction, net stress and eff. stress

The difference between the pressure of the air and the pressure of the water is called **suction**

$$s = p_a - p_w$$

The difference between the external stress and the pressure of the air is called **net stress**

$$\sigma_{net,ij} = \sigma_{ij} - p_a \delta_{ij} \quad \text{net stress tensor}$$

# Suction, net stress and eff. stress

The effective stress in presence of different fluids

Conversion of a multiphase and multi stress medium in an equivalent medium

$$\sigma'_{ij} = \sigma_{ij} - \sum_{\beta=1}^i \alpha_{\beta} p_{\beta} \delta_{ij}$$

$\sigma_{ij}$  : total stress

$\beta$ : generic fluid

$\alpha_{\beta}$ : scaling factor of the fluid  $\beta$

$p_{\beta}$ : pressure of the fluid  $\beta$

# Suction, net stress and eff. stress

The effective stress in the specific case of unsaturated soils

$$\sigma'_{ij} = \sigma_{ij} - \sum_{\beta=1}^2 \alpha_{\beta} p_{\beta} \delta_{ij}$$

$$\begin{aligned} \sigma'_{ij} &= \sigma_{ij} - (1 - \chi) p_a \delta_{ij} - \chi p_w \delta_{ij} \\ \sigma'_{ij} &= (\sigma_{ij} - p_a \delta_{ij}) + \chi (p_a - p_w) \delta_{ij} \end{aligned}$$

$$\sigma'_{ij} = \sigma_{net,ij} + \chi s \delta_{ij}$$

with  $\chi = f(S_r)$

Net stress tensor

Suction stress tensor

# Suction, net stress and eff. stress

The effective stress in the specific case of unsaturated soils

$$\sigma'_{ij} = \sigma_{net,ij} + \chi s \delta_{ij}$$

For granular soils and clays with low activity

$$\chi = S_r$$

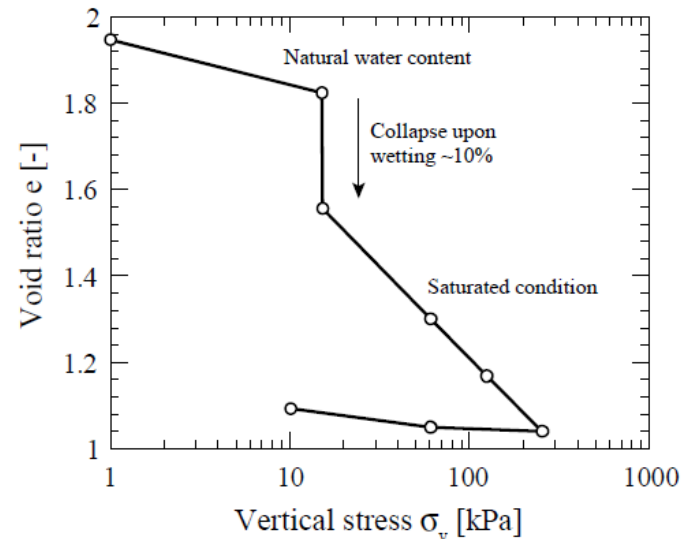

$$\sigma'_{ij} = \sigma_{net,ij} + S_r s \delta_{ij}$$

# Volumetric behavior

## Collapse upon wetting

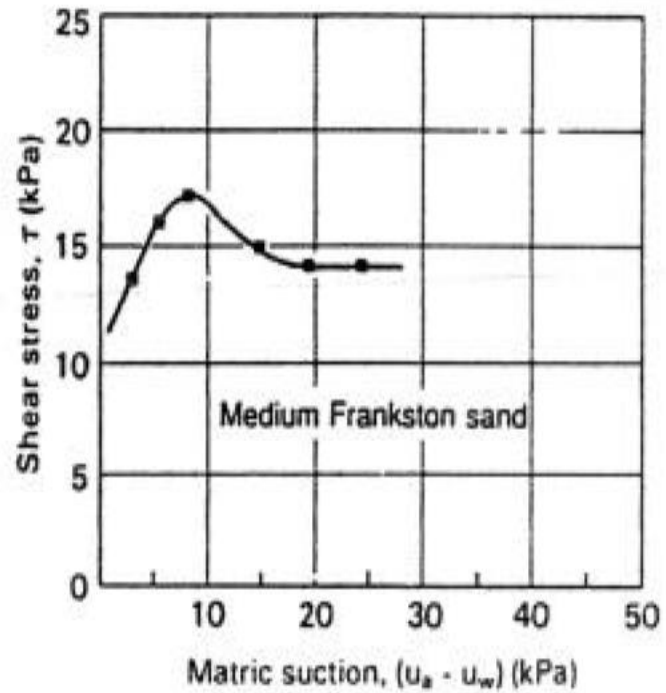

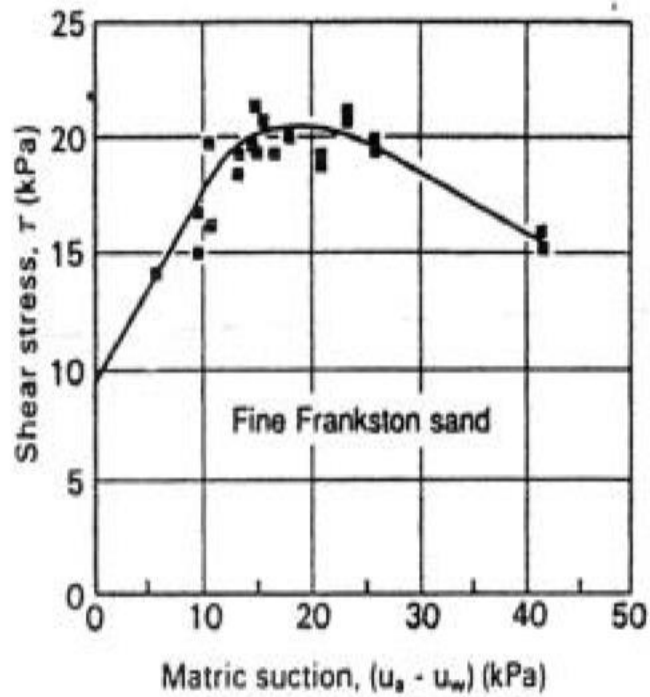

Collapse occurs when total stress is sufficiently high to induce particle slip when the stabilizing effect of menisci disappear

Collapse upon wetting behaviour of a volcanic soil wetted after loading at natural water content (Ferrari et al. 2013)

# Shear strength

Results of controlled suction direct shear tests on sands (Donald 1956)

# Shear strength

## Planar shear strength envelope

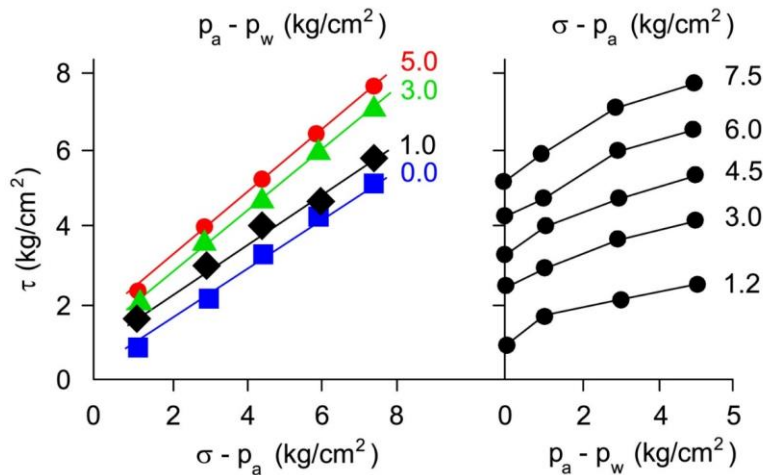

$$\tau_f = c' + (\sigma_n - p_a) \tan \phi' + (u_a - u_w) \tan \phi^b$$

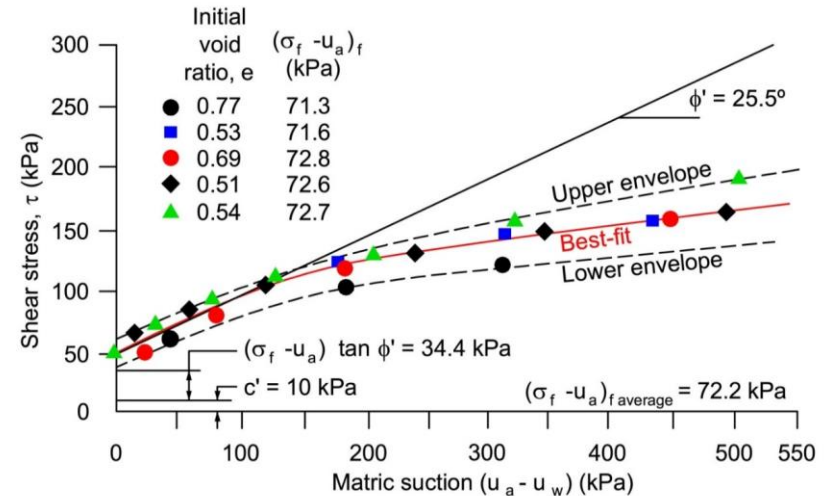

Formulation of shear strength criterion for unsaturated soils by Fredlund et al. (1978)

# Shear strength

## Curvature of the envelope

Direct shear tests under controlled suction for Madrid clayey sand ("Arena de miga") (Escario and Saez, 1986)

Controlled suction direct shear tests on a glacial till (Gan et al. 1988)

Experimental results show that the increase of strength with suction is not linear (i.e.  $f_b$  is not constant)

# Shear strength

## Example of non-linear strength envelope

$$\left( \frac{s_m - s}{s_m + s_o} \right)^{2.5} + \left( \frac{\tau + \tau_b}{\tau_m + \tau_b} \right)^{2.5} = 1$$

Ellipsoidal shear strength envelope proposed by Escario and Juca (1989)

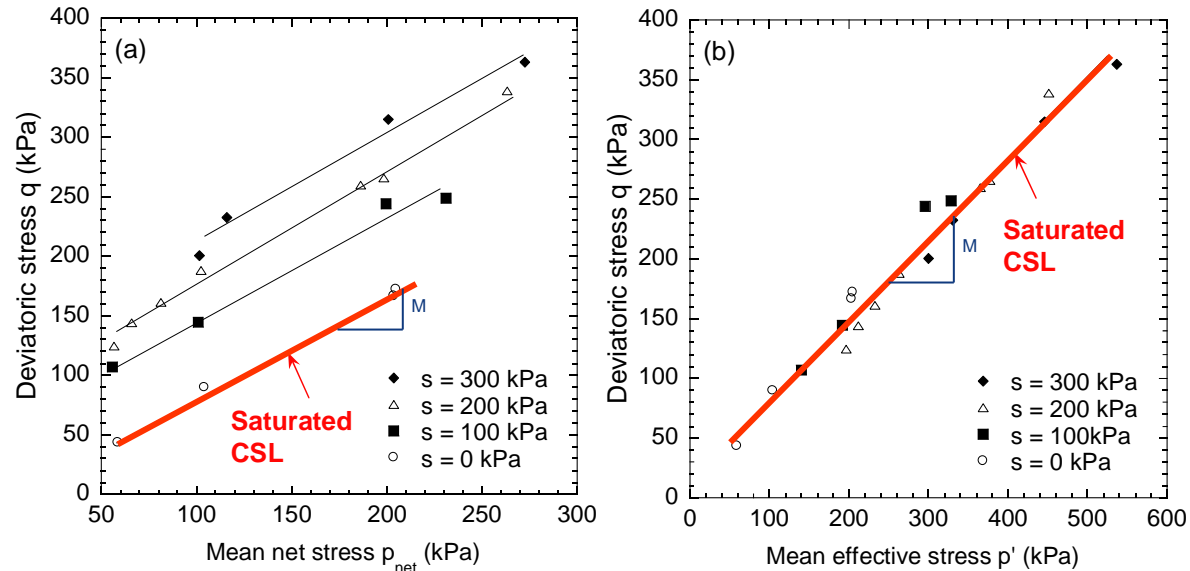

Data from Escario and Saez (1987)

# Shear strength

## Critical state behavior

Experimental data from Sivakumar (1993) on kaolin: conventional ( $q$ - $p_{net}$ ) plane vs effective ( $q$ - $p'$ ) plane

The adoption of a suitable definition of effective stress allows defining a unique shear strength envelope irrespective of the degree of saturation of the soil. An increase of the mean effective stress (related to an increase in suction or an increase of the mechanical load) results in an increase of the shear strength

# Summary

- Unsaturated soils are characterized by two fluids and a solid phase. The negative pore water pressure is usually expressed in terms of suction (i.e. the difference between the pressure of the air and the pressure of the pore water)
- The water retention curve describes how the degree of saturation evolves with suction
- The Darcy's law is still valid for unsaturated soils, the permeability coefficient depends also on the degree of saturation
- The Terzaghi's effective stress is still valid if the pore water pressure is negative and the degree of saturation is equal to 1. Otherwise, a more general expression has to be used
- The volumetric behavior and the shear strength of a soil are affected by variation in suction

# 1D infiltration models

1D Richard's Equation

$$\frac{\partial}{\partial z} \left( K_z \frac{\partial h}{\partial z} \right) = \rho_s A \frac{\partial h}{\partial t}$$

$$A = \frac{\partial \mathcal{G}}{\partial h} \quad \mathcal{G} = V_w / W_s$$

Fredlund et al. 1978

$$\tau_f = c' + (\sigma_n - u_a) \tan \phi' + (u_a - u_w) \tan \phi^b$$

Hyperbolic criteria

$$\tau_f = c' + (\sigma_n - u_a) \tan \phi' + \frac{s}{\cot \phi' + \frac{s}{c^*}}$$

Bishop's effective stress

$$\sigma'_n = \sigma_n + S_r s$$

$$\tau_f = c' + (\sigma_{net} + S_r \cdot s) \cdot \tan \phi'$$

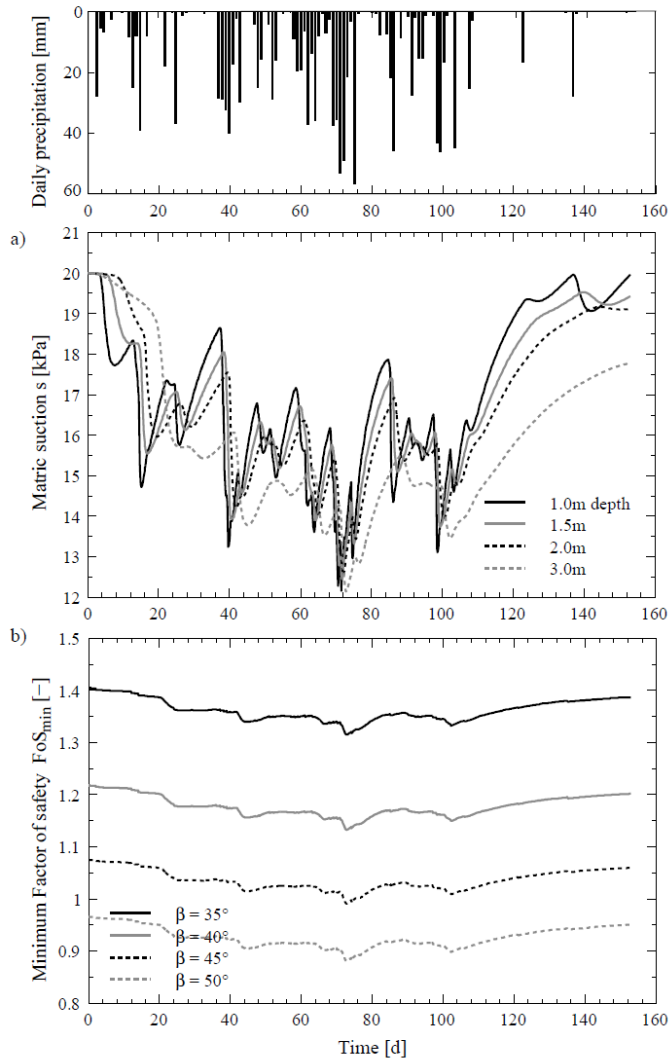

# Numerical modelling I: Stability analysis with a soil column model

$$FoS = \frac{c' + \left[ (\bar{\gamma} z \cos^2 \beta - p_a) + S_r (p_a - p_w) \right] \cdot \tan \phi'}{\bar{\gamma} z \cos \beta \sin \beta} = \frac{c' + \left[ (\bar{\gamma} z \cos^2 \beta) + S_r s \right] \cdot \tan \phi'}{\bar{\gamma} z \cos \beta \sin \beta}$$

(Eichenberger et al. 2013)

# Seasonal safety factors

The evolution of matric suction and factor of safety over the wet season show:

1. Worsening conditions in terms of FoS throughout the wet season
2. Importance of antecedent rainfall as predisposition factor for slope failure
3. Shorter dry periods of less than 10 days are not sufficient for a reestablishment of suctions at soil depths below 1m.
4. High intensity rainfall events have a particularly negative effect on slope stability if they occur after 10 days of cumulative rainfall over 70mm.

# EPFL Rainfall induced shallow slips in Alpine regions

- Involved soil masses range between a couple of hundred to thousand cubic meters
- The soil cover in these alpine regions rarely exceeds 2m.
- The reported slips occurred mostly in 1 to 2m depth.

I: mass movements due to rainstorms of high intensity

II: mass movements due to precipitations of several hours' duration with medium intensity

III: mass movements due to continuous heavy rainfall of one to two days duration frequently accompanied by heavy snow melting events

Moser & Hohensinn, 1983

## SW hillslope of the Irazu Volcano (Costa Rica)

Scar from a retrogressive landslide on the top hillslope occurred on December 15, 2005 (*photo @Holcim*)

# Debris Flow and Erosion Control Problems Caused by the Ash Eruptions of Irazú Volcano, Costa Rica

By HOWARD H. WALDRON

CONTRIBUTIONS TO GENERAL GEOLOGY

GEOLOGICAL SURVEY BULLETIN 1241-I

*Prepared in cooperation with the Oficina de Defensa Civil and Oficina de Planificación de Costa Rica under the auspices of the Agency for International Development, U.S. Department of State*

UNITED STATES GOVERNMENT PRINTING OFFICE, WASHINGTON : 1967

- The Irazu Volcano erupted ash almost continuously from March 1963 through February 1965
- Loose ash deposit of up to 30m exist in the surrounding slopes
- Many scars and landslide deposits are reported on the SW flank of the volcano indicating its high landslide susceptibility (*Mora 1985*)

# The Llano Grande quarry

- Ministry of Public Transportation opened the quarry to provide material for the construction of local roads
- In 1992, the site was converted in a pozzolana production quarry
- A large rainfall induced landslide was reported in November 2005 and it was closely followed by a second landslide in December 2005
- In 2010 Holcim Costa Rica decides to establish an earl-warning-system for the mine.

# Grain size distribution

# Collapse upon wetting behaviour

- Measured with contact filter paper and using an ad-hoc calibration for low matrix suction values

- Result: initial suction in the range 20–45 kPa for the natural water content of the samples in their 'as delivered' condition

- Combination of pressure plate measurements, controlled-suction oedometric tests and MIP investigations

- No significant dependency on the initial void ratio and no hysteresis between wetting and drying curves

# Hydraulic conductivity at variable saturation states

Permeability in variably saturated soil:

$$K(S_r, e_0, \varepsilon_v) = K_{sat}(e_0, \varepsilon_v) \cdot k_{r,w}(S_r, e_0, \varepsilon_v)$$

Saturated permeability:

$$K_{sat} = K_{sat,0}[e_0 - \varepsilon_v(1 + e_0)]^{c_k}$$

Hydraulic conductivity function:

$$k_{r,w} = S_r^{\lambda(e_0, \varepsilon_v)}$$

$$\lambda = c_l[e_0 - \varepsilon_v(1 + e_0)] + c_m$$

$S_r$  : degree of saturation

$e_0$  : reference void ratio

$\varepsilon_v$  : volumetric strain

$K_{sat,0}$  : saturated permeability  
at reference void ratio

$c_k, c_l, c_m$  : fitting parameters

# Effective stress-strain framework
