`-logically_exclusive`	Defines clock group with clocks that do not have any functional paths between them, but coexist in the design at the same time. The software considers aggressor interactions between these clocks for signal integrity considerations, but considers these as false paths for timing analysis. **Note:** The `-logically_exclusive` parameter does not have any impact on SI analysis. For example, clocks selected via a clock mux select.
`-name` *name_list*	Specifies the names of the clock groups to be added.
`-physically_exclusive`	Defines clock group with clocks that cannot exist in the design at the same time. The software does not consider aggressor interactions between clock groups that are physically exclusive for signal integrity considerations. From the perspective of SI analysis, all attackers that are physically exclusive with the victim net are ignored for both glitch and noise-on-delay analysis. Attacker nets that belong to physically exclusive groups cannot attack together. In this case, all sets of attackers belonging to all the physically exclusive groups are evaluated and the set of nets that has the highest impact on SI analysis is chosen. For timing analysis, the software considers these clock groups as false paths. Example: multiple clocks defined on the same source pin

Examples

- The following commands assert two different clocks on the same clock root port, and uses set_clock_group to isolate them from each other:

```
create_clock -name SYSCLK -period 10 [get_ports sclk]

create_clock -name SCANCLK -period 100 -add [get_ports sclk]

set_clock_groups -name PHY_EX_SCLK -physically_exclusive

-group {SYSCLK} -group {SCANCLK}
```

- The following command declares a single bus clock to be asynchronous to all of the other on board clocks in the design (which remain in the default clock group):

```
set_clock_groups -name ASYNCH_BUS -asynchronous -group {BUSCLK}
```

- The following example shows that the clock group {clkA clkB} is asynchronous only to clock group {clkC clkD}:

```
set_clock_groups -asynchronous -group {clkA clkB} -group {clkC clkD}
```

If an extra clock clkE is defined in the design, then timing check will be allowed in between the first group to clkE

and second group to clkE.

- In the following example since only one clock group is specified with the command `set_clock_groups`command, so the specified clock group is considered to be asynchronous to all the other clocks in the design:

```
set_clock_groups -asynchronous -group {clkA clkB}

set_clock_groups -asynchronous -group {clkC clkD}
```

Related Commands

- `create_clock`
- `reset_clock_groups`

set_clock_latency

```
set_clock_latency
[-source [-early | -late]]
[-rise]
[-fall]
[-dynamic jitter_val]
[-clock clock_list]
[-min]
[-max]
[-clock_gate]
value
obj_list
```

Specifies ideal internal clock value and external clock arrival delay.

Clock value has two components:

- Source value:
  - Specified using the `-source` parameter and is the delay from the external clock generator to the clock port of the design.
  - Applied when the clock is either ideal or propagated.
  - `set_clock_latency` set on a clock port has higher precedence than `set_clock_latency` set on a clock waveform.
  - Specified on clock waveforms with both the `set_input_delay` command and the `set_output_delay` command.
- Network value (clock tree delay):
  - Default value type and is the delay from the clock port to the register.
  - Applied only when the clock is ideal. When the clock is propagated, this delay is replaced by the actual clock tree delays.
  - Specified on a clock waveform or a clock port is ignored if the clock is propagated.
  - `set_clock_latency` set on a timing pin has higher precedence than `set_clock_latency` set on a waveform.
  - If there are multiple `set_clock_latency` and `set_propagated_clock` assertions between the clock waveform, clock root and clock endpoint, the closest assertion to the clock endpoint takes precedence.
  - Specified on internal circuit pins or hierarchical ports and used in the fanout cone of the network value pin, when a clock is ideal.

Use the `set_clock_latency` command in two ways:

- To specify clock value for a clock waveform:
  - Use the following syntax for source value associated with a clock signal:
    `set_clock_latency [-source] [-early | -late] [-min ][-max] value obj_list`
  - Use the following syntax for network value associated with a clock signal:

```
set_clock_latency [-min] [-max] value obj_list
```

You cannot specify the `-late` and `-early` parameters for network value.

Specifying value on a port or pin overrides any previous value specified on the port pin or waveform. The *obj_list* argument is the list of the clock waveform names as specified by the create_clock command.

- To specify clock value on clock pins:
  - Use the following syntax for source delay on a clock port:
    ```
    set_clock_latency -source [-early | -late] [-rise] [-fall]
    insertion_delay obj_list
    ```
  - Use the following syntax for network delay on a clock pin:
    ```
    set_clock_latency [-min] [- max] [-rise] [-fall]
    insertion_delay -pin obj_list
    ```

When a clock is ideal, the last specification along a path is used. This is useful when you want to intentionally skew the clock tree and model the physical hierarchical clock tree.

Parameters

`-clock` *clock_list*	Associates clock value constraints, placed at the pin level, with a specific clock. This makes it possible to specify a different value per clock. **Note:** You cannot use the `-clock` parameter with clock waveform objects.
`-clock_gate`	Allows setting the local clock value on pin or port objects. This setting overwrites the existing value of clock gating cells and is used when performing timing checks against the specified pins or ports.
`-dynamic` *jitter_val*	Specifies the portion of source clock latency value that can have cycle-to-cycle variation. When calculating CPPR adjustment this portion is removed from CPPR adjustment for different clock edge checks (e.g., setup), but it remains as part of cppr adjustment for same clock edge checks (e.g., hold).
`-early | -late`	Specifies clock arrival time with respect to the early or the late time of the clock signal. In setup analysis, launch path is the late path and capture path is the early path. In hold analysis, launch path is the early path and the capture path is the late path. If neither parameter is specified, the default is both early and late. Use these parameters only with the `-source` parameter. You cannot use these parameters with network value. Specify the clock value at the given operating corner. **Note:** The `-min` and `-max` parameters refer to the operating corner and the `-early` and `-late` parameters refer to the clock arrival time at the source. Use the `-early` and `-late` parameters with the `-source` parameter to specify the four different clock latencies.
value	Specifies the value of the latency, in library units, as a floating point.

obj_list	Specifies a list of clock waveform names or a list of pins to associate with the clock value. The pin can be a port or an instance pin. Setting source value on a pin is ignored.
-max	Specifies the clock value for a particular operating corner. Apply the -max parameter to the maximum operating corner.
-min	Specifies the clock value for a particular operating corner. Apply the -min parameter to the minimum operating corner.
-rise/-fall	Specifies the -rise or -fall parameter to the waveform at register clock pins for ideal value and to the waveform at the source for source value. Ideal network value does not change polarity when crossing negative unate arcs.
-source	Specifies a source value. If you do not specify the -source parameter, network value is applied.

Examples

- The following set of commands enable you to create a clock using the create_clock command and apply value to the created clock using the set_clock_latency command:

```
create_clock CLK2 -period 20 [get_ports {clkA clkB clkD}]
set_clock_latency -source 2 {clkB clkD} # Define port settings
set_clock_latency -rise 5 {clkB clkD} # Define port settings
set_clock_latency -early -late -source CLK1 # Define waveform settings
set_clock_latency 3 -early -late -source CLK1 # Define waveform settings
```

- set_output_delay
- set_propagated_clock
- reset_clock_latency

set_clock_sense

```
set_clock_sense
[-positive | -negative | -stop_propagation | -logical_stop_propagation | -stop type_list]
[-clocks clock_list]
pin_or_port_list
```

Selects which phase of the clock to filter at the specified point.

Parameters

`-help`	Prints out the command usage.
`-clocks clock_list`	Specifies a list of clocks passing through a specified point to which the constraint applies. When this parameter is not specified, the filtering of clock phase will be applicable to all the clocks passing through that specified point. This parameter must be used with a specified pin name and one of the parameters : `-positive`, `-negative`, `-stop_propagation`, `-logical_stop_propagation`, or `-stop`.
`-logical_stop_propagation`	Stops the propagation of specified clocks passing through the specified pins.
`-negative`	Specifies that positive phase filtered clocks pass through pins in the *pin_list*.
pin_or_port_list	Specifies the list or collection of cell output pins. The unateness specified by the set_clock_sense command is applied to clocks propagating through the specified point.
`-positive`	Specifies that negative phase filtered clocks pass through pins in the *pin_list*.
`-stop_propagation`	Stops the propagation of specified clocks and clock source data paths passing through the specified pins.

`-stop` *`type_list`*	Applies clock sense to object types specified in the *`type_list`*. The type list options are - `all`, `clock`, `data`, `clock_source_data`, `default_data`. These are explained below: • `all`: Stops all phases from propagating. This is equivalent to specifying both the `clock` and `data` options. • `clock`: Stops clock phases launched by clock(s) specified in the *`clock_list`* from propagating, and is equivalent to existing `-logical_stop_propagation`. • `data`: Stops all data phases launched by clock(s) specified in *`clock_list`*, starting from the pins/ports specified in *`pin_or_port_list`*. The objects in the *`pin_or_port_list`* can be selected anywhere in the design - clock/data network. • `clock_source_data`: Stops only clock source data phases from propagating. The combination of `clock_source_data` and `clock` is equivalent to the existing `-stop_propagation` option. • `default_data`: Stops only default data phases (representing constrained paths) from propagation. This option cannot be specified along with the *`-clock clock_list`*. The `-stop` parameter extends the capability of the `set_clocks_sense` command to selectively block data timing phases. This parameter provides a more generalized use model for selecting among all types of paths that should be filtered. The `-stop` parameter is mutually exclusive with the `-positive`, `-negative`, `-stop_propagation`, and `-logical_stop_propagation` options.

Examples

- The following command stops the propagation of clock CLK1 through the pin CLKBUF1/Z:
  ```
  set_clock_sense -logical_stop_propagation -clocks CLK1 CLKBUF1/Z
  ```
- The following command allows the positive phase clock CLK1 to pass through CLKBUF1/Z and filters out the negative phase clock CLK1:
  ```
  set_clock_sense -positive -clocks CLK1 CLKBUF1/Z
  ```
- The following command stops clock phases starting from pin1:
  ```
  set_clock_sense pin1 -stop {clock}
  ```
  or
  ```
  set_clock_sense pin1 -logical_stop_propagation
  ```
- The following command stops data phases based only on CK1 and CK2 starting from pin1:
  ```
  set_clock_sense pin1 -stop {data} -clocks {CK1 CK2}
  ```
- The following command stops only the clock source data phases starting from pin1:
  ```
  set_clock_sense pin1 -stop {clock_source_data}
  ```
- The following command stops the clock and clock source data phases:
  ```
  set_clock_sense pin1 -stop {clock clock_source_data}
  ```
  or
  ```
  set_clock_sense pin1 -stop_propagation
  ```

Related Commands

- reset_clock_sense

set_clock_transition

```
set_clock_transition
[-rise]
[-fall]
[-min]
[-max]
[-min |-max]
transition_time
clock_list
```

Specifies the slew time of register clock pins. This is useful for pre-layout static timing analysis before clock tree synthesis (CTS) is performed since net delays can be inaccurate with large fanout nets.

Use this command only with ideal clocks. In propagated mode, the software calculates slew times on register clock pins.

Parameters

`-help`	Prints out the command usage.
`clock_list`	Specifies a list of clocks only with ideal mode in the design, which affects the slew times on all register clock pins in the transitive fanout of the specified clocks. Specified `set_clock_transition` values on register clock pins in the fanout of a clock with propagated latency are ignored.
`-rise | -fall`	Specifies the rising or falling edge of the register clock pins on which the slew time is asserted.
`-min | -max`	Specifies the clock slew time for minimum or maximum process corner slew time.
`transition_time`	Specifies the slew time (transition time) of the clock pins.

Example

- The following commands specify a `2.0` rise slew time and a `1.0` fall slew time for register clock pins clocked by `CLKA`: `set_clock_transition -rise 2.0 [get_clocks CLKA] set_clock_transition -fall 1.0 [get_clocks CLKA]`

Related Information

- report_clocks
- set_clock_latency
- set_clock_uncertainty
- set_input_delay
- set_propagated_clock

set_clock_uncertainty

```
set_clock_uncertainty
uncertainty_value
[-setup]
[-hold]
[-half_cycle_jitter | -full_cycle_jitter]
[-rise | -fall]
{  {-from | -rise_from | -fall_from} clksig_from_list
   {-to | -rise_to | -fall_to} clksig_to_list
 | clock_or_clock_pin
}
```

Specifies the clock uncertainty (skew) on the clock network.

If you set multiple constraints with the `set_clock_uncertainty` command, the constraints set with the `-from* clksig_from_list`/`-to* clksig_from_list` parameters take precedence over simple constraints set on clock objects.

Clock uncertainty set on pins takes highest precedence and overrides clock based uncertainty.

The `set_clock_uncertainty` command can also support clock uncertainty for period, pulse width, skew, and separation checks. To enable this feature, you need to set `timing_enable_uncertainty_for_clock_checks` attribute to `true`. By default, the attribute is set to `false`.

Parameters

uncertainty_value	Specifies the uncertainty value.
-from | -rise_from | -fall_from *clksig_from_list*	Applies the uncertainty value to the specified list of launching clocks. **Note:** You must specify one of these parameters with one of the -to, -rise_to, or -fall_to parameters. You cannot use these parameters when *clock_or_clock_pin* is specified.
	-fall_from: Applies the uncertainty value only to the falling edge of the launching clocks.
	-from: Applies the uncertainty value to both the rising and falling edges of the launching clocks.
	-rise_from: Applies the uncertainty value only to the rising edge of the launching clocks.
-half_cycle_jitter *value* | -full_cycle_jitter *value*	Specifies the clock source jitter for half-cycle and for full-cycle paths. These parameters can accept different values, that can be specified in the same constraint. **Note**: These parameters can be used on clocks only. You cannot use them when any of the -from and -to parameter pairs are specified.

clock_or_clock_pin	Specifies a list of clocks or pins for target uncertainty. The uncertainty value is applied to the registers clocked by the target waveform, or register pins in the fanout of the specified pin. You can specify a list of clock names, or clock root pin or port names relative to the current module. You also can specify a collection of clocks, or clock root pins or ports. **Note:** You cannot use this parameter when any of the `-from` and `-to` parameter pairs are specified.
`-rise | -fall`	Specifies the rising or falling edge at the capture clock pin on which the uncertainty is applied. *Default*: Applies uncertainty on both edges **Note:** You must use these parameters with the `-to` and `-from` parameters.
`-setup/-hold`	Specifies whether the clock uncertainty applies to setup or hold checks. *Default*: Applies to both setup and hold check
`-to | -rise_to | -fall_to` *clksig_to_list*	Applies the uncertainty value to the specified list of capture clocks. **Note:** You must specify one of these parameters with one of the `-from`, `-rise_from`, or `-fall_from` parameters. You cannot use these parameters if *clock_or_clock_pin* is specified.
	`-fall_to`: Applies the uncertainty value only to the falling edge of the capture clocks.
	`-rise_to`: Applies the uncertainty value only to the rising edge of the capture clocks.
	`-to`: Applies the uncertainty value to both the rising and falling edges of the capture clocks.

Examples

- The following command gives all paths starting from registers clocked by `clk1` to registers clocked by the rising edge of `clk2` a hold uncertainty of `2.0`:

  ```
  set_clock_uncertainty 2.0 -from clk1 -to clk2 -rise -hold
  ```

  In case of multiple constraints, the actual uncertainty applied by the software depends on which constraint matches the specific path in question.

- The following command sets an uncertainty on the `clk_in` clock root pin that is applied to all the register pins in the fanout of `clk_in`:

  ```
  set_clock_uncertainty 1.2 clk_in
  ```

- The following command specifies an inter-clock uncertainty of `0.2` between clock waveforms `clk1` and `clk2`:

  ```
  set_clock_uncertainty 0.2 -from clk1 -to clk2
  ```

- The following command specifies a target uncertainty of `0.5` for all registers clocked by the clock waveform

```
ideal_clk1:
set_clock_uncertainty 0.5 ideal_clk1
```

Related Information

- report_clocks
- set_clock_latency
- set_clock_transition
- reset_clock_uncertainty

set_data_check

```
set_data_check
[-help]
<check_value>
[-clock <clock_object>]
[-hold]
[-setup]
{-from <pin_or_port_list> | -rise_from <pin_or_port_list> | -fall_from <pin_or_port_list>}
{-to <pin_or_port_list> | -rise_to <pin_or_port_list> | -fall_to <pin_or_port_list>}
```

Sets data-to-data checks using the specified values of setup and hold time. Data-to data checks are non-sequential checks that are designed to constrain a data signal with respect to another data signal.

In a normal sequential check, a data signal is constrained with respect to a clock signal. In these cases single-cycle timing is used - allowing one full clock cycle for the data transfer. In a non-sequential data-to-data check, there is no clock reference. Therefore zero-cycle timing rules are used. You can use the set_multicycle_path constraint to adjust the cycle accounting rules.

Parameters

`-clock` *clock_object*	Specifies the name of the clock that triggers the data event for the related (`-from`) pin. In the case where there are multiple data events triggered by different clock phases arriving at the `-from` pin, the `-clock` parameter allows you to specify which data event should be used for the "related pin" side of the timing check.
{`-from` <*pin_or_port_list*> | `-rise_from` <*pin_or_port_list*> | `-fall_from` <*pin_or_port_list*>}	Specifies the pins or ports that are set as related pins for data-to-data checks. The *pin_or_port_list* argument can contain either object IDs or hierarchical names relative to the current module. Use only one `-from`, `-rise_from`, or `-fall_from` parameter per command. By default, the `-from` parameter checks both the rising and the falling edges. Using `-rise_from` parameter checks at the rising edge of the signal on the from pins. Using `-fall_from` parameter checks at the falling edge of the signal on the from pins. **Note:** You cannot use the `-from` parameter to specify multiple objects.
`-setup` | `-hold`	Specifies whether the data check value is for setup or hold check. If you do not specify either `-setup` or `-hold` option, the value applies to both setup and hold.

{-to <*pin_or_port_list*> | -rise_to <*pin_or_port_list*> | -fall_to <*pin_or_port_list*>}	Specifies the pins or ports that are set as constrained pins for data-to-data checks. The *pin_or_port_list* argument can contain either object IDs or hierarchical names relative to the current module. Use only one -to, -rise_to, or -fall_to parameter per command. By default, the -to parameter constrains both the rising and the falling edges. Using -rise_to parameter constrains the rising edge of the signal on the to pins. Using -fall_to parameter constrains the falling edge of the signal on the to pins.
check_value	Specifies the value of the setup or hold time for the check.

Examples

- The following example demonstrates how the set_data_check command can be used to constrain signals: Consider two control signals, say XE and SE, going to a macro block. Both of these are derived from the same state machine, and hence launched from the same clock domain. You want XE to reach the macro earlier than SE. The set_data_check constraint can meet this design intent, by applying data checks on non-sequential signals, without setting path specific limits using the following command:

  ```
  set_data_check -from [get_pins {sub/XE}] -to [get_pins {sub/SE}] -setup 0.5
  ```

  The set_data_check command establishes data-to-data checks using similar ideas of setup and hold time as in sequential checks, with the -from parameter denoting the reference signal (the clock in a traditional setup/hold timing check), and the -to parameter indicating the signal being constrained.

Related Commands

- reset_data_check

set_disable_clock_gating_check

```
set_disable_clock_gating_check
pin_or_inst_list
```

Disables clock gating checks for the specified instances or pins.

Parameters

pin_or_inst_list	Specifies the list of pins or instances that are to be disabled.

Examples

- The following command disables clock gating checks for the specified instance:
  ```
  set_disable_clock_gating_check [get_cells clockgate1]
  ```

Related Commands

- reset_disable_clock_gating_check

set_disable_timing

```
set_disable_timing
[-from pin_name -to pin_name]
obj_list
```

Disables timing propagation through the specified arcs, or a collection of instance-specific arcs that are created using the `get_arcs` command.

Parameters

`-from pin_name -to pin_name`	Specifies the arc that is to be disabled. Specify the `-from` and `-to` options together. You can specify the `-from` and `-to` parameters when the *`obj_list`* contains instance or library cell objects. Do not specify the `-from` and `-to` parameters when the *`obj_list`* includes instance pin or library cell pin objects. The `-from` and `-to` options are optional. If not specified, all cell arcs found in the instance or library cell objects are disabled.
`obj_list`	Specifies the instance, instance pin, library cell, library cell pin objects, collection of library arcs, or collection of timing arcs. If the *`obj_list`* includes instance pin or library cell pin objects, all cell arcs attached to the specified pin objects are disabled. If the *`obj_list`* contains instance or library cell objects, and the `-from` and `-to` parameters are not specified, all arcs found in the specified instance or library cell objects are disabled.

Examples

- The following command disables the arcs that lead to the output pins of the `i1`, `i2`, and `i3` instances. Note that timing checks at the inputs of `i1`, `i2`, and `i3` are still active. `set_disable_timing [get_cells {i1 i2 i3}]`
- The following command disables the arc from pin `B` to pin `Z` in the `i1` and `i2` instances, and the arc from pin `A` to pin `Z` in the `i3` instance: `set_disable_timing -from B -to Z [get_cells {i1 i2}]`
  `set_disable_timing -from A -to Z [get_cells {i3}]`
- The following example disables timing check arcs from pin `CLK` to pin `D` of the `ff1` instance: `set_disable_timing -from CLK -to D [get_cells ff1]`
- The following example disables the outgoing cell arcs from instance input pin `i1/B`: `set_disable_timing [get_pins i1/B]`
- The following example disables all arcs found in any instances whose reference cell is `AN2`: `set_disable_timing [get_lib_cells AN2]`

- The following example disables a collection of timing arcs:

```
set arcs [get_lib_arcs -from typical/MX2X1/S0 -to typical/MX2X1/Y]
set_disable_timing [index_collection $arcs 3]
```

- The following example disables arcs created using `filter_collection` on library timing arcs:

```
set arc [filter_collection $arcs {when == "((A)&(!(B)))"}]
set_disable_timing $arc
```

Related commands

- `report_timing`
- `reset_disable_timing`

set_dont_touch

```
set_dont_touch
obj_list
[true | false]
```

Prevents the specified object from being modified during optimization. However, the specified object can be moved during optimization.

When you specify a net, it cannot be buffered or become a part of the logic cone restructuring. However, you can resize the instances connected to this net because the `dont_touch` attribute set of the net does not propagate on the connected instances.

Parameters

`true | false`	Sets or removes the `set_dont_touch` attribute for the specified *`obj_list`*. *Default:* `true`
`obj_list`	Specifies the list of instances, nets, library cells, or submodules.

Examples

- The following command prevents the specified instance from being modified:
  ```
  set_dont_touch [get_cells {TWA/FF1}]
  ```
- The following commands can be used to prevent any ECO inside RESULTS_CONV_INST hierarchical instance:
  ```
  set_dont_touch [get_cells RESULTS_CONV_INST/*] true
  set_dont_touch [get_nets RESULTS_CONV_INST/*] true
  ```

  The `set_dont_touch RESULTS_CONV_INST/* true` command will return `[get_cells RESULTS_CONV_INST/*]` only. This is because the software looks into the first match (type of object). If a match is not found, then the successive objects are searched.

Related Commands

- `get_cells`

set_dont_touch_network

```
set_dont_touch_network
[-help]
obj_list
[-no_propagate]
```

Prevents the combinational path connected to the given clocks, pins, or ports from being modified.

Parameters

`-help`	Prints out the command usage.
`object_list`	Specifies the objects - clocks, pins, or ports - to be preserved.
`-no_propagate`	Preserves all the nets driven by the specified pin up to the first leaf-cell input (combinational or sequential). If this parameter is omitted, then preserving stops at the first sequential cell in the network.

Examples

- The following command prevents the combinational path connected to the specified pin from being modified:
  ```
  set_dont_touch_network [get_pins and1/z]
  ```

Related Commands

- `get_pins`

set_dont_use

```
set_dont_use
[-help]
lib_cell_list
[true | false]
```

Prevents the specified design, hierarchical module, or library cells from being used during optimization. However, optimization is allowed to size out don't use cells if instances are already there in the initial netlist.

Parameters

lib_cell_list	Specifies the list of library cells.
true | false	Sets or removes the set_dont_use attribute for the specified object list. Default: true

Examples

- The following command prevents the specified library cell from being used during optimization:
  ```
  set_dont_use [get_lib_cells {and2}]
  ```

Related Commands

- set_clock_sense

set_drive

```
set_drive
[-rise] [-fall]
[-max] [-min]
resistance_value
port_list
```

Sets the drive resistance on the specified input and/or bidirectional ports of the top cell.

The drive resistance models the cell driving the port. This resistance is used to compute the load dependent delay and the slew at the specified ports. The load-dependent delay is added to the arrival times.

The load-dependent delay and the slew are computed by multiplying the drive resistance by the wire capacitance of the net connected to the port.

Use the `report_ports` command to view drive resistances asserted on ports.

Parameters

`-fall`	Specifies that the drive resistance is to be used for the falling transition at the specified ports. By default, if neither the `-rise` nor the `-fall` option are specified, the drive resistance applies to both the rising transition and the falling transition.
`-min`	Specifies that the drive resistance is to be used to compute the early path delay. By default, if neither the `-min` option nor the `-max` option is specified, the drive resistance applies to both the early path delay and the late path delay.
`-max`	Specifies that the drive resistance is to be used to compute the late path delay. By default, if neither the `-min` option nor the `-max` option is specified, the drive resistance applies to both the early path delay and the late path delay.
port_list	Specifies a list of input or bidirectional ports on which the drive resistance is set.
resistance_value	Specifies the value of the drive resistance. This value must be greater than or equal to zero. The drive resistance is in units found in the target technology library.
`-rise`	Specifies that the drive resistance is to be used for the rising transitions at the specified ports. By default, if neither the `-rise` option nor the `-fall` option are specified, the drive resistance applies to both the rising transition and the falling transition.

Example

- The following command sets a drive resistance of 2.0 for the early path, the late path, the rising and the falling transitions at the in1 and in2 ports and shows how drive resistances are reported using the report_ports command as shown in the example below:

```
> set_drive 2.0 [get_ports {in1 in2}]
> report_ports -type drive_resistance -pin [get_ports {in1 in2}]
```

  The following report is displayed:

```
-------------------------------------------------------------------
Early Late
-------------------------------------------------------------------
Pin     Dir   Assertion       Clock   Rise   Fall   Rise   Fall

set_driving_cell

```
set_driving_cell
[-library library_name]
-lib_cell cell_name
[-pin pin_name]
[-from_pin from_pin_name]
[-rise]
[-fall]
[-min]
[-max]
[-multiply_by factor]
[-no_design_rule]
[-input_transition_rise rise_slew_value]
[-input_transition_fall fall_slew_value]
port_list
```

Models the drive capability of an external driver connected to the input port. Use this command only for timing analysis. The command does not affect the electrical properties of the design, which means that the capacitance of the output pin of the driving cell does not add to the total capacitance of the input port.

To model the drive capability of the external driver, the timing analyzer computes an offset to the arrival time of an input, and changes the slew time used to compute the delay for the next cell. The timing analyzer computes the offset by subtracting the zero load delay from the total delay of the cell. The `set_driving_cell` command uses the offset value to identify a cell from the library to drive the specified input port(s).

This command overrides the `set_drive` command per port or per net, if it is the last command applied. Also, if the `set_driving_cell` command is set for a port, the `set_input_transition` command is ignored for that port. If you do not define drive using the `set_driving_cell` command, the software uses the default value defined in the configuration file. The default value is `0.1ps`.

Parameters

`-fall`	Annotates only the falling drive assertion. The default is to annotate both rise and fall delays.
`-from_pin` *from_pin_name*	Specifies the name of the input port of the driver cell that has an arc to the output port of the driver cell, which is connected to the input port of the design. This option is required only if there are multiple timing arcs in the driver cell from its input ports to its output ports, and the arcs from those pins have different drive characteristics. If you do not specify the `-from_pin` option, the default is to use the first timing arc found on the library cell.
`-input_transition_fall` *fall_slew_value*	Specifies the slew value for the falling signal at the input of the drive cell.

`-input_transition_rise` *rise_slew_value*	Specifies the slew value for the rising signal at the input of the drive cell.
`-lib_cell` *cell_name*	Specifies the name of the driver cell. This parameter supports wildcard patterns and collections.
`-library` *library_name*	Specifies the name of the library that contains the driving cell.
`-max`	Annotates only the late drive assertion. The default is to annotate both early and late.
`-min`	Annotates only the early drive assertion. The default is to annotate both early and late.
`-multiply_by` *factor*	Specifies a multiplier for the drive.
`-no_design_rule`	Does not allow transfer of design rules from the driving cell to the port. If you do not specify this option, the design rules (such as `max_capacitance`) of the library pin are applied to the port.
`-pin` *pin_name*	Specifies the name of the output port of the driver cell that drives the signal at the input port of the design. This option is required if there are multiple output ports on the driver. If there is only one output port on the driver cell, then using this option is not necessary.
port_list	Specifies the list of ports driven by the driver cell.
`-rise`	Specifies only the rising drive assertion is annotated.The default is to annotate both rise and fall delays.

Examples

The following command sets 'AND' cell (arc B -> Y) as the driving cell for the input port IN1:

```
> set_driving_cell -lib_cell AND -from_pin B -pin Y IN1
```

Related Information

- `all_inputs`
- `report_ports`

set_false_path

```
eset_false_path
[-hold | -setup]
[-rise]
[-fall]
{[{-from | -rise_from | -fall_from} from_list]
[{-through | -rise_through | -fall_through} through_list]
[{-to | -rise_to | -fall_to} to_list]}
```

Identifies false paths in a design, and breaks or disables specific instance timing arcs in a design.

To break combinational loops, use the set_disable_timing command instead of the `set_false_path` command.

The `set_false_path` command differs from the `set_disable_timing` command as follows:

- `set_false_path` command selectively disables the arrival time information depending on the precedence rules.
- `set_false_path` command does not affect constant values.
- `set_disable_timing` command physically snips a timing arc such that neither arrival times nor constant values propagate through it.
- `set_disable_timing` command is applied in all cases to valid timing arcs.

The `set_false_path -from fpin` command disables all timing paths whose source pin is an `fpin`. Similarly, the `set_false_path -to tpin` command disables all timing paths whose sink pin is a `tpin`. Using the `set_false_path -from fpin -to tpin` command disables all timing paths whose source is `fpin` and sink is `tpin`.

Specify a group of pins by enclosing the group with curly braces (`{}`) within one `set_false_path` command.

To set a false path for any path beginning at `p1` or `p2` and terminating at `t1` or `t2`, group the pins as follows:

```
set_false_path -from {p1 p2} -to {t1 t2}
```

Note: This method of pin grouping reduces the number of exceptions. Having large numbers of exceptions adversely impacts the run time of the timing analysis commands.

Parameters

`{-from | -rise_from | -fall_from} from_list`	Specifies a list of timing paths start points. The from_list argument can contain either object IDs or hierarchical names relative to the current module. The pins can be on intermediate hierarchical boundaries. The from_list argument can be a collection. The valid start points are: • Input port • Bidirectional port • Clock pin of sequential cell Clock pin of sequential cell is one of the following: • Structural clock pin that is part of latch or flip-flop. • Inferred clock pin in cells like macro cells. A pin is an inferred clock pin if it is associated with one of the following: • Reference end of setup check • Reference end of hold check • Reference end of removal check • Reference end of recovery check • Minimum period check • Minimum pulse width check • Pin associated with set_input_delay Specify one of the following:
	`-from`: Applies the false path constraint to all paths originating from the from_list list. If a clock is specified as the -from object, all primary inputs and registers clocked by that clock are used as start points. By default, the -from option applies the constraint to both the rising and the falling edges.
	`-rise_from`: Applies the false path constraint at the rising edge of the signal on the from pins.
	`-fall_from`: Applies the false path constraint at the falling edge of the signal on the from pins.
`-hold/-setup`	Sets false paths for either setup or hold analysis. Note: If you do not specify -setup or -hold, the software sets false paths for both setup and hold analysis.
`-rise | -fall`	Applies the assertion at the rising edge of the signal on the path endpoints. Applies the assertion at the falling edge of the signal on the path endpoints.

`{-through | -rise_through | -fall_through} through_list`	Specifies a list of timing paths through points. The through_list argument can contain either object IDs or hierarchical names relative to the current module. The pins can be on intermediate hierarchical boundaries. The through_list argument can be a collection. Specify one of the following:
	`-through`: When you use this parameter without using the -from or -to options, the false path constraint is set for all paths that go through the specified pins. When you use it with both the -from and -to options, any path starting at any pin on the -from list and going through any point on the -through pin list and going to any point on the -to list is affected by the constraint. By default, the -through option applies the constraint to both the rising and the falling edges.
	`-rise_through`: Applies the assertion at the rising edge of the signal on the through pins.
	`-fall_through`: Applies the assertion at the falling edge of the signal on the through pins.
`{-to| -rise_to | -fall_to} to_list`	Specifies a list of timing paths end points. The to_list argument can contain either object IDs or hierarchical names relative to the current module. The pins can be on intermediate hierarchical boundaries. The to_list argument can be a collection. The valid end points are: • Output port • Bidirectional port • Data pin of sequential cell Data pin of sequential cell is one of the following: • Structural data pin that is part of latch or flip-flop. • Inferred data pin in cells like macro cells. A pin is an inferred data pin if it is associated with one of the following: • Signal end of setup check • Signal end of hold check • Signal end of non-sequential setup check • Signal end of non-sequential hold check • Signal end of removal check • Signal end of recovery check • Pin associated with set_external_delay • Data pin of clock gating cell Select from one of the following:

	`-to`: Applies the false path constraint to all paths ending in the -to pin list. If a clock is specified as the -to object, all primary outputs and registers clocked by that clock are used as endpoint. By default, the -to option applies the constraint to both the rising and the falling edges.
	`-rise_to`: Applies the false path constraint at the rising edge of the signal on the to pins.
	`-fall_to`: Applies the false path constraint at the falling edge of the signal on the to pins.

Examples

- The following command disables hold checking from `ff1` to `ff2`:

  ```
  set_false_path -hold -from ff1 -to ff2
  ```

- The following command sets all timing paths from `ff1/CK` to `D` input of `ff2` that pass through `u1/Y` and one or more of `u2/Y` and `u3/Y` as false paths:

  ```
  set_false_path -from ff1/CK -through {u1/Y} -through {u2/Y u3/Y} -to ff2/D
  ```

- The following command sets all timing paths from the rise of `ff1/CK` to `ff2/D` through one or more of `u1/Y` and `u4/Y` as false paths:

  ```
  set_false_path -rise_from ff1/CK -through {u1/Y u4/Y} -to ff2/D
  ```

set_fanout_load

```
set_fanout_load
[-help]
value
port_list
```

Specifies the fanout load on a set of ports.

The library instance pins can have fanout loads defined in the technology library. The fanout does not have specific units so it is assumed that a fanout as used by the constraints is consistent with the fanout defined in the technology libraries. If a pin or port has no fanout attribute, either from the constraints or from the technology library, then the fanout load will be zero. The fanout load is used only for design rule checking and does not impact the timing results.

Parameters

`-help`	Prints out the command usage.
value	Specifies the fanout load value for the port or ports.
port_list	Specifies the list of ports for which the fanout load is applied.

Examples

- The following command sets the fanout load of port `out` to `2`:

  ```
  set_fanout_load 2 out
  ```

- The following command sets the fanout load of ports `in1` and `in2` to `1`:

  ```
  set_fanout_load 1 {in1 in2}
  ```

- The following command sets the fanout load of element `3` of port `out` to `12`:

  ```
  set_fanout_load 12 { out[3] }
  ```

- The following command sets the fanout load of all the ports to `2`:

  ```
  set_fanout_load 2 [get_ports *]
  ```

Related Information

- `report_net`
- `report_ports`

- `report_constraint`

set_ideal_latency

```
set_ideal_latency
[-help]
[-min]
[-max]
[-rise]
[-fall]
value
pin_or_port_list
```

Specifies the ideal latency to use for input or output leaf-cell pins and top-level ports that are part of an ideal network. These set a point delay on the specified object.

Note: You should specify `set_ideal_latency` with the `set_ideal_network` command to view the ideal latency result.

Parameters

`-help`	Prints out the command usage.
`-fall`	Specifies the ideal latency for the falling edge.
`value`	Specifies the ideal latency value.
`-max`	Specifies the ideal latency for the maximum corner.
`-min`	Specifies the ideal latency for the minimum corner.
`pin_or_port_list`	Specifies a list of objects - instance pins or ports.
`-rise`	Specifies the ideal latency for the rising edge.

Examples

- The following command adds an ideal latency of 1.5ns to the input pin A of cell FE_OFC413_scan_se:
  `set_ideal_latency 1.5 FE_OFC413_scan_se/A`

  Please note that the above command will only be valid if the pin is part of an ideal network.

  Now, this ideal latency value can be observed in the output of the following `report_timing` command:
  `report_timing -though FE_OFC413_scan_se/A`

```

```

Related Commands

- reset_ideal_latency
- report_timing
- set_ideal_network

set_ideal_network

```
set_ideal_network
obj_list
[-no_propagate]
```

Identifies driver pins or ports as sources of an ideal network. By default, all pins and nets in the transitive fanout of the specified port or driver pin are marked as ideal. Ideal network marking normally propagates through combinational cells and stops at sequential cells.

This command is not view/mode-based - it applies to all the active views.

The `set_ideal_network` command sets 0 slew for bi-directional pins. This ensures that unnecessary DRV violations do not occur.

Parameters

`-no_propagate`	Prevents propagation through transitive fanout.
`obj_list`	Specifies a list of objects - instance pins, ports, or nets.

Related Commands

- `reset_ideal_network`

set_ideal_transition

```
set_ideal_transition
[-min]
[-max]
[-rise]
[-fall]
value
pin_or_port_list
```

Specifies the ideal transition to use for input or output leaf-cell pins and top-level ports that are part of an ideal network. This sets a point delay on the specified object.

Note: You should specify `set_ideal_transition` with `set_ideal_network` to view ideal transition result.

Parameters

`-fall`	Specifies the ideal transition for the falling edge.
`-max`	Specifies the ideal transition for the maximum corner.
`-min`	Specifies the ideal transition for the minimum corner.
`pin_or_port_list`	Specifies a list of objects - instance pins or ports.
`-rise`	Specifies the ideal transition for the rising edge.
`value`	Specifies the ideal transition time.

Related Commands

- `reset_ideal_transition`

set_input_delay

```
set_input_delay
[-clock clock_name]
[-clock_fall]
[-rise] [-fall]
[-max] [-min]
[-add_delay]
[-network_latency_included]
[-source_latency_included]
[-reference_pin pin_name]
[-level_sensitive]
value
pin_or_port_list
```

Defines the arrival time relative to a clock edge on input ports or internal input pins. This input path delay models the delay from an external register to an input port of the module.

If the input delay is not specified on an input port, it is assumed to be zero.

Parameters

`-add_delay`	Adds delay information to the existing input delay. The additional delay information can be for multiple paths relative to different clocks or clock edges leading to an input port or internal input pins. If you do not use the `-add_delay` option, the software uses the last `set_input_delay` related to a pin when there are multiple `set_input_delay` statements for the same pin.
`-clock` *clock_name*	Specifies that the delay is relative to the rising edge of the given clock. If you do not specify the `-clock` parameter, the delay is relative to time zero. To specify a delay relative to the falling edge of the clock, use the -clock_fall option with the -clock option. When you specify multiple clocks, an error occurs and the constraint is ignored.
`-clock_fall`	Specifies that the delay is relative to the falling edge of the clock. You must specify the -clock parameter with this parameter. *Default:* Delay is relative to the rising edge. You cannot specify the `-clock_fall` parameter without the `-clock` parameter.
value	Specifies the value for the path delay.
`-fall`	Specifies that the input delay refers to the falling edge of the signal at specified ports or pins. If you do not specify the `-fall` option, the input delay applies to both the edges.

`-level_sensitive`	Models input delay that is launched by a positive level sensitive latch. Use the `-clock` parameter to model a positive level sensitive latch, or the `-clock_fall` parameter to model a negative level sensitive latch. You cannot specify the `-level_sensitive` parameter without the `-clock` parameter.
`-max`	Specifies that the delay refers to the setup analysis. If you do not specify the `-max` parameter, the input delay applies to both setup and hold analysis. **Note**: If for a specific clock the maximum delay is less than the minimum delay, then during analysis the software makes the maximum delay equal to the minimum delay.
`-min`	Specifies that the delay refers to the hold analysis. If you do not specify the `-min` parameter, the input delay applies to both setup and hold analysis.
`-network_latency_included`	Specifies that the clock network latency should not be added to the input delay value. If you do not specify this option, the clock network latency of the related clock is added to the input delay value. This parameter has no effect if the specified clock is in propagated mode.
pin_or_port_list	Specifies a list of input port or pin names. The pin_or_port_list argument can be a collection.
`-reference_pin` *pin_name*	Adds source and network latency of the specified reference pin to the input delay value in propagated mode. A reference pin is a leaf pin in the fanout cone of the clock source of the clock that you specify using the `-clock` parameter. You cannot use the `-reference_pin` parameter to specify multiple pins. If specified, the command issues a warning and accepts the first pin. You cannot use the `-reference_pin` parameter with the `-network_latency_included` or `-source_latency_included` parameters. You cannot use the `-reference_pin` parameter to specify hierarchical pins.
`-rise`	Specifies that input delay refers to the rising edge of the signal at the specified ports or pins. If you do not specify the `-rise` option, the input delay applies to the both edges.
`-source_latency_included`	Specifies that the clock source latency should not be added to the input delay value. With different delay values for `-rise/-fall` and `-min/-max`, only the last specified combination of `-network_latency_included` and `-source_latency_included` parameters is honored. The specified combination can be one of the following: a) Either `-network_latency_included` or `-source_latency_included` b) Both of these c) None of these

Examples

- The following command sets an input delay of 1.0 for all inputs in the current design relative to the rising edge of the `CLK1` clock:

  ```
  set_input_delay -clock CLK1 1.0 [all_inputs]
  ```

- The following command sets an input delay of 2.0 for the input `IN1` port relative to the falling edge of the `CLK1` clock: `set_input_delay -clock CLK1 2.0 -clock_fall { IN1 }`
- The following example shows an input `IN1` port that is constrained by both the rising edge and the falling edge of the same `CLK1` clock. The `-add_delay` option prevents the second `set_input_delay` statement from overwriting the first `set_input_delay`:

  ```
  set_input_delay -clock CLK1 1.0 { IN1 }
  set_input_delay -clock CLK1 -clock_fall -add_delay 2.0 { IN1 }
  ```

- When multiple `-min` and `-max` values are specified relative to the same clock using the `-add_delay` option at the same port or pin, the worst case value for each case is used. For the `-min` case the smallest value is retained, and for the `-max` case the largest value is retained. For example, the input delay value of 1.0 is stored for the shortest path and the value of 4.0 is stored for the longest path in the following example:

  ```
  set_input_delay -min -clock CLK1 1.0 { IN1 }

  set_input_delay -min -clock CLK1 2.0 -add_delay { IN1 }

  set_input_delay -max -clock CLK1 3.0 -add_delay { IN1 }

  set_input_delay -max -clock CLK1 4.0 -add_delay { IN1 }
  ```

Related Information

- `set_load`
- `set_output_delay`

set_input_transition

```
set_input_transition
[-help]
[-min]
[-max]
[-rise]
[-fall]
value
port_list
```

Specifies the slew time for a port on the top level module. This command is useful only in specifying a hard ramp signal as if the port were driven by a very powerful driver. The command does not change the arrival time of an input, but changes the slew time used to compute the delay of the cell on the sink of a net. If you do not define transition using the `set_input_transition` command, the software uses the default input port transition defined in the configuration file. The default value is `0.1ps`. You can also set the `delaycal_input_transition_delay attribute` to override the default value.

The `set_input_transition` command specification for clock signals does not impact setup/hold timing calculations.

Note: The `set_input_transition` command does not support internal pins. For specifying transition on internal pins use the `set_annotated_transition` command.

Note: The most recent command settings (of `set_driving_cell`, `set_input_transition`, or `set_drive`) that are applied to a port will be considered - the software will override the previous commands.

Parameters

`-help`	Prints out the command usage.
`-fall | -rise`	Specifies that the slew time should be applied to the rising edge or the falling edge of the signal (data or clock). If neither time is specified, the default is to use both.
`-min | -max`	Indicates whether the slew times are with respect to the early (hold) or the late (setup) time checks of the data signal. If neither option is specified, the default is to use both.
`port_list`	Specifies the list of ports for which the slew time is specified. **Note:** You cannot use the `set_input_transition` command to specify transition on output ports. **Note:** When you use both `set_input_transition` and `set_annotated_transition` commands for specifying transition on input ports, the worst value is used as the transition value.
`value`	Specifies the transition time.

Examples

- The following command specifies the slew time of `0.5` on port `input3`.

```
set_input_transition 0.5 input3
```

Related Commands

- `report_ports`

set_load

```
set_load
[-max] [-min]
[-pin_load]
[-wire_load]
[-subtract_pin_load]
capacitance_value
port_or_net_list
```

Sets the specified capacitance on the defined ports (or nets) of the top cell.

The specified capacitance overrides the capacitance from the wire load models and SPEF.

You can use the `report_ports` command to view capacitance of asserted ports. The pin load appears in the report as `port_cap` in the assertion column and the wire load appears as `port_wire_cap` in the assertion column.

In the timing report (generated using the `report_timing` command), the load value for ports is displayed as a sum of the `set_load` value on a port and the existing wire capacitance obtained from the SPEF file, and pin capacitance obtained from the library files.

Parameters

capacitance_value	Specifies the value for the capacitance. The capacitance is in units from the target technology library.
-min	Specifies the minimum capacitance. The minimum capacitance is used to compute best-case delays in BcWc analysis mode and early path delays in OCV analysis mode.
-max	Specifies the maximum capacitance. The maximum capacitance is used to compute worst-case delays in BcWc analysis mode and late path delays in OCV mode. It is also used to check the maximum capacitance design rule.
port_or_net_list	Specifies a list of ports or nets in the top cell.
-pin_load	Specifies the external pin capacitance for a port. You can use this parameter for ports only. For ports, the asserted capacitance is either the external pin capacitance when the `-pin_load` parameter is specified, or the external wire capacitance when the `-wire_load` parameter is specified, or the total external capacitance when neither option is specified.

`-subtract_pin_load`	This parameter can be used only if nets are specified in the object list. When this parameter is specified, the total net capacitance value will be the same as set by the `set_load` *capacitance_value object_list* command. When this parameter is not specified, the asserted load value will only change the wire capacitance value from the SPEF. The total net capacitance value will be the `set_load` capacitance value plus the pin capacitance from the library file.
`-wire_load`	Interprets the specified capacitance as the external wire capacitance of the port. Use this option only for ports. Use this option with the *`port_net_list`* argument if the list contains only ports.

Examples

Here are some examples.

- The following command sets an external minimum pin capacitance of 1.5 units on the `in1 in2` ports:
  ```
  set_load 1.5 -min -pin_load [get_ports {in1 in2}]
  ```
- The following command sets an external minimum wire capacitance of 1.2 units on the `in1 in2` ports:
  ```
  set_load 1.2 -min -wire_load [get_ports {in1 in2}]
  ```
- The following command sets an external maximum pin capacitance of 2.6 units on the `in1 in2` ports:
  ```
  set_load 2.6 -max -pin_load [get_ports {in1 in2}]
  ```
- The following command sets an external maximum wire capacitance of 3.0 units on the `in1 in2` ports:
  ```
  set_load 3.0 -max -wire_load [get_ports {in1 in2}]
  ```
- The following command reports the capacitances set on the ports, as shown in the example below:
  ```
  report_ports -pin [get_ports {in1}]
  ```

  ```
  report_ports -pin [get_ports {in1}]

set_logic_one

```
set_logic_one
-help
pin_or_port_list
```

Sets ports or pins to logic 1 in the design.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_logic_one` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_logic_one`.
`pin_or_port_list`	Specifies the list of the ports or pins that are to be set to logic 1.

Examples

- The following command sets the specified port to logic 1:
  ```
  set_logic_one [get_ports {din[1]}]
  ```

Related Commands

- `get_ports`

set_logic_zero

```
set_logic_zero
-help
pin_or_port_list
```

Sets ports or pins to logic 0 in the design.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_logic_zero` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_logic_zero`.
`pin_or_port_list`	Specifies the list of the ports or pins that are to be set to logic 0.

Examples

- The following command sets the specified port to logic 0:
  ```
  set_logic_zero [get_ports {din[0]}]
  ```

Related Commands

- `get_ports`

set_max_capacitance

```
set_max_capacitance
[-help]
limit
obj_list
[-clock_path]
[-data_path]
[-fall]
[-override]
[-rise]
```

Sets the maximum capacitance limit on the specified ports of the top cell, the specified modules, or clock waveforms.

When set on a port, the total capacitance of the net connected to that port must be less than or equal to the specified limit. Maximum capacitance limits also come from library objects, which is the default maximum capacitance limit of libraries and the maximum capacitance limit on library cell pins. Pins in the design inherit the limits from libraries.

Note: The limit set on the top cell applies to its ports. Thus, if maximum capacitance limits are set on the top cell and its ports, the most constraining limit will apply to the ports.

When limits are set on a clock waveform, you can use `-clock_path`, `-data_path`, `-rise`, and `-fall` parameters to provide more specifications.

The `set_max_capacitance` constraint on clock objects will be honored only by the `report_constraint` command for DRV violations. The constraint will not be used in optimizations.

Parameters

`-help`	Prints out the command usage.
`-clock_path`	Applies the max capacitance constraint only to pins in the clock network of the clocks defined in the object list.
`-data_path`	Applies the max capacitance constraint only to data path pins, where the path is launched by the clocks defined in the object list.
`-fall`	Applies the max capacitance constraint only to falling capacitance.
`-rise`	Applies the max capacitance constraint only to rising capacitance.
`limit`	Specifies the value for the minimum capacitance limit. The limit must be greater than or equal to zero. The limit is in capacitance units from the target technology library.
`obj_list`	Specifies a list of objects - ports, instance pins, library cell pins, modules, and/or clock waveforms.
`-override`	Overrides the maximum capacitance limit from other sources, such as, library or constraints. This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting. To enable this feature, make the following setting: `set timing_constraint_enable_drv_limit_override true`

Examples

Here are some examples.

- The following example sets a maximum capacitance limit of `1.2` units on all the ports of the top cell and a maximum capacitance limit of `0.5` units on the port named `d_out`:

  ```
  set_max_capacitance 1.2 [get_ports *]
  set_max_capacitance 0.5 d_out
  ```

- The following example uses the `report_ports` command to show the maximum capacitance limit set on ports:

  ```
  set_max_capacitance 0.9 [get_ports *]
  report_ports -type port_cap_limit -pin [get_ports *]
  ```

  The following report is displayed:

  ```
  ----------------------------------------
  Pin     Dir  Assertion       Value
  Name
  ----------------------------------------
  CLK2    IN   port_cap_limit  ( : 0.900 )
  CLK1    IN   port_cap_limit  ( : 0.900 )
  in2     IN   port_cap_limit  ( : 0.900 )
  in1     IN   port_cap_limit  ( : 0.900 )
  ```

```
out2    OUT  port_cap_limit  ( : 0.900 )
out1    OUT  port_cap_limit  ( : 0.900 )
----------------------------------------
```

Related Commands

set_max_delay

```
set_max_delay
value
[-combinational_from_to | -ignore_clock_latency]
[{-from |-rise_from | -fall_from} from_list]
[{-through | -rise_through | -fall_through} through_list]
[{-to | -rise_to | -fall_to} to_list]
[-comment string]
[-rise]
[-fall]
```

Specifies a maximum delay for a timing path. The `set_max_delay` command takes precedence over other path exceptions specified for the same path, except for the `set_false_path` command.

Use either the `-from`, `-to`, or `-through` option with the `set_max_delay` command to identify the paths. Specifying both the `-from` and `-to` options identifies a path with specific starting and ending points.

When you specify a sequential cell name for starting point of the timing path, the valid path starts from the clk pin. This means the latency and delay from clk to output Q is also included in the delay. For path segmentation, you can specify the path to start from Q output of the register by adding /Q after the cell name. In this case, path from clk to Q is not considered in the calculation.

Use only one `-from`, `-rise_from`, or `-fall_from`, `-to`, `-rise_to`, or `-fall_to` parameter per command. You can use multiple `-through` parameters in the same command.

Parameters

`-combinational_from_to`	Defines a path defined by -from/to pins as combinational. When this parameter is used, the path between the -`from`/-`to` pins is treated as purely combinational, that is, both the source/capture clock latencies are excluded from slack computation. The presence of -`from`/`-to` pins is required for this option to take effect; the -`from`/`-to` pins can be sequential or combinational start/end pins. The `-combinational_from_to` parameter will be deprecated in a future release. This parameter will continue to work in the current release, but for compatibility with future releases you should migrate your scripts to use the `-ignore_clock_latency` parameter. You can use the following attributes to match the semantics between the `-ignore_clock_latency` and `-combinational_from_to` parameters: • `timing_constraint_path_delay_exclude_check_delay_from_ignore_clock_latency` • `timing_constraint_path_delay_exclude_io_delay_from_ignore_clock_latency`
`-comment string`	Allows you to insert comments. The comments are read but are ignored with a one-time warning message. They are not used during timing analysis reporting nor are they written out during saving of constraints.

`-fall`	Apply the assertion at the falling edge of the signal on the path endpoints.
`-from |-rise_from |-fall_from` *from_list*	Specifies a list of timing paths start points. The *from_list* argument can contain either object IDs or hierarchical names relative to the current module or clock names. The pins can be on intermediate hierarchical boundaries. The *from_list* argument can be a collection. The valid start points are: • Input port • Bidirectional port • Clock pin of sequential cell Clock pin of sequential cell is one of the following: • Structural clock pin that is part of latch or flip-flop. • Inferred clock pin in cells like macro cells. A pin is an inferred clock pin if it is associated with one of the following: • Reference end of setup check • Reference end of hold check • Reference end of removal check • Reference end of recovery check • Minimum period check • Minimum pulse width check • Pin associated with `set_input_delay` Specify one of the following:
	`-from`: Applies the maximum delay constraint to all paths originating from the *from_list* list. If a clock is specified as the `-from` object, all primary inputs and registers clocked by that clock are used as start points. By default, the `-from` option applies the constraint to both the rising and the falling edges.
	`-rise_from`: Applies the maximum delay constraint at the rising edge of the signal on the from pins.
	`-fall_from`: Applies the maximum delay constraint at the falling edge of the signal on the from pins.

`-ignore_clock_latency`	When this parameter is specified, the software does not count the launch/capture clock latency delays into the timing path delay. The `-ignore_clock_latency` parameter is an industry-standard construct introduced in SDC 2.1 to control the handling of clock-related timing with respect to the `set_max_delay`/`set_min_delay` constraints.
`-rise`	Applies the assertion at the rising edge of the signal on the path endpoints.
`-through | -rise_through | -fall_through` *`through_list`*	Specifies a list of timing paths through points. The *`through_list`* argument can contain either object IDs or hierarchical names relative to the current module or clock names. The pins can be on intermediate hierarchical boundaries. The *`through_list`* argument can be a collection. Specify one of the following:
	`-through`: When you use this parameter without using the `-from` or `-to` options, all paths that go through the specified pins have the specified delay. When you use it with both the `-from` and `-to` options, any path starting at any pin on the `-from` list *and* going through any point on the `-through` pin list *and* going to any point on the `-to` list is affected by the constraint. By default, the `-through` option applies the constraint to both the rising and the falling edges.
	`-rise_through`: Applies the assertion at the rising edge of the signal on the through pins.
	`-fall_through`: Applies the assertion at the falling edge of the signal on the through pins.

`-to| -rise_to | -fall_to` *to_list*	Specifies a list of timing paths end points. The *to_list* argument can contain either object IDs or hierarchical names relative to the current module or clock names. The pins can be on intermediate hierarchical boundaries. The *to_list* argument can be a collection. The valid end points are: • Output port • Bidirectional port • Data pin of sequential cell Data pin of sequential cell is one of the following: • Structural data pin that is part of latch or flip-flop. • Inferred data pin in cells like macro cells. A pin is an inferred data pin if it is associated with one of the following: • Signal end of setup check • Signal end of hold check • Signal end of non-sequential setup check • Signal end of non-sequential hold check • Signal end of removal check • Signal end of recovery check • Pin associated with `set_external_delay` • Data pin of clock gating cell Select from one of the following:
	`-to`: Applies the maximum delay constraint to all paths ending in the `-to` pin list. If a clock is specified as the `-to` object, all primary outputs and registers clocked by that clock are used as endpoint. By default, the `-to` option applies the constraint to both the rising and the falling edges.
	`-rise_to`: Applies the maximum delay constraint at the rising edge of the signal on the to pins.
	`-fall_to`: Applies the maximum delay constraint at the falling edge of the signal on the to pins.
value	Specifies the maximum delay value.

Example

- The following command specifies that all paths from `in1` to `out1` must have delays less than `10` units:

```
set_max_delay 10 -from in1 -to out1
```

Related Commands

set_max_fanout

```
set_max_fanout
[-help]
[-override]
limit
obj_list
```

Sets the maximum fanout load limit constraint on the specified input ports of the top cell and the specified modules.

When set on a port, the fanout load of the net connected to the port must be less than or equal to the specified limit value to meet the constraint. The fanout load of a net is the sum of the fanout loads of the pins driven by the net. When set on a module, the limit applies to all the nets of that module. Libraries and library cell pins may also have the maximum fanout load limit. In this case the most constraining limit is applied to the nets.

Use the `report_ports -type fanout_load_limit` command to view the maximum fanout load limits set on ports of the top cell.

Fanout load limit can be asserted on input ports, output pins, bidirectional pins, or ports and library pins. You cannot apply the constraint on input pins and output ports.

Parameters

`-help`	Prints out the command usage.
limit	Specifies the value of the maximum fanout load limit constraint. This is a float number and it must be greater than or equal to zero.
obj_list	Specifies a list of objects - ports, instance pins, modules, or library cell pins.
`-override`	Overrides the maximum fanout limit from other sources, such as, library or constraints. This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting. To enable this feature, make the following setting: `set timing_constraint_enable_drv_limit_override true`

Examples

- The following example sets a maximum fanout load limit of `5.0` units on all the ports of the top cell:

  ```
  set_max_fanout 5.0 [get_ports *]
  ```

- The following example shows a report of the maximum fanout load limit set on ports using the `report_ports` command, as shown in the following example:

  ```
  set_max_fanout 5.0 [get_ports *] report_ports -type fanout_load_limit -pin [get_ports *]
  ```

set_max_time_borrow

```
set_max_time_borrow
value
object_list
```

Specifies the maximum time that can be borrowed by one stage from the next logic stage following a latch to meet timing constraints. Time borrowing is sometimes called cycle stealing. Time borrowing is performed automatically when performing timing analysis.

Use the `set_max_time_borrow` assertion on pins or waveforms. If the assertion is placed on a clock waveform, all latches triggered by this clock signal get the specified maximum time borrow limit. If both the clock waveform arriving at the clock pin of a latch and the clock pin itself have time borrow limit constraints, the maximum borrow limit on the latch is decided by the assertion on the latch clock pin.

Parameters

value	Specifies the maximum amount of time that can be borrowed. The minimum value allowed is `0`, which disables time borrowing. The maximum allowed is equal to the pulse width minus the setup time: Max = pulse width - setup
object_list	Specifies the list of instance pins, instances, or clocks on which the borrow value is applied. The *object_list* argument can be a collection.

Examples

```
set_max_time_borrow 2 [get_cells {i1, i2, i3}]

set_max_time_borrow 1.7 I4/g

set_max_time_borrow 2.5 [get_clocks CLK1]
```

Related Commands

- get_clocks

set_max_transition

```
set_max_transition
[-help]
[-clock_path]
[-data_path]
[-rise]
[-fall]
[-override]
transition_limit
object_list
```

Sets the maximum slew time limit (transition) on the specified ports of the top cell, and/or clock waveforms.

When set on a port, the slew time at the port must be less than or equal to the specified limit. Maximum transition limits on pins can come from library objects, which are the default maximum transition of the libraries or maximum transition on library cell pins. In this case, the most constraining limit, which is the smallest, will apply on pins and ports.

Use the `report_ports -type slew_limit` command to view the maximum transition limits set on ports of the top cell.

When limits are set on a clock waveform, you can use `-clock_path`, `-data_path`, `-rise`, and `-fall` parameters to provide more specifications.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_max_transition` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_max_transition`.
`-clock_path`	Applies the max transition constraint only to pins in the clock network of the clocks defined in the object list.
`-data_path`	Applies the max transition constraint only to data path pins, where the path is launched by the clocks defined in the object list.
`-fall`	Applies the max transition constraint only to falling transitions.
`object_list`	Specifies the list of objects - ports, instance pins, library cell pins, clock waveforms, or current design.
`-override`	Overrides the maximum transition limit from other sources, such as, library or constraints. This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting. To enable this feature, make the following setting: `set timing_constraint_enable_drv_limit_override true`
`-rise`	Applies the max transition constraint only to rising transitions.
`transition_limit`	Specifies the value of the maximum slew time limit (maximum transition), which must be greater than or equal to zero. The maximum slew time limit is in time units in the current session.

Examples

- The following command sets a maximum transition limit of `0.9` units on all the ports of the top cell:
  ```
  set_max_transition 0.9 [get_ports *]
  ```
- The following example shows a report of the maximum transition limit set on ports using the `report_ports` command, as shown in example:
  ```
  set_max_transition 0.9 [get_ports *]
  report_ports -type slew_limit -pin [get_ports *]
  ```

Maximum Transition Limit Set on Ports Report

Pin Name	Dir	Assertion	Value
in1	IN	slew_limit	(: 0.9000)
in2	IN	slew_limit	(: 0.9000)
out1	OUT	slew_limit	(: 0.9000)

out2	OUT	slew_limit	(: 0.9000)
out3	OUT	slew_limit	(: 0.9000)
out4	OUT	slew_limit	(: 0.9000)

- The following command sets the maximum transition limit of 0.001 units on pins in the `all_clocks` collection:
  `set_max_transition 0.001 -clock_path [all_clocks]`
- The following command sets the transitions to the specified value for your entire design:
  `set_max_transition` *`value`* `[current_design]`

Related Commands

- report_ports
- set_max_capacitance
- report_constraint

set_min_capacitance

```
set_min_capacitance
[-help]
[-clock_path]
[-data_path]
[-rise]
[-fall]
[-override]
capacitance_limit
obj_list
```

Sets the minimum capacitance limit on the specified ports of the top timing module and/or clock waveforms.

When set on a port, the total capacitance of the net connected to that port must be greater than or equal to the specified limit. When set on a module, the limit applies to all the nets of that module. The total capacitance of each net of the module must be greater than or equal the specified limit. The minimum capacitance limit also comes from library objects, which is the default minimum capacitance limit of libraries and minimum capacitance limit on library cell pins. Pins in the design inherit the limits from libraries. When limits are set on a module and the limit is inherited from libraries, the most constraining limit, which is the largest limit, is used.

Note: The limit set on the top timing module applies to its ports. Thus, if minimum capacitance limits are set on the top timing module and its ports, the most constraining limit will apply to the ports.

Use the `report_ports -type port_cap_limit` command to view the minimum capacitance limits set on ports.

When limits are set on a clock waveform, you can use `-clock_path`, `-data_path`, `-rise`, and `-fall` parameters to provide more specifications.

The `set_min_capacitance` constraint on clock objects will be honored only by the `report_constraint` command for DRV violations. The constraint will not be used in optimizations.

Note: This command syntax is applicable only when the flow-compatible mode is on.

Parameters

`-help`	Prints out the command usage.
`-clock_path`	Specifies all pins that are in the network of the specific clocks in the object list.
`-data_path`	Specifies all pins that are in the data paths launched by the specific clocks in the object list.
`-fall`	Specifies falling capacitance.
`-rise`	Specifies rising capacitance for all selected pins.
`capacitance_limit`	Specifies the value for the minimum capacitance limit. The limit must be greater than or equal to zero. The limit is in capacitance units from the target technology library.
`obj_list`	Specifies the list of objects - ports, instance pins, library cell pins, modules, and/or clock waveforms.
`-override`	Overrides the minimum capacitance limit from other sources, such as, library or constraints. This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting. To enable this feature, make the following setting: `set timing_constraint_enable_drv_limit_override true`

Examples

- The following example sets a minimum capacitance limit of `0.02` units on all the ports of the top timing module and a minimum capacitance limit of `0.05` units on the top timing module:
  ```
  set_min_capacitance 0.02 [get_ports *]
  set_min_capacitance 0.05 [current_design]
  ```
  The limit used for ports is `0.05`, which is the most restrictive limit set on the top timing module (`0.05`) and the limit set on ports (`0.02`).
- The following example uses the `report_port` command to show the minimum capacitance limit set on ports:
  ```
  set_min_capacitance 0.02 [get_ports *]
  report_ports -type port_cap_limit -pin [get_ports *]
  ```
- The following command sets the minimum capacitance limit of `0.001` units on pins in the `all_clocks` collection:
  ```
  set_min_capacitance 0.001 -data_path [all_clocks]
  ```

set_min_delay

```
set_min_delay
[-combinational_from_to | -ignore_clock_latency]
[{-from |-rise_from | -fall_from} from_list]
[{-through | -rise_through | -fall_through} through_list]
[{-to | -rise_to | -fall_to} to_list]
[-rise]
[-fall]
[-comment string]
value
```

Specifies a minimum delay for a timing path. The `set_min_delay` command takes precedence over other path exceptions specified for the same path, except for `set_false_path` command specifications.

Use either the `-from`, `-to`, or `-through` option with the `set_min_delay` command to identify the paths. Specifying both the `-from` and `-to` options identifies a path with specific starting and ending points. If a clock is specified as the `-to` object, all primary outputs and registers clocked by that clock are used as an endpoint.

When you specify a sequential cell name for starting point of the timing path, the valid path starts from the clk pin. This means the latency and delay from clk to output Q is also included in the delay. For path segmentation, you can specify the path to start from Q output of the register by adding /Q after the cell name. In this case, path from clk to Q is not considered in the calculation. For example, in the following set of commands, the valid path starts from different points:

```
set_min_delay 0.66 -from TR1/BR1 -to BLK/BR1/D

set_min_delay 0.66 -from TR1/BR1/Q -to BLK/BR1/D
```

For the first command, the valid path starts from clk, and for the second command the valid path starts from the Q output. In the second case, the path from clk to Q is not considered. For an example of the results generated for paths with and without path segmentation, see the Examples section below.

Use only one `-from`, `-rise_from`, or `-fall_from`, `-to`, `-rise_to`, or `-fall_to` parameter per command. You can use multiple `-through` parameters in the same command.

Parameters

`-combinational_from_to`	Defines a path defined by -from/to pins as combinational. When this parameter is used, the path between the -`from`/-`to` pins is treated as purely combinational, that is, both the source/capture clock latencies are excluded from slack computation. The presence of -`from`/`-to` pins is required for this option to take effect; the -`from`/`-to` pins can be sequential or combinational start/end pins. The `-combinational_from_to` parameter will be deprecated in a future release. This parameter will continue to work in the current release, but for compatibility with future releases you should migrate your scripts to use the `-ignore_clock_latency` parameter. You can use the following attributes to match the semantics between the `-ignore_clock_latency` and `-combinational_from_to` parameters: • `timing_constraint_path_delay_exclude_check_delay_from_ignore_clock_latency` • `timing_constraint_path_delay_exclude_io_delay_from_ignore_clock_latency`
`-comment` *string*	Allows you to insert comments. The comments are read but are ignored with a one-time warning message. They are not used during timing analysis reporting nor are they written out during saving of constraints.
`-fall`	Applies the assertion at the falling edge of the signal on the path endpoints.

`-from |-rise_from	-fall_from` *`from_list`*	Specifies a list of timing paths start points. The *`from_list`* argument can contain either object IDs or hierarchical names relative to the current module or clock names. The *`from_list`* argument can be a collection. The valid start points are: • Input port • Bidirectional port • Clock pin of sequential cell Clock pin of sequential cell is one of the following: • Structural clock pin that is part of latch or flip-flop. • Inferred clock pin in cells like macro cells. A pin is an inferred clock pin if it is associated with one of the following: • Reference end of setup check • Reference end of hold check • Reference end of removal check • Reference end of recovery check • Minimum period check • Minimum pulse width check • Pin associated with set_input_delay Specify one of the following:
	`-from`: Applies the minimum delay constraint to all paths originating from the *`from_list`* list. If a clock is specified as the `-from` object, all primary inputs and registers clocked by that clock are used as start points. By default, the `-from` option applies the constraints to both the rising and the falling edges.
	`-rise_from`: Applies the minimum delay constraint at the rising edge of the signal on the from pins.
	`-fall_from`: Applies the minimum delay constraint at the falling edge of the signal on the from pins.
`-ignore_clock_latency`	When this parameter is specified, the software does not count the launch/capture clock latency delays into the timing path delay. The `-ignore_clock_latency` parameter is an industry-standard construct introduced in SDC 2.1 to control the handling of clock-related timing with respect to the `set_max_delay`/`set_min_delay` constraints.

`-rise`	Applies the assertion at the rising edge of the signal on the path endpoints.
`-through | -rise_through | -fall_through` *`through_list`*	Specifies a list of timing paths through points. The *`through_list`* argument can contain either object IDs or hierarchical names relative to the current module or clock names. The pins can be on intermediate hierarchical boundaries. The *`through_list`* argument can be a collection. Specify one of the following:
	`-through`: When you use this parameter without using the `-from` or `-to` options, all paths that go through the specified pins have the specified delay. When you use it with both the `-from` and `-to` options, any path starting at any pin on the `-from` list *and* going through any point on the `-through` pin list *and* going to any point on the `-to` list is affected by the constraint. By default, the `-through` option applies the constraint to both the rising and the falling edges.
	`-rise_through: Applies the assertion at the rising edge of the signal on the through pins.`
	`-fall_through: Applies the assertion at the falling edge of the signal on the through pins.`

`-to	-rise_to	-fall_to` *`to_list`*	Specifies a list of timing paths end points. The *`to_list`* argument can contain either object IDs or hierarchical names relative to the current module or clock names. The pins can be on intermediate hierarchical boundaries. The *`pin_or_clock_list`* argument can be a collection. The valid end points are: • Output port • Bidirectional port • Data pin of sequential cell Data pin of sequential cell is one of the following: • Structural data pin that is part of latch or flip-flop. • Inferred data pin in cells like macro cells. A pin is an inferred data pin if it is associated with one of the following: • Signal end of setup check • Signal end of hold check • Signal end of non-sequential setup check • Signal end of non-sequential hold check • Signal end of removal check • Signal end of recovery check • Pin associated with `set_external_delay` • Data pin of clock gating cell Select from one of the following:
	`-to`: Applies the minimum delay constraint to all paths ending in the `-to` pin list. If a clock is specified as the `-to` object, all primary outputs and registers clocked by that clock are used as endpoint. By default, the `-to` option applies the constraint to both the rising and the falling edges.
	`-rise_to`: Applies the minimum delay constraint at the rising edge of the signal on the to pins.
	`-fall_to`: Applies the minimum delay constraint at the falling edge of the signal on the to pins.
`value`	Specifies the minimum delay value.

Examples

- The following command specifies a minimum delay of `2.5` for paths from `in1` to `out1`:

  ```
  set_min_delay 2.5 -from in1 -to out1
  ```

- The following commands show the difference in `report_timing` results when you specify a minimum delay with and without path segmentation:

  ```
  set_min_delay 9 -from dff1 -to dff2/d
  set_min_delay 9 -from dff1/q -to dff2/d
  ```

  The `report_timing` results for the first command with path segmentation are:

  ```
  report_timing -early -from dff1
  Path 1: VIOLATED Hold Check with Pin dff2/cp
  Endpoint: dff2/d (v) checked with leading edge of 'clk'
  Beginpoint: dff1/q (^) triggered by leading edge of 'clk'
  Other End Arrival Time 0.000
  + Hold -1.956
  + Path Delay 9.000
  = Required Time 7.044
   Arrival Time 6.148
   Slack Time -0.896
   Clock Rise Edge 0.000
   = Beginpoint Arrival Time 0.000
   +-------------------------------------------------------------+
   | Instance | Arc         | Cell    | Delay | Arrival  | Required |
   |          |             |         |       | Time     | Time     |
   |----------+-------------+---------+-------+----------+----------|
   |          | clk ^       |         |       | 0.000    | 0.896    |
   | dff1     | cp ^ -> q ^ | dfn3d1  | 4.250 | 4.250    | 5.146    |
   | inv3     | i ^ -> zn v | in01d1  | 1.898 | 6.148    | 7.044    |
   | dff2     | d v | dfn3d1 | 0.000 | 6.148 | 7.044    |
   +-------------------------------------------------------------+
  ```

  The report_timing results for the second command without path segmentation are:

  ```
  report_timing -early -from dff1
  Path 1: MET Hold Check with Pin dff2/cp
  Endpoint: dff2/d (v) checked with leading edge of 'clk'
  Beginpoint: dff1/q (^) triggered by leading edge of 'clk'
  Other End Arrival Time 0.000
  + Hold -1.956
  + Phase Shift 0.000
  = Required Time -1.956
   Arrival Time 6.148
  ```

```
Slack Time 8.104
Clock Rise Edge 0.000
= Beginpoint Arrival Time 0.000
+-------------------------------------------------------------+
| Instance  | Arc          | Cell    | Delay | Arrival | Required |
|           |              |         |       | Time    | Time     |
|----------+-------------+--------+-------+---------+----------|
|          | clk ^        |         |       | 0.000   | -8.104 |
| dff1     | cp ^ -> q ^  | dfn3d1  | 4.250 | 4.250   | -3.854 |
| inv3     | i ^ -> zn v  | in01d1  | 1.898 | 6.148   | -1.956 |

set_min_fanout

```
set_min_fanout
[-help]
[-override]
limit
obj_list
```

Sets the minimum fanout load limit constraint on the specified input ports of the top cell.

When set on a port, the fanout load of the net connected to the port must be greater than or equal to the specified limit value to meet the constraint. The fanout load of a net is the sum of the fanout loads of the pins driven by the net. When set on a module, the limit applies to all the nets of that module. The libraries and library cell pins may also have the minimum fanout load limit. In this case the most constraining limit is applied to the nets.

The constraint will not be used in optimizations.

Fanout load limit can be asserted on input ports, output pins, bidirectional pins, or ports and library pins. The constraint cannot be applied on input pins and output ports.

Parameters

`-help`	Prints out the command usage.
limit	Specifies the value of the minimum fanout load limit constraint. The specified value must be greater than or equal to zero.
obj_list	Specifies a list of objects - ports, instance pins, modules, or library cell pins.
`-override`	Overrides the minimum fanout load limit from other sources, such as, library or constraints. This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting. To enable this feature, make the following setting: `set timing_constraint_enable_drv_limit_override true`

Examples

- The following example sets a minimum fanout load limit of `0.001` units on all the ports of the top cell:
  set_min_fanout 0.001 [get_ports *]
- The following example shows a report of the minimum fanout load limit set on ports using the `report_ports` command, as shown in the example below:
  ```
  set_min_fanout 5.0 [get_ports *] report_ports -type fanout_load_limit -pin [get_ports *]
  ```

  Example: Minimum Fanout Load Limit Set On Ports Report

  ```
  > report_ports -type fanout_load_limit -pin [get_ports *]
  ----------------------------------------
  ```

```
Pin      Dir  Assertion           Value
Name
-----------------------------------------
CLK2     IN   fanout_load_limit   5.000
CLK1     IN   fanout_load_limit   5.000
in2      IN   fanout_load_limit   5.000
in1      IN   fanout_load_limit   5.000
-----------------------------------------
```

set_min_pulse_width

```
set_min_pulse_width
[-help]
[-low]
[-high]
[-waveform_aware_type {absolute | source_width_ratio}]
value
object_list
```

Selects the most restrictive value when multiple minimum pulse width checks are set.

Parameters

`-help`	Prints out the command usage.
`-high`	Applies the minimum pulse width check to high signal levels only. If neither the `-low` or `-high` option is specified, the value is applied to both low and high signal levels.
list	Specifies a list of pins or clock waveforms to which the minimum pulse width check is to be applied. If the list is not specified, the minimum pulse width check applies to all the pins in the clock tree of the current design. If a clock waveform is specified, all the pins driven by the clock are affected.
`-low`	Applies the minimum pulse width check to low signal levels only. If neither the `-low` or `-high` option is specified, the value is applied to both low and high signal levels.
object_list	Specifies list of objects: pins, ports, or clocks.
value	Specifies a non-negative floating minimum pulse width check value. No default value is assumed for minimum pulse width checks.
`-waveform_aware_type {absolute | source_width_ratio}`	Specifies the type of waveform-aware pulse width check to apply as `absolute` or `source_width_ratio`.

Examples

- The following command sets a minimum pulse width, both low and high, check of `1.0` to the clock network of the current design:
  ```
  set_min_pulse_width 1.0
  ```
- The following command sets a minimum pulse width low check of `2.0` to all the pins clocked by the `CLK1` clock:

```
set_min_pulse_width -low 2.0 [get_clocks CLK1]
```

- The following command sets a minimum pulse width `-high` check of `1.0` to the `CP` clock pin of register `ff1`, as shown in the following example:

```
set_min_pulse_width 0.5 u55/CK -low
set_min_pulse_width 1.0 u55/CK -high
report_min_pulse_width -pin u55/CK

set_min_transition

```
set_min_transition
[-help]
[-clock_path]
[-data_path]
[-rise]
[-fall]
[-override]
limit
obj_list
```

ⓘ This command syntax is applicable only when the flow-compatible mode is on.

Sets the minimum slew time limit (transition) on the specified ports of the top timing module and/or clock waveforms.

When set on a port, the slew time at the port must be greater than or equal to the specified limit. When set on a module, the limit applies to all the pins in the module and its ports if the module is the top timing module. The minimum transition limits on pins can come from library objects, which are the default minimum transition of the libraries or minimum transition on library cell pins. In this case, the most constraining limit, which is the largest, will apply on pins and ports.

Use the `report_ports -type slew_limit` command to view the minimum transition limits set on ports of the top timing module.

When limits are set on a clock waveform, you can use `-clock_path`, `-data_path`, `-rise`, and `-fall` parameters to provide more specifications.

The `set_min_transition` constraint on clock objects will be honored only by the `report_constraint` command for DRV violations. The constraint will not be used in optimizations.

Parameters

`-help`	Prints out the command usage.
`-clock_path`	Specifies all pins that are in the network of the specific clocks in the object list.
`-data_path`	Specifies all pins that are in the data paths launched by the specific clocks in the object list.
`-fall`	Specifies falling transition.
`obj_list`	Specifies the list of objects - ports, instance pins, library cell pins, modules, and/or clock waveforms.
`-override`	Overrides the minimum transition limit from other sources, such as, library or constraints. This parameter can be used to force a specific constraint value for a specified list of instance pins/port/library cell pins - this overrides the maximum/minimum values set prior to this setting. To enable this feature, make the following setting: `set timing_constraint_enable_drv_limit_override true`
`-rise`	Specifies rising transition for all selected pins.
`limit`	Specifies the value of the minimum slew time limit (minimum transition). This value must be less than or equal to zero. The minimum slew time limit is in time units from the target technology library.

Examples

- The following example sets a minimum transition limit of 0.9 units on all the ports of the top timing module, and a minimum transition limit of 0.7 units on the top timing module:

  ```
  > set_min_transition 0.9 [get_ports *]
  > set_min_transition 0.7 [current_design]
  ```

  The minimum limit that applies to ports is 0.9, which is the largest constraints value.

- The following example shows a report of the minimum transition limit set on ports using the `report_ports` command, as shown in the example below:

  ```
  > set_min_transition 0.9 [get_ports *]
  > report_ports -type slew_limit -pin [get_ports *]
  ```

  The following report is displayed:

  ```
  ------------------------------------------
  Pin     Dir    Assertion     Value
  Name
  ------------------------------------------
  CLK2    IN     slew_limit   ( 0.900 : )
  CLK1    IN     slew_limit   ( 0.900 : )
  in2     IN     slew_limit   ( 0.900 : )
  ```

```
in1    IN    slew_limit  ( 0.900 : )
out2   OUT   slew_limit  ( 0.900 : )
out1   OUT   slew_limit  ( 0.900 : )
-----------------------------------------

> report_constraint -drv_violation_type min_transition

Check type : min_transition
---------------------------
Pin : CLK4

Transition Time: 0.003
- min_transition: 0.900
-------------------------------------------------------
slack : -0.897 ( VIOLATED )
```

Related Commands

- set_max_transition
- reset_min_transition
- report_ports

set_mode

```
set_mode
[-type cell]
mode_list
inst_list
```

Specifies the Liberty timing library modes to be active for a specific instance.

A library mode is a subset of active timing arcs that is defined in the timing library. Library modes are similar to conditional timing arcs, but do not require the application of constants to set. Instead of changing a cell's mode by applying constants to its input pins, you can use the `set_mode` command to refer to sets of active arcs by name (such as `READ` or `WRITE`, for a memory cell).

By default, all library modes in the timing library are active. If you specify one or more library modes using the `set_mode` command, only the timing arcs consistent with the specified mode(s) are active for the instance. All other library modes become inactive.

To reset the library modes for an instance, use the reset_mode command.

Parameters

inst_list	Specifies the instances to which to apply the library mode.
mode_list	Specifies the name of the library mode value defined in the timing library. You can specify one or more mode values, but only one mode value per defined mode group in the Liberty library.
-type cell	Sets the library mode at the instance level. **Note:** Setting the library mode at the instance level is the only form of `set_mode` that is currently supported. This parameter exists to support constraints coming from external sources.

Examples

- The following command specifies the `test_mode` library mode active for instances of b1.

  ```
  set_mode test_mode [get_cells b1]
  ```

  The following command reports the status of all library modes associated with b1:

  ```
  tempus > report_mode b1
  -------------------------------
  Mode Group test_mode of b1
  -------------------------------
  Mode     Status     Condition
  Name
  -------------------------------
  test_B   Inactive   !(Y)
  test_A   ACTIVE      Y
  -------------------------------
  ```

  The above report shows that only the timing arcs consistent with the `test_A` library mode are active for instances of b1 - and `test_B` is inactive.

- If you specify the `report_inactive_arcs` command, the report shows the disabled arcs for the b1 instance are from the `test_mode` library mode:

  ```
  ------------------------------------------------------
  Flags :  const propagated constant
           snipped loop snipped arcs
           disable set_disable_timing
           disable_clock_gating set_disable_clock_gating
           library_disable set_disable_cell_timing
           Missing_Phase No Arc Phase Data
  From     To       DisableType   ArcType                 Reason
  ------------------------------------------------------------------
  u8/CK ^   u8/D ^   const        hold_rising_clk_rise    u8/D = 1
  u8/CK ^   u8/D v   const        hold_falling_clk_rise   u8/D = 1
  u8/CK ^   u8/D ^   const        setup_rising_clk_rise   u8/D = 1
  u8/CK ^   u8/D v   const        setup_falling_clk_rise  u8/D = 1
  ------------------------------------------------------------------
  ```

set_multicycle_path

```
set_multicycle_path
[-help]
number_of_cycles
[-comment string]
[-fall]
[-fall_through through_list]
[-hold]
[-rise]
[-rise_through through_list]
[-setup]
[-through through_list]
[-start | -end]
[-from from_list | -rise_from from_list | -fall_from from_list]
[-to to_list] | -rise_to to_list | -fall_to to_list]]
```

Specifies multicycle paths between specific timing paths in the design or between clock domains. Multicycle paths are timing paths that require more than one clock period for execution. By default, all paths are considered as one cycle paths for setup and hold check evaluation. The `set_multicycle_path` command lets you specify additional cycles for the paths.

Parameters

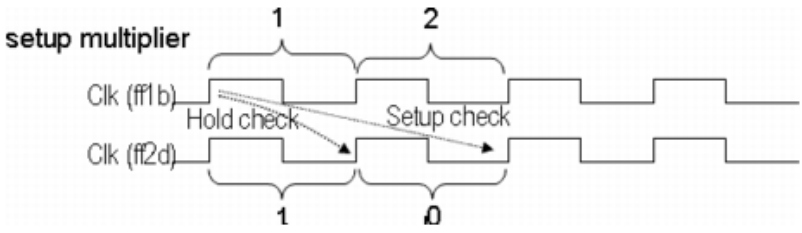
`-help`	Prints out the command usage.
`number_of_cycles`	Specifies the number of cycles allowed for the path.
`-comment` *`string`*	Allows you to insert comments. The comments are read but are ignored with a one-time warning message. They are not used during timing analysis reporting nor are they written out during saving of constraints.
`-fall`	Applies the assertion at the falling edge of the signal on the path endpoints.
`-fall_through` *`through_list`*	Applies the assertion at the falling edge of the signal on the through pins.

`-from` *`from_list`* `| -rise_from` *`from_list`* `| -fall_from` *`from_list`*	Specifies the clocks, ports, pins, or sequential instances that are at the start of the multicycle paths. The port direction can be either input or inout. Pins must be valid path startpoints such as sequential instance clock pins, latch data pins or pins on which input delays have been specified. Pins can be on intermediate hierarchical boundaries. The *`from_list`* variable can contain either collection IDs or object names. If the `-from` option is used without the `-to` option, all paths originating from the `from_list` are multicycle paths. Use either the `-from`, `-to`, or `-through` option with the `set_multicycle_path` command to identify the paths. Specifying both the `-from` and `-to` options identifies a path with specific starting and ending points. Use only one `-from`, `-rise_from`, or `-fall_from` option per command.
`-hold	-setup`	Specifies whether the multicycle adjustment applies to setup/hold check. The `-setup` parameter applies multicycles to setup check. The hold check is affected but the hold multiplier does not change. The `-hold` parameter applies multicycles to hold check only. *Default:* If you do not specify `-setup` or `-hold` parameter, the software considers the specified multicycle value for setup check and uses 0 for the hold check.
`-rise`	Applies the assertion at the rising edge of the signal on the path endpoints.
`-rise_through` *`through_list`*	Applies the assertion at the rising edge of the signal on the through pins.
`-start	-end`	Specifies whether the multicycle adjustment is to be applied relative to the starting clock edge for the path or relative to the ending clock edge for the path. Use these options for multiple clocks designs. By default, the setup check is relative to the end clock and the hold check is relative to the start clock. **Note:** The `-start` and `-end` parameters are mutually exclusive; you cannot specify them together. You can set the `timing_enable_multicycle_data_check_compatibility` attribute to `true` to enable checking for SDC compatible data checks. When the `-start` parameter is specified, the parameter reverses the reference clock by one clock cycle.

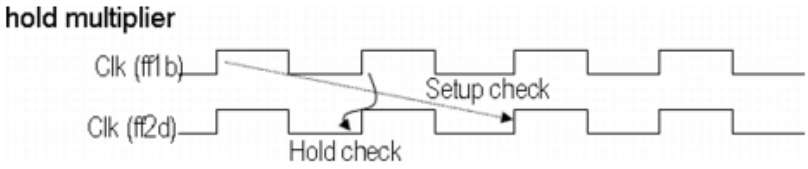
`-through` *`through_list`*	Specifies the ports, pins, instances, or nets that the path goes through. The pins can be on intermediate hierarchical boundaries. The *`through_list`* variable can contain either collection IDs or object names. When used without the `-from` or `-to` option, all paths that go through the `-through` pins are multicycle paths. When used with both the `-from` and `-to` options, any path starting at any pin on the `-from` list and going through any point on the `-through` pin list and going to any point on the `-to` list is affected by the assertion. You can use only one `-from` and `-to` option, but you can specify several `-through` options in the same command. By default, the `-through` option applies the assertion to both the rising and the falling edges. Using the `-rise_through` option applies the assertion at the rising edge of the signal on the through pins. Using the `-fall_through` option applies the assertion at the falling edge of the signal on the through pins.
`-to` *`to_list`*`]` `|` `-rise_to` *`to_list`* `|` `-fall_to` *`to_list`*	Specifies the clocks, ports, pins, or sequential instances that are at the end of the multicycle paths. The port direction can be either output or inout. Pins must be valid path end-points such as sequential instance data pins or pins on which output delays have been specified. Pins can be on intermediate hierarchical boundaries. The *`to_list`* variable can contain either collection IDs or object names. If the `-to` option is used without the `-from` option, all paths ending in the `-to` pin list are multicycle paths. Use only one `-to` option per command. Use only one `-to`, `-rise_to`, or `-fall_to` option per command.

Examples

- The following command sets all paths between ff1b + ff2d to two cycles for setup:
  ```
  set_multicycle_path -setup 2 -from {ff1b} -to {ff2d}
  ```



- The following command moves hold check to start clock preceding edge:
  ```
  set_multicycle_path -hold 1 -from {ff1b} -to {ff2d}
  ```



- The following commands show setup multiplier values from -1 to 3:

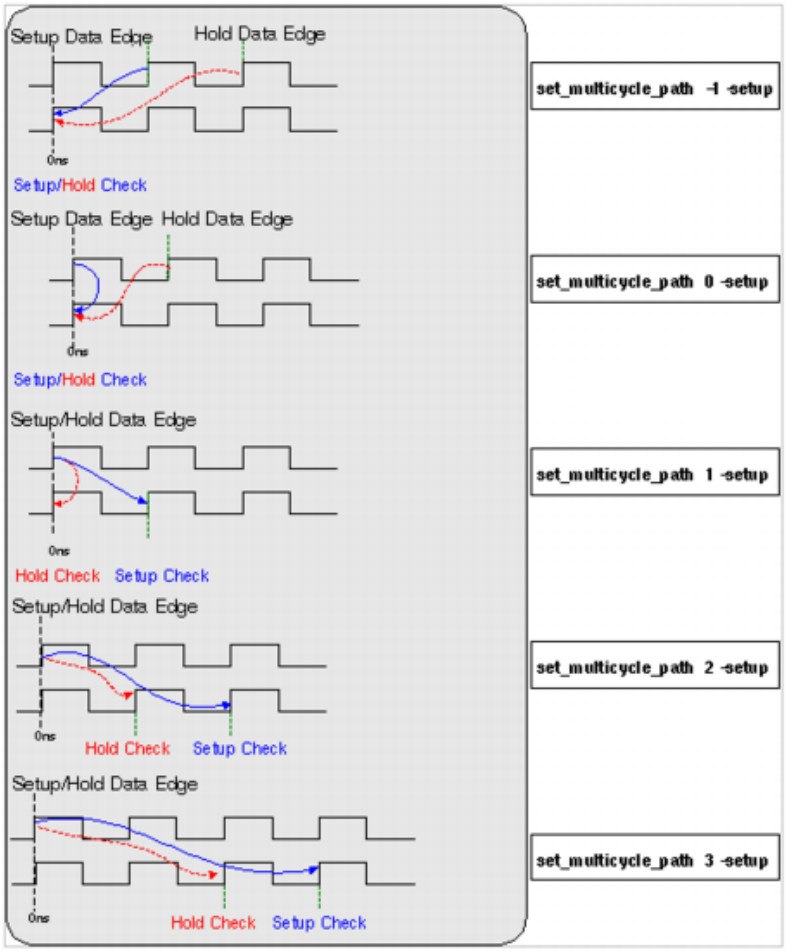
```
set_multicycle_path -1 -setup

set_multicycle_path 0 -setup

set_multicycle_path 1 -setup

set_multicycle_path 2 -setup

set_multicycle_path 3 -setup
```



- The following commands show hold multiplier values from -1 to 3:

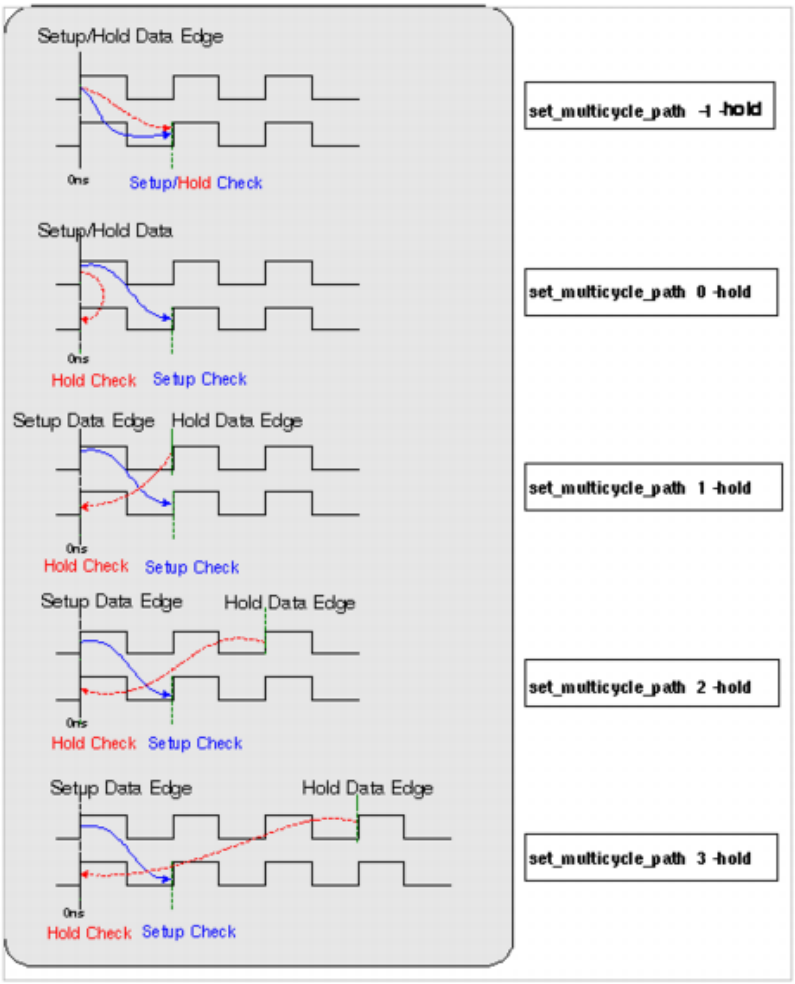
```
set_multicycle_path -1 -hold

set_multicycle_path 0 -hold

set_multicycle_path 1 -hold

set_multicycle_path 2 -hold

set_multicycle_path 3 -hold
```



Related Commands

- set_false_path

set_normalized_driver_waveform_lib

```
set_normalized_driver_waveform_lib
[-help]
[-fall_waveform string]
[-rise_waveform string]
-ref_lib string
-libs string
```

Specifies normalized driver waveform for a library. The normalized driver waveform given in the reference library is applied to all the specified libraries.

Note: This command must be specified after the design is loaded, that is, after `set_top_module` command has been run. For this command to take effect, you should set the `timing_generate_normalized_driver_waveform` global variable to `false` before loading libraries.

Parameters

`-help`	Prints out the command usage.
`-fall_waveform string`	Specifies the name of the fall normalized driver waveform.
`-libs string`	Specifies a list of space separated libraries to which normalized driver waveform is to be applied.
`-ref_lib string`	Specifies the reference library from which normalized driver waveform is to be selected.
`-rise_waveform string`	Specifies the name of the rise normalized driver waveform.

Examples

- The following example shows that normalized driver waveform given in $libDir/libs/ref.lib will be applied to all the cells in $libDir/1.lib $testDir/2.lib $libDir/libs/3.lib:

  ```
  set_normalized_driver_waveform_lib -libs "$libDir/1.lib $testDir/2.lib $libDir/libs/3.lib" -ref_lib
  $libDir/libs/ref.lib
  ```

set_output_delay

```
set_output_delay
-clock clock_name
[-clock_fall]
[-rise] [-fall]
[-max] [-min]
[-add_delay]
[-network_latency_included]
[-source_latency_included]
[-reference_pin pin_name]
[-level_sensitive]
[-group_path group_name]
value
pin_or_port_list
```

Specifies the data required time on output ports, hierarchical ports, or internal output pins.

Parameters

`-add_delay`	Adds delay information to the existing output delay. The additional delay information can be for multiple paths relative to different clocks or clock edges leading to an input port or internal input pins. If you do not use the `-add_delay` option, the software uses the last `set_output_delay` related to a pin when there are multiple `set_output_delay` statements for the same pin.
`-clock` *clock_name*	Specifies that the delay is relative to the specified clock. You cannot use the `set_output_delay` command without the `-clock` parameter. Such constraints are accepted but are ignored during timing analysis. When you specify multiple clocks, an error occurs and the constraint is ignored.
`-clock_fall`	Specifies that the delays are with respect to the falling edge of the clock waveform. If you do not specify the `-clock_fall` option, the delay is with respect to the rising edge of the clock waveform. You cannot specify the `-clock_fall` parameter without the `-clock` parameter.
value	Specifies the value for the path delay.
`-fall`	Specifies that the output delay refers to the falling edge of the signal at specified ports or pins. If you do not specify the `-fall` option, the output delay applies to both the edges.

`-group_path` *group_name*	Specifies the group name where paths ending at the specified ports or pins are to be added. The `-group_path` parameter is not honored in multi-mode multi-corner (MMMC) designs. If specified, a warning is issued and the constraints are applied as if the `-group_path` parameter is not specified.
`-level_sensitive`	Models output delay that is captured by a positive level sensitive latch. For setup checks, the timing system checks the arrival time at the output port with the opening edge of the latch. The timing system treats any arrival time exceeding the opening edge as negative slack. For hold checks, the timing system performs the checks with respect to the closing edge of the latch. Use the `-clock` parameter to model a positive level sensitive latch, or the `-clock_fall` parameter to model a negative level sensitive latch. You cannot use the `-level_sensitive` parameter without the `-clock` parameter.
`-max`	Specifies that the delay refers to the setup analysis. If you do not specify the `-max` parameter, the output delay applies to both setup and hold analysis.
`-min`	Specifies that the delay refers to the hold analysis. If you do not specify the `-min` parameter, the output delay applies to both setup and hold analysis.
`-network_latency_included`	Specifies that the clock network latency should not be added to the output delay value. If you do not specify this option, the clock network latency of the related clock is added to the output delay value. This parameter has no effect if the specified clock is in propagated mode.
pin_or_port_list	Specifies a list of output port or pin names. The pin_or_port_list argument can be a collection.
`-reference_pin` *pin_name*	Adds source and network latency of the specified reference pin to the output delay value in propagated mode. A reference pin is a leaf pin in the fanout cone of the clock source of the clock that you specify using the `-clock` parameter. You cannot specify multiple pins for `-reference_pin` parameter. The command issues a warning and accepts the first pin. You cannot use the `-reference_pin` parameter with the `-network_latency_included` or `-source_latency_included` parameters. You cannot use the `-reference_pin` parameter to specify hierarchical pins.
`-rise`	Specifies that output delay refers to the rising edge of the signal at the specified ports or pins. If you do not specify the `-rise` option, the output delay applies to the both edges.

`-source_latency_included`	Specifies that the clock source latency should not be added to the output delay value. With different delay values for `-rise/-fall` and `-min/-max`, only the last specified combination of `-network_latency_included` and `-source_latency_included` parameters is honored. The specified combination can be one of the following: a) Either `-network_latency_included` or `-source_latency_included` b) Both the parameters c) None of these

Examples

- The following example sets the input and output delays for the bidirectional `INOUT2` port.The input signal arrives at `INOUT2` at `4.5` units after the falling edge of `CLKB`. The output signal is required at `INOUT2` at `2.5` units before the rising edge of `CLKD`:
  ```
  set_input_delay 4.5 -clock CLKB -clock_fall { INOUT2 } set_output_delay 2.5 -clock CLKD { INOUT1 }
  ```
- The following example shows how to use the `-group_path` option to add ports into a named group:
  ```
  set_output_delay 2.5 -max -clock CLK -group_path busC {busC[*]}
  ```

Related Information

- `all_outputs`
- `create_clock`

set_pll_timing

```
set_pll_timing
[-help]
inst
-feedback_pin <feedback pin name>
-output_clock <clock name or ID>
-output_pin <output pin name>
[-reference_edge {rise | fall | both}]
-reference_pin <reference pin name>
```

This command identifies phase locked loop (PLL) insertion delays and the associated generated clock(s) that require adjustment. To remove the effect of clock tree latency, PLLs can be used to adjust the delay on the PLL output clock waveform so that the effective edges of the clock at the clock tree endpoints are aligned with the reference edges of the input clock to the PLL.

When you use the `set_pll_timing` command, the software uses the settings to automatically calculate and apply a delay offset to a PLL output clock to compensate for internal clock tree latency.

The `set_pll_timing` command works in conjunction with a generated clock definition to provide the correct clock timing at the output of the PLL. To use this command, you must first assert a generated clock on the `set_pll_timing -output_pin`. The `-source` option of the `create_generated_clock` command must also match the `-reference_pin` specified by the `set_pll_timing` command.

Parameters

`-help`	Prints out the command usage.
`inst`	Specifies the instance name or the object ID of a PLL cell, on the basis of which the reference pins, feedback pins, or the output pins will be searched.
`-feedback_pin <feedback pin name>`	Specifies the name of the PLL feedback pin.
`-output_clock <clock name or ID>`	Specifies the generated clock on the PLL output.
`-output_pin <output pin name>`	Specifies the PLL clock output pin name.
`-reference_edge {rise | fall | both}`	Defines adjustment edge(s). When this parameter is specified, the software selects the edges of the clocks at the reference and feedback pins that need to be aligned. If the rise or fall option is specified, then the clock latency from that reference edge to the related edge at the feedback pin will be used. In this case, both the rise and fall edges will use the same latency adjustment. If both of these options are specified, then the software will measure separate latency adjustments for both the rise and fall edges. *Default*: `rise`
`-reference_pin <reference pin name>`	Specifies the PLL reference pin name.

Examples

Here are some examples.

- The following example shows the defined clocks in a sample design:

  ```
  create_clock [get_ports {clk_in}] -name CLK -period 6 -waveform {0 3}
  create_generated_clock -name GCLK1 -source [get_pins {mypll/CLK}] -multiply_by 1 -master_clock
  [get_clocks {CLK}] -add [get_pins {mypll/GCLK}]
  ```

  The following `report_timing` command shows the insertion delay values at various points in the timing report:

  ```
  report_timing -from_rise mypll/GCLK -to_rise mypll/CEN -point_to_point

  Path 1:Endpoint: mypll/CEN (^) (unconstrained output)

  Beginpoint: mypll/GCLK (^) triggered by leading edge of 'GCLK1'
  ```

```
Arrival Time 0.496
Analysis View: default_analysis_view_setup
------------------------------------------------------------
Pin           Cell      Delay   Arrival   Generated Clock
                                Time      Adjustment
------------------------------------------------------------
mypll/CLK                       0.112
mypll/GCLK ->  PLL       0.133  0.246     GCLK1 Adj. = 0.000
clkTreeL0/Y    CLKBUFX1  0.139  0.385
clkTreeL1_1/Y  CLKBUFX1  0.118  0.503
mypll/CEN ->   PLL      -0.007  0.496
------------------------------------------------------------
```

From the above table, it can be seen that the rise insertion delay of clock CLK at pin mypll/CLK is 0.112ns.

Now, the following command will adjust the source latency of clock GCLK1 such that the edges at mypll/CLK and mypll/CEN are aligned i.e. the clock's rising edge should reach mypll/CEN at 0.112ns only:

```
set_pll_timing [get_cells mypll] -reference_pin CLK -feedback_pin CEN -output_pin GCLK -
output_clock [get_clocks GCLK1]
```

- The following `report_timing` command shows the source latency of GCLK clock as -0.138ns, and the clock reaches mypll/CEN pin at 0.112ns (same as on mypll/CLK):

```
report_timing -from_rise mypll/GCLK -to_rise mypll/CEN -point_to_point

Path 1:Endpoint: mypll/CEN (^) (unconstrained output)
Beginpoint: mypll/GCLK (^) triggered by leading edge of 'GCLK1'
Arrival Time 0.112
Analysis View: default_analysis_view_setup
+ Source Insertion Delay 0.112
- PLL Feedback Delay 0.250
= Beginpoint Arrival Time -0.138
------------------------------------------------------------------
Pin             Cell       Delay    Arrival    Generated Clock
                                    Time       Adjustment
------------------------------------------------------------------
mypll/GCLK ->                       -0.138    GCLK1 Pll Adj. = 0.000
clkTreeL0/Y     CLKBUFX1   0.139    0.001
clkTreeL1_1/Y   CLKBUFX1   0.118    0.120
mypll/CEN ->    PLL       -0.007    0.112
------------------------------------------------------------------
```

Related Commands

- create_generated_clock
- create_clock
- reset_pll_timing

set_propagated_clock

```
set_propagated_clock
[-help]
obj_list
```

Puts the `propagated_clock` assertion on the specified pin, port, or clock object. This will cause all clock endpoints in the fanout of the specified object to receive propagated clock timing unless there is a `set_clock_latency` with higher precedence. If there are multiple `set_clock_latency` and `set_propagated_clock` assertions between the clock waveform, clock root and clock endpoint, the closest assertion to the clock endpoint takes precedence.

There are two methods of clock propagation: depending on whether the clock is ideal or propagated.

- When a clock is ideal, the delay from a clock port to a register clock pin (network insertion delay) comes from design constraints using the `set_clock_latency` command.
- When a clock is propagated, the network insertion delay is computed from the actual gates and interconnects in the clock network.

To set the propagated_clock property on all clock waveform objects, use the following command:

```
set_propagated_clock [all_clocks]
```

When `set_propagated_clocks [all_clocks]` command is asserted, it will apply to all the currently defined clock waveform objects. This setting will not apply to clocks created later in the script. Whether all the clock endpoints receive propagated or ideal timing depends on the precedence of `set_clock_latency` in the fanout.

The `set_propagated_clock [all_clocks]` command puts the `propagated_clock` assertion on all clocks except virtual clocks. When you put the assertion on a real clock that is used to define I/O timing (with `set_input_delay -clock` or `set_output_delay -clock`), the software does not take the specified network latency into account. Instead, the software calculates the network latency, which changes the I/O timing. You can change this behavior by using the following attribute:

```
set_attribute timing_io_use_clock_network_latency always
```

You can use this command after creating the clock with the `create_clock` command.

Parameters

`-help`	Prints out the command usage.
`obj_list`	Specifies the objects on which you want to put the `propagated_clock` assertion. The *`pin_or_clock_list`* argument can be a collection. When a pin is specified, it affects the propagation mode for all the registers in the transitive fanout (TFO) of the pin.

Examples

- The following command puts the `propagated_clock` assertion on the clock waveform `CLK1`:

  ```
  set_propagated_clock CLK1
  ```

- The following command puts the `propagated_clock` assertion on all clock waveforms:
  `set_propagated_clock [all_clocks]`

set_property

```
set_property
[-obj_type {object_type}]
{obj_list}
property_name
property_value
[-quiet]
```

Sets user-defined properties on objects.

The `set_property` command needs a property to be defined using the `define_property` command.

Parameters

obj_list	Specifies a list of objects on which the property is to be applied.
-obj_type {*object_type*}	Specifies the type of object on which the property is to be defined.
property_name	Specifies the name of the property.
property_value	Specifies the value of the property.
-quiet	Specifies to exit quietly without issuing an error.

Examples

- The following command applies a user-defined property `slk` to pins `C1/A`:

  ```
  set_property [get_pins C1/A] slk 2
  ```

- The following command applies aocv_weight property to library arcs:

  ```
  set_property [get_lib_arcs -of_objects slow/INVX1] aocv_weight 8
  ```

set_pulse_clock_max_transition

```
set_pulse_clock_max_transition
limit
obj_list
[-transitive_fanout]
[-rise]
[-fall]
```

Sets the maximum pulse clock transition constraint on the specified pulse generator cells, pulse generator library cells, clocks, and/or current design.

Parameters

`-fall`	Sets transition limit value for falling transition.
obj_list	Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design.
`-rise`	Sets transition limit value for rising transition.
limit	Specifies the transition limit value.
`-transitive_fanout`	Specifies the transition limit value for transitive fanout.

Related Commands

- get_clocks
- get_cells
- reset_pulse_clock_max_transition

set_pulse_clock_max_width

```
set_pulse_clock_max_width
width
obj_list
[-transitive_fanout]
```

Sets the maximum pulse clock width constraint on the specified pulse generator cells, pulse generator library cells, clocks, and/or current design.

Parameters

obj_list	Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design.
width	Specifies the pulse width value.
-transitive_fanout	Specifies the pulse width value for transitive fanout.

Related Commands

- get_clocks
- get_cells
- reset_pulse_clock_max_transition
- reset_pulse_clock_max_width

set_pulse_clock_min_transition

```
set_pulse_clock_min_transition
limit
obj_list
[-transitive_fanout]
[-rise]
[-fall]
```

Sets the minimum pulse clock transition constraint on the specified pulse generator cells, pulse generator library cells, clocks, and/or current design.

Parameters

`-fall`	Sets transition limit value for falling transition.
obj_list	Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design.
`-rise`	Sets transition limit value for rising transition.
limit	Specifies the transition limit value.
`-transitive_fanout`	Specifies the transition limit value for transitive fanout.

Related Commands

- reset_pulse_clock_min_transition
- get_clocks
- get_cells

set_pulse_clock_min_width

```
set_pulse_clock_min_width
[-help]
pulse_width
object_list
[-transitive_fanout]
```

Sets the minimum pulse clock width constraint on the specified pulse generator cells, pulse generator library cells, clocks and/or current design.

When you set this constraint on a clock, the settings are applied to all the pulse generators that are driven by the clock. When this constraint is used for a design, the software applies the constraint to all the clock networks in the design.

The specified minimum pulse width is expected to be larger than the pulse width value. The width is defined when a clock object is created and its waveform is defined in the current design (using the `create_clock -waveform` parameter).

In case of conflicting minimum width constraints, the more restrictive constraint is used. When applied on a non-pulse generator object, or a non-clock target, this constraint has no effect.

Note: You must specify `set_interactive_constraint_modes` constraint prior to running the `set_pulse_clock_min_width` command.

Parameters

`-help`	Prints out the command usage.
`object_list`	Specifies a list of objects - pulse generator cells, pulse generator library cells, clocks, or current design.
`pulse_width`	Specifies the minimum pulse width value.
`-transitive_fanout`	Specifies the pulse width value for transitive fanout.

Examples

- The following example sets the min pulse clock width constraint of 0.3 ns on the pulse generator instance `pg_inst`:

  ```
  set_pulse_clock_min_width 0.3 pg_inst
  ```

  This constraint can be observed using the following command:
  `report_constraint pg_inst/Y -check_type pulse_clock_min_width`

  Fragmented output:

  ```
  ----------------------------------------
  Pin Required Actual Pulse Slack Clock Type

  Pulse Width Width
  ----------------------------------------
  pg_inst/Y (high)    0.300 0.366 0.066 PG
  ----------------------------------------
  ```

Related Commands

- `timing_enable_uncertainty_for_pulse_width_checks`

set_resistance

```
set_resistance
-help
[-max]
[-min]
value
net_list
```

Sets the wire resistance value on the specified nets of the top cell, which is used to compute the net delay of the specified nets. The resistance that you specify using this command overrides the resistance from wire load models and SPEF.

Note: In the best-case worst-case (BC-WC) analysis mode, the minimum resistance is used to compute the early path delay and the late path delay for the minimum corner. The maximum resistance is used to compute the early path delay and the late path delay for the maximum corner.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_resistance` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_resistance`.
`-max`	Specifies that the asserted resistance is the maximum resistance. *Default*: If the `-max` (or `-min`) parameter is not specified, the resistance value is used as both minimum and maximum resistance.
`-min`	Specifies that the asserted resistance is the minimum resistance. *Default*: If the `-min` (or `-max`) parameter is not specified, the resistance value is used as both minimum and maximum resistance.
`net_list`	Specifies a list of nets on which the wire resistance is set.
`resistance_value`	Specifies the value for the wire resistance. This value (in units) is found in the target technology library.

Examples

- The following example set the maximum wire resistance of `2.0` units on the net `n1`:

  ```
  set_resistance -max 2.0 [get_nets n1]
  ```

- The following example set the minimum wire resistance of `1.2` units and a maximum wire resistance of `2.0` units on the net `n1`:

  ```
  set_resistance 1.2 -min [get_nets n1]
  ```

```
set_resistance 2.0 -max [get_nets n1]
```

Related Commands

- reset_resistance

write_annotated_transition

```
write_annotated_transition
[-help]
out_file
[-direct]
[-exclude_ports]
[-include_output_pins]
[-max]
[-min]
[-view string]
```

Writes the value of transitions on each pin to an output file. You can either set the transitions using the `set_annotated_transition` command or the software computes them internally.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `write_annotated_transition` parameter.
`-direct`	Refers the ports directly for which the annotated transition will be applied in the output SDC. This option removes the dependency of using the `get_ports` and `get_pins` commands.
`-include_output_pins`	Writes the slews for input and output pins, and the output slew for bi-directional pins. If this option is not specified, the software writes the slew for input pins and the input slew of bi-directional pins.
`-min/-max`	Specifies whether to write out minimum or maximum transition. *Default:* Both minimum and maximum transitions are written out.
`-exclude_ports`	Skips writing the transition values for the primary ports (input and output).
out_file	Specifies the name of the output file.
`-view` *string*	Writes the transitions for the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode.

Related Commands

- `set_annotated_transition`
- `get_ports`
- `get_pins`

set_sense

```
set_sense
[-help]
pin_or_port_list
[-clocks clock_list]
{[-positive | -negative | -stop_propagation ] [-type <type_list> ]}
```

Selects which phase of the clock to filter at the specified point.

Parameters

`-help`	Prints out the command usage.
`-clocks` *`clock_list`*	Specifies a list of clocks passing through a specified point to which the constraint applies. When this parameter is not specified, the filtering of clock phase will be applicable to all the clocks passing through that specified point. This parameter must be used with a specified pin name and one of the parameters : `-positive`, `-negative`, or `-stop_propagation`.
`-negative`	Specifies that positive phase filtered clocks pass through pins in the *`pin_list`*.
`pin_or_port_list`	Specifies the list or collection of cell output pins. The unateness specified by the `set_sense` command is applied to clocks propagating through the specified point.
`-positive`	Specifies that negative phase filtered clocks pass through pins in the *`pin_list`*.
`-stop_propagation`	Stops the propagation of specified clocks and clock source data paths passing through the specified pins.

`-type type_list`	Applies clock sense to object types specified in the *`type_list`*. The type list options are - `all`, `clock`, `data`, `clock_source_data`, `default_data`. These are explained below: • `all`: Stops all phases from propagating. This is equivalent to specifying both the `clock` and `data` options. • `clock`: Stops clock phases launched by clock(s) specified in the *`clock_list`* from propagating. • `data`: Stops all data phases launched by clock(s) specified in *`clock_list`*, starting from the pins/ports specified in *`pin_or_port_list`*. The objects in the *`pin_or_port_list`* can be selected anywhere in the design - clock/data network. • `clock_source_data`: Stops only clock source data phases from propagating. The combination of `clock_source_data` and `clock` is equivalent to the existing `-stop_propagation` option. The `-type` parameter extends the capability of the `set_clocks_sense` command to selectively block data timing phases. This parameter provides a more generalized use model for selecting among all types of paths that should be filtered. The `-type` parameter is mutually exclusive with the `-positive`, `-negative`, and `-stop_propagation` options.

Examples

- The following command allows the positive phase clock CLK1 to pass through CLKBUF1/Z and filters out the negative phase clock CLK1:
  ```
  set_sense -positive -clocks CLK1 CLKBUF1/Z
  ```
- The following command stops clock phases starting from pin1:
  ```
  set_sense pin1 -type {clock}
  ```
- The following command stops data phases based only on CK1 and CK2 starting from pin1:
  ```
  set_sense pin1 -type {data} -clocks {CK1 CK2}
  ```
- The following command stops only the clock source data phases starting from pin1:
  ```
  set_sense pin1 -type {clock_source_data}
  ```
- The following command stops the clock and clock source data phases:
  ```
  set_sense pin1 -type {clock clock_source_data}
  ```
  or
  ```
  set_sense pin1 -stop_propagation
  ```

Related Commands

- reset_sense

reset_sense

```
reset_sense
[-help]
[-all | [[-clocks <clock_list>] <pin_or_port_list>]]
```

Resets clock sense constraint(s) specified using the `set_sense` command.

Parameters

`-help`	Prints out the command usage.
`-all`	Resets all the specified `clock_sense` constraints.
`-clocks` *`clock_list`*	Specifies the list of clocks for which the clock sense constraints are to be removed. The clocks must have previously been defined using the `set_sense -clocks` parameter.
`pin_or_port_list`	Specifies the list or collection of cell output pins or ports for which the clock sense constraints will be removed.

Examples

- The following command resets all the previously defined `clock_sense` constraints from a design:

  ```
  tempus > reset_sense -all
  ```

Related Commands

- `set_sense`

analyze_paths_by_bottleneck

```
analyze_paths_by_bottleneck
[-help]
{-category n | -delta_delay {worst|total}}
[-path_num m]
[-max_slack float]
[-min_slack float]
[-master master_category_name]
```

Creates categories according to the bottleneck analysis of the critical paths and fixes the violation according to the bottleneck information. Bottleneck Analysis detects the instances that are often involved in the critical paths in the design. Any change in timing for these instances impacts multiple critical paths in the design. Therefore you can use this information to change your design (floorplan, placement, constraints etc.) around these instances. The bottleneck analysis computes the number of occurrences that an instance appears in the paths that you display in the Timing Debug window, and provides the following output:

- Colors most used instance based on number of occurrences.
- Creates *n* number of path categories for the instances with the highest number of occurrences. *n* is the number you specify using the `-category` parameter.

Users can also perform bottleneck analysis of the critical paths based on incremental delay. Categories will be created based on the worst *m* paths with:

- The biggest worst `incr_delay` contribution
- The biggest total `incr_delay` contribution

The command can be applied wherever the user loads the machine readable timing report.

For more information on creating path categories, see the 'Creating Path Categories' section in the Debugging Timing Results chapter of the *Innovus User Guide* document.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_paths_by_bottleneck` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man analyze_paths_by_bottleneck`
`-category` *n*	Specifies the number of categories to be created for most occurring instances. *Data_type*: int, required
`-delta_delay {worst|total}`	Specifies that the categories are created based on worst `incr_delay` contribution or total `incr_delay` contribution. *Data_type*: enum, required
`-master` *master_category_name*	Specifies that the analysis should be performed only for the specified `master` category. *Data_type*: string, optional
`-max_slack` *float*	Specifies the max slack value of the critical paths for bottleneck analysis based on `incr_delay`. *Data_type*: float, optional
`-min_slack` *float*	Specifies the min slack value of the critical paths for bottleneck analysis based on `incr_delay`. *Data_type*: float, optional
`-path_num` *m*	Specifies the number of critical paths to be analyzed when performing bottleneck analysis based on `incr_delay`. *Data_type*: int, optional

Examples

- The following command creates path categories based on bottleneck analysis of the critical paths on the instances:

  ```
  analyze_paths_by_bottleneck -category 2
  ```

  The following categories are created: `BOT_instance1` and `BOT_instance2`. You can change the number of categories.

- The following command creates path categories based on bottleneck analysis of the critical 20 paths on the worst `incr_delay`:

  ```
  analyze_paths_by_bottleneck -path_num 20 -delta_delay worst
  ```

  The following category is created: `BOT_SI_WORST`.

analyze_paths_by_clock_domain

```
analyze_paths_by_clock_domain
[-help]
[-include_edges]
[-include_views]
[include_mode]
[-master master_category_name]
```

To find the possible timing issues in clock combinations, the command creates categories according to launch clocks - capture clock combinations.

Following categories are created:

- Paths with clock fully contained in a single domain, clk1.
- Paths with clocks starting one clock domain and ending at another, clk1-> clk2.

The command can be applied wherever the user loads the machine readable timing report.

For more information on creating path categories, see the 'Creating Path Categories' section in the Debugging Timing Results chapter of the *Innovus User Guide* document.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_paths_by_clock_domain` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man analyze_paths_by_clock_domain`
`-include_edges`	Considers leading or trailing edge of the clock while defining categories. *Data_type*: bool, optional
`-include_mode`	Considers constraint mode while defining categories. *Data_type*: bool, optional
`-include_views`	Considers analysis views while defining categories. *Data_type*: bool, optional
`-master` *master_category_name*	Specifies that the analysis should be performed only for the specified master category. *Data_type*: string, optional

Examples

- The following command creates path categories based on clock domain analysis of the critical paths, and considers the edges of the clock:
  ```
  analyze_paths_by_clock_domain -include_edges
  ```
- The following command creates path categories based on clock domain analysis of the critical paths, and considers the analysis views:
  ```
  analyze_paths_by_clock_domain -include_views
  ```

Related Topics

analyze_paths_by_critical_false_path

```
analyze_paths_by_critical_false_path
[-help]
-critical_false_paths
{false_path_only | exclude_false_path}
[-master master_category_name]
```

Identifies violating false paths, which are paths that appear as violations but cannot be exercised due to the structure of the netlist, and creates a category that contains them. With this command the user can, in advance, categorize the critical false paths together to analyze them.

The command can be applied wherever the user loads the machine readable timing report.

For more information on creating path categories, see the 'Creating Path Categories' section in the Debugging Timing Results chapter of the *Innovus User Guide* document.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_paths_by_critical_false_path` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man analyze_paths_by_critical_false_path`
`-critical_false_paths`	Specifies which paths to analyze. • `false_path_only` Includes only false paths when creating the category. • `exclude_false_paths` Excludes false paths when creating the category. *Default*: `false_path_only` *Data_type*: enum, optional
`-master` *master_category_name*	Specifies that the analysis should be performed only for the specified master category. *Data_type*: string, optional

Examples:

- The following command creates path categories based on the critical false paths:
  `analyze_paths_by_critical_false_path -critical_false_path\ false_path_only`
- The following category is created: `default_report_false_path_only`

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

analyze_paths_by_default_path_group

```
analyze_paths_by_default_path_group
[-help]
[-master master_category_name]
[-predefined]
```

Categorizes the timing paths based on basic path groups. The basic path groups are fundamental to timing analysis and help the user easily observe the timing information of different basic path groups. For instance, if user is only concerned about the paths from registers to registers, the user can analyze the paths in the category REG -> REG. The basic path groups categories are:

- Register to register
- Input to register
- Register to output
- Input to output

The following categories are created:

- `REG->REG`
- `IN->REG`
- `REG->OUT`
- `IN->OUT`

Timing debug can also convert user defined path groups into path categories. The command can be applied wherever the user loads the machine readable timing report.

Note: If your design does not have paths belonging to a type of path group, the software will not create that category.

For more information on creating path categories, see the 'Creating Path Categories' section in the Debugging Timing Results chapter of the *Innovus User Guide* document.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_paths_by_default_path_group` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man analyze_paths_by_default_path_group`
`-master` *`master_category_name`*	Specifies that the analysis should be performed only for the specified master category. *Data_type*: string, optional
`-predefined`	Creates path categories for user defined path groups. *Data_type*: bool, optional

Examples

- The following command create path categories based on basic path groups:
  `analyze_paths_by_default_path_group`
  The following categories are created: REG->REG, IN->REG, REG->OUT, IN->OUT.
- The following command create path categories based on predefined path group "critical" :
  ```
  group_path -name critical -from {ff*/CLK } -to {ff*/D} #create predefined path group
  analyze_paths_by_default_path_group -predefined
  ```
  The category "critical" will be created based on the predefined path group name.

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

analyze_paths_by_drv

```
analyze_paths_by_drv
[-help]
[[-load_cap_file capacitance_file] | [-generate_cap_file fileName]]
[[-load_transition_file transition_file] | [-generate_transition_file fileName]]
[-load_fanout_file fanout_file | [-generate_fanout_file fileName]]
[-master master_category_name]
```

Reads or generates a report containing max transition, max capacitance, and max fanout violations. Paths that are affected by the selected DRV type are grouped into a category. This command can be used if the user wants to debug the timing issues caused by DRV.

The command can be applied wherever the user loads the machine readable timing report.

For more information on creating path categories, see the 'Creating Path Categories' section in the Debugging Timing Results chapter of the *Innovus User Guide* document.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_paths_by_drv` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man analyze_paths_by_drv`
`-load_cap_file` *capacitance_file*	
	Reads a file containing a list of paths containing max capacitance violations. *Data_type*: string, optional
`-load_fanout_file` *fanout_file*	
	Reads a file containing a list of paths containing max fanout violations. *Data_type*: string, optional
`-load_transition_file` *transition_file*	
	Reads a file containing a list of paths containing max transition violations. *Data_type*: string, optional

`-generate_cap_file` *`fileName`*	
	Generates a file containing a list of paths containing max capacitance violations. *Data_type*: string, optional
`-generate_fanout_file` *`fileName`*	
	Generates a file containing a list of paths containing max fanout violations. *Data_type*: string, optional
`-generate_transition_file` *`fileName`*	
	Generates a file containing a list of paths containing max transition violations. *Data_type*: string, optional
`-master` *`master_category_name`*	
	Specifies that the analysis should be performed only for the specified master category. *Data_type*: string, optional

Examples:

The following command generates DRV report files, then creates path categories based on the critical paths which are affected by DRV:

```
analyze_paths_by_drv -generate_cap_file capViolation.rpt

-generate_transition_file tranViolation.rpt

-generate_fanout_file fanoutViolation.rpt
```

Related Topics

analyze_paths_by_hier_port

```
analyze_paths_by_hier_port
[-help]
[-generate_hier_file InstanceName_list]
[-load_hier_file file_name]
[-master master_category_name]
[-out_file]
```

Helps you to automatically group paths based on each hierarchical port of a given instance. You can use this command to perform the timing results analysis of a hierarchical design. For example, while looking at the setup/hold time at the same time of each port.

The command can be applied wherever the user loads the machine readable timing report.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_paths_by_hier_port` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man analyze_paths_by_hier_port`
`-generate_hier_file` *`InstanceName_list`*	
	Generates hier ports fanin/fanout file when the database is available based on the given InstanceName_list. Then uses that file to create the categories. *Data_type*: string, optional
`-load_hier_file` *`file_name`*	
	Uses a previously saved hier ports fanin/fanout file when the database is not available. *Data_type*: string, optional
`-master` *`master_category_name`*	
	Specifies that the timing paths should be categorized only for the specified master category. *Data_type*: string, optional
`-out_file`	Specifies the generated hier ports fanin/fanout file name. *Data_type*: string, optional

Example

The following command categorizes paths based on hierarchical port of the instance `DTMF_INST/TDSP_CORE_INST`:

```
analyze_paths_by_hier_port -generate_hier_file DTMF_INST/TDSP_CORE_INST
```

Related Topics

analyze_paths_by_hierarchy

```
  analyze_paths_by_hierarchy
[-master master_category_name]
{-floorplan_file floorplan_file [-include_macros]} | {-use_current_floorplan  [-all] [-
types type_list] [-port_to_port] [-port_to_macro] [-port_to_bbox] [-port_to_hinst] [-
port_to_stdcell] [-port_to_inst_group] [-macro_to_port] [-macro_to_macro] [-
macro_to_bbox] [-macro_to_hinst] [-macro_to_stdcell] [-macro_to_inst_group] [-
bbox_to_port] [-bbox_to_macro] [-blackbox_to_blackbox] [-bbox_to_hinst] [-
bbox_to_stdcell] [-bbox_to_inst_group] [-hinst_to_port] [-hinst_to_macro] [-
hinst_to_bbox] [-hinst_to_hinst] [-hinst_to_stdcell] [-hinst_to_inst_group] [-
stdcell_to_port] [-stdcell_to_macro] [-stdcell_to_bbox] [-stdcell_to_hinst] [-
stdcell_to_stdcell] [-stdcell_to_inst_group] [-inst_group_to_port] [-
inst_group_to_macro] [-inst_group_to_bbox] [-inst_group_to_hinst] [-
inst_group_to_stdcell] [-inst_group_to_inst_group]} | {-partitions partition_list | -
macros macro_list}
```

Creates categories according to the hierarchical characteristics of the paths. User can use either a user specified floorplan file or current floorplan file of the design in memory and can create categories according to the hierarchy of the design. This way, the paths can be narrowed down to small group.

Use Floorplan Plan

The software automatically extracts partition-boundary information from guides, regions, and fences in the floorplan file. Optionally you can specify option to sort paths based on the macros in the floorplan file.

- All paths fully contained in a single partition, Ptn1.
- Paths starting in one partition and ending in another partition, Ptn1–>Ptn2.
- Paths spanning several partitions, Ptn1–> Ptn2–>Ptn3.
- Top-level inputs to partitions, INPUT–>Ptn1.
- Paths from partitions to top-level outputs, Ptn1–>OUTPUT.

Use Current Floorplan

This method categorizes paths based on the current floor plan of the design in memory. It will rely on the grouped/ungrouped as a basis for what level to view the hierarchy as well as what levels to create timing categories.

Grouped/ungrouped status of an Hinst means whether or not its children are shown on the floor plan view.

It categorizes paths starting and ending on/within these hierarchical entities:

- Port
- Hard Macro (ungrouped)
- Black Box (ungrouped)
- Hinst (regular, partition, Black Blob, or Flex Model) (highest grouped)
- Stdcell (ungrouped)

For more information on creating path categories, see the 'Creating Path Categories' section in the Debugging Timing Results chapter of the *Innovus User Guide* document.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_paths_by_hierarchy` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man analyze_paths_by_hierarchy`
`-all`	Creates categories of paths within all types *Default:* All types are categorized. *Data_type*: bool, optional
`-bbox_to_hinst`	Creates categories of paths from black box to hierarchical instance. *Data_type*: bool, optional
`-bbox_to_inst_group`	Creates categories of paths from black box to instance group. *Data_type*: bool, optional

`-bbox_to_port`	Creates categories of paths from black box to port. *Data_type*: bool, optional
`-bbox_to_macro`	Creates categories of paths from black box to macro. *Data_type*: bool, optional
`-blackbox_to_blackbox`	Creates categories of paths from black box to black box. *Data_type*: bool, optional
`-bbox_to_stdcell`	Creates categories of paths from black box to standard cell. *Data_type*: bool, optional
`-floorplan_file floorplan_file`	Specifies the name of the floorplan file. *Default:* Uses the current floorplan file. *Data_type*: string, required
`-hinst_to_bbox`	Creates categories of paths from hierarchical instance to black box. *Data_type*: bool, optional
`-hinst_to_port`	Creates categories of paths from hierarchical instance to port. *Data_type*: bool, optional
`-hinst_to_macro`	Creates categories of paths from hierarchical instance to macro. *Data_type*: bool, optional
`-hinst_to_hinst`	Creates categories of paths from hierarchical instance to hierarchical. *Data_type*: bool, optional
`-hinst_to_inst_group`	Creates categories of paths from hierarchical instance to instance group. *Data_type*: bool, optional
`-hinst_to_stdcell`	Creates categories of paths from hierarchical instance to standard cell. *Data_type*: bool, optional

`-include_macros`	Includes macros in addition to guides and fences for creating categories. *Default:* Macros are not considered. *Data_type*: bool, optional
`-inst_group_to_bbox`	Creates categories of paths from instance group to black box. *Data_type*: bool, optional
`-inst_group_to_hinst`	Creates categories of paths from instance group to hierarchical instance. *Data_type*: bool, optional
`-inst_group_to_inst_group`	Creates categories of paths from instance group to instance group. *Data_type*: bool, optional
`-inst_group_to_macro`	Creates categories of paths from instance group to macro. *Data_type*: bool, optional
`-inst_group_to_port`	Creates categories of paths from instance group to port. *Data_type*: bool, optional
`-inst_group_to_stdcell`	Creates categories of paths from instance group to standard cell. *Data_type*: bool, optional
`-macro_to_bbox`	Creates categories of paths from macro to black box. *Data_type*: bool, optional
`-macro_to_port`	Creates categories of paths from macro to port. *Data_type*: bool, optional
`-macro_to_macro`	Creates categories of paths from macro to macro. *Data_type*: bool, optional
`-macro_to_hinst`	Creates categories of paths from macro to hierarchical instance. *Data_type*: bool, optional

`-macro_to_inst_group`	Creates categories of paths from macro to instance group. *Data_type*: bool, optional
`-macro_to_stdcell`	Creates categories of paths from macro to standard cell. *Data_type*: bool, optional
`-macros` *macro_list*	Specifies the names of the macros to be used. Use this parameter with the `-partitions` parameter. *Data_type*: string, required
`-master` *master_category_name*	Specifies that the timing paths should be categorized only for the specified master category. *Data_type*: string, optional
`-partitions` *partition_list*	Specifies the names of the partitions to consider for extracting hierarchical information. *Data_type*: string, required
`-port_to_bbox`	Creates categories of paths from port to black box. *Data_type*: bool, optional
`-port_to_port`	Creates categories of paths from port to port. *Data_type*: bool, optional
`-port_to_macro`	Creates categories of paths from port to macro. *Data_type*: bool, optional
`-port_to_hinst`	Creates categories of paths from port to hierarchical instance. *Data_type*: bool, optional
`-port_to_inst_group`	Creates categories of paths from port to instance group. *Data_type*: bool, optional
`-port_to_stdcell`	Creates categories of paths from port to std cell. *Data_type*: bool, optional
`-stdcell_to_bbox`	Creates categories of paths from standard cell to black box. *Data_type*: bool, optional

`-stdcell_to_port`	Creates categories of paths from standard cell to port. *Data_type*: bool, optional
`-stdcell_to_macro`	Creates categories of paths from standard cell to macro. *Data_type*: bool, optional
`-stdcell_to_hinst`	Creates categories of paths from standard cell to hierarchical instance. *Data_type*: bool, optional
`-stdcell_to_inst_group`	Creates categories of paths from standard cell to instance group. *Data_type*: bool, optional
`-stdcell_to_stdcell`	Creates categories of paths from standard cell to standard cell. *Data_type*: bool, optional
`-types type_list`	Creates categories of paths within the type_list. Valid types are: `port`, `macro`, `bbox`, `hinst`, `stdcell` *Data_type*: string, required
`-use_current_floorplan`	Uses the current floorplan. *Data_type*: bool, required

Examples

- By default, it categorizes all paths inter/intra the 5 hierarchical entities by following command:
  ```
  analyze_paths_by_hierarchy -use_current_floorplan -all
  ```
- The following command categorizes all paths from "port" or to "port":
  ```
  analyze_paths_by_hierarchy -use_current_floorplan -type port
  ```

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

analyze_paths_by_view

```
analyze_paths_by_view
[-help]
[-prefix string]
[-master master_category_name]
```

Categorizes the timing paths based on views that you create during multi-mode multi-corner analysis. By arranging the timing information of different views quickly, the command helps in analyzing timing paths.

For more information on creating path categories, see the 'Creating Path Categories' section in the Debugging Timing Results chapter of the *Innovus User Guide* document.

The command can be applied wherever the user loads the machine readable timing report.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `analyze_paths_by_view` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man analyze_paths_by_view`
`-master` *`master_category_name`*	Specifies that the timing paths should be categorized only for the specified master category. *Data_type*: string, optional
`-prefix` *`string`*	Adds a prefix to the category name. *Data_type*: string, optional

Example

The following command categorizes paths based on views that you created during mmmc analysis:

```
analyze_paths_by_view
```

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

create_histogram_png

```
create_histogram_png
[-help]
[-height integer]
-name string
[-width integer]
```

Dumps out the timing histogram image from global timing debug in the PNG format without bringing up the GUI. Earlier, this was done when the GUI was displayed by right-clicking the histogram window and selecting Snapshot. But that worked only when the snapshot was displayed in the GUI. This command has eliminated the necessity of bringing up the GUI to dump out the timing histogram.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `create_histogram_png` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man create_histogram_png`
`-height integer`	Specifies the height of the PNG image. *Minimum:* `1` *Maximum:* `10000` *Data_type*: int, optional
`-name string`	Specifies the name of the PNG file. *Data_type*: string, required
`-width integer`	Specifies the width of the PNG image. *Minimum:* `1` *Maximum:* `10000` *Data_type*: int, optional

```

This command creates path categories using conditions for grouping paths according to analyzed timing results. The command can be applied wherever the user loads the machine readable timing report. For more information on analyzing timing results and, see 'Analyzing Timing Results' and 'Creating Path Categories' sections in the Debugging Timing Results chapter of the *Innovus User Guide* document.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `create_path_category` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man create_path_category`
`-check_type {Setup Check | Hold Check | Clock Gating Setup Check | Library Clock Gating Setup Check | Clock Gating Hold Check | Library Clock Gating Hold Check | External Delay Assertion | Latch Borrowed Time Check | PulseWidth Check | ClockPeriod Check | Recovery Check | Removal Check}`	Indicates that the check type matches the specified option. *Data_type*: string, optional

`-clock {both | launch | capture}`	Helps you search the Clock Tree instead of the data path. If this option is not specified, the user searches the data path by default. You can use one of the following values: • `Both`: searches on launch or capture clock paths. • `Launch`: searches only on launch clock paths • `Capture`: searches only on capture clock paths **Note:** Supports simultaneous criteria on data path. *Data_type*: string, optional
`-comment {`*`commentText`*`}`	Specifies a comment that is associated with the category. *Data_type*: string, optional
`-critical_false_path`	*Data_type*: string, optional
`-master` *`existing_category_name`*	Specifies that the new category should be created as a nested category of the specified master category. The master category should be an existing category. *Default:* If you do not specify this parameter, the category is created as a new category at the top level. *Data_type*: string, optional
`-name` *`group_name`*	Specifies the name of the category to be created. *Data_type*: string, optional

`-overwrite`	Overwrites any predefined category with the same name in your category list. *Data_type*: bool, optional
`-sdc {`*`file_name line_number`*`}`	Creates a category based on the SDC constraint as per the specified SDC file name and line number. Creating a path category based on an SDC constraint helps you to analyze the affect of an SDC constraint by grouping the affected paths together. *Data_type*: string, optional
`-file` *`string`*	Specifies the file name. *Data_type*: string, optional
`-from_inst | -from_inst_pointer | -from_pin | -from_lib_cell | -from_clock | -from_port | -from_port_pointer` *`string`*	Indicates that the path must be from the specified instance, pin, library cell, clock, or port pattern. *Data_type*: string, optional
`-from_pdomain` *`string`*	Indicates that the path must be from the specified power domain. *Data_type*: string, optional
`-from_clock_edge`	Indicates that the path must be from the specified clock edge. *Data_type*: string, optional
`-not_from_inst | -not_from_pin | -not_from_cell | -not_from_clock | -not_from_port` *`string`*	Indicates that the path must not be from the specified instance, pin, cell, clock, or port pattern. *Data_type*: string, optional

`-not_from_pdomain` *string*	Indicates that the path must not be from the specified power domain. *Data_type*: string, optional
`-through_inst | -through_pin | -through_lib_cell | -through_net | -through_port` *string*	Indicates that the path must be through the specified instance, pin, net, library cell, or port pattern. *Data_type*: string, optional
`-through_pdomain` *string*	Indicates that the path must be through the specified power domain. *Data_type*: string, optional
`-not_to_clock_edge`	Indicates that the path must not be to the specified clock edge. *Data_type*: string, optional
`-slack` *float*	Indicates that the slack of the path must match the specified *float* value. *Data_type*: string, optional
`-not_from_clock_edge`	Indicates that the path must not be from the specified clock edge. *Data_type*: string, optional
`-not_through_inst | -not_through_pin | -not_through_net | -not_through_port | -not_through_pdomain` *string*	Indicates that the path must not be through the specified instance, pin, power domain, net, or port pattern. *Data_type*: string, optional
`-not_through_lib_cell` *string*	Indicates that the path must not be through the specified library cell. *Data_type*: string, optional

`-to_inst	-to_inst_pointer	-to_pin	-to_lib_cell	-to_clock	-to_port	-to_port_pointer	-to_pdomain` *string*	Indicates that the path must be the specified instance, pin, clock, power domain, library cell, or port pattern. *Data_type*: string, optional
`-not_to_inst	-not_to_pin	-not_to_lib_cell	-not_to_clock	-not_to_port	-not_to_pdomain` *string*	Indicates that the path must not be to the specified instance, pin, clock, library cell, power domain, or port pattern. *Data_type*: string, optional
`-skew` *float*	Indicates that the skew of the path must match the specified *float* value. *Data_type*: string, optional
`-launch_latency` *float*	Indicates that the launch latency of the path must match the specified *float* value. *Data_type*: string, optional
`-capture_latency` *float*	Indicates that the capture latency of the path must match the specified *float* value. *Data_type*: string, optional
`-uncertainty` *float*	Indicates that the uncertainty of the path must match the specified *float* value. *Data_type*: string, optional
`-number_of_insts` *integer*	Indicates that the number of instances in the data segment (with launch and capture clock paths) must match the specified *integer* value. *Data_type*: string, optional

`-number_of_insts_of_name` *`string_plus_integer`*	Indicates that the number of instances matching the specified instance name match the specified *`integer`* value. *Data_type*: string, optional
`-number_of_insts_not_of_name` *`string_plus_integer`*	Indicates that the number of instances not matching the specified instance name match the specified *`integer`* value. *Data_type*: string, optional
`-number_of_insts_of_lib_cell` *`string`*	Indicates that the number of instances matching the specified library cell match the specified *`integer`* value. *Data_type*: string, optional
`-number_of_insts_not_of_lib_cell` *`string`*	Indicates that the number of instances not matching the specified library cell match the specified *`integer`* value. *Data_type*: string, optional
`-to_clock_edge`	Indicates that the path must be to the specified clock edge. *Data_type*: string, optional
`-total_delay_of_insts` *`float`*	Indicates that the total delay of instances matches the specified *`float`* value. *Data_type*: string, optional
`-total_delay_of_level_of_chain_of_inst_type`	Indicates that the total delay of level of chain matching the specified insttype matches the specified string value. *Data_type*: string, optional

`-total_delay_of_path` *float*	Indicates that the total delay of path matches the specified *float* value. *Data_type*: string, optional
`-total_delta_delay_of_path` *float*	Indicates that the total incremental delay of path matches the specified *float* value. *Data_type*: string, optional
`-total_delay_of_nets` *float*	Indicates that the total delay of nets matches the specified *float* value. *Data_type*: string, optional
`-total_delay_of_insts_of_name` *string_plus_float*	Indicates that the total delay of instances matching the specified name matches the specified *float* value. *Data_type*: string, optional
`-total_delay_of_insts_not_of_name` *string_plus_float*	Indicates that the total delay of instances not matching the specified name matches the specified *float* value. *Data_type*: string, optional
`-total_delay_of_insts_not_of_lib_cell` *string*	Indicates that the total delay of instances not matching the specified library cell matches the specified *float* value. *Data_type*: string, optional
`-total_delay_of_insts_of_lib_cell` *string*	Indicates that the total delay of instances matching the specified library cell matches the specified *float* value. *Data_type*: string, optional

`-total_delay_of_nets_of_name` *`string_plus_float`*	Indicates that the total delay of nets matching the specified name matches the specified *`float`* value. *Data_type*: string, optional
`-total_delay_of_nets_not_of_name` *`string_plus_float`*	Indicates that the total delay of nets not matching the specified name matches the specified *`float`* value. *Data_type*: string, optional
`-delay_of_any_inst` *`float`*	Indicates that the delay of any instance in the design matches the specified *`float`* value. *Data_type*: string, optional
`-delay_of_any_inst_not_of_lib_cell` *`float`*	Indicates that the total delay of of any instance in the design not matching the specified library cell matches the specified *`float`* value. *Data_type*: string, optional
`-delay_of_any_net` *`float`*	Indicates that the delay of any net in the design matches the specified *`float`* value. *Data_type*: string, optional
`-delta_delay_of_any_net` *`float`*	Indicates that the incremental delay of any net in the design matches the specified *`float`* value. *Data_type*: string, optional
`-delta_delay_of_every_net` *`float`*	Indicates that the incremental delay of every net in the design matches the specified *`float`* value. *Data_type*: string, optional

`-delay_of_every_inst` *`float`*	Indicates that the delay of every instance in the specified library cell matches the specified *`float`* value. *Data_type*: string, optional
`-delay_of_every_inst_not_of_lib_cell` *`float`*	Indicates that the delay of every instance in the design not matching the specified library cell matches the specified *`float`* value. *Data_type*: string, optional
`-delay_of_every_net` *`float`*	Indicates that the delay of every instance in the design matches the specified *`float`* value. *Data_type*: string, optional
`-delay_of_any_inst_of_lib_cell` *`float`*	Indicates that the delay of any instance in the specified library cell matches the specified *`float`* value. *Data_type*: string, optional
`-delay_of_any_inst_of_name` *`string_plus_float`*	Indicates that the delay of any instance in the design matching the specified name matches the specified *`float`* value. *Data_type*: string, optional
`-delay_of_any_inst_not_of_name` *`string_plus_float`*	Indicates that the delay of any instance in the design not matching the specified name matches the specified *`float`* value. *Data_type*: string, optional

`-delay_of_any_net_of_name` *`string_plus_float`*	Indicates that the delay of any net in the design matching the specified name matches the specified *`float`* value. *Data_type*: string, optional
`-delay_of_any_net_not_of_name` *`string_plus_float`*	Indicates that the delay of any net in the design not matching the specified name matches the specified *`float`* value. *Data_type*: string, optional
`-delay_of_every_inst_of_name` *`string_plus_float`*	Indicates that the delay of every instance in the design matching the specified name matches the specified *`float`* value. *Data_type*: string, optional
`-delay_of_every_inst_of_lib_cell` *`string`*	Indicates that the delay of every instance in the design matching the specified name matches the specified *`float`* value. *Data_type*: string, optional
`-delay_of_every_inst_not_of_name` *`string_plus_float`*	Indicates that the delay of every instance in the design not matching the specified name matches the specified *`float`* value. *Data_type*: string, optional
`-delay_of_every_net_of_name` *`string_plus_float`*	Indicates that the delay of every net in the design matching the specified name matches the specified *`float`* value. *Data_type*: string, optional

`-delay_of_every_net_not_of_name` *`string_plus_float`*	Indicates that the delay of every net in the design not matching the specified name matches the specified *`float`* value. *Data_type*: string, optional
`-view`	Specifies the view name. *Data_type*: string, optional

Examples

- The following command categorizes paths whose source clock is `vclk1`:
  ```
  create_path_category -name vclk1 -from_clock vclk1
  ```
  The category `vclk1` is created.
- The following command categorizes paths whose skew is larger than 0.2:
  ```
  create_path_category -name worst_skew -skew {> 0.2}
  ```
  The category `worst_skew` is created.
- The following command creates paths from the macros in the design:
  ```
  create_path_category -name from_RAM_128x16 -from_inst RAM_128x16
  ```
- The following command creates paths to the macros in the design:
  ```
  create_path_category -name to_RAM_128x16 -to_inst RAM_128x16
  ```
- The following command creates paths between the macros in the design:
  ```
  create_path_category -name between_RAM_128_256 -from_inst RAM_128x16 -to_inst
  RAM_256x16
  ```

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

delete_path_category

```
delete_path_category
[-help]
category_name
```

Deletes the selected category name.

The command can be applied when categories are created in Global Timing Debug.

For more information on creating path categories, see the 'Creating Path Categories' section in the Debugging Timing Results chapter of the *Innovus User Guide* document.

Parameter

`-help`	Outputs a brief description that includes the type and default information for each `delete_path_category` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man delete_path_category`
`category_name`	Specifies the name of the category to be deleted. *Data_type*: string, optional

Example

The following command deletes the category `worst_paths`:

```
delete_path_category worst_paths
```

gui_gtd_highlight_timing_report

```
gui_gtd_highlight_timing_report
[-help]
[-append]
[-color_index integer]
[-in_file filename]
[-no_arrow]
[-paths path_number | -all]
```

Highlights the selected paths in the user interface.

For more information on creating path categories, see the 'Creating Path Categories' section in the Debugging Timing Results chapter of the *Innovus User Guide* document.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `gui_gtd_highlight_timing_report` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man gui_gtd_ighlight_timing_report`
`-all`	Highlights all the paths. The option is of type boolean and required. *Data_type*: bool, required
`-append`	Appends a path to the current highlight. *Data_type*: bool, required
`-color_index` *integer*	Specifies the `color_index` of the path from 1 to 8. The option is of type int and optional with minimum value 1, and maximum value 8. *Data_type*: int, optional
`-in_file` *filename*	Name of the file. *Data_type*: string, optional
`-no_arrow`	Removes the highlighted arrow. *Data_type*: bool, optional
`-paths` *path_number*	Specify the number of the path. *Data_type*: string, required

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

gui_open_gtd

```
gui_open_gtd
[-help]
```

Opens the global timing debugger in the common user interface mode for accessing the GTD files report.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `gui_open_gtd` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man gui_open_gtd`

read_path_categories

```
read_path_categories
[-help]
in_file filename
```

Loads the path category file in the Timing Debug form. The path category file contains category definitions that you saved in an earlier timing debug analysis. To save path categories, use the `write_path_categories` command.

For more information on creating path categories, see the 'Creating Path Categories' section in the Debugging Timing Results chapter of the *Innovus User Guide* document.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `read_path_categories` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man read_path_categories`
`in_file` *`filename`*	Specifies the name of the category file. *Data_type*: string, required

Example

The following command loads the path category file `category.cat`:

```
read_path_categories in_file category.cat
```

Related Topics

- `write_path_categories`
- The Timing Budgeting chapter of the *Innovus User Guide* document.

read_timing_debug_report

```
read_timing_debug_report
[-help]
[-name report_name]
[{-proto [-slack_margin number]  [-num_path number]}]
[-num_path]
timing_report_filename
```

Loads the violation report in Innovus for debugging timing results.

Note: The violation report that you specify in this command has a special machine readable format. Use the `report_timing -machine_readable` command or `time_design -timing_debug_report` command to generate the machine readable violation report.

For more information on creating path categories, see the 'Creating Path Categories' section in the Debugging Timing Results chapter of the *Innovus User Guide* document.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `read_timing_debug_report` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man read_timing_debug_report`
`timing_report_filename`	Specifies the name of the timing debug timing_report_file. *Data_type*: string, required
`-name`	Specifies the report name to load the machine readable timing report timing_report_files incrementally. *Data_type*: string, optional
-num_path	Specifies the number of paths to be reported in the detailed path violations. *Data_type*: int, optional
-proto	Creates flex model categories and displays the top path of the top 8 (by default) categories. This option can be used for design that has flexModels. *Data_type*: bool, required
-slack_margin number	Specifies the additional specified slack. *Data_type*: float, optional

Examples

- The following command loads the machine readable timing report `top.mtarpt`:
  ```
  read_timing_debug_report top.mtarpt
  ```
- The following commands load two machine readable timing reports `top1.mtarpt` and `top2.mtarpt` together:
  ```
  read_timing_debug_report -name default_report top1.mtarpt
  read_timing_debug_report -name default_report top2.mtarpt
  ```
  GTD will first load the report `top1.mtarpt`, then append `top2.mtarpt` incrementally to the

current report.
Note: The `name` can be specified by user with any string, it is not the `timing_report_file` name.

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

write_category_summary

```
write_category_summary
[-help]
out_file <string>
[[-sort_low_to_high | -sort_high_to_low ]
[-sort_by_tns | -sort_by_wns ]]
[-csv | {-no_frame_fix_width [-no_split ]}]
```

Writes a text file containing the following information.

- Category name
- Total number of paths
- Number of passing paths
- Number of failing paths
- Worst negative slack
- Total negative slack

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_category_summary` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man write_category_summary`
`-sort_low_to_high`	Specifies that the report in ascending order, should specify option `-sort_by_tns` or `-sort_by_wns`. *Data_type*: bool, optional
`-sort_by_tns`	The TNS value specified by the sorting key through the option `-sort_low_to_high` or `-sort_high_to_low`. *Data_type*: bool, optional

`-sort_by_wns`	The WNS value specified by the sorting key through the option `-sort_low_to_high` or `-sort_high_to_low`. *Data_type*: bool, optional
`-csv`	Reports entries in csv format. *Data_type*: bool, optional
`-sort_high_to_low`	Specifies that the report in descending order, should specify option `-sort_by_tns` or `-sort_by_wns`. *Data_type*: bool, optional
`-no_frame_fix_width`	Specifies that the table columns have a fixed minimum width, but no maximum width (the data does not wrap). Column data that fits within the column's minimum width will left-justify and pad its location to fill the specified column space. Column data that is longer than the column's minimum width will take as much space in the table as needed. If a column is overwritten by the data from the preceding column, its data will begin on a new line at the correct column location. *Default:* `-frame` *Data_type*: bool, optional
`-no_split`	Specifies that each column follows the preceding column without splitting to a new line, if the data in one column overruns the next column. The wrapping behavior for data is controlled by the size of the display window. This format is useful for machine parsing the report. **Note:** You must specify `-no_frame_fix_width` in order to use this parameter. *Data_type*: bool, optional
out_file `fileName`	Specifies the name of the category report file. *Default*: `category.rpt` *Data_type*: string, required

Examples

The following command writes a category summary file `category.rpt`:

```
write_category_summary out_file category.rpt
```

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

write_histogram_view

```
write_histogram_view
[-help]
file_name string
[-type string]
```

Saves (dumps) the image of the histogram shown in *Global Timing Debug* automatically during the process.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_histogram_view` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man write_histogram_view`
`file_name string`	Specifies the name of the image file to save the histogram. *Data_type*: string, required
`-type string`	Specifies the type of file (image format) to be saved. Options are `bmp/jpg/gif/tif/csv`. *Default*: `bmp` *Data_type*: string, optional

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

write_path_categories

```
write_path_categories
[-help]
out_file filename
```

Saves the selected categories in a path category file. You can use the category file to load saved category definitions in a new timing debug session. To load the saved category definitions, use the `read_path_categoriess` command.

For more information on creating path categories, see the 'Creating Path Categories' section in the Debugging Timing Results chapter of the *Innovus User Guide* document.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_path_categories` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man write_path_categories`
`out_file` *`filename`*	Specifies the name of the category file. *Data_type*: string, required

Example

The following command saves the path category file `category.cat`:

```
write_path_categories out_file category.cat
```

Related Topics

- `read_path_categories`
- The Timing Budgeting chapter of the *Innovus User Guide* document.

write_path_list_summary

```
  write_path_list_summary
[-help]
[-category string]
[-compress]
[-csv]
-report fileName
```

Writes the Path List categorized summary into a text and/or CSV file.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_path_list_summary` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man write_path_list_summary`
`-category string`	Specifies the category of paths to be stored into the CSV file. *Data_type*: string, optional
`-compress`	Compresses the output file in the `.gzip` file format. *Data_type*: bool, optional
`-csv`	Reports entries in the CSV format. *Data_type*: bool, optional
`-report fileName`	Specifies the name of the CSV output file. *Data_type*: string, required

Related Topics

The Timing Budgeting chapter of the *Innovus User Guide* document.

write_text_timing_report

```
write_text_timing_report
[-help]
[-machine_readable file.mtarpt |
-category category_name]
[-format{{column1 width1} {column2 width2} ...} ]
[-path_spec path_specification]
[-summary] |
report_file file.tarpt
```

Writes a text file containing information about paths that have been loaded from a `.mtarpt` file from Timing Debug, either with the `load_timing_debug_report` command or in the *Display/Generate Timing Report* form in the GUI.

Paths are selected as follows:

- If only one `.mtarpt` file is loaded and no other parameters are specified, then the tool writes all the paths contained in the loaded `.mtarpt` file.
- If there are several `.mtarpt` files loaded, you must specify the `.mtarpt` file from which the tool can select the paths, except if a category is specified.

You can use this report for performing timing analysis.

If only one machine-readable report file is loaded, then the tool writes all paths from that file into the output report. If more than one file is loaded, then the tools issues an error message.

Note: The generated report cannot be read back into the timing debug environment.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_text_timing_report` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man write_text_timing_report`
`-category category_name`	

	Specifies the category of paths to write to the text file. You cannot specify `-machine_readable` if you specify this parameter. *Data_type*: string, optional
`-format{{`*`column1 width1`*`} {`*`column2 width2`*`} ...}`	
	Formats the report according to the specified column name and its width. The column-width pair specifies the column to display in the report and the width of that column. Multiple column names can be specified. *Data_type*: string, optional
`-machine_readable` *`file.mtarpt`*	
	Specifies the name of the `.mtarpt` file to read and convert to a text file. You cannot specify this parameter if you specify `-category`. *Data_type*: string, optional
`-path_spec` *`path_specification`*	
	Writes a single number or path range separated by blank space. A path range is two numbers separated by a minus "-" sign. You can use this parameter only if a single file is specified or loaded. *Data_type*: string, optional
`report_file` *`file.tarpt`*	
	Specifies the name of the text output file. *Data_type*: string, required
`-summary`	Writes the file header only. Use this parameter if you do not need a detailed table. *Data_type*: bool, optional

Examples

- The following command loads machine-readable report `top.mtarpt`:
  `load_timing_debug_report top.mtarpt`
- The following command reads the `top.mtarpt` report and reports paths 1 through 50 in the `top_tarpt.txt` file.

```
write_text_timing_report -machine_readable top.mtarpt -path_spec {1-50}
report_file top_tarpt.txt
```

Timing Modeling Commands

- check_timing_model
- merge_model_timing
- report_timing_model
- write_timing_model

check_timing_model

```
check_timing_model
[-help]
[-absolute_cap_tolerance float]
[-absolute_tolerance float]
[-absolute_transition_tolerance float]
-compare_file string
[-ignore_view]
-out_file string
[-percentage_cap_tolerance float]
[-percentage_tolerance float]
[-percentage_transition_tolerance float]
-reference_file string
```

Compares two reports that contain interface timing characteristics generated by the `report_timing_model` command.

This command compares the interface timing report generated by using the `report_timing_model` command on the original netlist with the interface timing report generated on the model extracted for the same design.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `check_timing_model` parameter. For a detailed description of the command and all of its parameters, use the man command: `man check_timing_model`.
`-absolute_cap_tolerance` *float*	Specifies the tolerance value for capacitance (as an absolute value) while comparing two report files. This parameter specifies the permissible difference, as an absolute value, between the capacitance values of two report files. If the difference in the value of capacitance exceeds the absolute tolerance value specified, the comparison status is set to `FAIL`. **Note:** When this parameter is not specified, the software uses the absolute value specified with the `-absolute_tolerance` parameter. If the `-absolute_tolerance` parameter is not specified, the value defaults to `0`.  When the `-percentage_cap_tolerance` and `-absolute_cap_tolerance` parameters are used together, the comparison status is set to `FAIL` only when the difference in the value of capacitance exceeds the specified absolute as well as percentage tolerance values.
`-absolute_tolerance` *float*	Specifies the absolute tolerance value. The tolerance value is used when there is a difference between the timing characteristics of the reference file (`-reference_file`) and the file that is being compared (`-compare_file`) to determine the `PASS` or `FAIL` status of the comparison. If the difference in the value of a timing characteristic exceeds the absolute tolerance value, the comparison status is set to `FAIL`. **Note:** When used with the `-percentage_tolerance` option, the difference in the value of a timing characteristic should exceed both absolute and percentage tolerance values for the comparison result status of an arc to be `FAIL`. *Default*: `0`

`-absolute_transition_tolerance` *`float`*	Specifies the name of the report file that contains the interface timing characteristics extracted from the model. The timing characteristics of this file are compared with the timing characteristics of the reference file that you specify with the `-reference_file` option.
`-compare_file` *`string`*	Specifies the name of the report file that contains the interface timing characteristics extracted from the model created using the model extraction command.
`-ignore_view`	Compares non-MMMC design `report_timing_model` output report with the MMMC design output report (of `report_timing_model` command). When you specify this parameter, the software ignores the view information while comparing the reports. So you do not require to create dummy views for timing model validation flow.
`-out_file` *`string`*	Specifies the name of the output file in which the comparison results will be generated. This file contains the `PASS` or `FAIL` status for the timing data comparison.

`-percentage_cap_tolerance` *float*	Specifies the tolerance value for capacitance (as a percentage) while comparing two report files. This parameter specifies the permissible difference, in percentage, between the capacitance values of two report files. If the percentage difference in the value of capacitance exceeds the percentage tolerance value specified, the comparison status is set to `FAIL`. **Note:** When this parameter is not specified, the software uses the percentage value specified with the `-percentage_tolerance` parameter. If the `-percentage_tolerance` parameter is not specified, the value defaults to `0`. When the `-percentage_cap_tolerance` and `-absolute_cap_tolerance` parameters are used together, the comparison status is set to `FAIL` only when the difference in the value of capacitance exceeds the specified absolute as well as percentage tolerance values.
`-percentage_tolerance` *float*	Specifies the percentage tolerance value for comparing the timing data of two report files. The percentage tolerance value is used when there is a difference between the timing characteristics of the reference file (`-reference_file`) and the file that is being compared (`-compare_file`) to determine the `PASS` or `FAIL` status of the comparison. If the percentage difference in the value of a timing characteristic exceeds the percentage tolerance value, the comparison status is set to `FAIL`. **Note:** When used with the `-absolute_tolerance` option, the difference in the value of a timing characteristic should exceed both percentage and absolute tolerance values for the comparison result status of an arc to be `FAIL`. *Default*: `0`

`-percentage_transition_tolerance` *float*	Specifies the tolerance value for transition time at ports (as a percentage) while comparing two report files.This parameter specifies the permissible difference, in percentage, between the transition time at ports of two report files. If the percentage difference in the transition time exceeds the percentage tolerance value specified, the comparison status is set to `FAIL`. **Note:** When this parameter is not specified, the software uses the percentage value specified with the `-percentage_tolerance` parameter. If the `-percentage_tolerance` parameter is not specified, the value defaults to `0`. When the `-percentage_transition_tolerance` and `-absolute_transition_tolerance` parameters are used together, the comparison status is set to `FAIL` only when the difference in the value of transition exceeds the specified absolute as well as percentage tolerance values.
`-reference_file` *string*	Specifies the name of the reference file that is used for comparison. This is the report file that was generated by using the `write_timing_model` command on the original design. The file specified with the `-compare_file` option is compared with this file.

Examples

- The following command compares the timing characteristics of the `sample_compare.rpt` file with the `sample_reference.rpt` file and generates the comparison results in the `sample_output.rpt` file:

```
check_timing_model -reference_file sample_reference.rpt -compare_file
sample_compare.rpt
-out_file sample_output.rpt
```

```

merge_model_timing

```
merge_model_timing
[-help]
-input_library_file string
[-keep_separate_arc]
[-merged_library_file string]
-mode_group string
-modes string
[-pin_cap_tolerance float]
[-tolerance float]
```

Merges extracted timing models (ETM) for various analysis views into a single output.

The `merge_model_timing` command should be the last command in the run script. Also, this command should be run separately in a session when a design is not loaded.

When the DRV values are different in the libraries that are merged, then the software saves the worst value of the DRV with a warning message.

If the DRV values are not equal, the greater value is stored for the following:

- Minimum transition
- Minimum capacitance
- Minimum fanout

The smaller value is stored for the following, in case of unequal DRVs:

- Maximum transition
- Maximum capacitance
- Maximum fanout
- Fanout load

Parameters

`-keep_separate_arc`	Enables creating separate timing arcs with respective modes.
`-input_library_file` *string*	Specifies input library files that are to be merged.
`-modes` *string*	Specifies the mode names required for merging the libraries. The number of mode names should be equal to the number of input libraries.
`-mode_group` *string*	Specifies the name of the mode group.
`-merged_library_file` *string*	Specifies the name of the merged library output file name. By default, the output file name is `merge.lib`.
`-pin_cap_tolerance` *float*	Specifies the pin capacitance tolerance for making tolerance comparison for library merging.
`-tolerance` *float*	Specifies the tolerance value for making tolerance comparison for library merging.

Examples

- The following command merges library files `model1.view1.lib` and `model1.view1.lib.ref` into a single output file:

```
merge_model_timing -input_library_file "model1.view1.lib model1.view1.lib.ref"
-modes "v1 v2" -mode_group v1_v2
```

Related Information

- `write_timing_model`

report_timing_model

```
report_timing_model
[-help]
model_timing_report_file
[-in_ports <string>]
[-nworst <integer>]
[-out_ports <string>]
[-slew_propagation {worst | path_based}]
[-type {arc | slack}]
[-verbose]
[-view <string>]
-setup string | -hold string
```

Writes the interface timing characteristics of the design in the specified timing model report file.

The report file contains the following sections:

- `Worst-Case Arc/Slack`: Contains details about the extracted arcs and the slack or delay across them depending on the argument specified with the `-type` option.
- `Transition Time`: Contains information about transition time at ports.
- `Capacitance`: Contains the capacitance values for the ports.
- `Design Rules`: Contains the design rules applied to the ports.

The command reports unconstrained arcs delays by default.

Parameters

`-help`	Prints out a brief description that includes type and default information for each `report_timing_model` parameter. For a detailed description of the command and all of its parameters, use the man command: man `report_timing_model`.
`-hold` *string*	Write the paths corresponding to early analysis.

`-in_ports {`*`port_list`*`}`	Restricts the `report_timing_model` report to the input ports specified with this parameter. As a result, the software considers the timing paths related to the specified input ports only, while generating the report. If this parameter is not specified, all the input ports in the design are considered while generating the report.
`model_timing_report_file`	Specifies the name of the interface timing model report file that will be generated with the interface timing characteristics of the loaded design.
`-nworst` *`value`*	Specifies the number of paths to be enumerated for each end point. **Note:** The extracted model will contain greater number of setup/hold paths per end point because it will have lesser end points compared to the original netlist. Therefore, it is recommended that you use a greater `-nworst` value such as`40` while writing a timing report for the extracted model to derive better correlation.
`-out_ports {`*`port_list`*`}`	Restricts the `report_timing_model` report to the output ports specified with this parameter. As a result, the software considers the timing paths related to the specified output ports only, while generating the report. If this parameter is not specified, all the output ports in the design are considered while generating the report.
`-setup` *`string`*	Writes the paths corresponding to late analysis.
`-slew_propagation {worst | path_based}`	Sets the slew propagation mode to use for dumping the timing characteristics of the design.
`-type {arc | slack}`	Determines whether to report arc delay values (`arc`) or the worst-slack values (`slack`).
`-view` *`view_name`*	Specifies a view name. The report can be generated for a specific view name.
`-verbose`	Prints the command progress details.

Example

- The following command extracts the interface timing characteristics of the currently loaded design and writes out the report file named `sample.rpt` with the arc delay information:

```
report_timing_model -type arc sample.rpt
```

```

```

Builds a Liberty (`.lib`) format model for the top cell, which is the timing model equivalent of the original design. The model is extracted for the given analysis modes, PVT conditions, and parasitics. If any one of these parameters change, then you must extract the model again. The model is extracted for a range of input slews and load capacitances. If you do not specify these ranges, the software automatically computes the default values. The extracted model defines all of the top-level ports of the design as pins. Additionally, all other design pins that are targets of `create_clock` or `create_generated_clock` are retained as internal pins.

For model extraction, your design must be properly constrained. For example, no clock or data conflicts can be present. Use the `check_timing` command and correct all errors prior to model extraction.

Parameters

`-help`	Prints out the command usage.
`-absolute_tolerance_validation` *float*	Specifies the absolute tolerance value to be used during the validation of extracted ETM. For more details refer to `check_timing_model -absolute_tolerance`. The integer value specified with this parameter is read as ns/ps depending upon the time unit. *Default:* 3ps
`-absolute_tolerance_optimistic_validation` *float*	Specifies the absolute tolerance limit for flagging an optimistic failure. An optimistic path violating the absolute as well as percentage tolerance limit will be flagged as FAIL in the `check_timing_model` command output report. You can use this parameter when the `-validation_dir` is used with model extraction. *Default*: 15ps
`-absolute_tolerance_pessimistic_validation` *float*	Specifies the absolute tolerance limit for flagging a pessimistic failure. A pessimistic path violating the absolute as well as percentage tolerance limit will be flagged as FAIL in the `check_timing_model` command output report. You can use this parameter when the `-validation_dir` is used with model extraction. *Default*: 15ps

`-assertions` *`constraint_filename`*	Dumps the false and multicycle path exceptions associated with the internal pins, which will be preserved in the grey box models. The exceptions are dumped in SDC format and can be used while instantiating grey box models. *Default*: `model.asrt`
`-cell_name` *`cell_name`*	Specifies the cell name used in the timing model. *Default:* The name of the top cell to be extracted.
`-clock_transitions {`*`clk_slew1 clk_slew2...`*`}`	Specifies a range of slew values used at all clock pins. The list of values must be enclosed by curly braces. If this parameter is not specified, the software automatically computes the appropriate values.
`-gain` *`integer`*	Represents an increase in the number of delay arcs if a pin is removed. This option reduces the extracted model size in scenarios where removing a pin can result in increased model size. The gain at an internal pin can be defined as: `(number of incoming delay arcs * number of outgoing delay arcs) - (number of incoming delay arcs + number of outgoing delay arcs` If an internal pin has a gain greater than the specified number, then that pin needs to be preserved in order to reduce the extracted model size. *Default*: `0`

`-include_aocv_weights`	Writes the stage weight on individual arcs. Before using this option, it is mandatory that the AOCV libraries are read in and AOCV analysis is enabled. The weights written in ETM are not meant to derate the model. Model itself will be containing the derated delays. The stage weight extracted on arcs will be used to calculate the stage count of chip level paths going across the ETM. The stage weights in the extracted model are dumped as user defined attributes. This will require defining two attributes at arc level.
	• `define ("aocv_weight","timing","float");`
	• `define ("clock_aocv_weight","timing","float");`
	The first attribute will be used for combinational and trigger arc and will be dumped at arc level as below.
	`timing () { timing_type : combinational; timing_sense : positive_unate; aocv_weight : 4; . }`
	The check arcs will be dumped with two separate stage weights for data and clock.
	`timing () { timing_type : setup_rising; aocv_weight : 4; clock_aocv_weight : 3; . }`

`-input_transitions {`*`input_slew1 input_slew2 ...`*`}`	Specifies a range of slew values used at all input pins. Enclose the list of values with curly braces. If this parameter is not specified, the software automatically computes the appropriate values.
`-lib_name` *`lib_name`*	Specifies the library name used in the timing model. Write extracted timing models in the liberty format by specifying the `.lib` file suffix. *Default:* The name of the top cell to be extracted.
`-max_num_loads` *`value`*	Specifies the maximum number of output load values used for delay arc characterization. A low value of 1 or 2 improves runtime and memory usage but may significantly degrade model accuracy. Use this parameter only if the model size or model extraction time is critical. *Default:* `64`
`-max_num_transitions` *`value`*	Specifies the maximum number of input slews or clock slews used for delay and check arc characterization. Specifying a low value of 1 or 2 improves runtime and memory but may significantly degrade model accuracy. Using the `-max_num_transitions` parameter has a larger impact on runtime and memory than the `-max_num_loads` parameter. Use this parameter only if the model size or the model extraction time is critical. *Default:* `64` The `max_num_slews` and `max_num_loads` parameters specify only the maximum limits on how many slew and load points are chosen. The software scans the gates connected to the input and output ports to calculate the number of points.

model_file	Specifies the name of the output file. Avoid problems with rebind by using the -lib_name and -cell_name parameters instead of using the default names.
-output_loads {*output_load1output_load2 ...*}	Specifies a range of load values used at all output pins. Enclose the list of values by curly braces. If this parameter is not specified, the software automatically computes the appropriate values.
-include_power_ground	Allows power or ground related pin information to be extracted inside the extracted model.
-percent_tolerance_validation *float*	Specifies the percentage tolerance value to be used during the validation of extracted ETM. For more details refer to check_timing_model -percent_tolerance. *Default:* 3%
-percent_tolerance_optimistic_validation *float*	Specifies the percentage tolerance limit for flagging an optimistic failure. An optimistic path violating percentage as well as absolute tolerance limit will be flagged as FAIL in the check_timing_model command output report. You can use this parameter when the -validation_dir is used with model extraction. *Default*: 3%
-percent_tolerance_pessimistic_validation *float*	Specifies the percentage tolerance limit for flagging a pessimistic failure. A pessimistic path violating percentage as well as absolute tolerance limit will be flagged as FAIL in the check_timing_model command output report. You can use this parameter when the -validation_dir is used with model extraction. *Default*: 3%

`-post_check`	Checks the generated ETM library using Valus.
`-precision` *value*	Specifies the floating point precision used for the timing model. For example, the floating point precision for 3.0089 can be changed as follows:
	Precision Data Value in .lib 4 3.0089 3 3.009 2 3.01 1 3.0 *Default:* `4`
`-resolution` *value*	Specifies the magnitude of delay difference that can be ignored by the extractor. *Default:* `0.001` *Type*: Float
`-tolerance` *value*	Specifies the accuracy level of extractor in percent. For example, 5.0 represents a plus or a minus 5.0 percent allowable error in the extracted model. The higher the tolerance, the faster the extraction time. *Default:* `1.0` *Type:* Float
`-validation_dir` *string*	Enables the validation of generated ETM for corresponding view and displays number of failures at the end of validation. It is mandatory to specify the name of validation directory with this option, this contains the `report_timing_model`, `check_timing_model`, and summary reports.
`-view` *viewname*	Specifies the current active view.

`-verilog_shell_file` *`filename`*	Generates a Verilog shell file that instantiates the timing model. This parameter is useful for validating the model. Use the `-verilog_shell_module` parameter to specify the name of the top module in this Verilog file.
`-verilog_shell_module` *`top_module_name`*	Specifies the top module name of the Verilog shell file. *Default:* `test_shell`

Examples:

- The following command builds a `.lib` model (`block.lib`) for the block:

  ```
  write_timing_model block.lib
  ```

- The following command creates the timing model for the `test_model` cell belonging to the `test_lib` library, and writes the model into the `test.lib` liberty file:

  ```
  write_timing_model -cell_name test_model -library_name test_lib test.lib
  ```

add_repeater_by_rule

```
add_repeater_by_rule
[-help]
[-copy_net_attribute]
[-exclude_nets_file exclude_net_file]
[-include_nets_file inlcude_net_file]
[-net_mapping file_name]
[-pre_route | -post_route | -along_route]
[-report_dir directory_name]
[-report_ignored_nets ignored_net_file]
[-rule file_name]
[-template]
```

Inserts buffers and/or inverters to nets, as defined in a rule file. By default, inserts available buffers and/or inverters with the smallest total area cost while satisfying the rules. As compared to DRV fixing, `add_repeater_by_rule` does not consider transition violations (maxTran) or any timing information. Instead, it constrains max total net length, max radius length, max capacitance, max fanout count, and so on. Also, `add_repeater_by_rule` does not legalize newly added buffers. You need to legalize the added buffers to a legal location.

The command provides an efficient, buffering method for top-level designs.

Note: Max radius length refers to the sum of wire lengths from the driver to the farthest sink and max total net length refers to the total (sum) wire lengths throughout the target net.

The command has the following features:

- Supports multiple buffer/inverter/AO cells simultaneously
- Supports multiple types of constrains simultaneously
- Provides complete MSV compatibility solution
- It is multithreaded

The rule file may contain two categories of constraints, where each category further breaks down to several constraint types. All constraints share the same syntax of ‘command value’.

1. Individual repeaters’ rule: constrains each repeater’s driving capability.

- max net total length (um): SetInverterMaxNetLength, SetBufferMaxNetLength, SetBufferMinLayerMaxNetLength, SetInverterMinLayerMaxNetLengt

h

- max radius length (um): SetInverterMaxRadiusLength, SetBufferMaxRadiusLength
- max capacitance (pF): SetInverterMaxCap, SetBufferMaxCap
- max fanout count: SetInverterMaxFanout, SetBufferMaxFanout
- max fanout at sink count: SetMaxFanoutAtSink
- max wirelength (um) of the net driving the sink term: SetMaxNetLengthAtSink

2. Global default rule: constrains all other instances beyond those newly inserted repeater instances.

- default max net total length (um): SetDefaultMaxNetLength, SetDefaultMinLayerMaxNetLength
- default max radius length(um): SetDefaultMaxRadiusLength
- default max cap length (pF): setDefaultMaxCap
- default max fanout count: setDefaultMaxFanout
- default max sink radius length (um): SetDistLastRepToSink
- default max wirelength (um) of the net driving the sink term: SetMaxNetLengthAtSink

Those constraints can be used individually or combined. However, at least one valid repeater must be specified in the rule file. If the global default rule for certain constraint type is omitted from the rule file, the command automatically picks the tightest constraint from the repeaters defined in the rule file under the ***same*** type of constraint as the default constraint. A sample rule file is shown in the "Example" section.

The following three layer-based rules are provided to support specifying net length constraints independently for each user specified layer:

- minimum layer for max net total length (um): SetBufferMinLayerMaxNetLength and SetInverterMinLayerMaxNetLength
- default minimum layer for max net total length (um): SetDefaultMinLayerMaxNetLength

Note: You must specify the bottom_preferred_routing_layer/top_preferred_routing_layer attribute for the nets that need layer-based buffering. If no attribute is present, the net will be routed with the default rule on default layers.

Use Model

When max layer constraint is specified:

```
SetBufferMaxNetLength BUF_X4M_A9TR 300.0
```

In the above scenario, ARR will buffer the net with `BUF_X4M_A9TR` at length intervals of `300um`.

When minimum layer support is also specified along with max layer constraint, then the following two scenarios are possible:

Example 1:

```
SetBufferMaxNetLength          BUF_X4M_A9TR     300.0
SetBufferMinLayerMaxNetLength  BUF_X4M_A9TR 6   500.0
```

In the above example, layers 2-5 will have a `300um` max length, and becasue there is a minimum layer constraint on the net of layer 6 or higher, the length constraint will be increased from `300` to `500um`.

Example 2:

When multiple minimum layer constraints are specified:

```
SetBufferMaxNetLength            BUF_X4M_A9TR     300.0
SetBufferMinLayerMaxNetLength    BUF_X4M_A9TR 6   500.0
SetBufferMinLayerMaxNetLength    BUF_X4M_A9TR 11  800.0
```

In the above example, layers 2-5 will have a `300um` max length; layers 6-9 will have a `500um` max length; and 11+ a `800um` max length.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `add_repeater_by_rule` parameter. For a detailed description of the command and all of its parameters, use `man add_repeater_by_rule` .
`-along_route`	Allows repeater insertion along the route. The database should be global-routed with pre-Route RC extraction before calling this option. **Note**: Run `place_detail` and `route_eco` if you specify this parameter. *Data_type*: bool, optional
`-copy_net_attribute`	When this parameter is specified, the net attributes set on the original nets are copied to the nets inserted by this command. *Data_type*: bool, optional
`-exclude_nets_file` *file_name*	

	Specifies a file that contains the names of hierarchical nets to exclude from rule violation repair. If a net appears in the files specified by both `-exclude_nets_file` and `-include_nets_file`, it is excluded from rule violation repair. *Data_type*: string, optional
`-include_nets_file` *file_name*	
	Specifies a file that contains the names of hierarchical nets considered by this command. If a net appears in the files specified by both `-exclude_nets_file` and `-include_nets_file`, it is excluded from rule violation repair. *Data_type*: string, optional
`-net_mapping` *file_name*	

	When specified, generates a file that maps the original net names to the nets inserted by this command. An example of the file format is provided below. In this example, `netA` is split into two nets; `FE_new_net1_netA` and `FE_new_net2_netA`.
	`netA FE_new_net1_netA`
	`netA FE_new_net2_netA`
	If, in the next iteration, `FE_new_net1_netA` is split again, the file would contain the following:
	`FE_new_net1_netA FE_new_net1_FE_new_net1_netA`
	`FE_new_net1_netA FE_new_net2_FE_new_net1_netA`
	Data_type: string, optional

`-post_route`	Allows repeater insertion along the route. The database should be detailed-routed with detailed RC extraction before calling this option. Preserves routing so that changes are minimized. **Note** : Run `place_detail` and `route_eco` if you specify this parameter. *Data_type*: bool, optional

`-pre_route`	Allows repeater insertion with different routing topologies. The database should be global-routed with pre-Route RC extraction before calling this option. When this parameter is specified, the software explores different typologies to optimally insert repeaters. *Data_type*: bool, optional
`-report_dir` *`directory_name`*	Specifies the directory where the software writes detailed failure reason report that is generated when this command runs. By default, the failure reason report is dumped in the `timingReports/ARRFailureReason/<design>` directory. For example, `timingReports/ARRFailureReason/<design>.arr.preRoute.rpt.gz` *Default*: `timingReports` *Data_type*: string, optional
`-report_ignored_nets` *`file_name`*	
	Reports the nets where no buffers were inserted and the reason the nets were ignored. *Data_type*: string, optional
`-rule` *`file_name`*	Specifies a file you create that should list the buffers and inverters and the length and capacitance rules for inserting each of them. Only buffers and inverters included in the rule file are inserted. *Data_type*: string, optional
`-template`	Writes a template rule file. **Note**: When the `-template` parameter is specified, the software does not honor any other parameters for this command. *Data_type*: bool, optional

Examples

- The following command explores different typologies to optimally insert repeaters:
  ```
  add_repeater_by_rule -rule rule1 -pre_route
  ```
- In a detailed routed database with RC extraction, the following command inserts repeaters along the route and preserves routing, so that changes are minimized:
  ```
  add_repeater_by_rule -rule rule1 -post_route
  ```
- The following command inserts repeaters on those nets specified in the file, `net_file1`:
  ```
  add_repeater_by_rule -rule rule1 -include_nets_file net_file1
  ```
- The following is an example of a template rule file:

```

add_tieoffs

```
add_tieoffs
[-help]
[-create_hport {true|false}]
[-keep_existing {true|false}]
[-lib_cell tieCellName+]
[-matching_power_domains {true|false}]
[-post_mask {true|false}]
[-power_domain powerDomainName]
[-prefix prefixName]
[-report_hier_ports {true|false}]
[-cell_pin cellName:cellPin | -instance_pin file_name | -exclude_pin file_name]
```

Adds instances of specified tie-off cells to the logical hierarchy of the design and connects the tie-off pins of netlist instances to the tie-off pins of the added instances. Thus, these instances provide the connectivity between the tie-high and tie-low pins of the netlist instances to power and ground. Use this command after placing the standard cells in the flow.

Note: If you do not specify parameters, this command uses the global parameters specified by the `add_tieoffs` attributes.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `add_tieoffs` parameter. For a detailed description of the command and all of its parameters, use the man command: `man add_tieoffs`.
`-cell_pin` *cellName:cellPin*	Specifies the cell pins that are to be tied. The cell format could be "`cellName1:cellPin cellName2:cellPin cellName3:cellPin`". Only the cell pins that have tie 0/1 connections and are specified in `-cell_pin` are changed to the tie cell. The left tie connections do not change. Default: `""` (empty string) *Data_type*: string, optional

`-create_hport {true | false}`	Allows the added tie cells to connect to tie pins across hierarchical boundaries if other constraints, such as maximum fanout and maximum distance, allow it. *Default:* `false` *Data_type*: bool, optional
`-exclude_pin` *file_name*	Specifies the excludePin file name. The file format is "instanceName/instancePin". Each line in the file contains one instance pin. Only the instance pins that have tie 0/1 connections and are not defined in this file are changed to the tie cell. The left tie connections do not change. Default: `""` (empty string) *Data_type*: string, optional
`-instance_pin` *file_name*	Specifies the instance pins file name. The file format is "instanceName/instancePin". Each line in the file contains one instance pin. Only the instance pins that have tie 0/1 connections and are defined in this file are changed to the tie cell. The left tie connections do not change. Default: `""` (empty string) *Data_type*: string, optional
`-keep_existing {true|false}`	When set to `true`, preserves the existing tie-offs, added in the previous run, in the design and adds new ones. *Default:* `false` *Data_type*: bool, optional
`-lib_cell` *tieCellName+*	Specifies the tie cells to add. You can only specify a maximum of two tie-cells, where one cell must be a tie-high driver, and the other a tie-low driver. The two tie-cell names must be surrounded by quotation marks. This parameter overrides cell name(s) specified by the add_tieoffs Category Attributes. Default: "" (empty string) *Data_type*: (base_cell)+, optional

`-matching_power_domains {true|false}`	Inserts tie cells in all power domains. *Data_type*: bool, optional
`-post_mask {true | false}`	Insert tie cells in post mask flow. Instructs the software to reuse existing tie cells to tie off a newly created spare instance in the design instead of adding or deleting tie cells. Searches for input pins that are tied to logical 1 or logical 0 and attempts to tie them off to tie high or tie low cells. *Default:* `false` *Data_type*: bool, optional
`-power_domain` *powerDomainName*	Inserts tie-off cell to the named PD. Default: `""` (empty string) **Note:** When this option is not specified, tool only inserts tie cells in the "default" power domain. *Data_type*: string, optional
`-prefix` *prefixName*	Specifies a prefix for the added tie-cell instances. Default: `""` (empty string) *Data_type*: string, optional
`-report_hier_ports {true | false}`	When the value of `-create_hport`is `true`, reports created port connections to a file named `tiehilo.rpt`. *Default:* `false` *Data_type*: bool, optional

Examples

- The following command adds tie-high and tie-low connectivity for designs with libraries that have cell named TIEOFF that provides both tie-high and tie-low connections. The instances added are prefixed with tieOff:

  ```
  add_tieoffs -lib_cell TIEOFF -prefix tieOff
  ```

- The following command adds tie-high and tie-low connectivity for designs with libraries that have separate tie-high and tie-low cells named TIEHI and TIELO respectively:

```
add_tieoffs -lib_cell "TIEHI TIELO"
```

- The following commands add tie-off connectivity for MSV designs with two power domains named `PD1` and `PD2`. The last command is necessary for the part of the design that is not in either of the two specified power domains.

```
add_tieoffs -lib_cell "TIEHI TIELO" -power_domain PD1
add_tieoffs -lib_cell "TIEHI TIELO" -power_domain PD2
add_tieoffs -lib_cell "TIEHI TIELO"
```

Related Information

- `check_tieoffs`
- `delete_tieoffs`
- The following section in Optimizing Timing chapter of *Innovus Stylus Common UI User Guide*
  - Adding Logical Tie-Off Cells

add_tieoffs Category Attributes

The root attributes in the add_tieoffs category are:

- add_tieoffs_cells
- add_tieoffs_create_hports
- add_tieoffs_honor_dont_touch
- add_tieoffs_honor_dont_use
- add_tieoffs_max_distance
- add_tieoffs_max_fanout
- add_tieoffs_module_prevention
- add_tieoffs_prefix
- add_tieoffs_report_hports

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `add_tieoffs` category, use the following command:

```
get_db -category add_tieoffs
```

add_tieoffs_cells

```
add_tieoffs_cells {{tieHi1 tieLo1} {tieHi2 tieLo2} ...}
```

Default: `""`

Data_type: string

Specifies the pairs of tie cells to be used by the `add_tieoffs` command. You can specify a maximum of two tie-cells in a cell list, where one cell must be a tie-high driver, and the other a tie-low driver.

A single cell with both tie connections, high and low, can be specified as below.

```
add_tieoffs_cells {{TieHiLo1} {TieHiLo2} {TieHiLo3} ….}
```

The software selects the nearest cell pair to make new tie connections during the post_mask flow.

Related Command

- `add_tieoffs`

add_tieoffs_create_hports

`add_tieoffs_create_hports {true | false}`

Default: `false`

Data_type: bool, read/write

Allows the added tie cells to connect to tie pins across hierarchical boundaries if other constraints, such as maximum fanout and maximum distance, allow it.

add_tieoffs_honor_dont_touch

`add_tieoffs_honor_dont_touch {true | false}`

Default: `false`

Data_type: bool, read/write

Allows both `add_tieoffs` and `add_tieoffs` commands to honor the `dont_touch` attribute set on instances, nets, cells, and modules.

Related Commands

- `add_tieoffs`
- `delete_tieoffs`

add_tieoffs_honor_dont_use

`add_tieoffs_honor_dont_use {true | false}`

Default: `false`

Data_type: bool, read/write

Honors `dont_use` attribute on cells.

add_tieoffs_max_distance

`add_tieoffs_max_distance` *`distanceValue`*

Default: `0`

Data_type: double, read/write

Specifies the maximum distance, in microns, between the tie-cell driver and the tie-pins. A value of `0` implies no distance constraint.

add_tieoffs_max_fanout

`add_tieoffs_max_fanout` *`fanOutValue`*

Default: `0`

Data_type: int, read/write

Specifies the number of tie-pins a tie-net can drive. A value of `0` implies no fanout constraint.

Example

The following set of commands set `TIEHI` and `TIELO` cells a maximum distance of 20 microns between the tie-cell pin and the tie-off input pins and a tie-net can drive up to 10 tie-pins:

```
set_db add_tieoffs_max_fanout 10
set_db add_tieoffs_max_distance 20
set_db add_tieoffs_cells "TIEHI TIELO"
```

add_tieoffs_module_prevention

`add_tieoffs_module_prevention {true | false}`

Default: false

Data_type: bool, read/write

When this attribute is set to `true`, the `add_tie_offs` command adds tie-cells for module instantiation port. Tie-cells may also be added inside the module to tie the output port of the module so that module function can be prevented.

add_tieoffs_prefix

`add_tieoffs_prefix` *`prefixName`*

Default: `""`

Data_type: string, read/write

Specifies a prefix for the added tie-cell instances.

add_tieoffs_report_hports

`add_tieoffs_report_hports {true | false}`

Default: `false`

Data_type: bool, read/write

Report created ports when `add_tieoffs_create_hports` is set. Report is saved to a file named `tiehilo.rpt`.

check_footprint

```
check_footprint
[-help]
```

Checks the timing library for missing footprint functions or timing information.

To view the above information in the software, use the man command: `man check_footprint`.

Related Topics

    - Using Cell Footprints

create_basic_path_groups

```
create_basic_path_groups
[-help]
[-expanded]
[-reset]
```

Explicitly creates standard path groups irrespective of the design stage. The following path groups are created:

- reg2reg (register-to-register)
- reg2cgate (register-to-clock-gate)
- default

Note:

- If a design does not have any reg2reg paths, or reg2cgate paths, this command will create the corresponding path group(s).
- If the specified path group, say `reg2reg`, already exists, the software will give the following warning:

  ```
  **WARN: (IMPOPT-3666): Path group reg2reg already exists. Skipping the creation of
  this path group.
  ```

Parameters

`-help`	Outputs a brief description that includes type and default information for each `create_basic_path_groups` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_basic_path_groups`.
`-expanded`	When this parameter is specified, the following path groups are created: • reg2reg • reg2cgate • in2reg • reg2out, and • in2out When this parameter is not specified, only the default path groups, reg2reg and reg2cgate, are created. **Note**: Timing optimization will consider these path groups in the same way as paths grouped using the `group_path` command. *Data_type*: bool, optional
`-reset`	Deletes all existing path groups. This is equivalent to running the `reset_path_group` command. **Note**: After deleting the existing path groups, new path groups, reg2reg and reg2cgate are created. *Data_type*: bool, optional

Examples

- The following command is used to create the standard path groups and assigns an effort level to each group:

  ```
  create_basic_path_groups
  ```

  The software returns the following information:

  ```
  Created reg2reg path group
  Effort level <high> specified for reg2reg path_group
  Created reg2cgate path group
  Effort level <high> specified for reg2cgate path_group
  ```

- The following commands are used to set the effort level for the reg2reg path group to high, and report the parameters of the path groups that are created:

  ```
  set_path_group_options reg2reg -effort_level low
  report_path_group_options
  ```

  The software prints the following report:

  ```
  ------------------------------------------------------------------------------
  -------------
  |Path Group|Effort|Adjustment(early/late)|Target
  Slack|weight|SkewingSlackCons|view          |
  ------------------------------------------------------------------------------
  -------------
  |reg2reg   | high | 0.1    /-0.2         | 0          |  2   |    0.3
  |AV_HL_FUNC_MIN_RC1 |
  |reg2cgate | high | 0.2    /0            | 0          |  1   |    0.5
  |AV_HL_FUNC_MAX_RC1 |
  ```

delete_buffer_trees

```
delete_buffer_trees
[-help]
[-exclude_nets_file excfilename]
[-footprint footprintname]
[-nets_file netsfilename | -nets list_of_nets]
[-preserve_route]
[-verbose]
```

Removes all buffers and inverter pairs, of all footprint types, on all nets in the design. With specific settings, this command can remove buffers and inverter pairs of the specified footprint type, or on specified nets only.

Note:

1. place_opt_design will automatically call `delete_buffer_trees` in the beginning, before global placement.
2. If you want to have a clean design with reduced density, or just clear all buffers and inverter pairs of a certain list of nets, it is recommended to call this command. This may allow you to do ECO on those nets.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `delete_buffer_trees` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_buffer_trees`
`-exclude_nets_file` *excfilename*	Specifies the input file that contains the names of nets to exclude from buffer removal. If a net appears in the files specified by both `-exclude_nets_file` and `-nets_file`, it is excluded. *Data_type*: string, optional
`-footprint` *footprintname*	Specifies the footprint of buffers to remove. If you do not specify this parameter, the Innovus software removes buffer instances with one input and one output terminal, and whose timing arc is not `SPECIAL`. *Data_type*: string, optional
`-nets` *list_of_nets*	Specifies the hierarchical nets to include during buffer removal. **Note**: The `-nets` and `-nets_file` parameters are mutually exclusive. *Data_type*: string, optional
`-nets_file` *netsfilename*	Specifies the file that contains the names of hierarchical nets to include during buffer removal. The Innovus software excludes all other nets. If a net appears in the files specified by both `-exclude_nets_file` and `-nets_file`, it is excluded. **Note**: The `-nets` and `-nets_file` parameters are mutually exclusive. *Data_type*: string, optional
`-preserve_route`	Specifies that nets not impacted by the buffer/inverter deletion process must have their routing unchanged. By default, the tool removes all the routes after running this command. *Data_type*: bool, optional
`-verbose`	When specified, displays additional debug messages in log file. For example, the failure reason for deletion of buffer and inverter pairs. *Data_type*: bool, optional

Example

- The following command Removes all buffers and inverter pairs, of all footprint types:

```
delete_buffer_trees
*** Start delete_buffer_trees ***
Info: Detect buffers to remove automatically.
Analyzing netlist ...
Updating netlist

*summary: 79 instances (buffers/inverters) removed
*** Finish deleteBufferTree (0:00:09.6) ***
```

- The following command removes all buffers of footprint type B_1P:

```
delete_buffer_trees -footprint B_1P
```

delete_tieoffs

```
delete_tieoffs
[-help]
[-cells tieCellName | "listOfTieCellNames"]
[-prefix prefixName]
```

Deletes placed tie cells from the netlist and reconnects the tie input pins back to `1'b1` and `1'b0`. Use this command if there are existing tie cells in design.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `delete_tieoffs` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_tieoffs`
`-cells` *tieCellName* | "*listOfTieCellNames*"	
	The *tieCellName* argument specifies the cell name to delete. The "*listOfTieCellNames*" argument specifies the list of cell names to be deleted, which must be surrounded by quotation marks. **Note**: The *tieCellName* and "*listOfTieCellNames*" arguments are mutually exclusive. *Data_type*: string, optional
`-prefix` *prefixName*	Specifies the prefix of the instances to delete. *Data_type*: string, optional

Note: If you do not specify any parameters, the command uses the global cell names if they were set previously with the `add_tieoffs` Category attributes.

Example

- The following command deletes all placed tie-off cell instances with the prefix `ABC`:
  ```
  delete_tieoffs -prefix ABC
  ```
- The following command deletes all placed tie-off cells named: `TIEOFF`:

```
delete_tieoffs -cells TIEOFF
```

eco_clone

```
eco_clone
[-help]
[-allow_sequential]
[-auto]
[-balance num]
[-cells list_of_cells]
[-delete_buffer_trees]
[-dont_legalize]
[-dont_resize]
[-force]
[-from pin names]
[-instances instance names]
[-locs list_of_locations]
[-loop number]
[-max_levels integer]
[-max_num_loads integer]
[-min_num_loads integer]
[-nets list_of_nets]
[-num_clones number]
[-pins list_of_term_lists]
[-preview]
[-radius number]
[-same_hier_only]
[-to pin names]
[-verbose]
```

Clones combinational logic if logic does not have any user constraints like don’t size/touch and so on. This command is used when you want to clone combinational logic as manual ECO. It does not work for sequential logic like flops. The `-from` and `-to` parameters are used to specify the 'from' and 'to' pins for cloning.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `ecoClone` parameter. For a detailed description of the command and all of its parameters, use the man command: `man ecoClone`

`-allow_sequential`	Used with `-auto` to try cloning at the sequential gates too. *Data_type*: bool, optional
`-auto`	Applies cloning and buffering automatically. The software identifies and clones combinational logic based on critical endpoints distance-based clustering. *Data_type*: bool, optional
`-balance` *number*	When specified, forces the number of loads on each clone to be within the specified number percentage (*num %*). The default balance is 10%. *Data_type*: integer, optional
`-cells` *list_of_cells*	Specifies the list of cells to use for the clones. **Note**: ◦ If this parameter is not specified, the clones have the same cell as the original gate. ◦ If only one cell is specified in the list, all the clones are created with that cell. ◦ If the `-locs` and `-terms` parameters are not specified, you can only specify one cell in that list. ◦ If the `-locs` and/or `-terms` parameters are specified, you can also specify numClones cells, which is one cell for each clone. ◦ It is not possible to specify a new cell for the original gate, so the original gate is not resized. *Data_type*: string, optional
`-delete_buffer_trees`	When specified, the software attempts to delete buffer trees driven by instances to clone. **Note**: The deletion of buffer trees with user constraints is skipped. *Data_type*: bool, optional

`-dont_legalize`	When specified, the software may leave cloned instances overlapped with the original ones. This means the software will not try to legalize instances. This means that if space is available, it will place legally, otherwise it will leave cloned instances overlapped with the original ones. *Data_type*: bool, optional
`-dont_resize`	Specifies that neither the original nor the new (cloned) instances should be resized. *Data_type*: bool, optional
`-force`	When specified, forces instance cloning, even if it worsens QoR or causes illegal placement. *Data_type*: bool, optional
`-from` *pin names*	Specifies 'from' pins. You can specify a single pin or a list of pins. *Data_type*: string, optional
`-instances` *instance_names*	Specifies the instances to be cloned. You can specify a single instance or a tcl list of instances to be cloned. **Note**: The `-nets` and `-instances` parameters are mutually exclusive. *Data_type*: string, optional
`-locs` *list_of_locations*	Specifies the location of each clone. This parameter is used along with the `-num_clones` parameter. When this parameter is specified, a location should be specified for each clone, so the length should be numClones. The length can be numClones+1, in which case, the first location is used for the original gate. When the locations are specified, the sink partitions are assigned to the closest clone. *Data_type*: string, optional
`-loop` *number*	Repeat cloning at most *number* times, as far as new instances are being created. The original and new instances within the min/max number of loads range are valid targets at each iteration. *Default*: `0` (means no limit) *Data_type*: integer, optional

`-max_levels` *integer*	Specifies the level of instances that the software needs to traverse for cloning. Zero value means the software will clone everything till the origin of logic. *Default*: 0 (meaning infinite) *Data_type*: integer, optional
`-max_num_loads` *integer*	Specifies that cloning should be skipped for instances driving more than the specified number of loads. *Default*: `50000` *Data_type*: integer, optional
`-min_num_loads` *integer*	Specifies that cloning should be skipped for instances with less than or equal to the specified number of loads. **Note**: The `-min_num_loads` and `-num_clones` parameters are mutually exclusive. *Data_type*: integer, optional
`-nets` *list_of_nets*	Specifies the nets to be cloned. You can specify a single net or a tcl list of nets to be cloned. **Note**: The `-nets` and `-instances` parameters are mutually exclusive. Wildcards are allowed for this parameter. *Data_type*: string, optional
`-pins` *list_of_term_lists*	Specifies the partitions, so it is a list of term lists. This parameter is used along with the `-numClones` parameter. When this parameter is specified, there should be one partition for each clone, so the length should be numClones. The terms that are not in any partition are assigned to the partition driven by the original gate. The length can be numClones+1, in which case the first partition is for the original gate. In that case, all the sinks should be in a partition. *Data_type*: string, optional

`-preview`	When specified, provides a preview of what would be done, while leaving the netlist untouched. This means that the software will report instances that will be cloned and the changes that will be applied to the netlist without actually changing the netlist. *Data_type*: bool, optional
`-num_clones` *number*	Specifies the number of clones to create. The default value is `0` and in that case, it is computed from the `-min_num_loads` parameter. **Note**: The `-min_num_loads` and `-num_clones` parameters are mutually exclusive. *Default:* `0` *Data_type*: integer, optional
`-radius` *number*	Specifies that the clones should be placed within a radius of the specified number of rows from their preferred location based on the original instance location and the center of mass of the new set of loads. *Default*: `10` *Data_type*: integer, optional
`-same_hier_only`	Specifies that only those loads will be considered that are in the same hierarchy as the driver. *Data_type*: bool, optional
`-to` *pin names*	Specifies 'to' pins. You can specify a single pin or a list of pins. *Data_type*: string, optional
`-verbose`	When specified, verbose messages are displayed during the cloning of instances. *Data_type*: bool, optional

Example

The following command will clone logic till `$to` pins with more then `6` loads, while forciby deleting the buffer tree:

```
eco_clone -to $to -verbose  -min_num_loads 6 -delete_buffer_trees -force
```

eco_clone_flop

```
eco_clone_flop
[-help]
[-force]
-instances flop_instance_name
[-max_num_loads num_of_loads]
[-num_clones number]
[-radius num_of_rows]
[-verbose]
```

Clones flop instances as long as the flops meet the following criteria:

- They are not FIXED
- They are allowed to be resized
- When they do not share synchronization signals with some other instance

This command is used when you want to clone a flop as manual ECO. Manual flop cloning is usually performed on control signal flip-flops, when the output needs to reach sections of the floorplan that are spread out. Cloning the flip-flops allows you to place each clone close to its sink points, thereby reducing the timing closure effort.

This command should not be used to clone a flop that drives a clock net, which is a net with the attribute `isDefInclock`, because this may lead to problems during optimization or timing. The default behavior of the command may reject the flip-flop cloning due to design constraints or QOR impact.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `eco_clone_flop` parameter. For a detailed description of the command and all of its parameters, use the man command: `man eco_clone_flop`
`-force`	When specified, forces the flop instance to clone. This parameter is used when flop cloning is rejected by the software. *Data_type*: bool, optional
`-instances` *flop_instance_name*	Specifies the list of flop instances to be cloned. This is a required parameter. *Data_type*: string, optional
`-max_num_loads` *num_of_loads*	Specifies that cloning should be skipped for instances driving more than the specified number of loads. *Default*: `50000` *Data_type*: int, optional
`-num_clones` *number*	Specifies the cloned numbers for the flop instance. *Data_type*: int, optional
`-radius` *num_of_rows*	Specifies that the clones should be placed within a radius of the specified number of rows from their preferred location based on the original instance location and the center of mass of the new set of loads. *Default*: `10` *Data_type*: int, optional
`-verbose`	When specified, verbose messages are displayed during the cloning of flop instances. *Data_type*: bool, optional

Example

The following command will clone the flip-flop `$inst` 3 times:

```
eco_clone_flop -instances $inst -num_clones 3
```

eco_merge_combinational_cell

```
eco_merge_combinational_cell
[-help]
[-area]
[-force]
-inst comboInstName | -list_file instNamesFile | -all
[-power]
-pre_cts | -post_cts
```

Merges combinational cells into multi-bit cells for the specified instance. You can specify the names of the combinational instances to be merged or you can specify the file containing names of single bit instances to merge.

Naming Convention During Merging

When the combinational cells in the specified file are merged, the corresponding instance names are combined as follows:

- `hier1/hier2/i_0 + hier1/hier2/i_1 + hier1/hier2/i_2 + hier1/hier2/i_3`
  TO
  `hier1/hier2/CDN_MB_i_0_MB_i_1_MB_i_2_MB_i_3`
- `abc_x[0] + abc_x[1] + abc_x[2] + abc_x[3]`
  TO
  `CDN_MB_abc_x[0]_MB_x[1]_MB_x[2]_MB_x[3]`

Parameters

`-help`	Outputs a brief description that includes type and default information for each `eco_merge_combinational_cell` parameter. For a detailed description of the command and all of its parameters, use the man command: `man eco_merge_combinational_cell`.
`-all`	Specifies that all single-bit cell instances should be merged into multi-bit cell instances. This parameter is mutually exclusive with the `-list_file` and `-inst` parameters. At least one of these parameters must be specified.

`-area`	Specifies to merge the combinational cells for area purposes. *Default*: `false`
`-force`	Forces the merging of the combinational cell regardless of the timing gains. *Default*: `false`
`-inst` *`comboInstName`*	Specifies the name of the combinational instance to be merged. This is a required parameter. This parameter is mutually exclusive with the `-list_file` and `-all` parameters. At least one of these parameters must be specified.
`-list_file` *`instNamesFile`*	Specifies the file containing the names of single bit instances to merge. Specify one instance on one line. Comment with Instance name should not contain spaces or backslashes This parameter is mutually exclusive with the `-inst` and `-all` parameters. At least one of these parameters must be specified.
`-post_cts`	Specify this parameter if the design stage is post-CTS. **Note**: This parameter is mutually exclusive with the `-pre_cts` parameter. One of the two parameters must be specified.
`-power`	Specify this parameter to merge the combinational cells for power purposes. *Default*: `false`
`-pre_cts`	Specify this parameter if the design stage is pre-CTS. This is a required parameter. **Note**: This parameter is mutually exclusive with the `-post_cts` parameter. One of the two parameters must be specified.

eco_split_combinational_cell

```
eco_split_combinational_cell

[-help]
[-force]
[-full_split]
[-legal]
[-skip_route]
-inst combInstName | {{Mbcb1 combCell1} {Mbcb2 combCell2}...} | -list_file fileName | -all
-pre_cts | -post_cts | -post_route
```

Splits all multi-bit combinational cell instances to single-bit combinational cells. You can specify the names of the combinational instances to be merged or you can specify the file containing names of multi-bit instances to be split.

Naming Convention During Splitting

When splitting Multibit combinational cells, it will split the names as follows:

- `hier1/hier2/i_[0:3]`
  TO
  `hier1/hier2/i_[0:3]__0, hier1/hier2/i_[0:3]__1, hier1/hier2/i_[0:3]__2, hier1/hier2/i_[0:3]__3`
- `CDN_MB_abc_MB_def`
  TO
  `abc, def`

Parameters

`-help`	Outputs a brief description that includes type and default information for each `eco_split_combinational_cell` parameter. For a detailed description of the command and all of its parameters, use the man command: `man eco_split_combinational_cell`.

`-all`	Splits all multi-bit combinational cell instances to SBFF instances. This parameter is mutually exclusive with the `-inst` and `-list_file` parameters. At least one of these parameters must be specified. *Default*: `false`
`-force`	Forces the splitting of the combinational cell regardless of the timing gains. *Default*: `false`
`-full_split`	Set this parameter to completely split the multi-bit combinational cells to single bits.
`-inst` *`comboInstName`* `{{`*`Mbcb1 combCell1`*`} {`*`Mbcb2 combCell2`*`}...}`	
	Specifies the names of the combinational instance to be split. If the input is a string of multi-bit combinational (MBCB)/Cell pairs list, it will split the MBCB to the specified cell without evaluation This parameter is mutually exclusive with the `-list_file` and `-all` parameters. At least one of these parameters must be specified.
`-legal`	Specifies to place the split flip-combinational cells at legal location. *Default*: `false`
`-list_file` *`fileName`*	Specifies the file containing names of MBCB instances to split. Specify one instance on one line. Comment with #. Instance name should not contain spaces or backslashes. And if one instance and one cell is specified on one line, it will split the MBCB to the specified cell without evaluation. This parameter is mutually exclusive with the `-inst` and `-all` parameters. At least one of these parameters must be specified.
`-post_cts`	Specify this parameter if the design stage is post-CTS. This is a required parameter. One of these parameters, `-pre_cts`, `-post_cts`, or `-post_route` must be specified.
`-post_route`	Specify this parameter if the design stage is postRoute. This is a required parameter. One of these parameters, `-pre_cts`, `-post_cts`, or `-post_route` must be specified.

`-pre_cts`	Specify this parameter if the design stage is preCTS. This is a required parameter. One of these parameters, `-pre_cts`, `-post_cts`, or `-post_route` must be specified.
`-skip_route`	Specify this parameter if the design stage is post-Route and global detail routing is not required after the split.

  - Multi-Bit Combinational Cell Optimization

eco_split_flop

```
eco_split_flop
[-help]
[-batch]
[-force]
[-full_split]
[-legal]
[-power]
{-inst flopInstName | {{Mbff1 flopCell1} {Mbff2 flopCell2}...} | -list_file <fileName>
| -all}
{-pre_cts | -post_cts | -post_route}
[-skip_route]
```

Splits a multi-bit flip-flop (MBFF) into single-bit flip-flops for the specified instance. By default, a specific flip-flop is split only if equivalent single-bit flip-flops can be found in libraries and there is timing gain after the split. You can also specify that the split flip-flops should be placed in legal locations. By default, the positions of the split flip-flops are not guaranteed to be legal.

Note:

- This command is not controlled by the `opt_multi_bit_flop_opt` attribute setting of opt Category Attributes
- The command calls refinePlace at the end. To disable this, set the `eco_refine_place` attribute to `false`
- MBFFs must be identified by the the command `report_multi_bit_ffs -all`
- A placeable location for the split FFs is required

Parameters

`-help`	Outputs a brief description that includes type and default information for each `eco_split_flop` parameter. For a detailed description of the command and all of its parameters, use the man command: `man eco_split_flop`.

`-all`	When specified, splits all MBFFs into smaller-bit flip-flops including single-bit flip-flops (SBFFs). Only timing critical bits are split into single-bit flops, and the remaining, non-critical bits, are split into smaller bit width MBFFs, to preserve power as much as possible. For example, a 4-bit MBFF may be split into two single-bit flops and one 2-bit flop. **Note**: The `-all`, `-inst` and `-list_file` parameters are mutually exclusive. If the `-all` parameter is not specified, one of these two parameters, `-inst` or `-list_file`, must be specified. *Default*: `false` *Data_type*: bool, optional
`-batch`	When specified, splits the MBFFs in batches. For example, `eco_split_flop -list_file list -post_cts -batch -force` *Default*: `false` *Data_type*: bool, optional
`-force`	Forces the flip-flop splits irrespective of timing gains. *Default*: `false` **Note**: • If there is no timing gain and this parameter is not specified, the flip-flops for the specified instance will not be split. • If this option is set along with the `-legal` option, the software will first look for legal locations. However, the flip-flops will be split even if no legal location is found. *Data_type*: bool, optional
`-full_split`	Forces the MBFFs to be completely split into all single-bit flip-flops. *Data_type*: bool, optional
`-inst flopInstName | {{Mbff1 flopCell1} {Mbff2 flopCell2}...}`	

	Specifies pairs of MBFFs to be split and the corresponding single-bit flops to be used. You can also specify a single instance or a tcl list of instances to be split. **Note**: The `-all`, `-inst`, and `-list_file` parameters are mutually exclusive. If the `-all` parameter is not specified, one of these two parameters, `-inst` or `-list_file`, must be specified. *Data_type*: string, required
`-list_file` *fileName*	
	Specifies the file containing pairs of MBFFs to be split and the corresponding single-bit flops to be used. You can also just specify the names of MBFF instances to be split. You can specify up to 50,000 instances to split. Specify each instance on a line and comment with #. Instance name should not contain spaces or backslashes. **Note**: The `-all`, `-inst`, and `-list_file` parameters are mutually exclusive. If the `-all` parameter is not specified, one of these two parameters, `-inst` or `-list_file`, must be specified. *Data_type*: string, required
`-legal`	Places the split flip-flops at legal locations. **Note**: If both the `-legal` and `-force` parameters are specified, the software will first look for legal locations. However, the flip-flops will be split even if no legal location is found. In this case, the split instances will be placed in the original location of the MBFFs. *Default*: `false` *Data_type*: bool, optional
`-power`	Splits the flip-flop for power purpose. *Default*: `false` *Data_type*: bool, optional
`-pre_cts`	Specify this parameter, if the design stage is pre-CTS. Default: `-post_route` *Data_type*: bool, optional

`-post_cts`	Specify this parameter, if the design stage is post-CTS. Default: `-post_route` *Data_type*: bool, optional
`-post_route`	Specify this parameter, if the design stage is post-Route. This is the default setting. *Data_type*: bool, optional **Note**: One of the three options, `-pre_cts, -post_cts,` or `-post_route` must be specified.
`-skip_route`	Specify if the stage is `post_route` and globalDetailRoute is not required to be performed after the split. Since `post_route` is also the default stage, globalDetailRoute is also skipped when the stage is default and `-skip_route` is specified. However, for the default case, when the stage is postRoute but this parameter is not specified, after splitting the instances, globalDetailRoute will be called. *Default*: `false` *Data_type*: bool, optional

Example

- The following command will force the flip-flop split for the instance, `ff_0`:

```
eco_split_flop -inst ff_0 -force
```

  - Using the Multi-Bit Flip-Flop Flow

eco_split_complex_flop

```
eco_split_complex_flop
[-help]
[-force]
{-inst {inst1, inst2,...} | -list_file instNamesFile | -all}
[-legal]
[-power]
[-pre_cts | -post_cts | -post_route]
[-skip_route]
```

Splits a complex flip-flop into a simple flip-flop and combinational logic for the specified instance. A complex flip-flop means the D side has some combinational logic, such as AND, OR, MUX, AOI, and so on. By default, a specific flip-flop is split only if equivalent simple flip-flops and combinational logic can be found in libraries and there is timing gain or power gain after the split.

You can also specify that the split flip-flops should be placed in legal locations. By default, the positions of the split flip-flops are not guaranteed to be legal.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `eco_split_complex_flop` parameter. For a detailed description of the command and all of its parameters, use the man command: `man eco_split_complex_flop`
`-all`	Specifies that all MBFF instances should be split to SBFF instances. *Default*: `false` **Note**: The `-inst`, `-listFile`, `-all`, and `batch` parameters are mutually exclusive. One of these must be specified. *Data_type*: bool, optional
`-force`	When specified, forces the complex flip-flops to split regardless of the timing gains. *Data_type*: bool, optional
`-inst {inst1, inst2,...}`	

	Specifies the names of the flop instances to be split. You can specify a single instance or a tcl list of instances to be split. **Note**: The `-inst`, `-listFile`, and `-all` parameters are mutually exclusive. One of these must be specified. *Data_type*: string, required
`-legal`	When specified, places the split flip-flop at a legal location. *Data_type*: bool, optional
`-list_file` *instNamesFile*	
	Specifies the file containing the names of the MBFF instances to split. Specify one instance on one line. Comment with #. Instance name should not contain spaces or backslashes. **Note**: The `-inst`, `-listFile`, and `-all` parameters are mutually exclusive. One of these must be specified. *Data_type*: string, required
`-pre_cts`	Specify this parameter, if the design stage is pre-CTS. *Data_type*: bool, optional
`-post_cts`	Specify this parameter, if the design stage is post-CTS. *Data_type*: bool, optional
`-post_route`	Specify this parameter, if the design stage is post-Route. *Data_type*: bool, optional
`-power`	When specified, complex flops are split to reclaim power. By default, the flops are split for timing. *Data_type*: bool, optional
`-skip_route`	Skip globalDetailRoute after split in post_route stage. *Data_type*: bool, optional

Examples

- Use the following command to force the flip-flop split for power for all instances during the pre_cts stage.

  ```
  eco_split_complex_flop -force -pre_cts -power -all
  ```

- Use the following command for flip-flop split for timing for the instance ff1 during the pre_cts stage.

  ```
  eco_split_complex_flop -inst ff1 -pre_cts
  ```

Related Information

- `eco_split_flop`
- `eco_clone_flop`
- Optimizing Timing chapter of *Innovus Stylus Common UI User Guide*

get_scheduling_file

```
get_scheduling_file
[-help]
```

Returns the name of the current scheduling file used by the `opt_clock_skew` command. If no scheduling file name is set, `get_scheduling_file` returns nothing. If you have already run `opt_clock_skew`, this command reports the default file name. If you have specified or changed the scheduling file name using `set_scheduling_file`, then this command returns this name.

To view the above description in the software, use `man get_scheduling_file`.

Related Information

- `opt_clock_skew`
- `set_scheduling_file`
- The following section in Optimizing Timing chapter of *Innovus Stylus Common UI User Guide*
  - Performing Optimization Before Clock Tree Synthesis

opt_area

```
opt_area
[-help]
[-hold_aware]
[-no_declone]
[-no_delete_buffer]
[-no_down_size]
```

Creates space in the design by downsizing and deleting buffers, without worsening the slack or increasing the design rule violations.

Note: Cadence recommends using the `opt_design` command to correct timing violations during timing optimization instead of using this command. For information on using `opt_design`, see Optimizing Timing in the *Innovus stylus Common UI User Guide* .

Parameters

`-help`	Outputs a brief description that includes type and default information for each `opt_area` parameter. For a detailed description of the command and all of its parameters, use the man command: `man opt_area`
`-no_declone`	Stops the software from decloning instances to reclaim area. By default, the software declones instances to reclaim area. *Data_type*: bool, optional
`-no_delete_buffer`	Prohibits Innovus from deleting buffers to reclaim area. *Default:* The software deletes buffers to reclaim area. *Data_type*: bool, optional
`-no_down_size`	Prohibits Innovus from downsizing instances to reclaim area. *Default:* The software downsizes instances to reclaim area. *Data_type*: bool, optional
`-hold_aware`	Runs the hold aware area reclaim. This is only supported after the design has been routed. *Data_type*: bool, optional

Example

By default area reduction is happening only on positive slack instances. To allow the tool to reclaim area on instances that have a negative slack, you can set a negative setup target slack:

```
set_db opt_setup_target_slack current_negative_slack
opt_area
```

opt_clock_skew

```
opt_clock_skew
[-help]
[-hold]
[-post_cts]
[-post_route]
```

Modifies the clock arrival time on sequential elements in order to improve the data path timing between two sequential elements. The `opt_clock_skew` command outputs depend on whether the clock tree is built or not.

- In pre-CTS mode, `opt_clock_skew` generates two files: a scheduling file and a latency file.
- In post-CTS and post-Route mode, `opt_clock_skew` inserts buffers and/or inverters in an existing clock tree. In addition, resizing of buffers and/or inverters can also be committed.

> Cadence recommends using the attribute, `opt_useful_skew`, and the command `opt_design -pre_cts`, `-post_cts`, or `post_route` to run useful skew optimization during timing optimization. For information on how to use `opt_design`, see "Optimizing Timing" in the *Innovus Stylus Common UI User Guide*.

Pre-CTS mode

The `opt_clock_skew` command identifies elements that can be advanced or delayed, and computes target delay for each. An advancable element is a sequential gate on which the clock signal can be safely made to arrive early without worsening the slack on the critical path. In general, this is true for sequential elements where the slack on the output pin (SQ) is negative (SQ < 0) and is worse than the slack on the input pin (SD) : (SQ < SD).

The `opt_clock_skew` command generates the following files:

- **Scheduling file**: The CTS scheduling file lists the delays to consider on sequential elements by the clock tree synthesis tool. When loaded in CTS, the scheduling file constrains CTS to build a tree that fulfills the targets computed by `opt_clock_skew`. The scheduling file must be loaded in addition to the original clock tree specification file (see "Examples" section below).

  The syntax of the scheduling file is as follows:

```
Macromodel pin lefPinName maxRiseDelay minRiseDelay maxFallDelay minFallDelay
inputCap
```

An entry in the configuration file is available to specify the scheduling file:

```
set rda_input ui_scheduling_file scheduling_file.cts
```

When the design is saved, the scheduling file is copied in the design directory, and the line above is added to the configuration file of the saved design.

- **Latency file**: This file lists the delays to be considered on sequential elements by the timing analysis tool. These delays are computed by `opt_clock_skew`.

  The file syntax is as follows:
  ```
  set_clock_latency rise delay pinName
  ```

  The timing engine takes the latency file into account when the following attribute is specified:
  ```
  set_db timing_analysis_useful_skew
  ```

  When building the timing graph, Innovus first loads the timing constraints, and then the latency file, as specified in the configuration file, for example
  ```
  set_rda_input (ui_latency_file) latency_file.sdc
  ```

  When the design is saved, the latency file is copied to the design directory, and the line above is added to the configuration file of the saved design.

Post-CTS and Post-Route Mode

The `opt_clock_skew` command identifies delayable elements and delays the clock for each element. A delayable element is a sequential element on which the clock signal can be safely delayed without worsening the slack on the critical path. In general, this is true for each sequential element where the slack on the data pin (SD) is negative (SD<0) and is worse than the slack on the output pin (SQ) : (SD < SQ). The `opt_clock_skew` command inserts and/or resizes buffers and/or inverters on an existing clock tree.

- The opt_clock_skew net name prefix is `FE_%sN`

- The opt_clock_skew instance name prefix is `FE_%sC`
- The default instance name added during useful skew optimization is `FE_USKC`
- The default net name added during useful skew optimization is `FE_USKN`

If SD > SQ, the elements before the D pin can be advanced, and `opt_clock_skew` can do resizing on the buffers and/or inverters to compensate the timing on Q pin.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `opt_clock_skew` parameter. For a detailed description of the command and all of its parameters, use the man command: `man opt_clock_skew`
`-hold`	Allows optimization for hold timing. *Data_type*: bool, optional
`-post_cts`	The `opt_clock_skew` command allows the use of an algorithm in the post_cts mode. When this parameter is specified, only setup timing optimization is performed. When it is specified along with the `-hold` parameter, only hold timing optimization is performed. This means, • The `opt_clock_skew -post_cts` command will only optimize setup timing. • The `opt_clock_skew -post_cts -hold` command will only optimize hold timing, without degrading setup timing. To optimize both setup and hold violations, run the following commands: `opt_clock_skew -post_cts` opt_clock_skew -post_cts -hold *Data_type*: bool, optional

`-post_route`	The `opt_clock_skew` command allows the use of an algorithm in the post_route mode. It forces the command to end with ECO routing for the modified clock nets. An `route_eco` is followed by clock skewing. The difference between post-CTS mode and post-Route mode is that the former is not limited to be legal only, while the latter is in a legal only mode.
	
	When this parameter is specified, only setup timing optimization is performed. When it is specified along with the `-hold` parameter, only hold timing optimization is performed.
	
	This means,
	• The `opt_clock_skew -post_route` command will only optimize setup timing.
	• The `opt_clock_skew -post_route -hold` command will only optimize hold timing, without degrading setup timing.
	
	To optimize both setup and hold violations, run the following commands:
	`opt_clock_skew -post_route`
	`opt_clock_skew -post_route -hold`
	
	Data_type: bool, optional

Examples

- The following example shows how to use `opt_clock_skew` in a pre-CTS flow without using `opt_design`:

  ```
  set_db timing_analysis_useful_skew true
  time_design -pre_cts
  set_scheduling_file scheduling_file.cts
  opt_clock_skew
  time_design -pre_cts
  ```

  Note: The recommended method for useful skew in pre-CTS mode is as follows:

  ```
  set_db opt_useful_skew true
  set_db opt_useful_skew_pre_cts true
  place_opt_design
  ```

- The following example shows how to use `opt_clock_skew` in post-CTS mode as an incremental fixing after normal post-CTS optimization:

  ```
  ccopt_design
  ```

```
opt_clock_skew -post_cts
time_design -post_cts
```

opt_design

```
opt_design
[-help]
[-drv]
[-exclude_nets fileName]
[-expanded_views]
[-hold]
[-hold_violation_report fileName]
[-ideal_clock]
[-include_nets fileName]
[-include_pins fileName]
[-incremental]
[-no_eco_route]
[-post_cts]
[-post_route]
[-pre_cts]
[-report_dir directoryName]
[-report_prefix fileNamePrefix]
[-setup]
[-targeted]
[-timing_debug_report]
[-use_transition_files]
```

Performs timing optimization before or after the clock tree is built, or after routing and generates timing reports. You can optimize with or without useful skew.

In multi-mode, multi-corner mode, `opt_design` optimizes all analysis views concurrently.

Performs the following optimizations:

- Corrects design rule violations.
- Reduces total negative slack.
- During the initial pass, optimizes setup time by working on the design's worst paths until the slack cannot be further improved, then, if the worst slack is not on a register-to-register path, optimizes the register-to-register paths on the second pass.
- Corrects hold time violations (optional).
- Optimizes useful skew (optional).
- Reclaims area (optional).
- Optimizes leakage power (optional).

- Merges flops to multi-bit FFs, or split the multi-bit FFs (optional).

Uses some or all of the following techniques, depending on the design stage (that is, before or after CTS, or after routing) and the specified parameters:

- Adds buffers.
- Resizes gates.
- Restructures the netlist.
- Remaps logic.
- Swaps pins.
- Deletes buffers.
- Moves instances.
- Applies useful skew.
- Applies layer promotion and/or NDR assertions.
- Applies flip-flop merge and split.

Sets the minimum recommended and appropriate set of attributes in the following categories:

- `timing` category attributes
- `route_trial` category attributes
- `opt` category attributes
- `extract_rc` category attributes

Tip: You can set additional parameters by specifying attributes using the appropriate `set_db` *`attribute_name value`* command or before using `opt_design`.

Before running `opt_design`, complete the following steps:

- Generate the default and detailed extraction scale factors by using the following commands:
  - `report_rc_factors`
- Set input transitions for the high fanout nets for delay calculation to use on high fanout networks.

Note: The `opt_remove_redundant_insts` attribute is allowed to remove unnecessary or redundant level shifter/isolation instances although those would be internally set as `dont_touch` by `opt_design`.

Parameters

Note: The "opt_design Parameter Matrix" section shows which parameters can be used together.

`-help`	Outputs a brief description that includes type and default information for each `opt_design` parameter. For a detailed description of the command and all of its parameters, use the man command: `man opt_design`
`-drv`	Corrects `max_cap` and `max_tran` violations. To correct `fanout_load` violations, specify `opt_fix_fanout_load` attribute before you specify `opt_design`. You cannot use this attribute if you specify `-incremental`. When applying this attribute, `opt_design` will fix only the DRV and not the setup/hold timing violation. *Data_type*: bool, optional
`-exclude_nets` *fileName*	
	Specifies the file that contains the hierarchical names of nets. Timing optimization excludes nets specified in the `-exclude_nets` file. If a net appears in both `-exclude_nets` and `-include_nets`, it is excluded. Note: Excluded nets, especially those with large fanout, might still be buffered to fix Setup timing problems. Use the dont_touch option in the SDC constraints file to prevent opt_design from modifying selected nets. For Hold Optimization however, the nets specified will be excluded when optimizing the Hold Timing. *Data_type*: string, optional
`-expanded_views`	Generates detailed view-specific timing reports at the end of the opt_design command run. A separate directory is created for each view. For example, if a design has two analysis views, view1 and view2, then the output reports are generated in the `./timingReports/view1` and `./timingReports/view2` directories. If the views were pruned during optimization, they will be restored at the end by this parameter and a view-specific summary and data will be reported on all the active views in the design. *Data_type*: bool, optional

`-hold`	Corrects hold violations. You cannot use this parameter if you specify `-pre_cts`. You can specify `-include_nets` or `-include_pins` if you use this parameter. This parameter creates a summary file in the output directory for the design. The file is named prefix_hold.summary. Use the -report_prefix parameter to specify the prefix. To report detailed debugging information, use `set_db opt_fix_hold_verbose true`. For more information, see opt Category Attributes. **Note**: Even though the hold-timing violation fixing algorithm is setup-timing aware, some setup timing degradation may appear due to different trialRoute topology during the post-CTS stage. In most cases, this can be overlooked because the violations will be easily fixed during the `opt_design -post_route` flow step. **Note**: You need to use the `add_fillers_cells` attribute to identify the filler cells. The `opt_design` command will remove filler cells that have been identified with the `add_fillers_cells` attribute at the beginning of optimization and add them back at the end of optimization. *Data_type*: bool, optional
`-hold_violation_report` *`fileName`*	Generates the following report files for the violation data that remains after hold fixing: *`fileName.txt`:* provides a list of the top 50 hold violation paths (text format) *`fileName.csv`*: provides a list of the top 50 hold violation paths (csv format) *`fileNameDetailed.txt`*: provides detailed information for the top 50 hold violation paths This parameter is used with the `-hold` parameter. **Example**: `opt_design -post_route -hold -hold_violation_report` *`fileName`* *Data_type:* string, optional

`-ideal_clock`	Performs timing optimization in post-CTS or post-Route modes using ideal clocks instead of propagated clocks. Using ideal clocks enables you to optimize timing without building a clock tree first, or ignore the existing clock tree, to close ideal timing. If this parameter is not specified, the software assumes the clock tree has been built, and optimizes timing based on propagated clocks. *Data_type*: bool, optional
`-include_nets` *fileName*	
	Specifies the file that contains the hierarchical names of nets to consider for design-rule violation repair or hold-timing violations fixing. Timing optimization excludes all other nets. If a net appears in both -exclude_nets and -include_nets, it is excluded. This option is only accepted when either `-drv` or `-hold` is selected. **Note**: The `-include_nets` parameter forces `opt_design` to work on all the selected nets, including the ones set using dont_touch. *Data_type*: string, optional
`-include_pins` *fileName*	
	Specifies the file that contains the hierarchical names of instance terminals to consider for timing optimization. Only nets connected to those terminals are optimized; for example, during hold fixing, delay cells are added only on the nets driving the terminals specified in the file. *Data_type*: string, optional

`-incremental`	Performs setup optimization incrementally on the violated paths until they cannot be optimized any more. Both, WNS and TNS are optimized. Both, high-effort path and low-effort path groups are optimized. Area reclaim may also take place if `-post_route` is not specified. A setup recovery is called depending on the timing bump after the re-route. This parameter has the following limitations: • You cannot use it if you also specify `-drv` or `-hold`. • You must have already run `opt_design` on all path groups before running it with `-incremental`. • When specified, this option disables power optimizations. *Data_type*: bool, optional
`-no_eco_route`	Prohibits the software from performing ECO routing with the NanoRoute® router during post-Route optimization. *Data_type*: bool, optional
`-post_cts`	Performs timing optimization on a design whose clock tree has been created. By default, -post_cts repairs design rule violations and setup violations. If the worst negative slack does not occur on a register-to-register path, `-post_cts` performs an additional optimization pass on the register-to-register critical paths when clock domains are not set. Does not repair maximum fanout design rule violations unless you first specify `opt_fix_fanout_load` attribute. *Data_type*: bool, optional

`-post_route`	Performs timing optimization on a design whose routing is complete. By default, `-post_route` repairs design rule violations, glitch Violations and setup violations on Base & SI Delay. If the worst negative slack does not occur on a register-to-register path, `-post_route` performs an additional optimization pass on the register-to-register critical paths when clock domains are not set. Maximum fanout design rule violations are not repaired by default. To do this, first specify `opt_fix_fanout_load` attribute. The `opt_design -post_route` command provides accurate results when Innovus runs using the footprintless flow methodology. By default, Innovus creates an internal footprint structure based on cell functionality. This methodology does not require you to specify a footprint file. For library database (LDB) conversion, this is the recommended methodology since all of it is automated. For more information, see the "Using the Footprintless Flow" section in the Optimizing Timing chapter of *Innovus Stylus Common UI User Guide*. *Data_type*: bool, optional
`-pre_cts`	Performs timing optimization on the placed design, before the clock tree is built. By default, `-pre_cts` repairs design rule violations and setup violations. If the worst negative slack does not occur on a register-to-register path, `-pre_cts` performs an additional optimization pass on the register-to-register critical paths when clock domains are not set. Maximum fanout design rule violations are not repaired by default. To do this, first specify `opt_fix_fanout_load` attribute. **Note**: Before optimizing a design in pre-CTS mode, you must break all timing loops by disabling arcs in the constraint file. If you do not disable the arcs, the software cannot make a valid comparison of WNS between two different runs since it might not break the loops at the same point each time. To disable the arcs, use the `set_disable_timing` command. *Data_type*: bool, optional
`-report_dir` *directoryName*	

	Specifies the directory where the software writes timing reports generated when this command runs. *Default*: `timingReports` *Data_type*: string, optional
`-report_prefix` *fileNamePrefix*	
	Specifies a prefix for `opt_design` report file names. *Default:* *DesignName_DesignStage*, where *DesignStage* is `pre-CTS`, `post-CTS`, or `post-Route`. *Data_type*: string, optional
`-setup`	Corrects setup violations for the post-Route optimization flow. When specified along with the `-hold` parameter, a combined setup and hold optimization is performed. For example, `opt_design -post_route -setup -hold` **Note**: This parameter is only applicable to the post-Route optimization flow and should be used along with the `-hold` parameter. *Data_type*: bool, optional

`-targeted`	This parameter is used only with the `-post_route` parameter. Specifying this parameter invokes target-based optimization (TBOpt), which is a fine grain local optimization functionality. This will target critical nodes at the post-Route stage and optimize these by giving worst negative slack (WNS), area, power, and max transition improvements with minimum disturbance to NanoRoute. This parameter can be used optionally along with the `opt_target_based_opt_file` and `opt_target_based_opt_file_only` attributes. **Note**: Area, power, and max transition targeting can only be done using the above settings. For more information on the syntax of a sample TBOpt file, see the opt Category Attributes documentation. Target-based optimization is best used after post-Route optimization is already completed and there are still some violating paths or nodes that might need further improvement. *Data_type*: bool, optional
`-timing_debug_report`	When specified, generates a machine-readable timing debug report after completing optimization. This report is used for debugging timing results using the timing debug feature in Stylus. **Note**: You can select the number of paths that should be reported per path group in the final summary reports by specifying the `opt_time_design_num_paths` attribute. The default number of paths is 50. *Data_type*: bool, optional
`-use_transition_files`	Uses the transition file specified by the `read_transition_file` command for transition violation fixing during post-Route SI optimization. *Data_type*: bool, optional

opt_design Parameter Matrix

The table below shows the compatibility of `opt_design` parameters.

opt_design	-pre_cts	-post_cts	-post_route	-drv	-setup	-hold	-ideal_clock	-incr	-no_eco_route
-pre_cts	NA	-	-	+	-	-	-	+	-
-post_cts	-	NA	-	+	-	+	+	+	+
-post_route	-	-	NA	+	+	+	+	+	+
-drv	+	+	+	NA	-	-	+	-	+
-setup	-	-	+	-	NA	+	+	-	+
-hold	-	+	+	-	+	NA	+	-	+
-ideal_clock	-	+	+	+	+	+	NA	+	+
-incr	+	+	+	-	-	-	+	NA	+
-no_eco_route	-	+	+	+	+	+	+	+	NA

Legend

+	You can use this parameter in the row with the parameter in the column.
-	You cannot use this parameter in the row with the parameter in the column.
NA	The parameters in the row and column are identical.

Examples

Pre-CTS Optimization

- To optimize timing for first time, use the following command:
  ```
  opt_design -pre_cts
  ```
- To repair design rule violations only, use the following command:
  ```
  opt_design -pre_cts -drv
  ```

- To run incremental setup-only optimization, use the following command:

  ```
  opt_design -pre_cts -incremental
  ```

- To optimize using low-effort mode for design prototyping, use the following attribute and command:

  ```
  set_db opt_effort low
  opt_design -pre_cts
  ```

  The `opt_design` command performs gate resizing and global buffer insertion, but does not perform netlist restructuring or design rule violation repair.

- To run optimization with useful skew, use the following attribute and command:

  ```
  set_db opt_useful_skew true
  set_db opt_useful_skew_pre_cts true
  opt_design -pre_cts
  ```

- To run optimization on specific path groups, use the following commands:

  ```
  group_path -name path_group_name -from from_list -to to_list -through through_list
  set_path_group_options  ..
  opt_design -pre_cts
  ```

  Or you can use:

  ```
  create_basic_path_groups
  set_path_group_options ..
  opt_design -pre_cts
  ```

  For example, to run optimization on reg2reg & reg2gate paths only, use the following commands:

  ```
  create_basic_path_groups -expanded
  set_path_group_options reg2out -target_slack -1000.0
  set_path_group_options in2reg -target_slack -1000.0
  set_path_group_options in2out -target_slack -1000.0
  opt_design -pre_cts
  ```

  Note: If you specify a path group, `opt_design` preserves the path group setting. In the previous example, subsequent commands may affect the reg2reg & reg2cgate path groups only. To set new groups, specify `reset_path_group -all` , followed by the definition of the groups you want to use.

For example, to reset the path group to a specific group of paths, use the following commands after you run `opt_design`:

```
reset_path_group -all
group_path -name pathgroup1 -through an1/Z -through an2/Z -through an3/Z
```

To specify all path groups, use the following command:

```
reset_path_group -all
```

- To reclaim area during optimization, use the following attribute and command:

  ```
  set_db opt_area_recovery true
  opt_design -pre_cts
  ```

- To run incremental optimization with useful skew, use the following attribute and command:

  ```
  set_db opt_useful_skew true
  opt_design -pre_cts -incremental
  ```

- To run an incremental optimization including reclaiming area, use the following attributes/commands:

  ```
  opt_design -pre_cts
  set_db opt_area_recovery true
  opt_design -pre_cts -incremental
  ```

Post-CTS Optimization

- To optimize timing after the clock tree is built, use the following command:

  ```
  opt_design -post_cts
  ```

  The `opt_design` command corrects design rule violations, then setup violations.

  Note: The software does not correct fanout violations in `-post_cts` and `-post_route` modes. To repair fanout violations, specify the following attribute before you run `opt_design`:

  ```
  set_db opt_fix_fanout_load true
  ```

- To repair setup and hold violations, use the following commands:

  ```
  opt_design -post_cts
  opt_design -post_cts -hold
  ```

- To repair design rule violations only, use the following command:

```
opt_design -post_cts -drv
```

- To repair hold violations only, use the following command:

  ```
  opt_design -post_cts -hold
  ```

- To run optimization on specific path groups, use the following commands:

  ```
  group_path -name path_group_name -from from_list -to to_list -through through_list
  set_path_group_options  ..
  opt_design -post_cts
  ```

  Or you can use:

  ```
  create_basic_path_groups
  set_path_group_options ..
  opt_design -post_cts
  ```

  For example, to run optimization on reg2reg & reg2gate paths only, use the following commands:

  ```
  create_basic_path_groups -expanded
  set_path_group_options reg2out -target_slack -1000.0
  set_path_group_options in2reg -target_slack -1000.0
  set_path_group_options in2out -target_slack -1000.0
  opt_design -post_cts
  ```

- To reclaim area during optimization, use the following attribute and command:

  ```
  set_db opt_area_recovery true
  opt_design -post_cts
  ```

- To take advantage of useful skew when optimizing timing in post-CTS mode, use the following attribute and command:

  ```
  set_db opt_useful_skew true
  opt_design -post_cts
  ```

  If you specify `-no_eco_route`, the software uses trial routing to estimate clock delays.

- To run post-CTS optimization if your design has a clock mesh, use the following attribute and command:

  ```
  set_db opt_useful_skew false
  opt_design -post_cts
  ```

- To run incremental optimization on specific path groups, use the following commands:

  ```
  group_path -name path_group_name -from from_list -to to_list -through through_list
  set_path_group_options  ..
  opt_design -post_cts -incremental
  ```

  For example, to run incremental optimization on reg2reg & reg2gate paths only, use the following commands:

  ```
  create_basic_path_groups -expanded
  set_path_group_options reg2out -target_slack -1000.0
  set_path_group_options in2reg -target_slack -1000.0
  set_path_group_options in2out -target_slack -1000.0
  opt_design -post_cts -incremental
  ```

- To optimize setup time incrementally and reduce area, use the following attribute and command:

  ```
  set_db opt_area_recovery true
  opt_design -post_cts -incremental
  ```

- To take advantage of useful skew when optimizing timing in incremental post-CTS mode, use the following attribute and command:

  ```
  set_db opt_useful_skew true
  opt_design -post_cts -incremental
  ```

- To run incremental post-CTS optimization if your design has a clock mesh, use the following attribute and command:

  ```
  set_db opt_useful_skew false
  opt_design -post_cts -incremental
  ```

Post-Route Optimization

- To optimize base & SI timing after detailed routing (repair setup violations), use the following command:

  ```
  opt_design -post_route
  ```

- If you wish to optimize only the base timing after detailed routing, use the following attribute and command:

  ```
  set_db delaycal_enable_si false
  opt_design -post_route
  ```

- **Note:** The software does not correct fanout violations in `-post_cts` and `-post_route` modes. To repair fanout violations, set the following attribute before you run `opt_design`:
  ```
  set_db opt_fix_fanout_load true
  ```
- To correct hold base & SI timing violations, specify the following command:
  ```
  opt_design -post_route -hold
  ```
- To correct setup and hold (both base & SI) violations, use the following commands:
  ```
  opt_design -post_route
  opt_design -post_route -hold
  ```

  The software repairs a hold violation only if it does not make setup slack worse than the setup target slack on a path. The software repairs a hold violation only if it does not make setup slack worse than the setup target slack on a path. An alternative way is to run setup and hold fixing within one command, and this may reduce the number of ecoRoute(s):
  ```
  opt_design -post_route -setup -hold
  ```
- To take clock reconvergence pessimism removal (CPPR) into consideration when running timing optimization, use the following `timing category` commands and attributes before you run `opt_design`. For example:
  ```
  set_timing_derate -max -clock -early 0.8 -late 1.2
  set_timing_derate -min -clock -early 0.8 -late 1.2
  set_db timing_analysis_cppr true
  opt_design -post_route
  ```

opt_power

```
opt_power
[-help]
[-allow_resize]
[-effort_level {high}]
[-force]
[-pre_cts | -post_cts | -post_route]
[-pre_place]
[-seq_only]
```

Optimizes the power consumption of the design by swapping gates for those with lower power, or deleting buffers/inverters without degrading timing. This works in conjunction with the `opt_leakage_to_dynamic_ratio` attribute to determine the type of optimization being performed - leakage, dynamic, or a combination of both.

Since the default for opt_leakage_to_dynamic_ratio attribute is 1.0, opt_power will perform leakage optimization only by default using LEF-safe optimization (if no other switch is set). It is vital to set up the design correctly before starting power optimization. For more information, see the Optimizing Power During opt_design section of the "Optimizing Timing" chapter in the *Innovus Stylus Common UI User Guide*.

The setup steps include the following:

- Setting the correct power views for both leakage and dynamic optimization
- Ensuring that the libraries contain `cell_leakage_power` information
- Ensuring that the switching activity has been correctly specified either through `read_activity_file -format {VCD | TCF | SAF} file_name` or the `set_default_switching_activity` command

Parameters

`-help`	Outputs a brief description that includes type and default information for each `opt_power` parameter. For a detailed description of the command and all of its parameters, use the man command: `man opt_power`.

`-allow_resize`	Specifies that optimization uses resizing for power reclaim and, if needed, for recovery. Since the cells will be of different physical footprint, placement refinement and routing ECO will be used. The DRV and timing recovery steps will also be performed, as required. Due to these extra steps, an increase in runtime is expected. As this is a more aggressive optimization, the power savings should be superior to the default opt_power values, but this may cause timing degradations in some cases. *Data_type*: bool, optional
`-effort_level {high}`	Specifies the effort level as `high`. When this parameter is specified, power optimization uses aggressive reclaim. The software performs a timing recovery step and there is a reasonably large increase in runtime on an average as compared to when regular power optimization is performed. *Data_type*: enum, optional
`-force`	Resizes each instance to a cell with the lowest leakage power, disregarding design rule violations and optimum timing. This only works when `opt_leakage_to_dynamic_ratio` attribute is set to `1.0`. *Data_type*: bool, optional
`-pre_cts`	Performs power optimization on the placed design, before the clock trees are created. *Data_type*: bool, optional
`-pre_place`	When specified, performs power optimization on an unplaced design. This parameter must be used with the `-force` parameter. *Data_type*: bool, optional
`-post_cts`	Performs power optimization on a design whose clock trees have been created. *Data_type*: bool, optional
`-post_route`	Performs power optimization on a design whose routing is complete. *Data_type*: bool, optional
`-seq_only`	Specifies that dynamic power opt should be done on sequential cells only. This parameter works with the `-force` parameter in all modes; `pre_cts`, `pre_place`, `post_cts`, and `post_route`. *Data_type*: bool, optional

Examples

- Use the following attribute and command to optimize the design targeting total power at the pre-CTS stage:

```
set_db opt_leakage_to_dynamic_ratio 0.5
opt_power -pre_cts
```

- Use the following command to optimize the design, targeting leakage power only at the post-CTS stage (assuming the `opt_leakage_to_dynamic_ratio` attribute has been untouched or has been set to the default of 1.0):

```
opt_power -post_cts
```

- Use the following commands to optimize dynamic power only at the post-Route stage:

```
set_db opt_leakage_to_dynamic_ratio 0.0
opt_power -post_route
```

- Use the following attribute and command to perform resizing for total power optimization in the design at the pre-CTS stage:

```
set_db opt_leakage_to_dynamic_ratio 0.5
opt_power -pre_cts -allow_resize
```

- Use the following attribute and command to perform aggressive dynamic power optimization in the design at the post-CTS stage:

```
set_db opt_leakage_to_dynamic_ratio 0.0
opt_power -post_cts -effort_level high
```

- Use the following attribute and command to optimize leakage power by forcing all cells to their lowest leakage equivalent, disregarding DRV and timing degradations at the pre-CTS stage:

```
set_db opt_leakage_to_dynamic_ratio 1.0
opt_power -pre_cts -force
```

- Use the following attribute and command to optimize dynamic power by swapping sequential cells only in the design at the pre-CTS stage:

```
set_db opt_leakage_to_dynamic_ratio 0.0
opt_power -pre_cts -seq_only
```

- Use the following attribute and command to allow the tool to swap gates, including the gates with negative slack, up to the current negative slack at the post-Route stage:

```
set_db opt_setup_target_slack <current_negative_slack>
opt_power -post_route
```

- To prevent power optimization from working on near critical paths, you can set a different target to that of the timing optimization. A typical example is shown below where power optimization will not work on paths less than 0.1ns but the target for timing will remain `0.0`:

```
set_db opt_setup_target_slack 0.0
set_db opt_area_recovery_setup_target_slack 0.1
set_db opt_leakage_to_dynamic_ratio 0.5
opt_power -pre_cts
```

Related Information

opt_signoff

```
opt_signoff
[-help ]
[-all]
[-area]
[-drv]
[-dynamic]
[-hold]
[-leakage]
[-no_eco_route]
[-power]
[-report_dir dir_name]
[-report_full_clock_path]
[-report_prefix prefix_name]
[-setup]
```

Runs timing, area, DRV, dynamic or leakage optimization on signoff timing.

This command must be run on a design that has gone through the implementation flow. It allows you to fix timing violations or to improve area and power visible in signoff STA mode while staying in the implementation tool.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `opt_signoff` parameter. For a detailed description of the command and all of its parameters, use the man command: `man opt_signoff`
`-all`	Performs DRV, Setup, Hold, and Power optimization in the path-based analysis (PBA) mode. It also includes embedded calls to route_eco, parasitic extraction and signoff timing analysis. **Note**: The all-in-one mode does not replace all customized fine-tuned flows. It provides the Stylus users easy access to Tempus ECO technology. The existing Tempus ECO flow using individual optimization steps within Stylus is still supported and can sometimes be more efficient than the all-in-one mode. *Data_type*: bool, optional

`-area`	Reclaims area on the netlist without causing any DRV/Setup/Hold degradation. *Data_type*: bool, optional
`-drv`	Triggers DRV fixing in signoff timing mode. *Data_type*: bool, optional
`-dynamic`	Triggers dynamic optimization in signoff timing mode. *Data_type*: bool, optional
`-hold`	Triggers hold fixing in signoff timing mode. *Data_type*: bool, optional
`-leakage`	Triggers leakage optimization in signoff timing mode. *Data_type*: bool, optional
`-power`	Optimizes total power in the design. During total power optimization, the software performs swapping and sizing on both the combinational and the sequential cells, and also removes buffers. This reduces leakage, internal, and switching power in the design. *Data_type*: bool, optional
`-no_eco_route`	Allows `opt_signoff` command to skip ECO routing and final signoff STA. *Data_type*: bool, optional
`-report_dir`	Specifies the directory in which the reports will be saved. **Note**: In case `opt_signoff` is reusing ECO timing DB generated earlier by `time_design_signoff` or when the `-no_eco_route` parameter is applied, no timing reports are saved. *Data_type*: string, optional
`-report_full_clock_path`	When this parameter is specified, the detailed timing report that is generated contains the full clock path. *Data_type*: bool, optional
`-report_prefix`	Specifies the prefix for the timing report file names. *Data_type*: string, optional

`-setup`	Triggers setup fixing in signoff timing mode. *Data_type*: bool, optional

Examples

- Use the following commands to perform setup optimization followed by a leakage power optimization. The setup optimization is with no ECO route, while the leakage power optimization calls the ECO Route along with final signoff STA results.

  ```
  opt_signoff -setup -no_eco_route
  opt_signoff -leakage
  ```

- Use the following commands to perform an area reclaim optimization that is based on external spef files:

  ```
  read_spef -rc_corner rc_max rc_max.spef.gz
  read_spef -rc_corner rc_min rc_min.spef.gz
  time_design_signoff -report_only
  opt_signoff -area
  ```

- Use the following command to dump out the final STA results in a folder named "RPT". The timing report files inside the "`RPT`" folder will be named "`SIGNOFF_ECO_*`".

  ```
  opt_signoff -hold -report_dir RPT -report_prefix SIGNOFF_ECO
  ```

- Use the following set of commands to perform DRV, Setup, Hold, and Power optimization in the PBA mode:

  ```
  set_multi_cpu_sage -local_cpu 16 -remote_host 4 -cpu_per_remote_host 4
  set_db opt_signoff_allow_skewing true
  set_db opt_signoff_clock_cell_list {…}
  opt_signoff -all
  ```

  Stylus will run Tempus ECO for PBA-based DRV, timing, and power closure. The Setup fixing will be done using useful skew technology. Signoff timing analysis will use 4 remote hosts each using 4 CPUs while ECO fixing, ECO routing, and parasitic extraction will use 16 CPUs.

- opt_signoff_write_eco_opt_db

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `opt_signoff` category, use the following command:

```
get_db -category opt_signoff
```

opt_signoff_add_inst

```
opt_signoff_add_inst {true | false}
```

Default: `true`

Data_type: bool, read/write

Specifies whether or not Setup/Hold/DRV optimizer is allowed to add buffer/delay/swap cell instances.

Note: If set, this attribute must be applied before opt_signoff.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_add_load

```
opt_signoff_add_load {true | false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether Hold optimizer is allowed to add dummy cell instances.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_allow_skewing

```
opt_signoff_allow_skewing {true | false}
```

Default: `false`

Data_type: bool, read/write

Allows clock skewing to be done during Setup timing optimization to further improve Setup slack. When set to true, `opt_signoff -setup` works on the last level of the clock tree to modify the clock skew in order to improve Setup timing closure. Modification on the clock tree can be either resizing of the last level of the clock tree or buffering to pad endpoint clock pin.

Default: false

Note:

- If set, this parameter must be applied before `opt_signoff`.
- When `opt_signoff_allow_skewing` is active, `opt_signoff` will automatically unfix all clock tree instances/nets. This is also performed when implementing the ECOs.
- As for data path optimization, skewing is not allowed to create new Hold violated paths.

Example:

The following commands perform clock skewing during setup fixing. Only `CKBUFX1` and `CKBUFX4` can be added to the clock tree.

```
set_db opt_signoff_clock_cell_list {CKBUFX1 CKBUFX4}
set_db opt_signoff_allow_skewing true
opt_signoff -setup
```

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_along_route_buffering

```
opt_signoff_along_route_buffering {true | false}
```

Default: false

Data_type: bool, read/write

When set to 1, the software uses node location provided through the parasitic data in order to insert buffers along the routing topology not only at the start or end of the net. This helps to better balance the slew or the load for long nets, which is typically needed for setup timing optimization or DRV fixing.

Note:

- A prerequisite of this parameter is that parasitic with the node location is provided to signoffOptDesign. In addition, the node location parasitic should be read using the -keep_star_node_locations parameter. For example: read_spef -keep_star_node_locations.
- If set, this attribute must be applied before opt_signoff.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_buffer_cell_list

```
opt_signoff_buffer_cell_list cell_list
```

Default: "" (empty string)

Data_type: string, read/write

Specifies a list of buffer/delay cells that can be used for the timing optimizer, regardless of whether those cells have a dont_use attribute. When the list is empty, the software will automatically identify

the list of usable buffer/delay cells.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_check_drv_from_hold_views

opt_signoff_check_drv_from_hold_views `{true | false}`

Default: `false`

Data_type: bool, read/write

Enables optimization of DRV violations (max_capacitance/max_transition) in hold views as well in setup views during DRV optimization. Also, when enabled, this attribute ensures that timing/area/power optimization will not create any new DRV violation in hold and setup views.

Note: If set, this attribute must be applied before `opt_signoff` and `time_design_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_check_type

```
opt_signoff_check_type {early | late | both}
```

Default: both

Data_type: enum, read/write

Specifies the type of ECO Timing DB to be generated in PBA mode. The `early` argument specifies hold ECO Timing DB and `late` specifies setup ECO Timing DB. When set to `both`, the ECO Timing DB generation will be done in PBA for both Setup and Hold timing.

Note:

- This attribute is only active when the `opt_signoff_retime` attribute is being set.
- If set, this attribute must be applied before `time_design_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_clock_cell_list

`opt_signoff_clock_cell_list` *`cell_list`*

Default: "" (empty string)

Data_type: string, read/write

Restricts the list of buffers that are allowed to be used by ECO on the clock tree.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_clock_max_level

`opt_signoff_clock_max_level` *`integer`*

Default: `0`

Data_type: int, read/write

Specifies the maximum levels in clock skewing thus limiting the amount of clock tree levels and avoiding the creation of an unbalanced clock tree. This attribute sets an upper boundary when adding a buffer or pair of inverters to the clock nets. The software counts the number of levels in the clock tree branch that is being modified to ensure that the maximum level will be equal to or less than the value set by this attribute.

Note: If set, this attribute must be applied before `opt_signoff`

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_delete_inst

```
opt_signoff_delete_inst {true | false}
```

Default: true

Data_type: bool, read/write

Enables buffer deletion when doing timing, power, or area reduction. This attribute is not honored by the `-leakage` parameter of `opt_signoff` since it performs only swapping.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_disable_geometry_checks

```
opt_signoff_disable_geometry_checks {true | false}
```

Default: false

Data_type: bool, read/write

Performs Vth swapping without checking the pins and geometry of a design. You can relax/stop/avoid the geometry checks during Vth swapping so that the tool just checks the cell size while performing Vth swapping. This will lead to more Vth swaps. The counterpart to this is that ecoRouting will be needed once the ECOs are applied since pin geometries might always match between old and new cells.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_drv_margin

```
opt_signoff_drv_margin value
```

Default: 0

Data_type: double, read/write

Specifies the ratio by which DRV check would be relaxed or tightened. It scales the maximum capacitance and maximum transition constraints according to the margin decimal value specified. For example, specifying a value of 0.2 for this attribute tightens the margin (makes it more pessimistic) by 20 percent during optimization and specifying a value of -0.2 relaxes the margin (makes it more optimistic) by 20 percent.

This margin is honored for DRV optimization.

Note: The software only accepts values from -0.7 to +0.7. A positive value indicates tighter constraints.

Note: If set, this attribute must be applied before `signoffOptDesign`.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_eco_file_prefix

```
opt_signoff_eco_file_prefix prefix
```

Default: "" (empty string)

Data_type: string, read/write

Specifies the prefix name for the ECO files that are generated.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_em_type

```
opt_signoff_em_type {all | avg | rms | peak}
```

Default: `all`

Data_type: enum, read/write

Specifies the current waveform calculation method when doing EM fixing.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_fix_cell_em

```
opt_signoff_fix_cell_em {true | false}
```

Default: `false`

Data_type: bool, read/write

When set to `true`, fixes the cell-level signal electromigration violations during DRV fixing using resizing and additional transforming techniques.

Note:

- If set, this attribute must be applied before `opt_signoff -drv`.
- If set during DRV fixing, the software will fix only the cell EM violations. This means that fixing of max_transition/max_capacitance/SI glitch/SI Xtalk/IR drop will be disabled.

Related Commands

- opt_signoff

opt_signoff_fix_clock_drv

`opt_signoff_fix_clock_drv {true | false}`

Default: `false`

Data_type: bool, read/write

Fixes maxCap/maxTran violations on the clock networks. This is performed only when the `opt_signoff -drv` command is run.

Note: For clock network DRV fixing, only the cells listed in the clock cell list (specified using the `opt_signoff_clock_cell_list` attribute), is used. The DRV fixing is not performed if a cell list is not provided.

Note: If set, this attribute must be applied before `opt_signoff`.

opt_signoff_fix_data_drv

`opt_signoff_fix_data_drv {true | false}`

Default: `false`

Data_type: bool, read/write

Fixes maxCap/maxTran violations on the data networks. This is performed only when the `opt_signoff -drv` command is run.

opt_signoff_fix_glitch

`opt_signoff_fix_glitch {true | false}`

Default: `false`

Data_type: bool, read/write

Performs SI glitch fixing during DRV fixing using resizing and buffering techniques.

Notes:

- If set, this attribute must be applied before `time_design_signoff`.
- The glitch fixing is done before max_tran/max_cap fixing.

opt_signoff_fix_hold_allow_setup_optimization

```
opt_signoff_fix_hold_allow_setup_tns_degrade {true | false}
```

Default: `false`

Data_type: bool, read/write

When set to `true`, incremental Setup fixing is performed during Hold fixing in order to create more Setup margins on Hold violated nodes that could not be fixed earlier due to Setup timing conflict.

Note: If set, this attribute must be applied before `opt_signoff`.

opt_signoff_fix_hold_allow_setup_tns_degrade

```
opt_signoff_fix_hold_allow_setup_tns_degrade {true | false}
```

Default: `false`

Data_type: bool, read/write

When specified, the Setup Total Negative Slack can be degraded during Hold time violations fixing while still maintaining the Setup Worst Negative Slack in every Setup active views.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_fix_hold_with_margin

```
opt_signoff_fix_hold_with_margin value
```

Default: `0`

Data_type: double, read/write

Specifies a slack margin value in nanoseconds for Hold time violations fixing. The purpose is to overfix any Hold violations by the amount of the margin value. This margin is not applied on nets that are already meeting the Hold target slack.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_fix_ir_drop

```
opt_signoff_fix_ir_drop  {true | false}
```

Default: `false`

Data_type: bool, read/write

Fixes the IR drop voltages for all instances in the design.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_fix_max_cap

```
opt_signoff_fix_max_cap  {true | false}
```

Default: `true`

Data_type: bool, read/write

Specifies that nets with max_cap violations should be fixed.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_fix_osus_glitch

`opt_signoff_fix_osus_glitch {true | false}`

Default: `false`

Data_type: bool, read/write

When set to `true`, fixes nets with overshoot and undershoot glitches during DRV optimization.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_fix_max_transition

`opt_signoff_fix_max_transition {true | false}`

Default: `true`

Data_type: bool, read/write

Specifies that nets with max_tran violations should be fixed.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_fix_slack_in_range_lower_limit

`opt_signoff_fix_slack_in_range_lower_limit` *`value_in_ns`*

Default: `-1e+30`

Data_type: bool, read/write

Sets the lower slack limit for a violated path to be considered during timing closure. The value is specified in ns.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_fix_slack_in_range_upper_limit

`opt_signoff_fix_slack_in_range_upper_limit` *`value_in_ns`*

Default: `1e+30`

Data_type: bool, read/write

Sets the upper slack limit for a violated path to be considered during timing closure. The value is specified in ns.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_fix_si_slew

`opt_signoff_fix_si_slew {true | false}`

Default: `false`

Data_type: bool, read/write

Reports signal integrity (SI) slews violations and fixed during DRV optimization. This is run as the first step of optimization before proceeding for any other incremental optimization.

When this attribute is set to `true`, it automatically sets the value of the `opt_signoff_max_tran` attribute to `true`.

Note: If set, this attribute must be applied before `opt_signoff` and `time_design_signoff`.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_fix_xtalk

```
opt_signoff_fix_talk  {true | false}
```

Default: false

Data_type: bool, read/write

Reduces the crosstalk on the net that violates the thresholds set by you.

Note: If set, this attribute must be applied before `opt_signoff` and `time_design_signoff`.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_hold_target_slack

```
opt_signoff_hold_target_slack value
```

Default: 0

Data_type: double, read/write

Specifies a target slack value in nanoseconds for hold timing optimize.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_hold_xtalk_delta_threshold

```
opt_signoff_hold_xtalk_delta_threshold value_in_ns
```

Default: `0.3 ns`

Data_type: double, read/write

Fixes the nets with the crosstalk delta delay value equal to or greater than a specified threshold value for hold views.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_hold_xtalk_slack_threshold

```
opt_signoff_hold_xtalk_slack_threshold value_in_ns
```

Default: `1000 ns`

Data_type: double, read/write

Fixes nets with the slack threshold value equal to or less than a specified threshold value for hold views.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_ignore_drv_checks

```
opt_signoff_ignore_drv_checks  {true | false}
```

Default: `false`

Data_type: bool, read/write

Specifies that DRV checks should be ignored in setup/hold/area/leakage/dynamic optimization.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_keep_tmp_files

```
opt_signoff_keep_tmp_files  {true | false}
```

Default: `false`

Data_type: bool, read/write

Keeps all the temporary files generated by the distributed multi-mode multi-corner (DMMMC) and Tempus clients for debugging purposes.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_legal_only

```
opt_signoff_legal_only {true | false}
```

Default: true

Data_type: bool, read/write

Enables the tool to use the physical data to search for legal location while doing any buffer insertion or instance movement. This ensures that there is no instance overlap at the end of the ECO fixing stage, and after sourcing the ECO file in the implementation tool, you can directly run ECO routing.

When this attribute is set to `false`, `opt_signoff` will not check for legal location although physical

data is provided. In this mode, `opt_signoff` behaves in a Logical mode flow, which means that physical data will be ignored and this might create an instance overlap and will not check local density while inserting buffers. So it is recommended that you first run ECO fixing in the legal-only mode (which is the default mode) and then, depending on the requirement, you may perform an incremental run by setting `opt_signoff_legal_only` to `false`.

Default: `true`

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_load_cell_list

`opt_signoff_load_cell_list` *`cell_list`*

Default: `""` (empty string)

Data_type: string, read/write

Specifies the list of load cells to be inserted during Hold fixing, regardless of whether those cells have a dont_use attribute.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_max_cap_margin

`opt_signoff_max_cap_margin` *`cap_margin_value`*

Default: 0

Minimum value: -10.000000

Maximum value: 0.990000

Data_type: double, read/write

Specifies the ratio by which the max_cap check should be relaxed or tightened.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_max_transition_margin

`opt_signoff_max_transition_margin` *`tran_margin_value`*

Default: 0

Minimum value: -10.000000

Maximum value: 0.990000

Data_type: double, read/write

Specifies the ratio by which the max_tran check should be relaxed or tightened.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_max_opt_runtime

`opt_signoff_max_opt_runtime` *`integer`*

Default: 0

Data_type: int, read/write

Specifies the time out period for only the timing/power optimization phase after which

opt_signoff will exit the session.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_max_paths

```
opt_signoff_max_paths integer
```

Default: -1

Data_type: int, read/write

Specifies the worst path found for each endpoint up to the number specified by the -maxPaths parameter during ECO Timing DB generation. By default, the tool will automatically set a value for `opt_signoff_max_paths` that would lead to good PBA coverage of the design within reasonable run time. You can overwrite this by setting a specific `opt_signoff_max_paths` value, but it is recommended to keep it larger than 1 million. In any case, you must ensure that `opt_signoff_max_paths` value is superior or equal than the `opt_signoff_nworst` value multiplied by the number of GBA violated endpoints.

Note:

- This attribute is only active when the `opt_signoff_retime` attribute is set.
- If set, this attribute must be applied before `time_design_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_max_runtime

```
opt_signoff_max_runtime integer
```

Default: 0

Data_type: int, read/write

Specifies the time out period, in minutes, after which `opt_signoff` will exit the session.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_max_slack

```
opt_signoff_max_slack value
```

Default: `0`

Data_type: double, read/write

Specifies the maximum slack value to be used during ECO Timing DB generation when using PBA. Setting a positive `opt_signoff_max_slack` value forces the software to retime positive GBA slack paths so that ECO optimization engine can benefit from an extra PBA Setup slack credit when doing Hold fixing or Power recovery. A positive `opt_signoff_max_slack` value implies larger runtime during ECO Timing DB generation, but the software will retime only as many paths as what is specified through the `opt_signoff_max_paths` attribute.

- **Note**:
- This attribute is only active when the `opt_signoff_retime` attribute is set.
- If set, this attribute must be applied before `time_design_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_num_report_paths

```
opt_signoff_num_report_paths integer
```

Default: `50`

Data_type: int, read/write

Specifies the number of paths printed after signoff timing analysis per view.

Note: If set, this attribute must be applied before `time_design_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_nworst

```
opt_signoff_nworst integer
```

Default: `-1`

Data_type: int, read/write

Specifies the nworst control for path-based analysis.

Note:

- This attribute is only active when the `opt_signoff_retime` attribute is set.
- If set, this attribute must be applied before `time_design_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_optimize_core_only

```
opt_signoff_optimize_core_only {true | false}
```

Default: `false`

Data_type: bool, read/write

Performs only reg2reg optimization, when set to `true`.

Note:

- This attribute is not applicable for DRV optimization.
- If set, this attribute must be applied before `opt_design`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_optimize_replicated_modules

```
opt_signoff_optimize_replicated_modules {true | false}
```

Default: false

Data_type: bool, read/write

Allows the software to perform timing optimization inside replicated hierarchies while generating only one ECO file per sets of clones. The cell names of the replicated hierarchies have to be listed in a file pointed by the `opt_signoff_partition_list_file` attribute.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_optimize_sequential_cells

```
opt_signoff_optimize_sequential_cells {true | false}
```

Default: `true`

Data_type: bool, read/write

Allows the software to perform timing optimization for sequential cells.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_partition_list_file

```
opt_signoff_partition_list_file filename
```

Default: "" (empty string)

Data_type: string, read/write

Specifies the file containing list of partitions in the design.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_pba_eco_route

```
opt_signoff_pba_eco_route {true | false}
```

Default: `false`

Data_type: bool, read/write

When set to `true`, enables `route_eco` to use accurate path-based analysis (PBA) timing during the ECO signoff timing/power closure flow. This attribute must be applied at the start of the `opt_signoff/time_design_signoff flow`.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_pba_effort

```
opt_signoff_pba_effort {medium | high}
```

Default: `medium`

Data_type: enum, read/write

When high effort mode is specified, all the optimization engines will perform more aggressive timing closure or area/power recovery with respect to path-based (PBA) timing.

Note: If set, this attribute must be applied before `opt_signoff` and `time_design_signoff`.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_post_mask

```
opt_signoff_post_mask {true | false}
```

Default: `false`

Data_type: bool, read/write

Enables the timing closure engine to perform the following netlist changes without touching the base layer mask:

- Inserts the Gate Array buffers or an inverter pair in place of existing Gate Array filler cells.
- Resizes regular cells to Gate Array cells. It also resizes Gate Array cells to Gate Array cells.
- Deletes a regular cell.

The software automatically identifies the Gate Array cells by checking which library instances have the same SITE name as the Gate Array filler cells specified by the user. Here, empty spaces are filled up by the Gate Array filler cells to ensure 100% placement density.

Note:

- This is supported by DRV, Setup, and Hold fixing.
- When `add_tieoffs_cells{{tieLo_name tieHi_name}}` setting is used, the Metal ECO flow will insert the TieLo cells to connect dangling input pins, in case the existing TieLo cells in the floorplan are extremely far or too overloaded.

Related Commands

- `opt_signoff`
- `add_tieoffs` Category Attributes

opt_signoff_post_mask_decap_cells

`opt_signoff_post_mask_decap_cells` *`list_of_decap_cells`*

Default: `""`

Data_type: string, read/write

Lists all the programmable decap cells that are allowed to be removed in post-mask mode.

Note: This attribute is applicable in the post-mask mode only.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_post_mask_filler_cells

`opt_signoff_post_mask_filler_cells` *`list_of_filler_cells`*

Default: `""`

Data_type: string, read/write

Lists all the programmable filler cells that are allowed to be removed/reinserted in post-mask mode.

Note: This attribute is applicable in the post-mask mode only.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_post_mask_gate_array_filler_cells

`opt_signoff_post_mask_gate_array_filler_cells` *`list_of_Gate_Array_filler_cells_name`*

Default: `""`

Data_type: string, read/write

Enables the software to list all the Gate Array filler cells that can be deleted or inserted back.

Note: This attribute is applicable in the Metal ECO mode only.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_post_mask_logic_cells

`opt_signoff_post_mask_logic_cells` *`list_of_regular_cells`*

Default: `""`

Data_type: string, read/write

Lists all the programmable regular logic/ECO cells that are allowed to be inserted in place of filler/decap cells during optimization in post-mask mode.

Note: This attribute is applicable in the post-mask mode only.

Example:

The following set of commands allow Hold timing closure in post-mask mode using programmable filler cells:

```
set_db opt_signoff_post_mask true
```

```
set_db opt_signoff_post_mask_filler_cells {ln10_ecofiller40x … ln10_ecofiller4x}
set_db opt_signoff_post_mask_decap_cells {ln10_ecofillsgcap40x … ln10_ecofillsgcap4x}
set_db opt_signoff_post_mask_logic_cells {ln10_ecodlybt01 ln10_ecobuft04 …
ln10_ecoand02 … ln10_ecoinv04 …}
opt_signoff -hold
```

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_post_sta_tcl

```
opt_signoff_post_sta_tcl filename
```

Default: "" (empty string)

Data_type: string, read/write

Specifies the file containing the TCL code that will be executed immediately after signoff timing analysis per view.

Note:

- These TCL codes should follow Tempus syntax.
- If set, this attribute must be applied before `time_design_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_power_aware

```
opt_signoff_power_aware {true / false}
```

Default: false

Data_type: bool, read/write

Enables power awareness in all optimizers and transforms.

Tempus ECO provides the ability to take power as part of the overall cost function when doing timing closure.

When this attribute is enabled before the start of an optimization session, the current optimization and any subsequent optimizations (if running in incremental mode) checks for power changes for all optimizers and transforms during any changes in the design. In any case, the first priority remains getting the best final timing but enabling this option will get there with possibly slighter ECO although resulting in lesser final power.

For example, during to fix a Setup timing path violation, by default the tool would potentially choose to size one instance to a high leakage cell, while with `opt_signoff_power_aware` mode, the tool would try to get to same timing by doing multiple sizing to non-high leakage cells.

Note

- This feature requires power activity to be annotated on the netlist with `report_power` command, either through external activity file (recommended) or using propagated activity based on some default toggling rate.
- This feature honors the `opt_signoff_power_opt_focus` attribute, which means that the user can decide to force the tool in reducing more total or leakage or dynamic power increase.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_power_opt_focus

`opt_signoff_power_opt_focus total | leakage | dynamic | leakageOnly | dynamicOnly`

Default: `total`

Data_type: enum, read/write

Specifies whether a given netlist should be optimized only for leakage or dynamic power reduction, or more for leakage or dynamic power while still reducing the overall total power during total power optimization.

The following options are available:

- `total`: The power optimization engine focuses on getting the optimal total power in the design.

- `leakage`: The power optimization engine optimizes total power but focuses more on leakage power reduction than on dynamic power reduction.
- `dynamic`: The power optimization engine optimizes total power but focuses more on dynamic power reduction than on leakage power reduction.
- `leakageOnly`: The power optimization engine focuses only on leakage power reduction.
- `dynamicOnly`: The power optimization engine focuses only on dynamic power reduction.

Note:

- This parameter is honored by `opt_signoff -power` and also by `opt_signoff -drv/-setup/-hold` when the `opt_signoff_power_aware` attribute is set to `true`.
- If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_pre_sta_tcl

```
opt_signoff_pre_sta_tcl filename
```

Default: "" (empty string)

Data_type: string, read/write

Specifies the file containing the TCL code that will be executed immediately before signoff timing analysis per view.

Note: If set, this attribute must be applied before `time_design_signoff`.

Related Commands

- `time_design_signoff`

opt_signoff_prefix

```
opt_signoff_prefix prefix
```

Default: ESO

Data_type: string, read/write

Specifies the prefix to be assigned to the new instances inserted.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_preserve_filler

```
opt_signoff_preserve_filler  {true | false}
```

Default: `true`

Data_type: bool, read/write

When set to `true`, saves and restores filler states during signoff timing optimization. This helps improve the runtime as it saves the time taken to re-insert all the fillers.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_read_eco_opt_db

```
opt_signoff_read_eco_opt_db dir_name
```

Default: "" (empty string)

Data_type: string, read/write

Specifies the path of directory where previously generated database files are stored.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_read_irdrop_db

```
opt_signoff_read_irdrop_db dir_name
```

Default: "" (empty string)

Data_type: string, read/write

Specifies the path of directory where previously generated IR drop database files are stored.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_resize_inst

```
opt_signoff_resize_inst {true | false}
```

Default: `true`

Data_type: bool, read/write

Enables or disables resizing transform.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_retime

```
opt_signoff_retime {none |aocv | path_slew_propagation | aocv_path_slew_propagation}
```

Default: `none`

Data_type: enum, read/write

Selects the retime mode for path-based analysis.

Note: If set, this attribute must be applied before `opt_signoff` and `time_design_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_retime_mode

```
opt_signoff_retime_mode {none | path | exhaustive}
```

Default: `path`

Data_type: string, read/write

Retimes mode for path based analysis.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_retime_depth

```
opt_signoff_retime_depth {default | infinite}
```

Default: `default`

Data_type: string, read/write

Retimes depth for exhaustive path based analysis.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_retime_depth_early

```
opt_signoff_retime_depth_early {default | infinite}
```

Default: `default`

Data_type: string, read/write

Retimes depth for exhaustive path based early analysis.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_routing_congestion_aware

```
opt_signoff_routing_congestion_aware {true | false}
```

Default: `false`

Data_type: bool, read/write

Checks routing congestion before adding buffers.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_select_hold_endpoints

```
opt_ signoff_select_hold_endpoints  file_name
```

Default: " " (empty string)

Data_type: string, read/write

Specifies a file containing the list of selected endpoints for hold fixing.

Note: When including endpoints, the `opt_signoff_optimize_core_only` attribute must be set to `false`.

Related Command

- `opt_signoff`

opt_signoff_select_drv_net_file

```
opt_signoff_select_drv_net_file file_name
```

Default: " " (empty string)

Data_type: string, read/write

Specifies a file containing the list of nets to be optimized during DRV fixing. The fixing of max_transition and max_capacitance violations occurs only on the specified nets and the other violating nets are ignored. The file specified includes one net per line.

Note:

- Wild cards and regular expressions are not supported in this file.
- If set, this attribute must be applied before `opt_signoff`.

Related Command

- `opt_signoff`

opt_signoff_select_drv_pin_file

```
opt_signoff_select_drv_pin_file file_name
```

Default: `" "` (empty string)

Data_type: string, read/write

Specifies a file containing the list of pins to be optimized during DRV fixing. The fixing occurs only on the specified instance pins and the other violating pins are ignored. The file specified includes one pin per line.

Note:

- Wild cards and regular expressions are not supported in this file.
- If set, this attribute must be applied before `opt_signoff`.

Related Command

- `opt_signoff`

opt_signoff_select_setup_endpoints

```
opt_ signoff_select_setup_endpoints  file_name
```

Default: `" "` (empty string)

Data_type: string, read/write

Specifies a file containing the list of selected endpoints for setup fixing.

Note:

- When including endpoints, the `opt_signoff_optimize_core_only` attribute must be set to `false`.
- If set, this attribute must be applied before `opt_signoff`.

Related Command

- `opt_signoff`

opt_signoff_setup_recovery

```
opt_signoff_setup_recovery {true | false}
```

Default: `false`

Data_type: bool, read/write

Specifies power-aware setup recovery for setup fixing.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_setup_target_slack

`opt_signoff_setup_target_slack` *`slack`*

Default: `0.0`

Data_type: double, read/write

Specifies a target slack value in nanoseconds for Setup timing optimization.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_setup_xtalk_delta_threshold

`opt_signoff_setup_xtalk_delta_threshold` *`value_in_ns`*

Default: `0.3 ns`

Data_type: double, read/write

Fixes the nets with the crosstalk delta delay value equal to or greater than a specified threshold value for setup views.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_setup_xtalk_slack_threshold

opt_signoff_setup_xtalk_slack_threshold *value_in_ns*

Default: 1000 ns

Data_type: double, read/write

Fixes the nets with the slack threshold value equal to or less than a specified threshold value for setup views.

Note: If set, this attribute must be applied before opt_signoff.

Related Commands

- opt_signoff
- time_design_signoff

opt_signoff_skip_drv_net_file

opt_signoff_skip_drv_net_file *file_name*

Default: " " (empty string)

Data_type: string, read/write

Specifies a file containing the list of nets to be excluded during DRV fixing. The fixing of max_transition and max_capacitance violations occurs on nets other than specified nets. The file specified includes one net per line.

Note:

- Wild cards and regular expressions are not supported in this file.
- If set, this attribute must be applied before opt_signoff.

Related Command

- opt_signoff

opt_signoff_set_hold_endpoints_margin

```
opt_signoff_set_hold_endpoints_margin file_name
```

Default: " " (empty string)

Data_type: string, read/write

Specifies endpoint-specific margin for hold fixing.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Command

- opt_signoff

opt_signoff_set_setup_endpoints_margin

```
opt_signoff_set_setup_endpoints_margin file_name
```

Default: " " (empty string)

Data_type: string, read/write

Specifies endpoint-specific margin for setup fixing.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Command

- opt_signoff

opt_signoff_swap_inst

```
opt_signoff_swap_inst {true | false}
```

Default: `true`

Data_type: bool, read/write

Enables/disables VT swap resizing. The setup/leakage optimizers do not honor this attribute and always perform VT-swapping.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_verbose

```
opt_signoff_verbose {true | false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether the command should output log file reporting with verbosity or not.

Note: If set, this attribute must be applied before `opt_signoff`.

Related Commands

- `opt_signoff`
- `time_design_signoff`

opt_signoff_write_eco_opt_db

```
opt_signoff_write_eco_opt_db dir_name
```

Default: `ecoTimingDB`

Data_type: string, read/write

Specifies a path of directory where generated database files are kept.

Note: If set, this attribute must be applied before `time_design_signoff`.

Related Commands

- opt_signoff
- time_design_signoff

opt_virtual

```
opt_virtual
[-help]
[-out_dir dir_name]
[-timing_reports]
```

This command is based on the gigaOpt infrastructure and it provides prototyping capability at several steps of the hierarchical flow to specify and refine the top-level timing constraints and floorplan. It performs, at preRoute stages, fast virtual optimization using buffering and driver resizing. This command updates the timing graph without modifying the netlist. Using gigaOpt infrastructure, the command has the following capabilities:

- Provides a good QOR (AAE DC, gigaOpt global optimizer, and DRV-based)
- Run in multi-threaded mode
- Supports masters and clones

Parameters

`-help`	Outputs a brief description that includes type and default information for each `opt_virtual` parameter. For a detailed description of the command and all of its parameters, use the man command: `man opt_virtual`.
`-out_dir` *dir_name*	Specifies the name of the directory where the software writes timing reports. This parameter is used only when the `-timing_reports` parameter is specified. *Data_type*: string, optional
`-timing_reports`	Generates timing reports that reflect virtual optimization. *Data_type*: bool, optional

opt Category Attributes

The root attributes in the `opt` category are:

- opt_activity_refresh_args
- opt_add_always_on_feed_through_buffers
- opt_add_insts
- opt_add_ports
- opt_add_repeater_report_failure_reason
- opt_all_end_points
- opt_allow_only_cell_swapping
- opt_allow_multi_bit_on_flop_with_sdc
- opt_area_recovery
- opt_area_recovery_setup_target_slack
- opt_concatenate_default_and_user_prefixes

- opt_verbose

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `opt` category, use the following command:

```
get_db -category opt
```

opt_activity_refresh_args

```
opt_activity_refresh_args "list_of_arguments"
```

Default: `""`

Data_type: string

Specifies the list of simulation options to be passed for Joules Xreplay. The attribute accepts all arguments of the `xreplay_stimulus` command.

The following arguments can be specified using this attribute:

- `[-xrun_path]` Specify xrun binary path to run Xcelium for replay simulation.
- `[-rtl_stim]` Specify the input RTL stimulus file.
- `[-stim_format]` Suboption of `-rtl_stim`, provides format of rtl stimulus.
- `[-dut_instance]` Suboption of `-rtl_stim`, provides dut hierarchy in rtl stimulus.
- `[-start]` Specify start time to run replay for particular stimulation time duration, for example 24ns. Default is simulation start time.
- `[-end]` Specify end time to run replay for stimulation time duration, for example 100ns. Default is simulation end time.
- `[-verilog_model_files]` Specify list of library verilog models
- `[-stim_annotation]` Honor stim annotation of only the specified objects.
- `[-joules_setting]` Specify the Tcl file to be sourced before xreplay_stim command
- `[-out]` Specify the output replayed gate-level stimulus file. Default is

joulesWorkDir/replayed_stim.shm

- `[-reset_activity_before_readback]` Will reset the previous activity before reading the xreplayed activity file.
- `[-delay_mode none | zero | unit | punit | delay | pdelay] (default: none)`

For setting the arguments: `set_db opt_activity_refresh_args "<args>"`

For querying the arguments: `get_db opt_activity_refresh_args`

opt_add_always_on_feed_through_buffers

```
opt_add_always_on_feed_through_buffers {true | false}
```

Default: false

Data_type: bool

Used by `opt_design` and PD-aware `add_repeater_by_rule`. When this attribute is set to `true`, `opt_design` will use always-on buffers in both pre-Route and post-Route for all the optimization steps; and `add_repeater_by_rule` will use always-on buffer for repeater insertion. It should be used for aggressive always-on buffering during optimization.

The default `opt_design` behavior is to use always-on buffers only during pre-Route DRV fixing.

Related Commands

- `opt_design`
- `add_repeater_by_rule`

opt_add_insts

```
opt_add_insts {true | false}
```

Default: true

Data_type: bool

Specifies whether or not timing optimization can add instances.

Related Command

- opt_design

opt_add_ports

```
opt_add_ports {true | false}
```

Default: `true`

Data_type: bool

Controls whether or not timing optimization adds ports to the lower-level hierarchies of the design. Prohibiting the software from adding ports (when this attribute is set to false) might not be optimal because buffers are not allowed to be added exactly where needed; however, this preserves hierarchical boundaries of the design so that generated test vectors are still valid, and module-by-module verification is possible.

Related Command

- opt_design

opt_add_repeater_report_failure_reason

```
opt_add_repeater_report_failure_reason {true | false}
```

Default: `false`

Data_type: bool

When set to `true`, enables the printing of detailed failure reasons for each net for the `add_repeater_by_rule` command. By default, the report will be generated in the `timingReports` directory. If the directory is not available, it will be created. For example,

```
<run_dir>/timingReports/ARRFailureReason/ARRRpt.preRoute.1
```

Use Model

```
set_db  opt_add_repeater_report_failure_reason true

add_repeater_by_rule -include_nets_file ./net.list -rule $scr/rule -pre_route -
report_ignored_nets ignore_nets
```

Note the following:

- The ignored nets report is appended at the beginning of the failure reason report file. If "`-report_ignored_nets IGNORE_NET_REPORT_NET_FILE_NAME`" is specified, then the ignored nets report is also saved to the file "`IGNORE_NET_REPORT_NET_FILE_NAME`".
- For multiple calls of ARR with different set of nets and constraints, equal number of failure reports will be generated under the `ARRFailureReason` directory. A suffix, "`_<n>`" will be added, with n being the nth call of ARR. For example, three calls of ARR will lead to the generation of the following three files:

  `<run_dir>/timingReports/ARRFailureReason/ ARRRpt.preRoute.1`

  `<run_dir>/timingReports/ARRFailureReason/ ARRRpt.preRoute.2`

  `<run_dir>/timingReports/ARRFailureReason/ ARRRpt.preRoute.3`
- The default mode of ARR reporting is pre_route. If you specify `-post_route` or `-along_route`, the following will be appended in the report names:`<run_dir>/timingReports/ARRFailureReason/ ARRRpt.postRoute.1`

  `<run_dir>/timingReports/ARRFailureReason/ ARRRpt.alongRoute.1`

Note: The behavior of the parameter, `-report_ignored_nets`, remains unchanged. It writes the reports with user-specified file name under the run directory.

Related Command

- `opt_design`

opt_all_end_points

```
opt_all_end_points {true | false}
```

Default: false

Data_type: bool

Runs total negative slack optimization in addition to the worst negative slack optimization and does so on all end points to ensure a high quality timing result.

This feature is automatically activated while running either of the `set_db design_flow_effort standard | extreme` timing-closure flows. So, despite the default being `false` it is overwritten by the `design_flow_effort` attribute setting.

Note: When this attribute is set to `false`, there may still be some fast TNS optimization done during `pre_route` optimization but there is no effect on `post_route` setup optimization. It also has no

effect on hold optimization, which means that regardless of this setting, all hold violating paths will always be optimized.

Related Commands

- `opt_design`
- `place_design`

opt_allow_only_cell_swapping

```
opt_allow_only_cell_swapping {true | false}
```

Default: false

Data_type: bool, read/write

Forces the post-route optimization to perform only same-size Vth swapping for timing improvements. This attribute works best on multi-Vth library designs.

Note: Use this attribute for reoptimizing the timing in specific cases where routing should remain unchanged.

Related Command

- `opt_design`

opt_allow_multi_bit_on_flop_with_sdc

```
opt_allow_multi_bit_on_flop_with_sdc {true | false | merge_only | split_only}
```

Default: `true`

Data_type: bool, read/write

When this attribute is set to `true`, or by default, the software will not honor the SDC constraints while merging or splitting of flops in the multi-bit flip flop flow. Set this attribute to `false` to honor SDC constraints while merging or splitting of flops.

Use `merge_only` to ignore the SDC constraints while merging but honor for splitting. Use `split_only` to ignore the SDC constraints while splitting but honor for merging.

Note: When this attribute is set to `true`, the software will do merge/split even if there is SDC on D/Q

pins and the SDC will be copied to the corresponding D/Q pins in the new flop.

But if there are SDC constraints on SE/SI pin, the merging becomes more complicated. For example, a single flop A and flop B have 1 SE pin and D/Q pin. When merging is done, the SDC on D/Q pin will be copied to the new D0/Q0 and D1/Q1, and the SDC information will not be lost. But in the new 2-bit flop, there will be only one SE pin. This raises the issue of which SDC should be copied into the new flop. In this case, the software will check the SE pin SDC in flop A and flop B. If they are compatible, then it will do merging. Otherwise, the merging will not be done, even if the attribute is set to `true`.

Related Command

- `opt_design`

opt_area_recovery

```
opt_area_recovery {false | true | default}
```

Default: `default`

Data_type: enum, read/write

Controls whether timing optimization creates additional space by downsizing gates or deleting buffers, while maintaining worst slack and total negative slack.

This attribute can be used in three modes: `default`, `true`, and `false`.

- `default`: By default, area reduction is always called after global optimation and after the second TNS optimization. During the rest of `opt_design`, area reduction is called depending on the density level of the current design.
- `true`: When this attribute is set to `true`, area reduction is always called before the global optimization stage, after the global optimization stage, and after the second TNS optimization. During the rest of `opt_design`, area reduction is called depending on the density level of the current design.
- `false`: No area reduction is performed during `opt_design`.

Note: This attribute is used to reclaim area during pre-Route optimization. For reclaiming area during post-Route optimization, use the `opt_post_route_area_reclaim` attribute.

Related Command

- opt_design

opt_area_recovery_setup_target_slack

```
opt_area_recovery_setup_target_slack slack
```

Default: 0.0s

Data_type: double, read/write

Specifies a user-defined target slack for area reclaim vs. timing. When a slack value is specified, the software prevents area reclaim optimization from creating or working on near critical paths. Typically, you can set this attribute to 0.1 with opt_setup_target_slack attribute at the default value of 0.0. This implies that the area reclaim will not work on any paths less than 0.1ns.

Note that the value for opt_setup_target_slack attribute takes higher priority. For example, if opt_area_recovery_setup_target_slack is set to -0.1 and opt_setup_target_slack is at 0.0 then setup timing will not be allowed to degrade past 0ps and a warning will be issued.

Similarly, if say opt_area_recovery_setup_target_slack is at +0.1 and opt_setup_target_slack is set to +0.2 then timing will target +0.2 and a warning will be issued.

You need to set this attribute before any area reclaim is done.

Related Command

- opt_design

opt_concatenate_default_and_user_prefixes

```
opt_concatenate_default_and_user_prefixes {true | false}
```

Default: true

Data_type: bool, read/write

Controls whether to combine the default prefix for cells and nets added by timing optimization with the prefixes specified by opt_new_net_prefix and opt_new_inst_prefix attributes. By default, the software combines the specified prefixes with the default prefix. Specify false for this attribute to ignore the default prefix and use only the prefix specified by opt_new_net_prefix and opt_new_inst_prefix attributes.

For example, if the default prefix is PSN_000234 and you set the following attributes:

```
opt_concatenate_default_and_user_prefixes true

opt_new_net_prefix POSTROUTE_N

opt_new_inst_prefix POSTROUTE_C
```

The software uses the following prefixes:

- For cells added by optimization: `POSTROUTE_C_PSN_00234`
- For nets added by optimization: `POSTROUTE_N_PSN_00234`

If the default prefix is `PSN_000234` and you set the following attribute:

```
opt_concatenate_default_and_user_prefixes false

opt_new_net_prefix POSTROUTE_N

opt_new_inst_prefix POSTROUTE_C
```

The software uses the following prefixes:

- For cells added by optimization: `POSTROUTE_C`
- For nets added by optimization: `POSTROUTE_N`

Note: If you specify `false` for this attribute, you must also specify `opt_new_inst_prefix` and `opt_new_net_prefix` attributes. In addition, you must specify a different prefix for instances and nets.

Related Command

- `opt_design`

opt_consider_routing_congestion

```
opt_consider_routing_congestion {auto | false | true}
```

Default: `auto`

Data_type: enum, read/write

Checks the routing congestion at the post-Route stage during optimization of setup, hold, drv, or glitch. This attribute also impacts post-CTS hold fixing. By default, this attribute is set to `auto` for both `opt_design -post_route` and `opt_design -post_route -hold` options. This attribute helps improve NR DRC's as well as Timing jumps caused by routing detours on congested designs.

Related Command

- opt_design

opt_constant_inputs

```
opt_constant_inputs {true | false}
```

Default: `false`

Data_type: bool, read/write

Forces optimization of instances with constant inputs, even if it worsens the objective gain - in terms of area, power, and delay.

Related Command

- opt_design

opt_constant_nets

```
opt_constant_nets {true | false}
```

Default: true

Data_type: bool, read/write

Specifies whether or not timing optimization optimizes constant nets.

Related Command

- opt_design

opt_delete_insts

```
opt_delete_insts {true | false}
```

Default: true

Data_type: bool, read/write

Specifies whether or not timing optimization can delete instances.

Related Command

- opt_design

opt_detail_drv_failure_reason

```
opt_detail_drv_failure_reason {true | false}
```

Default: false

Data_type: bool, read/write

When set to true, enables the printing of detailed DRV failure reason report file that contains the faliure summary with the net name. The log file contains a simple version of failure summary without the net name. In addition, the top number(default 50) of violating nets are printed in separate files along with the violation reasons.

By default, this attribute is set to false, which means that only a simple version of failure summary without the net name is printed in the log file and no other files are created.

Note: If there is no DRV failure during the optimization flow, the failure reason report file will not be generated even when this attribute is set to true.

Related Command

- opt_design

opt_detail_drv_failure_reason_max_num_nets

```
opt_detail_drv_failure_reason_max_num_nets value
```

Default: 50

Data_type: int, read/write

Specifies the number of violating nets for which the DRV failure reasons are to be printed in the report files. The default value is 50, which means failure reasons for 50 violating nets are printed by default. The minimum value that can be specified is 1. The maximum value that can be specified is 9999. If this value is specified, failure reasons for all the violating nets are printed.

For example, if you set this attribute to 100, then the top 100 max tran violating nets, if present, will be printed in file, "xx.maxTran" and the top 100 max cap violating nets, if present, will be printed in file, "xx.maxCap". Also, a file, "xx.maxFanout" may also be generated.

For each file that is generated, the first printed net has the worst violation value. The file is sorted based on violation values while printing.

Related Command

- opt_design

opt_down_size_insts

```
opt_down_size_insts {true | false}
```

Default: true

Data_type: bool, read/write

Specifies whether or not timing optimization can downsize instances.

Related Command

- opt_design

opt_drv_margin

```
opt_drv_margin margin
```

Default: 0.0

Data_type: double, read/write

Scales the maxCap and maxTran constraints according to the *margin* decimal value specified. For example, specifying a value of 0.2 for this attribute tightens the margin (makes it more pessimistic) by 20 percent during optimization and specifying a value of -0.2 relaxes the margin (makes it more optimistic) by 20 percent. Introducing a pessimistic margin improves correlation between the number of DRC violations before and after routing.

Value range: -0.7 ~ 0.7

Related Command

- opt_design

opt_enable_data_to_data_checks

```
opt_enable_data_to_data_checks {true | false}
```

Default: false

Data_type: enum, read/write

Enables data to data checks during optimization. During optimization the data to data timing checks are set to off by default to ensure that the engine focuses on other paths. To allow checks to be visible during optimization you can set this option to true.

Related Command

- `opt_design`

opt_enable_podv2_clock_opt_flow

`opt_enable_podv2_clock_opt_flow {true | false}`

Default: `false`

Data_type: bool, read/write

When set to `true`, enables the place_opt_design V2 (PODV2) and `clock_opt_design` flow.

opt_enable_restructure

```
opt_enable_restructure {true | false}
```

Default: true

Data_type: bool, read/write

Specifies whether or not timing optimization swaps pins and restructures the netlist.

Note: This attribute is not enabled when the `design_flow_effort` attribute is set to `express`.

Related Command

- `opt_design`

opt_drv

```
opt_drv {true | false}
```

Default: `true`

Data_type: bool, read/write

Repairs all nets that are constrained for maximum capacitance violations and maximum transition violations. The capacitance and transition constraint values are specified in the timing constraint file or in the library. If you specify false for this attribute, the software repairs only the paths with timing violations.

Related Command

- `opt_design`

opt_drv_with_miller_cap

```
opt_drv_with_miller_cap {true | false}
```

Default: `false`

Data_type: bool, read/write

When set to `true`, enables ECSM/CCS miller capacitance DRV reporting and fixing for `time_design` and `opt_design`. However, the `timing_report_use_receiver_model_capacitance` attribute must also be set to `true`.

By default, this parameter is set to `false`, which means that miller cap DRV reporting and fixing is disabled.

Related Command

- `opt_design`
- `time_design`

opt_fix_fanout_load

```
opt_fix_fanout_load {true | false}
```

Default: `false`

Data_type: bool, read/write

Forces timing optimization to correct fanout load violations, which can either be maximum load or maximum fanout count violations, depending on the libraries.

Related Command

- `opt_design`

opt_hold_allow_overlap

```
opt_hold_allow_overlap {auto | true | false}
```

Default: `auto`

Data_type: enum, read/write

Allows hold-fixing algorithm to insert buffers with overlap when large enough empty space locations are not available. The placement will then be legalized before ECO routing. Setting this attribute allows the tool to fix hold violations, but might have some negative impact on setup timing.

- `auto`: Hold fixing will run in the "allow overlapping" mode in post-CTS and not in post-Route stage.
- `true`: Hold fixing will run in the "allow overlapping" mode in both post-CTS and post-Route stage.
- `false`: Hold fixing will run in "allow overlapping" mode in both post-CTS and post-Route stage.

Related Command

- `opt_design`

opt_hold_allow_resize

```
opt_hold_allow_resize {true | false}
```

Default: `true`

Data_type: bool, read/write

Controls the resizing capability inside hold optimization. When set to `true` or `false`, resizing is turned "on" or "off" in both post-CTS and post-Route hold optimization.

Related Command

- `opt_design`

opt_hold_allow_setup_tns_degradation

```
opt_hold_allow_setup_tns_degradation {true | false}
```

Default: true

Data_type: bool, read/write

Controls whether the software allows total negative slack to degrade during hold fixing operations or not. By default, the software allows the slack to degrade in order to fix more hold violations. To override the default behavior and ensure that the setup total negative slack is maintained during hold fixing, set this attribute to `false`.

Related Command

- `opt_design`

opt_hold_ignore_path_groups

```
opt_hold_ignore_path_groups {groupAgroupB....}
```

Default: `""` (empty string)

Data_type: string, read/write

Specifies the clock domains or path groups that should be excluded from hold timing optimization. This attribute impacts only `opt_design -post_cts/-post_route -hold`.

Note: To reset this attribute, apply an empty list.

Note: If a violated path is in two path groups and only one of those paths is specified using this attribute, this path is still fixed during hold fixing.

Related Command

- opt_design

opt_hold_cells

```
opt_hold_cells list_of_buffers
```

Default: "" (empty string). This will trigger the default flow.

Data_type: string, read/write

Allows you to force the usage of only a specific list of buffer and delay cells. The *list_of_buffers* contains regular buffers and delay buffer cells. When this list contains at least one cell, use only the specified cells.

Note: This attribute does not support wildcards. The *list_of_buffers* must contain only exact cell names.

Note: When this list of buffers is specified, the opt_design command disables automatic cell filtering, which could impact the runtime/QOR/leakage of opt_design.

Note: The opt_design command uses the specified cells without honoring the dont_use attribute.

Related Command

- opt_design

opt_hold_on_excluded_clock_nets

```
opt_hold_on_excluded_clock_nets {true | false}
```

Default: false

Data_type: bool, read/write

Controls whether or not hold fixing will be performed on excluded clock nets. This attribute is applicable for both post-CTS and post-Route Hold optimization.

Related Command

- opt_design

opt_hold_slack_threshold

```
opt_hold_slack_threshold slack
```

Default: `-1000ns`

Data_type: double, read/write

Allows you to provide a hold slack threshold beyond which the hold timing violations will not be fixed. This is used to avoid fixing out of bound violations at an early stage when the timing constraints and design environment might not be mature enough. The slack value is specified in nano seconds (ns).

Note: When the hold slack threshold value is specified using this attribute, the hold fixing timing table excludes the violations with slack worse than the specified value.

Note: The threshold value specified is for hold WNS.

Related Command

- `opt_design`

opt_hier_add_antenna_cell

```
opt_hier_add_antenna_cell {true | false}
```

Default: false

Data_type: bool, read/write

Adds antenna cells to the interface nets crossing partition boundaries. The antenna violations could not be created due to the partition boundary nets. These violations are seen only when the full design is assembled. Therefore, when this attribute is set to `true`, it will add antenna cells to fix these violations.

opt_hier_opt_stage

```
opt_hier_opt_stage {type {enum pre_cts post_cts unset}}
```

Default: unset

Data_type: enum, read/write

Ensures proper settings are turned on for

corresponding `opt_design` stages. `opt_hier_opt_stage` should be set before `opt_design`, and in cases where module view types are defined, `opt_hier_opt_stage` should be defined after module view types for all partitions (including FlexILMs) are defined.

For example, `opt_hier_opt_stage pre_cts` ensures that `opt_design -pre_cts` honors fence, keep partition boundary port, etc.

Related Command

- `opt_design`

opt_high_effort_cells

```
opt_high_effort_cells list_of_cells
```

Default: `""` (empty string)

Data_type: string, read/write

Specifies the list of cells to be used for high-effort optimization. This attribute is applicable in both pre-Route and post-Route setup optimization.

Note: If the `dont_touch` constraint is set to `true` for the specified cells, then these cells will not be used for high-effort optimization.

Related Command

- `opt_design`

opt_hold_target_slack

```
opt_hold_target_slack holdTargetSlack
```

Default: `0.0`

Data_type: double, read/write

Specifies a target slack value in nanoseconds to use for hold analysis only. During setup violation repair, the setup target slack is defined by the attribute, `opt_setup_target_slack` and the hold target slack value is 0. Generally, you use both the `opt_setup_target_slack` and the `opt_hold_target_slack` attributes for hold analysis. If you specify only `opt_hold_target_slack` attribute, the setup target slack value is 0.

Related Command

- opt_design

opt_honor_density_screen

```
opt_honor_density_screen {true | false}
```

Default: false

Data_type: bool, read/write

Controls whether or not density screens (partial placement blockages used to control congestion) are honored while optimizing timing. By default, this attribute is set to false , which means that the density screens are not honored.

Related Command

- opt_design

opt_honor_fences

```
opt_honor_fences {true | false}
```

Default: false

Data_type: bool, read/write

Specifies that the timing optimization takes fences or region constraints into account. This attribute is honored by each opt_design step. If you optimize the design with this attribute set to true, the placement is legal.

This feature is useful for hierarchical designs. Because this attribute adds constraints to timing optimization, enable it only when needed.

Note: opt_design will not honor very small fences when this attribute is set to true if it would cause fence utilization to be greater than 100 percent.

Related Command

- opt_design

opt_leakage_to_dynamic_ratio

```
opt_leakage_to_dynamic_ratio ratio
```

Default: `1.0`

Data_type: double, read/write

Controls the priority of the power-driven optimization. You can set any value between 0 and 1. Use this attribute along with the `opt_power_effort` attribute.

Some examples of what the value of this attribute indicates are provided below:

- `opt_leakage_to_dynamic_ratio 1.0`
  This is the default value and implies that timing optimization will be purely leakage-power driven optimization.
- `opt_leakage_to_dynamic_ratio 0`
  This implies that timing optimization will be purely dynamic power-driven optimization.
- `opt_leakage_to_dynamic_ratio 0.5`
  This implies that timing optimization will be both dynamic and leakage power-driven and trade-offs may need to be done to get a balance between the leakage and dynamic power optimization.
- `opt_leakage_to_dynamic_ratio 0.1`
  This implies that timing optimization will be both dynamic and leakage power-driven but dynamic power optimization will be favored.
- `opt_leakage_to_dynamic_ratio 0.9`
  This implies that timing optimization will be both dynamic and leakage power-driven but leakage power optimization will be favored.

Related Command

- `opt_design`

opt_max_density

```
opt_max_density value
```

Default: 0.95

Data_type: double, read/write

Specifies the maximum value for density (area utilization). The `opt_design` command does not grow the netlist above this value. When reaching a density close to the value specified by this attribute, `opt_design` has limited optimization capability.

Related Command

- `opt_design`

opt_max_length

```
opt_max_length length
```

Default: `-1.0`

min=-1, max=2147483647

Data_type: double, read/write

Specifies that `opt_design` honors the maxLength rule as any other DRV rule (`max_cap/max_tran/max_fanout`). The `opt_design` command will fix all the nets that are violating this rule and will ensure to not create any long nets that violate it. The value is specified in micrometer.

Note: This attribute implies that more buffers gets inserted in the netlist. This attribute is disabled by default.

Note: During the pre-Route stage, some maxLength violations might still exist after running `opt_design` due to routing topology changes taking place during the flow.

Related Command

- `opt_design`

opt_move_insts

```
opt_move_insts {true | false}
```

Default: `true`

Data_type: bool, read/write

Allows cells in the critical path to move when the software repairs setup violations or optimizes

timing along the critical path, if allowing them to move improves timing.

Related Command

- `opt_design`

opt_multi_bit_combinational_mode

`opt_multi_bit_combinational_mode {auto | power | area}`

Default: `auto`

Data_type: enum, read/write

Enables the user-specific multi-bit combinational cell (MBCC) merging and splitting based on area and power.

`auto`: Enables merging or splitting of MBCCs based on area (*if power effort is none*), otherwise based on power.

`power`: Enables merging or splitting of MBCCs based on power.

`area`: Enables merging or splitting of MBCCs based on area.

Default: `auto`

Related Command

- `opt_design`

opt_multi_bit_combinational_opt

`opt_multi_bit_combinational_opt {false | true | mergeOnly | splitOnly}`

Default: `splitOnly`

Data_type: enum, read/write

Enables and disables the multi-bit combinational flow. This flow is called as a part of the pre-CTS optimization stage. The following settings are available:

- true: enables both merging and splitting of combinational cells
- `false`*:* disables the flow

- `mergeOnly`: only merges the combinational cells
- `splitOnly`: only splits the combinational cells

Related Command

- `opt_design`

opt_multi_bit_combinational_merge_timing_effort

```
opt_multi_bit_combinational_merge_timing_effort {none | low | medium | high}
```

Default: `medium`

Data_type: enum, read/write

Specifies the timing effort-level for multi-bit combinational merging.

- If the attribute is set to `high`, the software merges the combinational cell to maintain or improve the timing.
- If the attribute is set to `low`, the software merges the combinational cell with allowing timing degradation.
- If the attribute is set to `medium`, the software allows merging without/minimal degradation in timing.

Related Command

- `opt_design`

opt_multi_bit_combinational_split_timing_effort

```
opt_multi_bit_combinational_split_timing_effort {none | low | medium | high}
```

Default: `low`

Data_type: enum, read/write

Specifies the timing effort-level for multi-bit combinational splitting.

- If the attribute is set to `low`, the software allows splitting to critical paths only.

- If the attribute is set to `medium`, the splitting happen to critical paths to improve timing.
- If the attribute is set to `high`, the software performs aggressive splitting to improve timing.

Related Command

- `opt_design`

opt_multi_bit_flop_merge_bank_label_inference

`opt_multi_bit_flop_merge_bank_label_inference {true | false}`

Default: `false`

Data_type: bool, read/write

Enables soft merging of flops with the same bank label.

This is a root attribute.

- To set the value of any root attribute, use the `set_db` command:
  `set_db *attribute_name value*`
- To get the current value of any root attribute, use the `get_db` command:
  `get_db *attribute_name*`

Related Commands

- `opt_design`

opt_multi_bit_flop_merge_timing_effort

`opt_multi_bit_flop_merge_timing_effort {low | medium | high}`

Default: `medium`

Data_type: enum, read/write

Specifies the timing effort level for MBFF merging.

- `low` effort setting allows degrading in timing to achieve merging.
- `medium` effort means that merging happens either without or with minimal degradation of timing

after merging.

- `high` effort setting does not allow any degradation and does merging only if it either maintain or improves timing.

Related Command

- `opt_design`

opt_multi_bit_flop_opt

```
opt_multi_bit_flop_opt {true | false | mergeOnly | splitOnly}
```

Default: `splitOnly`

Data_type: bool, read/write

Enables and disables the multi-bit flip flop flow. This flow is called as a part of the pre_CTS optimization stage. Set this attribute to `true` to enable both merging and splitting of flops. Set it to `false` to disable the flow. Set it to `mergeOnly` to only merge flops. By default, the attribute is set to `splitOnly`, which means the flow is enabled only for splitting MBFFs.

Note:

- This option is independent of `opt_enable_restructure, opt_resize_flip_flops`, and `opt_preserve_all_sequential` attributes.
- To ensure sufficient multi-bit conversion ratio, allow more usable multi-bit flop cells from the libraries. Use the command, `report_multi_bit_ffs -all -equivalence` to write out the corresponding multi-bit flop cells to the single-bit flop cells.
- To reduce long runtime in flop merge steps, ensure that the scan enable signal nets connecting to the flops are buffered, which means without max-fanout violations.

Related Command

- `opt_design`

opt_multi_bit_flop_name_prefix

```
opt_multi_bit_flop_name_prefix prefix_name
```

Default: `CDN_MBIT_`

Data_type: string, read/write

Specifies the MBFF name prefix. When single-bit flip-flops are merged into a multi-bit flip-flop, you can use this attribute to specify the prefix for the new merged flip-flop. If no prefix is specified, the name of the merged flip-flop starts with the default name, `CDN_MBIT_`.

Related Command

- `opt_design`

opt_multi_bit_flop_name_separator

`opt_multi_bit_flop_name_separator` *separator_name*

Default: `_MB_`

Data_type: string, read/write

Specifies the flip-flop merge and split name separator. The separator is used while splitting and merging flip-flops. The default separator name is `_MB_` . The use model is detailed below.

Scenario1:

When two or more SBFFs are merged, the separators are used between names of single bit flip-flops. The MBFF is named as; `prefix_bit1_separator_bit2_separator_bit3..._separator_bit#`.

Scenario2:

When an MBFF is split into smaller bits, then each smaller bit is named as; `prefix_bit1_separator_bit2`.

Scenario3:

When an MBFF is split into the original number of single-bit flip-flops, then each SBFF reverts to its original name, which is without prefix and separator such as; `bit1, bit2`...

Consider the example below to understand the above scenarios:

There are four SBFFs: `bit1, bit2, bit3,` and `bit4`.

- With default settings, when they are merged, the following MBFF is generated:
  CDN_MBIT_bit1_**MB**_bit2_**MB**_bit3_**MB**_bit4
  This MBFF has the default prefix and the default separator.
- When the above MBFF is split into two-bit MBFFs, the following is generated:

CDN_MBIT_bit1_**MB**_bit2, and
CND_MBIT_bit3_**MB**_bit4

- When the MBFF is split into the original SBFFs, the names of the SBFFs revert to the original names:
  bit1, bit2, bit3, and bit4

Related Command

- opt_design

opt_multi_bit_flop_name_suffix

```
opt_multi_bit_flop_name_suffix _user_suffix
```

Default: ""

Data_type: string, read/write

Specifies the MBFF name suffix. When this parameter is set, the software adds the user-specified suffix at the end of the multi-bit cell instance name along with the bit-width of the multi-bit cell.

For example, the below command is used to specify _FTREG as suffix:

```
set_db opt_multi_bit_flop_name_suffix  _FTREG

CDN_MBIT_bit1_MB_bit2_FTREG2                    for a 2-bit multibit cell

CDN_MBIT_bit1_MB_bit2_MB_bit3_MB_bit4_FTREG4    for a 4-bit multibit cell
```

Related Command

- opt_design

opt_multi_bit_flop_reorder_bits

```
opt_multi_bit_flop_reorder_bits {false | true | timing | power}
```

Default: false

Data_type: enum, read/write

Enables swap MBFF bits to take advantage of mixed-drive strength (MDS) multi-bit cells. The following settings are possible:

- `false`: the software does not identify the MDS cells and no bit-reordering is done
- `timing`: software identifies and uses the MDS cells for timing optimization
- `power`: software identifies and uses the MDS cells for power optimization
- `true`: software identifies and uses the MDS cells for both timing and power optimization

Note: When this attribute is set to `true`, `power`, or `timing`, a "Bit-strength (strong to weak)" column will be added in the report generated using the `report_multi_bit_ffs -info`, `-all`, and `-cell` parameters.

Related Command

- `opt_design`

opt_multi_bit_flop_split_report_failure_reason

```
opt_multi_bit_flop_split_report_failure_reason {true | false}
```

Default: `true`

Data_type: bool, read/write

When set to `false`, disables the printing of MBFF split failure reasons. By default this parameter is set to `true`, which means the reasons for MBFF instances not splitting are printed. This is the default behavior.

Related Command

- `opt_design`

opt_multi_bit_flop_split_timing_effort

```
opt_multi_bit_flop_split_timing_effort {low | medium | high}
```

Default: `low`

Data_type: enum, read/write

Specifies the timing effort level for MBFF splitting.

- `low` effort setting means splitting will be done only when absolutely necessary for critical paths.
- `medium` effort setting means splitting happens for more critical paths to improve timing and remove critical timing bottlenecks .
- `high` effort setting does aggressive splitting and try to improve timing.

Related Command

- `opt_design`

opt_multi_bit_unused_bits

```
opt_multi_bit_unused_bits {true | false | pre_place | pre_cts}
```

Default: `pre_place`

Data_type: enum, read/write

Specifies whether a mapped multi-bit instance can have one or more unused bits. By default, at `pre_place` stage the software tries to merge the single-bit registers to multi-bit instances without unused bits. If during merging, the software is unable to find a suitable multi-bit lib_cell with a width that matches the left-over bits of a bus, it will choose the closest matching width, which leaves the minimum unused bits and, therefore, increases the multi-bit merging coverage.

When set to `false`, any merging that results in unused (undriven/unloaded) bits is prevented.

When set to `true`, the software tries to merge the single-bit register to multi-bit instances with unused bits at both, `pre_place` and `pre_cts` stages.

When set to `pre_cts`, the software merges the single-bit register to multi-bit instances with unused bits at the pre_cts stage.

Related Command

- `opt_design`

opt_multi_bit_unused_bit_count

```
opt_multi_bit_unused_bit_count integer
```

Default: `0`

Min: `1`

Max: `32`

Data_type: int, read/write

Specifies the maximum number of unused bits to be allowed in each multi-bit cell.

Note: To use this attribute, set the `opt_multi_bit_unused_bits` attribute to `true`.

Related Command

- `opt_design`

opt_new_inst_prefix

```
opt_new_inst_prefix prefix
```

Default: "" (empty string)

Data_type: string, read/write

Specifies a prefix string to add to instances created by timing optimization. For example, if a default prefix is `OFC_000234`, when you use this attribute to specify the prefix, `POSTROUTE_`, the combined prefix added to the instance name is `POSTROUTE_OFC_00234`.

Note: To ignore the default prefix, set the `opt_concatenate_default_and_user_prefixes` attribute to `false`.

Related Command

- `opt_design`

opt_new_net_prefix

```
opt_new_net_prefix  prefix
```

Default: "" (empty string)

Data_type: string, read/write

Specifies a prefix string to add when timing optimization creates nets. For example, if a default prefix is `PSN_000234`, when you use this attribute to specify the prefix, `POSTROUTE_`, the combined prefix added to the net name is `POSTROUTE_PSN_00234`.

Note: To ignore the default prefix, set the `opt_concatenate_default_and_user_prefixes` attribute to false.

Related Command

- `opt_design`

opt_one_pass_lec

```
opt_one_pass_lec {true | false}
```

Default: `false`

Data_type: bool, read/write

When set to `true`, enables the one pass Logical Equivalence Check (LEC) flow. In one pass LEC, you can do a Register Transfer Level (RTL) to netlist comparison between RTL and post-route optimization (PRO) netlist - any place and route (PnR) stage netlist - in a single step.

Related Command

- `opt_design`

opt_podv2_flow_effort

```
opt_podv2_flow_effort {auto | standard | extreme}
```

Default: `auto`

Data_type: enum, read/write

Specifies the effort level for the place_opt_design V2 (PODV2) flow. See `clock_opt_design`.

The following settings are available:

- `auto`: The software follows the `design_flow_effort` attribute setting to perform optimization.
- `standard`: The software performs a fast prects optimization and runtime is less. This option is recommended in the early design stage or in simple designs for PPA estimation.
- `extreme`: The software performs a deep optimization to chase the best PPA. Runtime is high.

opt_pin_swapping

```
opt_pin_swapping {true | false}
```

Default: `true`

Data_type: bool, read/write

Controls whether timing optimization allows pin swapping.

Note: This attribute is not enabled when the `design_flow_effort` attribute is set to `express`.

Related Command

- `opt_design`

opt_post_route_allow_overlap

```
opt_post_route_allow_overlap {true | false}
```

Default: `true`

Data_type: bool, read/write

Controls whether timing optimization allows overlap during `opt_design -post_route`.

Related Command

- `opt_design`

opt_post_route_area_reclaim

```
opt_post_route_area_reclaim {none | setup_aware | hold_and_setup_aware}
```

Default: `none`

Data_type: enum, read/write

This attribute can be used after routing to reclaim area during `opt_design -post_route`. It safely reclaims area while not impacting the timing and DRV violations. You can use the following options:

- `none`: No area reclaim is done. This is the default setting.
- `setup_aware`: Reclaim is done but is not hold aware. This may degrade hold timing significantly but will maintain the setup timing while giving the best possible reclaim results.
- `hold_and_setup_aware`: Reclaim is done but is both hold and setup aware. It will not give as good reclaim results as `setup_aware` alone. But it will mean both setup and hold timing will be maintained.

Related Command

- `opt_design`

opt_post_route_art_flow

```
opt_post_route_art_flow {true | false}
```

Default: false

Data_type: bool, read/write

Ensures that timing optimization applies to ART-based flow. In the ART-based flow, it partially activates the design at the top-level and at the interface path of partition blocks so that there is a reduction in memory usage and run time if the design is large. This attribute marks the core logic inside the partition as dont_touch, so the logic is not optimized.

Note: This attribute requires partition definition information and applies to the post-Route mode only.

Related Command

- `opt_design`

opt_post_route_check_antenna_rules

```
opt_post_route_check_antenna_rules {true | false}
```

Default: `true`

Data_type: bool, read/write

Allows optimization to check/ignore antenna rules for LEF-safe swaps. The default behavior is to check the antenna rules, in order to avoid antenna violations caused by the cell swappings. The LEF files have certain antenna rules defined in them. By default, when doing LEF-safe swaps for leakage power optimization and for LEF-safe timing recovery, it is ensured that the cells have the same antenna rules. If cells do not have the same antenna rules, they are not swapped.

However, if this attribute is set to `false`, in post-Route mode, antenna rules will not be considered when doing LEF-safe swaps. Therefore, setting this attribute to `false` improves timing and leakage but it can potentially lead to routing having antenna violations, which will require a call to the `route_eco` command for cleanup.

Related Command

- `opt_design`

opt_post_route_drv_recovery

```
opt_post_route_drv_recovery {auto | false | true}
```

Default: `auto`

Data_type: enum, read/write

Controls the DRV/glitch recovery step performed when `opt_design -post_route -setup -hold` and `opt_design -post_route -hold` commands have been specified. You can specify the following options:

- `false`: Disables DRV/glitch recovery.
- `auto`: Allows the software to determine when to trigger DRV/glitch recovery. Here recovery will be triggered if any of the DRV's or glitches degrade beyond a certain margin. Note that DRV/glitch recovery is disabled for `opt_design -post_route -hold` by default.
- `true`: Always triggers DRV/glitch recovery if there are any left in the design.

Related Command

- opt_design

opt_post_route_fix_clock_drv

```
opt_post_route_fix_clock_drv {true | false}
```

Default: `true`

Data_type: bool, read/write

Controls whether `clock_post_route_repair` is called or not at the start of post-Route optimization.

By default this attribute is set `true`, which means that `ccopt_post_route` is called to repair clock tree design rule violations (DRVs) that have occurred in the clock tree after routing. These DRVs are most commonly the user-set clock transTime violations. To disable the fixing of DRVs, set the attribute to `false`.

Related Command

- opt_design

opt_post_route_fix_glitch

```
opt_post_route_fix_glitch {true | false}
```

Default: `true`

Data_type: bool, read/write

Determines whether to fix glitch violations during SI optimization or not. To disable fixing of glitch violations, set this attribute to `false`.

Related Command

- opt_design

opt_post_route_fix_si_transitions

```
opt_post_route_fix_si_transitions {true | false}
```

Default: false

Data_type: bool, read/write

Enables fixing of SI-induced slew violations in post-Route optimization.

Note: The transition values will be used for maximum transition violation fixing only and will not affect the timing calculation in the timing engine. This is because the transition effect is considered by the internal SI engine during delay pushout calculation.

Related Command

- `opt_design`

opt_post_route_hold_recovery

```
opt_post_route_hold_recovery  {auto | false | true}
```

Default: `false`

Data_type: enum, read/write

Controls the Hold Recovery step performed when `opt_design -post_route -setup -hold` and `opt_design -post_route -hold` commands have been specified. You can specify the following options:

- `false`: Disables hold recovery.
- `auto`: Allows the software to determine when to trigger setup recovery. Here recovery will be triggered if WNS or TNS degrade beyond a certain margin.
- `true`: Always triggers hold recovery if timing is not met, irrespective of the gain/degradation in post-route timing.

Related Command

- `opt_design`

opt_post_route_report_si_transitions

```
opt_post_route_report_si_transitions {true | false}
```

Default : `false`

Data_type: bool, read/write

Enables reporting of SI slews for DRV maximum transition reporting only. The delay calculation will continue to use base slews for timing analysis commands, such a as `reportTranViolation` , `report_constraint` , `report_delay_calculation` , and `report_timing` . The DRV violations will be reported by `time_design` under the `./timingReports/<design name>.tran file` only and the number of maximum transition violations due to SI slews will be listed in the `time_design` summary report.

Note : The `opt_post_route_report_si_transitions true` setting does not enable fixing of SI slews, this command only enables reporting of them for `time_design` DRV reporting. To enable SI slew fixing, use `opt_post_route_fix_si_transitions true` .

opt_post_route_setup_recovery

```
opt_post_route_setup_recovery  {auto | false | true}
```

Default: `auto`

Data_type: enum, read/write

Controls the Setup Recovery step performed when `opt_design -post_route -setup -hold` and `opt_design -post_route -hold` commands have been specified. You can specify the following options:

- `false`: Disables setup recovery.
- `auto`: Allows the software to determine when to trigger setup recovery. Here recovery will be triggered if WNS or TNS degrade beyond a certain margin.
- `true`: Always triggers setup recovery if timing is not met, irrespective of the gain/degradation in post-route timing.

Related Command

- `opt_design`

opt_power_effort

```
opt_power_effort {none | low | high}
```

Default: `none`

Data_type: enum, read/write

Specifies the power-driven optimization functionality. This attribute provides the effort level for optimizing leakage power and dynamic power in the design. Use this attribute along with the `opt_leakage_to_dynamic_ratio` attribute to give a superior QOR and to trigger power-driven optimization. Power-driven optimization implies that the `opt_design` command now performs Power, Performance, and Area (PPA) trade-offs at the transform level at every step of timing optimization.

You can specify any one of the following options:

`none` : Specifies that no power optimization is to be performed.

low: Specify this option when power optimization is not the highest priority. Using the low effort level option indicates the following:

- Power optimization is performed only at certain stages of the `opt_design` flow, which is dependent on the value of the `opt_leakage_to_dynamic_ratio` attribute. When the `opt_leakage_to_dynamic_ratio` attribute is 1.0, `opt_design` will optimize leakage power after each timing optimization step and no high leakage cells are inserted during hold fixing. When `opt_leakage_to_dynamic_ratio` attribute is 0.0, `opt_design` will optimize dynamic power at the preCTS stage. For all values of `opt_leakage_to_dynamic_ratio` attribute between 0.0 and 1.0, both of the above are done.
- Timing optimization is power-aware but uses only low-effort techniques when choosing the best timing optimization fixes to implement.
- Timing closure remains the first priority and the worst negative slack achieved is the same as that in effort mode “ `none` ”.
- On an average, the CPU full flow runtime impact is +26% for a `opt_leakage_to_dynamic_ratio` of 0.5 as compared to that in effort mode “ `none` ”. This can vary depending on both the ratio being used and on the design.
- On an average, the MEM full flow impact is +5%.
- Utilization remains roughly at par with effort level “ `none` ” results.
- On an average, the overall standard cell dynamic power saving is -30% and can go up to -

69% as compared to that achieved in effort mode “none”. On an average, the overall standard cell leakage power saving is -41% and can go up to -90% on some designs. This is achieved with a opt_leakage_to_dynamic_ratio of 0.5 and will vary if this ratio is changed.

Note: The above numbers are estimates and are completely dependent on the type of design.Therefore, they may be very different from the averages given above.

high : Use the high effort level option when having low power is the highest priority. Using the high effort level option indicates the following:

- Power optimization is performed during all calls to opt_design , which is dependent on the value of the opt_leakage_to_dynamic_ratio attribute. Timing Optimization is power aware and uses high-effort techniques when choosing the best timing optimization fixes to implement.
- Timing closure should still be achievable, if it was previously, and in the majority of cases the same worst negative slack is reached as effort mode " none ".
- CPU full flow runtime impact is on an average +63% for a opt_leakage_to_dynamic_ratio of 0.5 compared to effort " none ". This can vary depending on both the ratio being used and on the design.
- MEM full flow impact is on an average +11%.
- Utilization is generally improved by -1.3% on average compared to effort level " none " results.
- On an average, the overall standard cell dynamic power saving is -32% and can go up to -70% as compared to that achieved in effort mode “none”. On an average, the overall standard cell leakage power saving is -54% and can go up to -98% on some designs. This is achieved with a opt_leakage_to_dynamic_ratio of 0.5 and will vary if this ratio is changed.

  Note : The above numbers are estimates and are completely dependent on the type of design.Therefore, they may be very different from the averages given above.

Related Command

- opt_design

opt_pre_route_ndr_aware

```
opt_pre_route_ndr_aware list
```

Default: "" (empty string)

Data_type: string, read/write

Enables NDR-based optimization by providing a list of NDR names. Using NDR-based optimization, GigaOpt assigns NDR on timing critical nets in order to improve timing. GigaOpt will automatically assess the list of NDRs provided and choose the one that can help timing. It is not recommended to use many NDRs from turn-around-time (TAT) point of view.

Related Command

- `opt_design`

opt_preserve_all_sequential

```
opt_preserve_all_sequential {true | false}
```

Default: `false`

Data_type: bool, read/write

Preserves sequential elements when netlists are optimized. When the `opt_remove_redundant_insts` attribute is set to `false`, unobservable or useless logic is removed. However, you can retain sequential elements by setting this attribute to `true`.

Related Command

- `opt_design`

opt_preserve_hpin_function

```
opt_preserve_hpin_function {true | false}
```

Default: false

Data_type: bool, read/write

Determines whether to preserve logical functions at hierarchical module ports. When set to false, only the hierarchical module ports that have a timing assertion applied on them will be preserved

(not deleted, duplicated, or polarity changed). This is the recommended setting since it allows more freedom for timing optimization while not impacting the netlist functionality or the timing constraints.

When set the true, every port of every hierarchical mode will be preserved (not deleted, duplicated, or polarity changed). This is very constraining.

Related Command

- `opt_design`

opt_remove_redundant_insts

```
opt_remove_redundant_insts {true | false}
```

Default: `true`

Data_type: bool, read/write

Controls whether or not timing optimization simplifies the netlist. The software recovers area, decreases congestion, and improves runtime by simplifying the netlist in the following ways:

- Removing dangling output instances
- Propagating constants
- Removing unobservable logic
- Remapping useless logic

The software respects the set_dont_touch constraint, so it does not remove the constrained flip-flops, and does not touch non-uniquified modules.

Note: This attribute is not enabled when the `design_flow_effort` attribute is set to `express`.

Note: If a netlist contains spare cells, ensure that you define them using the `set_spare_insts` command else they might be removed by this attribute.

Related Commands

- `opt_design`
- `set_spare_insts`

opt_resize_flip_flops

```
opt_resize_flip_flops {true | false}
```

Default: `true`

Data_type: bool, read/write

Controls whether timing optimization upsizes or downsizes flip-flops.

Related Command

- opt_design

opt_resize_level_shifter_and_iso_insts

```
opt_resize_level_shifter_and_iso_insts {true | false}
```

Default: `false`

Data_type: bool, read/write

Controls whether timing optimization resizes shifters and isolation instances. In default mode (false), shifters and isolations are considered "don't-touch" instances and are not changed during timing optimization. When this attribute is set to true, the shifters and isolation cells are resized for timing optimization by using opt_design.

Note: When this attribute is set to true, all the shifters and isolation cells can be resized even if they are marked as dont_touch.

Related Command

- opt_design

opt_resize_power_switch_insts

```
opt_resize_power_switch_insts {true | false}
```

Default: `false`

Data_type: bool, read/write

When set to `true`, enables resizing of power switch instances during optimization. By default, this

attribute is set to `false`, which means the power switch instances are not resized during optimization.

Related Command

- `opt_design`

opt_flop_pins_report

```
opt_flop_pins_report {true | false}
```

Default: `false`

Data_type: bool, read/write

Set this attribute to `true` for printing out full hierarchical pin names used in the incoming netlist for flops deleted during simplifyNetlist. The output file name format is `<userPrefix>_flops_pins.rpt`.

You can choose to write both files with pins or without pins (`opt_flops_report`) in same session .

Related Command

- `opt_design`

opt_flops_report

```
opt_flops_report {true | false}
```

Default: `false`

Data_type: bool, read/write

Set this attribute to `true` for printing full hierarchical flop names used in the incoming netlist for flops deleted during simplifyNetlist. The output file name format is `<userPrefix>_flops.rpt`.

You can choose to write both files with pins (`opt_flop_pins_report`) or without pins in same session.

Related Command

- `opt_design`

opt_sequential_genus_restructure_report_failure_reason

```
opt_sequential_genus_restructure_report_failure_reason {true | false}
```

Default: `false`

Data_type: bool, read/write

When set to true, the sequential critical region resynthesis (CRR) failure reasons are reported in the `SeqCrrFailReasons.rpt` file. The report includes the instance name and the corresponding failure reason.

Note: When CRR is enabled, Innovus uses Genus to restructure portions of the design to improve timing/area/power during setup optimization.

Related Command

- `opt_design`

opt_setup_target_slack

```
opt_setup_target_slack setuptargetslack
```

Default: `0.0`

Data_type: double, read/write

Specifies a target slack value in nanoseconds for setup analysis. During setup violation repair, the setup target slack is `opt_setup_target_slack` and the hold target slack is set to 0. Generally, you use both `opt_setup_target_slack` and `opt_hold_target_slack` for hold analysis. If you specify `opt_hold_target_slack` only, the `opt_setup_target_slack` value is 0.

Related Command

- `opt_design`

opt_target_based_opt_file

```
opt_target_based_opt_file  filename
```

Default: `"" (empty string)`

Data_type: string, read/write

Specifies the file containing information that target-based optimization (TBOpt) will use to do fine grain target-based optimization using the `opt_design -post_route -targeted` command.

The format of the TBOpt file is as follows:

```
NETS : {net1} {net2} {netN}
FROMTOS : {fromTerm1 toTerm1} {fromTerm2 toTerm2} {fromTermN toTermN}
INSTS : {inst1} {inst2} {instN}
PATHS : {endpoint1} {endpoint2} {endpointN}
END_POINT_ADJ : {endpoint1} {slack_adj: value in ps}
AREA_RECLAIM : {ModuleName} {x1 y1 x2 y2}
PWR_RECLAIM : {ModuleName} {x1 y1 x2 y2}
DRVS : {netName1} {netName2} {max_tran: e.g. 100}
```

An example of a TBOpt file is provided below:

```
NETS : {mod_i/mod_sub_i/reset_l_sync_3} {mod_i/mod_sub_i/FE_OCPN210_reset_l_sync_3}
INSTS : {mod_i/mod_sub_i/reset_l_sync_reg_15}
{mod_i/mod_sub_i/FE_OCPC210_reset_l_sync_16}
PATHS : {mod_i/mod_sub_i/ser_en/data_d1_reg_32/D}
```

Related Command

- opt_design

opt_target_based_opt_hold_file

```
opt_target_based_opt_hold_file hold_file_name
```

Default: `"" (empty string)`

Data_type: string, read/write

Specifies the file containing information that target-based optimization (TBOpt) will use to perform hold optimization.

```
set_db opt_target_based_opt_hold_file hold_file_name

opt_design -post_route -targeted -hold
```

Note: You can launch setup optimization followed by hold optimization using the following command:

```
opt_design -post_route -targeted -setup -hold
```

Hold optimization is only called in the `opt_target_based_opt_file_only` mode.

Related Command

- `opt_design`

opt_target_based_opt_file_only

```
opt_target_based_opt_file_only {true | false}
```

Default: true

Data_type: bool, read/write

This attribute is used along with the `opt_target_based_opt_file` attribute. It is set to `true` by default. When set to `true`, TBOpt will only optimize the nodes contained within the file specified using the `opt_target_based_opt_file` attribute. When set to `false`, the TBOpt will optimize other nodes in addition to those specified in the file, if the software considers them to be critical.

Related Command

- `opt_design`

opt_tied_inputs

```
opt_tied_inputs {true | false}
```

Default: `false`

Data_type: bool, read/write

When set to `true`, forces optimization of instances with inputs tied together, even if it worsens the objective gain - in terms of area, power, and delay.

Note: This attribute does not need to be set when the `eco_remove_tied_inputs` command is run. In that case this attribute is automatically set to `true` and instances with inputs tied together are optimized. After the command has been run, the attribute reverts to the value before executing the command.

Related Command

- opt_design

opt_time_design_compress_reports

```
opt_time_design_compress_reports {true | false}
```

Default: true

Data_type: bool, read/write

When set to `true`, this attribute forces `time_design` and `opt_design` to output timing reports in a compressed format.

Related Commands

- opt_design
- time_design

opt_time_design_expanded_view

```
opt_time_design_expanded_view {true | false}
```

Default: `false`

Data_type: bool, read/write

When set to true, this attribute will force `time_design` or `opt_design` to print summary timing reports as per the view in the log file.

Related Commands

- opt_design
- time_design

opt_time_design_num_paths

```
opt_time_design_num_paths number_of_paths
```

Default: `50`

Data_type: int, read/write

Allows you to select the number of paths that should be reported per path group during `time_design` or `opt_design` final summary reports.

Related Commands

- `opt_design`
- `time_design`

opt_time_design_report_net

```
opt_time_design_report_net {true | false}
```

Default: `true`

Data_type: bool, read/write

When set to `true`, it forces `time_design` or `opt_design` to print timing reports with the net section.

Related Commands

- `opt_design`
- `time_design`

opt_time_design_vertical_timing_summary

```
opt_time_design_vertical_timing_summary {true | false}
```

Default: `false`

Data_type: bool, read/write

When set to `true`, prints vertical timing summary after `time_design` and final summary report.

Related Commands

- opt_design
- time_design

opt_unfix_clock_insts

```
opt_unfix_clock_insts {true | false}
```

Default: true

Data_type: bool, read/write

Controls whether the software is allowed to resize fixed sequential elements and to move them during placement legalization. opt_design temporarily removes the fixed attribute of each sequential element at the beginning of this step and sets it back to its original value at the end. This attribute does not remove the routed wires of the clock tree. It minimizes the movement of sequential elements as much as possible. This attribute impacts only opt_design -post_cts and opt_design -post_route. You can set the following options:

- When set to true, the software is allowed to resize and move fixed registers.
- When set to false, the software is not allowed to resize or move fixed registers.

Note: If you specify true for this attribute, Cadence recommends you use the route_design command for routing your design.

Related Commands

- opt_design
- route_design

opt_skew

```
opt_skew {true | false}
```

Default: true

Data_type: bool, read/write

Controls whether timing optimization runs the opt_clock_skew command. This attribute produces

scheduling and latency files before CTS runs, or adds buffers and inverters after CTS, just as `opt_clock_skew` does. This attribute sets the `timing_analysis_useful_skew` attribute to true, so timing analysis can read the latency file. Useful skew optimization is run iteratively within `opt_design`, so you do not need to set this attribute more than once.

Note: This attribute is not enabled when the `design_flow_effort` attribute is set to `express`.

Note: This attribute is not supported during `opt_design -post_route`.

Related Commands

- `opt_design`
- `opt_clock_skew`

opt_skew_apply_delay_limits_to_full_flow

`opt_skew_apply_delay_limits_to_full_flow {true | false}`

Default: `false`

Data_type: bool, read/write

When set to `true`, specifies that the useful skew limit is to be applied to the whole flow. With this setting, the Early Clock Flow is modified so that pre-existing tool-generated useful skews count towards the limit imposed by the `opt_skew_max_allowed_delay` attribute. The tool-generated useful skew comprises any pin insertion delay (PID) of category useful_skew or global_skew. PIDs of other categories are not considered.

By default, this attribute is set to `false`, which means the pre-existing skews are not considered while calculating the limit imposed by using the `opt_skew_max_allowed_delay` attribute.

opt_skew_ccopt

`opt_skew_ccopt {none | standard | extreme}`

Default : `standard`

Data_type: enum, read/write

Specifies the effort for useful skew in both CTS and post-CTS flow. It replaces the attributes, `opt_skew_pre_cts, opt_skew_post_cts .`

This attribute setting is only respected by `ccopt_design` and `opt_design -post_cts`.

- `none`: low effort `ccopt_design` with no skewing
- `standard`: low effort `ccopt_design`. This is the default setting.
- `extreme`: high effort `ccopt_design`

Note: To achieve the best possible timing result, the `extreme` setting will significantly increase the execution time of the `ccopt_design` command. Also, for best results the extreme setting should be used with `set_db design_flow_effort extreme` attribute setting.

Related Commands

- `opt_design`
- `opt_clock_skew`

opt_skew_post_route

```
opt_skew_post_route {true | false}
```

Default : `true`

Data_type: bool, read/write

When set to `false` , it disables useful skew in post-Route optimization.

Related Commands

- `opt_design`
- `opt_clock_skew`

opt_skew_pre_cts

```
opt_skew_pre_cts {true | false}
```

Default : `true`

Data_type: bool, read/write

When set to `false` , it disables useful skew in preCTS optimization.

Related Commands

- `opt_design`
- `opt_clock_skew`

opt_skew_delay_pre_cts

```
opt_skew_delay_pre_cts {true | false}
```

Default: true

Data_type: bool, read/write

Specifies that the useful skew feature is allowed to delay sequential elements in preCTS stage, in addition to just advancing them. This enables a more aggressive algorithm which is recommended when timing closure is gated by optimal skewing.

Related Commands

- `opt_design`
- `opt_clock_skew`

opt_skew_macro_only

```
opt_skew_macro_only {true | false}
```

Default: false

Data_type: bool, read/write

Allows you to limit skewing only for macro cells. When set to true, regular sequential elements (such as flip flops) will not be skewed.

Related Commands

- `opt_design`
- `opt_clock_skew`

opt_skew_max_allowed_delay

```
opt_skew_max_allowed_delay delay
```

Default: 1.0ns

Data_type: double, read/write

Limits the amount of slack (in nanoseconds) that the software can borrow from neighboring flip-flops when performing useful skew operations. The delay calculation and RC extraction methods might differ from those of sign-off tools, so other setup violations might occur if the software borrows too much slack. By having control over slack borrowing, you can prevent these setup violations. Limiting borrowed skew also limits the clock tree skew to avoid large hold violations.

Value Range: `min=0 max=1000`

Note:

This attribute is not honored in the `post_cts` mode of `opt_clock_skew`.

Note: In the non-early clock flow, when `opt_clock_skew` is triggered inside opt_design, and this attribute is set to its default value, the default value of this attribute will change from 1 to become a certain percentage of clock cycle. This is determined by the software on the basis of internal calculations.

Related Commands

- `opt_design`
- `opt_clock_skew`

opt_skew_min_allowed_delay

```
opt_skew_min_allowed_delay delay
```

Default: `0.0`

Data_type: double, read/write

Allows the tool to skip any skewing that would be smaller than the minimum delay that is set. The purpose is to avoid creating very small delay macro models which would not be correctly honored during CTS stage but also to reduce the amount of macro models generated.

Value Range: `min=0 max=1000`

Note: This attribute is supported in both standalone `opt_clock_skew` command and for

`opt_useful_skew` command called within `opt_design`. This is called by setting the `opt_skew` attribute to true.

Related Commands

- `opt_design`
- `opt_clock_skew`

opt_skew_no_boundary

```
opt_skew_no_boundary {true | false}
```

Default: false

Data_type: bool, read/write

Excludes or includes boundary sequential cells in addition to ordinary sequential elements in useful skew calculations.

Related Commands

- `opt_design`
- `opt_clock_skew`

opt_verbose

```
opt_verbose {true | false}
```

Default: `false`

Data_type: bool, read/write

Controls the amount of information timing optimization outputs to the log file. Specify true to output additional information to use to debug design issues. When you set this attribute to true, the various reasons for not fixing hold violations are listed in the log file.

For more information, see the section below.

Reasons for Hold Violations to Remain Unfixed

The following table lists the various reasons for hold violations to remain unfixed:

Reason	Description
No legal location	There are no valid locations to insert buffers on those violated nets. Limit the local placement congestion and use instance/cell padding during initial placement. In parallel, to allow the tool to insert buffers at non-legal location, set the following attribute to true: `set_db opt_hold_allow_overlap true`
Degradation in setup register-to-register WNS	The nets are violated in hold but they are also a part of the register-to-register setup timing-critical paths. So inserting a buffer would degrade the setup register-to-register WNS. To fix these nets at the cost of register-to-register setup degradation, set a negative setup target slack using the `opt_setup_target_slack` attribute.
Degradation in setup TNS	The nets are violated in hold but they are also timing critical during setup. So, inserting a buffer would increase the setup TNS. To fix these nets at the cost of setup TNS degradation, set the following attribute to true: `set_db opt_hold_allow_setup_tns_degradation true`
Degradation in setup WNS	The nets are violated in hold but they are also setup timing critical. So inserting a buffer would degrade the setup WNS. To fix these nets at the cost of setup degradation, set a negative setup target slack using the `opt_setup_target_slack` attribute.
Degradation in hold	The nets are violated in hold but inserting a buffer would further degrade hold timing. Check the topology of those nets and probably enlarge the list of available buffer/delay cells that are allowed to be used.

Degradation in maximum capacitance violation	The nets are violated in hold but inserting a buffer would create a new setup maximum capacitance violation. To fix these nets at the cost of DRV degradation, set the following attribute: `set_db opt_drv false`
Degradation in maximum transition violation	The nets are violated in hold but inserting a buffer would create a new setup maximum transition violation. To fix these nets at the cost of DRV degradation, set the following attribute: `set_db opt_drv false`
DRV violations	The nets are violated in hold but also in setup DRV, so they are skipped. To fix these nets at the cost of DRV degradation, set the following attribute: `set_db opt_drv false`
Nets are set as `dont_touch`	To allow hold fixing on these nets, remove the `dont_touch` attribute.
Nets are routed incorrectly	Verify the routing wires for those nets.
Nets are clock nets	No buffers can be inserted on clock nets. You should check your timing constraint file.
None of the always-on-buffers are usable	Verify the environment to allow the use of always-on-buffers.
None of the valid mode is found on a net	The tool is not able to insert a buffer on such a net. This could be related to specific design cases.
Any internal failure	The tool was not able to find a solution for fixing the violation of those nets. This could be related to libraries or specific design cases.

Related Command

- `opt_design`

opt Category Object Attributes

The following categories of object attributes are available in the opt category:

Object Category Name	Attributes
inst	dont_touch dont_touch_sourcesdont_touch_effective
hinst	dont_touch dont_touch_sourcesdont_touch_effective read_only_effective dont_use_cells use_cells dont_use_cells_effective dont_touch_hports is_ilm
module	dont_touch dont_use_cellsuse_cells dont_use_cells_effective dont_touch_hports is_ilm
design	read_only dont_touchdont_touch_sources dont_use_cells use_cells dont_use_cells_effective
partition	read_only
net	dont_touch
hnet	dont_touch
pin	dont_touch
hpin	dont_touch

base_cell	dont_touch dont_use

To view help for any object type attribute across different object types, type the following command:

```
help attributeName
```

For example, for help on `dont_touch`, `dont_touch_effective`, and `dont_touch_source` for all objects type this:

```
help dont_touch*
```

For help on one object attribute, use this:

```
help inst dont_touch
```

read_footprint

```
read_footprint
[-help]
file_name
```

Loads a footprint file to update the footprint information, which is obtained from the timing library file during design import. Loading a footprint file takes precedence over what is currently defined in the Stylus session. That is, after a footprint file is loaded for a session, only the cells in the footprint file are considered. This feature lets you run individual timing optimization commands with a limited set of cell footprints.

When the command is run successfully, the software gives the following message:

```
----------------------------------------
Clearing footprints for all libraries
Loading footprints for all corners.
----------------------------------------
```

Parameters

`-help`	Outputs a brief description that includes type and default information for each `read_footprint` parameter. For a detailed description of the command and all of its parameters, use the man command: `man read_footprint`.
`file_name`	Specifies the name of the footprint file. *Data_type*: string, required

Examples

- The following command loads the footprint file `INV.fpt`:

  ```
  read_footprint INV.fpt
  ```

  After loading the footprint file, the software ignores the previous footprint information.

- When the `read_footprint` command reads the output from the `report_footprints` command, the `read_footprint` command ignores all other fields except the library name, cell name, and the footprint name. The footprint file format for the `read_footprint` command is as follows:

```
Library:library_name
cell_name footprint_name
cell_name footprint_name
```

For example:

```
Library:stdcellLib
xr03d1 xr03_5
xr03d2 xr03_5
```

Related Information

  - Using Cell Footprints

report_always_on_buffer

```
report_always_on_buffer
[-help]
[-all]
[-power_domain power_domain_name]
[-verbose]
```

Reports the available always-on buffers and inverters per domain.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `report_always_on_buffer` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_always_on_buffer`
`-all`	Reports the always-on buffers and inverters for all domains. If you specify no parameter, even then it reports the always-on buffers and inverters for all domains. *Data_type*: bool, optional
`-power_domain` *power_domain_name*	Reports the always-on buffers and inverters for the specified domain. **Note**: Parameters `-all` and `-power_domain` are mutually exclusive. *Data_type*: string, optional
`-verbose`	Reports the possible reason why a domain does not have always-on buffers and inverters. It can also report the always-on cell list per domain if the always-on cells are available for the domain. *Data_type*: bool, optional

Examples

- The following command reports the always-on buffers and inverters for the `PD1` domain:

  ```
  report_always_on_buffer -power_domain PD1
  ```

  The software displays the following message:

  ```
  PowerDomain "PD1" (pd tag = "1") has 2 always on buffer(s) to use
  ```

report_critical_nets

```
report_critical_nets
[-help]
[-max_slack double]
[-number integer]
-out_file fileName
[-view viewName]
```

Generates a file containing a list of nets which have critical slack for the currently specified (setup or hold) timing analysis mode.

Parameters

`-help`	Prints a brief description that includes type and default information for each `report_critical_nets` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_critical_nets`
`-max_slack double`	Reports nets with slack less than the specified slack value. *Data_type*: float, optional
`-number integer`	Restricts the number of critical nets reported to the first *integer* most critical nets. *Data_type*: int, optional
`-out_file fileName`	Specifies the name of report file. *Data_type*: string, optional
`-view viewName`	Generates the report based on the specified analysis view only. You can specify this parameter only when the software is in multi-mode multi-corner timing analysis mode. *Data_type*: string, optional

Command Order

Use this command after the timing graph is built.

Example

The following command generates a report named `critnet` that lists critical nets:

```
report_critical_nets -out_file critnet
```

Related Information

- `opt_design`
- `set_db`
- `time_design`
- opt Category Attributes

report_critical_insts

```
report_critical_insts
[-help]
[-cost_type {worst_slack | total_slack | path_count | start_end_point_count}]
[-estimate]
[-include_sequential]
[-max_insts value]
[-max_slack slack]
[-out_file file_name]
[> file]
[>> file]
```

Reports instances in critical paths where the slack is less than the target slack.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `report_critical_insts` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_critical_insts`.

`-cost_type`	Specifies the criteria for choosing the critical instance. You can use the `-max_slack` and `-cost_type` parameters together to filter the paths to only those with slack worse than the specified *`slack`* value, then report the filtered set of paths based on the specified cost. *Default:* `worst_slack` Select one of the following options: `worst_slack`: Sets the criteria as the worst slack of all points that pass through an instance. `total_slack`: Sets the criteria as a sum of the slack of the end points. `path_count`: Sets the criteria as the sum of the total paths through the instance. `start_end_point_count`: Sets the criteria as the sum of the total start and end points connected to the instance. *Data_type*: string, optional
`-estimate`	Generates a critical instance report based on the fast algorithm (linear-complexity) when cost type = `total_slack` to give a slightly pessimistic estimation that may include some false paths. Use this parameter in early design phase. *Default:* `false` *Data_type*: bool, optional
`file`	Redirects report to the outfile. If the file already exists, the software overwrites it. **Note:** The file name must be the last argument in the list. *Default:* `stdout` *Data_type*: redirect_operator, optional
`-include_sequential`	Includes the sequential instances group in the output. *Default:* false (Reports combinatorial instances only.) *Data_type*: bool, optional

`-max_insts` *value*	Specifies the number of worst cost instances to report. *Default:* `20` *Data_type*: int, optional
`-max_slack` *slack*	Specifies the lower bound of the slack range. Only paths with slack worse than the specified *slack* value are reported. You can use the `-max_slack` and `-cost_type` parameters together to filter the paths to only those with slack worse than the specified *slack* value, then report the filtered set of paths based on the specified cost. *Default:* `0` *Data_type*: float, optional
`-out_file` *file_name*	Specifies the report output file. *Default:* `stdout` *Data_type*: string, optional

Command Order

Use this command after the timing graph is built by `time_design/opt_design`.

Examples

The following command reports the critical instance information based on the worst slack of all points that pass through an instance:

```
report_critical_insts -cost_type worst_slack
# ----------------------------------------
# Inst:combinatorial  Cell        Cost
# ----------------------------------------
I3                    BUFX2       -0.336
I10                   AND2X1      -0.336
I1                    BUFX2       -0.117
I2                    BUFX2       -0.117
----------------------------------------
```

The following command reports the critical instance information based on the worst slack of all points that pass through an instance, for paths with slack worse than -0.2:

```
report_critical_insts -cost_type worst_slack -max_slack -0.2
# ------------------------------------------------
# Inst:combinatorial    Cell          Cost
# ------------------------------------------------
I3                      BUFX2       -0.336
I10                     AND2X1      -0.336
------------------------------------------------
```

The following command reports the critical instance information based on the sum of the slack of the end points:

```
report_critical_insts -cost_type total_slack
# ------------------------------------------------------
# Inst:combinatorial    Cell       Cost    Start  End
# ------------------------------------------------------
I3                      BUFX2     -0.336    1     1
I10                     AND2X1    -0.336    2     1
I1                      BUFX2     -0.117    0     1
I2                      BUFX2     -0.117    0     1
------------------------------------------------------
```

The following command reports the critical instance information based on the sum of the total paths through the instance:

```
report_critical_insts -cost_type path_count
# ------------------------------------------------
# Inst:combinatorial   Cell       Cost    Start  End
# ------------------------------------------------
I10                    AND2X1      4       2     1
I3                     BUFX2       2       1     1
I1                     BUFX2       2       0     1
I2                     BUFX2       2       0     1
------------------------------------------------
```

The following command reports the critical instance information based on the sum of the total start and end points connected to the instance:

```
report_critical_insts -cost_type start_end_point_count
# ------------------------------------------------------
# Inst:combinatorial    Cell       Cost    Start  End
# ------------------------------------------------------
I10                      AND2X1      2       1     1
I3                       BUFX2       2       1     1
I1                       BUFX2       2       1     1
I2                       BUFX2       2       1     1
------------------------------------------------------
```

The following command reports the critical instance information based on the sum of the total start and end points connected to the instance, for paths with slack worse than -0.2:

```
report_critical_insts -cost_type start_end_point_count -max_slew -0.2
# ------------------------------------------------------
# Inst:combinatorial    Cell       Cost    Start  End
# ------------------------------------------------------
I10                     AND2X1      2       1     1
I3                      BUFX2       2       1     1
------------------------------------------------------
```

The following command generates an output file named `inst.rpt`, which includes all the instance names and cell names. The instances are on the critical paths whose slack is less than 0 ns.

```
report_critical_insts -out_file inst.rpt
```

The following command generates an output file named `inst.rpt2`, which includes all the instance names and the cell names. The instances are on critical paths whose slack is worse than `-0.3` ns.

```
report_critical_insts -out_file inst.rpt2 -max_slack -0.3
```

Related Information

- `opt_design`
- `set_db`
- `time_design`
- opt Category Attributes

report_critical_pins

```
report_critical_pins
[-help]
-out_file file_name
```

Performs slack analysis and writes the names of all critical terminals to the specified file. As a result, deterioration of setup slack can be avoided while the Innovus software repairs hold time violations.

Parameters

`-help`	Prints a brief description that includes type and default information for each `report_critical_pins` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_critical_pins`
`-out_file file_name`	Specifies the name of report file. *Data_type*: string, required

Command Order

Use this command after the timing graph is built by `time_design/opt_design`.

Example

- The following attribute and command write the setup critical terminals into a file called `critTerm`:

  ```
  set_db timing_analysis_check_type setup
  report_critical_pins -out_file critTerm
  ```

Related Information

- `opt_design`
- `set_db`
- `time_design`
- opt Category Attributes

report_footprints

```
report_footprints
[-help]
[-dont_touch_and_use]
[footprint_cell]
-out_file file_name
```

Creates a file that contains footprint_cell attribute information from the timing library. Use this file to check your design for missing footprint_cell function names and timing information. You can edit the output file and use it to load the correct footprint_cell information.

Parameters

`-help`	Prints a brief description that includes type and default information for each `report_footprints` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_footprints`
`-dont_touch_and_use`	When this parameter is specified, cell footprint_cells are reported for all cells, including those cells that have dont_touch or dont_use attribute. When this parameter is not specified, cell footprint_cells are reported for only those cells that do not have dont_touch and dont_use attributes. *Data_type*: bool, optional
footprint_cell	Specifies the footprint_cell to report. If you do not specify this parameter, reports all footprint_cells. *Data_type*: string, optional
`-out_file` *file_name*	Specifies the footprint_cell report file. *Data_type*: string, optional

Command Order

Use this command after importing the design or after using the `read_footprint` command.

Examples

- The following command creates a footprint_cell report file named `INV.rpt`:

  ```
  report_footprints -out_file INV.rpt
  ```

- The following output from the `report_footprint_cells` command shows the format of the footprint_cell file:

  ```
  # Format:
  # Library:<library name>
  # cell footprint_cell drvResR drvResF functions

  # footPrint: INV nrCell: 1 Library: dp_ram128x32_4x1
  Library:stdCellLib
  inv_2 INV     1            110.983    89.427    x=(~a)
  ```

  Lines beginning with a # are comment lines, which are ignored when the footprint_cell file is loaded. The header shows the meaning of each field:

  - `Library: stdCellLib` (with no spaces in the string) is the library where the footprint_cell is defined.
  - `inv_2` is a footprint_cell cell.
  - `INV` is the footprint_cell name.
  - `1` is the number of functions.
  - `110.983` is the average rise driving resistance.
  - `89.427` is the average fall driving resistance.
  - `x=(~a)` is the output function of the cell.

  - Using Cell Footprints

report_ignored_nets

```
report_ignored_nets
[-help]
-out_file file_name
```

Generates a report that lists the nets that are ignored by timing optimization (`opt_design`) or that might impact timing closure. You can use this command after loading a design with timing constraints.

The report lists the following types of nets:

- Nets that are ignored by timing optimization
- Nets that might impact timing closure but are not ignored

Nets that are ignored by timing optimization are listed below:

`dontTouchNets`	Nets set as don't touch by the `set_dont_touch` SDC constraint
`externalNets`	Nets connected to I/O pad or area I/O instances
`topLevelPotentialTriStateNets`	Nets connecting tristate drivers to top-level I/Os
`clockNets`	Nets marked `clock` by the timing engine
`specialNets`	Nets that have the attribute `specialnet`
`pwrGndNets`	Nets that have the attribute `power/ground`
`analogNets`	Nets that have the attribute `analog`
`noDriverNets`	Nets that do not have a driver
`Fixed Wires/Cover Wires`	Nets that have a `Fixed/Cover` wire attribute

Nets that might impact timing closure but are not ignored are listed below:

`multiDriverNets`	Nets that have multiple drivers

Parameters

`-help`	Prints a brief description that includes type and default information for each `report_ignored_nets` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_ignored_nets`
`-out_file` *`file_name`*	Specifies a file name for the report. *Data_type*: string, required

Related Information

- `opt_design`
- opt Category Attributes

report_lef_equivalent_cells

```
report_lef_equivalent_cells
[-help]
-lib_cell cell_name
[-out_file file_name]
```

Provides support to debug certain cells that may be non-equivalent without detailed analysis of the LEF. For example, if two cells have the same function and size they still may not be LEF equivalent.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `report_lef_equivalent_cells` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_lef_equivalent_cells`
`-lib_cell` *`cell_name`*	Specifies the cell names. You can also use wildcards or specify individual cells. *Data_type*: string, required
`-out_file` *`file_name`*	Specifies the output file name for reporting LEF equivalent cells. All the equivalent and non-equivalent cells are saved in the output file. *Data_type*: string, optional

Examples

- The following example command reports equivalence information on all cells and outputs to a file:

  ```
  report_lef_equivalent_cells -lib_cell * -out_file equivalency_file.txt
  ```

- To report equivalence information on a specific cell, say `SCBUF1X`, you can use the following command:

  ```
  report_lef_equivalent_cells -lib_cell SCBUF1X
  ```

- To report equivalence information on all cells that begin with `SCBUF`, you can use the following

command:

```
report_lef_equivalent_cells -lib_cell SCBUF*
```

report_length_violations

```
report_length_violations
[-help]
[-all | -no_global_nets]
[-excluded_nets_file exc_net_file_name]
[-histogram]
[-included_nets_file sel_net_file_name]
[-out_file file_name]
[-significant_digits integer]
```

Runs timing analysis and reports nets that exceed the maximum length constraint set by `opt_max_length` attribute.

Parameters

`-help`	Prints a brief description that includes type and default information for each `report_length_violations` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_length_violations`
`-all`	Reports violations on all nets. *Data_type*: bool, optional
`-excluded_nets_file` *exc_net_file_name*	Specifies a file that lists the names of hierarchical nets that are to be excluded from the report. *Data_type*: string, optional
`-histogram`	Generates a histogram in addition to the default reporting. *Data_type*: bool, optional
`-included_nets_file` *sel_net_file_name*	Specifies a file that lists the names of hierarchical nets to consider in the report. Only violations on the nets listed in the file are considered in the report. **Note**: The parameters, `-included_nets_file` and `-excluded_nets_file` are not mutually exclusive. If both parameters are specified, the `-excluded_nets_file` parameter overides the `-included_nets_file` parameter. *Data_type*: string, optional
`-no_global_nets`	Reports violations on all nets except for power, ground, and clock nets. **Note**: The parameters, `-all` and `-no_global_nets` are mutually exclusive. *Data_type*: bool, optional
`-out_file` *file_name*	Specifies the report file name. *Data_type*: string, optional
`-significant_digits` *integer*	Allows you to specify the number of significant digits. *Default*: 3 *Data_type*: int, optional

report_multibit

```
report_multibit
[-help]
[-out_file file_name]
[-cell cell_name | -library | -reason_not_merged unmerged_reason | -not_merged_summary
| -equiv]
[-cell cell_name | -type {comb | latch | flop | seq | iso | ls}]
[-hinst hinst_name | -library | -cell cell_name | -equiv ]
```

Reports all the multi-bit flip-flops that have been identified during loading the design. Use this command after all the libraries are loaded. When this command is specified with no parameters, a default summary report is printed. By default, the seqential cells will be reported. Both, the multi-bit percentages merged, and a summary of why flops were not merged is printed. This is equivalent to the `report_multi_bit_ffs -statistics` setting, with the addition of unused bits.

There are three basic types of multibit: sequential, combo, and isolation/level shifter. This command supports specifying the type of multibit to report. The `-type` parameter is a global filter for all other options.

The default option is `seq`. If the `-type` option is not specified then reporting will take place for sequential cells.

A set of options separated by a "`|`" in one "`[ ]`" listed below cannot be used together and the software will report an error in that case. Although options from different "`[ ]`" can be coupled together. The sets of mutually exclusive options are provided below.

```
[-cell <cell name> | -library | -reason_not_merged <unmerged reason> | -
not_merged_summary | -equiv ]
```

```
[-cell <cell name> | -type <type>]
```

```
[-hinst <hinst> | -library | -cell <cell name> | -equiv ]
```

Parameters

`-help`	Prints a brief description that includes type and default information for each `report_multibit` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_multibit`.

`-cell` *cell_name*	Reports the cell details and equivalence information of a single library cell.
`-equiv`	Reports equivalence summary of the library cells of the selected type.
`-hinst` *hinst_name*	Specifies the hinst on which the reporting is to be done. The default is the design.
`-library`	Reports the flip-flop/latch equivalence. This parameter is similar to the `report_multi_bit_ffs -all -info/-equivalence` setting. This parameter honors the `-type` parameter setting. *Data_type*: bool, optional
`-not_merged_summary`	When specified, reports the summary of unmerged instances. *Data_type*: bool, optional
`-out_file` *file_name*	Specifies the name of the output file. *Data_type*: string, optional
`-reason_not_merged {partition cell_equivalent constraint scan_connection location timing power user legalization bus all}`	
	Reports the instances that could not be merged for the specified reason. Specify any of the reasons in the argument or specify `all` to report all instances along with the reason why they could not be merged. `partition`: odd number of flops in one partition `cell_equivalent`: no usable equivalent multi-bit flip-flop cell `constraint`: Constraints by sdc, rule, or user settings `scan_connection`: no scan connection to other flops in the same group `location`: too far away with other flops in the same group `timing`: exceed critical path threshold or MBFF merging that degrades timing `power`: all available multi-bit cells causing power degradation `user`: user set to be excluded in flop merge `bus`: non-bus flops `all`: all the reasons of not merged *Data_type*: enum, optional

`-type {comb | latch | flop | seq | iso | ls}`	Reports for the specified type of cells. By default, only sequentials are reported. You can specify anyone of the following reports: `comb`: reports all multibit cells implementing a combinational function. For example, a cell implementing 3 ANDs – so, 6 inputs and 3 outputs `latch`: reports multi-bit latches in the design. `flop`: reports multi-bit flops. `seq`: reports all sequential cells. isolation/level shifter (`iso/ls`): reports multi-bit cells implementing a low power function. For example, as 8-bit level-shifter cell. *Default*: `seq` *Data_type*: enum, optional

Examples

Use the following command to print a default summary report. By default, the seqential cells will be reported.

```
report_multibit
```

The software returns the following information:

```

Guide

- Reporting the MBFFs

report_multi_bit_ffs

```
report_multi_bit_ffs
[-help]
[-flops]
[-latches]
[[[-info | -equivalence | -usage] -all] | -cell cell name | -statistics | -
not_merged_inst_list | -reason_not_merged unmerged_reason]
[-out_file file_name]
```

Reports all the multi-bit flip-flops that have been identified during loading the design. Use this command after all the libraries are loaded. You can choose to report information about either all the multi-bit flip-flops or one multi-bit flip-flop cell by specifying the name of the cell. The reported information can be printed on the console and written to a file.

Parameters

`-help`	Prints a brief description that includes type and default information for each `report_multi_bit_ffs` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_multi_bit_ffs`.
`-all`	Reports all the multi-bit flip-flops in the design. The parameters `-all` and `-cell` are mutually exclusive. If neither `-all` nor `-cell` is specified, the command considers -`all` by default and reports all the MBFFs in the design. The parameters, `-equivalence`, `-info`, and `-usage` are used along with the `-all` parameter. However, If none of these parameters are specified, the command will report all the information reported by the `-info` , `-equivalence` , and `-usage` parameters. *Default*: `report_multi_bit_ffs -all` is used for `report_multi_bit_ffs`. **Note**: When the `opt_multi_bit_flop_reorder_bits` attribute is set to `true`, `power`, or `timing`, a "Bit-strength (strong to weak)" column will also be added in the report. *Data_type*: bool, optional

`-cell` *cell_name*	Specifies the name of the flip-flop for which information is to be reported. This parameter reports information, equivalence, and usage for the specified flip-flop. You can specify both single-bit and multi-bit flip flops for reporting this information. **Note**: When the `opt_multi_bit_flop_reorder_bits` attribute is set to `true`, `power`, or `timing`, a "Bit-strength (strong to weak)" column will also be added in the report. *Data_type*: string, optional
`-equivalence`	Reports multi-bit flip-flop equivalence. This parameter is used along with the `-all` parameter. It reports all the equivalent multi-bit flip-flop cells and corresponding single-bit flip-flop cells in the design. The cells are reported in groups and ordered on size. **Note**: The parameters, `-equivalence`, `-info`, and `-usage` are mutually exclusive. *Data_type*: bool, optional

`-flops`	When this parameter is specified, the software will report information about the flops. When no parameter is specified, `report_multi_bit_ffs` command prints the information for both, latches and flops. This parameter can be specified along with the following parameters: `report_multi_bit_ffs -flops -all`: Reports all multi-bit flops in the design. `report_multi_bit_ffs -flops -equivalence`: Reports multi-bit flops equivalence. `report_multi_bit_ffs -flops -usage`: Reports all multi-bit flops usage. `report_multi_bit_ffs -flops -info`: Used along with `-all`. This parameter reports the properties of all the multi-bit flops in the design. For example, `Name`, `NumBits`, `Don't Use/ Don't Touch`, `Dimensions`, `ScanType`, `Stateless Leakage`, `Stateless Dynamic`, and `LibName`. `report_multi_bit_ffs -flops -cell`: Specifies the name of the flop for which information is reported. `report_multi_bit_ffs -flops -statistics`: Reports the single-bit and multi-bit flop count in the current design.
`-info`	This parameter is used along with the `-all` parameter. This parameter reports the following properties of all the multi-bit flip-flop cells in the design: `Name`, `NumBits`, `Don't Use/ Don't Touch`, `Dimensions`, `ScanType`, `Stateless Leakage`, `Stateless Dynamic`, and `LibName`. **Note**: The unit of the numbers reported in the "Dimensions" column is in terms of DB-unit (`dbu`). To convert it to `um`, use the following conversion: `set dimUm [expr $dimInDbU / [uu2dbu 1]]` **Note**: When the `opt_multi_bit_flop_reorder_bits` attribute is set to `true`, `power`, or `timing`, a "Bit-strength (strong to weak)" column will also be added in the report. *Data_type*: bool, optional

`-latches`	When specified, reports multi-bit latches in the design similar to the reporting of MBFFs. All other parameters work with this paramater just as they work with the flip-flops. When this parameter is specified with the below parameters, the follwowing information about the latches is reported: • `-all`: Reports all the multi-bit latches in the design. • `-cell` *`cell_name`*: Specifies the name of the latch for which information is reported. You can specify both, single-bit and multi-bit latch for reporting this information. • `-equivalence`: Reports multi-bit latch equivalence. It reports all the equivalent multi-bit latch cells and corresponding single-bit latch cells in the design. This parameter is used along with the `-all` parameter. • `-info`: This parameter reports the following properties of all the multi-bit latch cells in the design: *Name, NumBites, Don't Use/ Don't Touch, Dimensions, ScanType, Stateless Leakage, Stateless Dynamic, and LibName* This parameters is used along with the `-all` parameter. • `-statistics`: Reports the single-bit and multi-bit latch count in the current design. • `-usage`: Reports the multi-bit latch usages. This parameter reports the following usage of all the multi-bit latch cells in the design: *Name, NumBits, Count, Total Area, Total Leakage, Total Dynamic, and Min-Max Total Power Range* This parameter is used along with the `-all` parameter.
`-not_merged_inst_list`	When specified, reports the number of unmerged instances. *Data_type*: bool, optional
`-out_file` *`file_name`*	Specifies the name of the output file. *Data_type*: string, optional
`-reason_not_merged {partition cellequivalent contsraint scanconnection location timing power user legalization bus all}`	

	Reports the instances that could not be merged for the specified reason. Specify any of the reasons in the argument or specify `all` to report all instances along with the reason why they could not be merged. `partition`: odd number of flops in one partition `cellequivalent`: no usable equivalent multi-bit flip-flop cell constraint: Constraints by sdc, rule, or user settings `scanconnection`: no scan connection to other flops in the same group `location`: too far away with other flops in the same group `timing`: exceed critical path threshold or MBFF merging that degrades timing `power`: all available multi-bit cells causing power degradation `user`: user set to be excluded in flop merge `legalization`: `bus`: non-bus flops `all`: all the reasons of not merged *Data_type*: enum, optional

`-statistics`	Reports the single-bit and multi-bit flip flop count in the current design. The number is computed as follows:
	
	`----------------------------------------------`
	`Current design flip-flop statistics`
	
	`Single-Bit FF Count : 45573`
	
	`Multi-Bit FF Count : 29213`
	`- 2-Bit FF Count : 9068`
	`- 4-Bit FF Count : 4463`
	`- 6-Bit FF Count : 15682`
	`Total Bit Count : 175653`
	`Total FF Count : 74786`
	`Bits Per Flop : 2.349`
	`----------------------------------------------`
	The number is computed as below:
	`Total Bit Count = 45573 + 9068 * 2 + 4463 * 4 + 15682 * 6 = 175653`
	`Total FF Count = 45573 + 29213 = 74786`
	`Bits Per Flop = 175653 / 74786 = 2.349`
	
	Data_type: bool, optional

`-usage`	Reports the multi-bit flip-flop usage. This parameter is used along with the `-all` parameter. This parameter reports the following usage of all the multi-bit flip-flop cells in the design: `Name, NumBits, Count, Total Area, Total Leakage, Total Dynamic,` and `Min-Max Total Power Range`. **Note**: The last three columns of the report will be generated only when this command is called after running the `report_power` command. **Note**: The unit of the numbers reported in the "Total area" column is in terms of DB-unit-square (`dbu^2`). To convert it to `um^2`, use the following conversion: `set areaUm [expr $areaInDbU / [uu2dbu 1] / [uu2dbu 1]]` *Data_type*: bool, optional

Examples

Use the following command to display information about all the flip-flops in the design.

```
report_multi_bit_ffs -all
```

The software returns the following information:

```

report_path_group_options

```
report_path_group_options [-help]
```

Reports the values for each parameter (path_group_name, effort_level, slack_adjustment, and target_slack) for each path group. If no path groups are created, the software issues a warning.

To report the names of the path groups, use the `report_path_groups` command.

Parameter

`-help`	Prints a brief description that includes type and default information for the `report_path_group_options` command. For a detailed description of the command, use the man command: `man report_path_group_options`

Example

Use the following set of commands to create the basic path groups, set the parameters, and report the values of these parameters:

```
create_basic_path_groups

Created reg2reg path group

Effort level <high> specified for reg2reg path_group

Created reg2cgate path group
Effort level <high> specified for reg2cgate path_group

set_path_group_options reg2reg -effort_level low -skewing_slack_constraint 0.3 -
view AV_HL_FUNC_MIN_RC1
set_path_group_options reg2cgate -effort_level high-skewing_slack_constraint 0.5 -
view AV_HL_FUNC_MAX_RC1

report_path_group_options
```

The software generates the following report:

```
-------------------------------------------------------------------------------
-------
|Path Group|Effort|Adjustment(early/late)|Target Slack|weight|SkewingSlackCons|view
```

```
      |
-------------------------------------------------------------------------------------------
-------
|reg2reg    | high | 0.1    /-0.2          | 0           |  2    |     0.3
|AV_HL_FUNC_MIN_RC1 |
|reg2cgate | high | 0.2    /0             | 0           |  1    |     0.5
|AV_HL_FUNC_MAX_RC1 |
```

For detailed descriptions of the above columns, see the table in `set_path_group_options`.

report_route_type_constraints

```
report_route_type_constraints
[-help]
[-out_file file_name]
[-stack_via_rule]
[-stack_via_rule_only]
[-threshold value]
[-summary  | -detailed ] [-detailed  [-timing ]]
```

Reports the route type constraints that are being added on nets during the Stylus flow. It allows you to monitor the number of constraints, the preferred bottom layer used, the adherence of the different constraint type by the router, and the type of non-default rule (NDR) being used.

The command extracts information about the following groups of route type constraints:

- **INNOVUS**: includes all route types being added by the software and that are using a bottom preferred layer and the default rule.
- **INNOVUS_NDR**: includes all route types being added by the software and that are using an NDR.
  `set_db opt_pre_route_ndr_aware` makes this type of constraint.
- **INNOVUS_CLK**: includes all route types of clock nets that are being added by the software and that are using default rule.
  `create_route_type` without `-non_default_rule` and cts category attribute, `cts_route_type` make this type of constraint.
- **INNOVUS_CLK_NDR**: include all route types of clock nets that are being added by the software and that are using an NDR.
  `create_route_type` with `-non_default_rule` and cts category attribute, `cts_route_type` make this type of constraint.
- **USER**: includes all route types being added by the user. This can be done using the `set_route_attributes` command.
- **USER_NDR**: includes all route types being added by the user and that are using an NDR. This can be done using the `set_route_attributes` command.

When via pillar report is enabled, using the `-stack_via_rule`/`-stack_via_rule_only` parameters, the command checks via pillar assigned on data/clock nets and on the secondary PG nets. For sample reports, see Use Model Scenarios.

Parameters

Parameters

`-help`	Outputs a brief description that includes type and default information for each `report_route_type_constraints` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_route_type_constraints`.
`-detailed`	Prints detailed information on each net with a route type constraints such as the wire length, the routing adherence, some timing information, and so on. **Note**: The parameters, `-detailed` and `-summary` are mutually exclusive. *Data_type*: bool, optional
`-out_file` *file_name*	Specifies the file name in which the results will be written. If this parameter is not specified, the information is written out in the console and the log file. *Data_type*: string, optional
`-stack_via_rule`	When specified, reports pins with stack via rule constraints. *Data_type*: bool, optional
`-stack_via_rule_only`	When specified, reports only those pins that have stack via rule constraints. *Data_type*: bool, optional
`-summary`	Prints a summary of the layer constraint usage per layer, per NDR, and per constraint type. **Note**: The parameters, `-detailed` and `-summary` are mutually exclusive. *Data_type*: bool, optional

`-threshold value`	Specifies the maximum routing adherence for a net to be included in detailed report. This parameter is specified along with the `-detailed` paramater. The default value is 80, which means only nets with adherence < 80 % will be included in detailed report. **Note**: It is recommended that you do not use the `-threshold` parameter along with the `-stack_via_rule_only` parameter because stack via rule has no “routing adherence ratio” metric. *Data_type*: float, optional
`-timing`	When this parameter is specified, the report will display timing information on the nets such as slack, delay, and incremental delay while generating the detailed information. *Data_type*: bool, optional

Use Model Scenarios

The use model scenarios for reports including via pillar constraints applied on secondary PG pins are provided below.

Reporting stack via rule (including stack via rule used on secondary PG pins) and bottom layer constraint:

```
report_route_type_constraints -stack_via_rule
```

The following information is included in the summary report:

```
**INFO (OILAM) : Summary of current layer assignment usage:
        # num nets with bottom preferred layer constraint                  :  38225
        List NDR used                                                      :  TrunkNDR LeafNDR
        List stack via rule used                                           :
        Num nets with incorrect stack via rule constraint applied on driver  :  0
        Num nets with incorrect stack via rule constraint applied on sinks   :  0
        Num library cells with stack via rule defined                      :  0
        Num library cells with required stack via rule defined             :  0
        Num instances with pillar rule list associated to them             :  0
        List stack via rule used on second PG pins                         :  VPPERF_M2_M4_1_3_1 VPPERF_M2_M4_1_2_1
        Num second PG pins with stack via rule constraint                  :  24785
```

Reporting only stack via rule

```
report_route_type_constraints -stack_via_rule_only
```

The above command prints information about only stack via rule including the summary of via pillar rule applied on secondary PG pins.

```
**INFO (OILAM) : Summary number of stack via rule constraint applied on second PG pins:
        +----------------------+--------------+--------------+----------+--------------+
        | Stack via rule name  | Routing Cost | # stack via rule applied               |
        +                      +              +--------------+----------+--------------+
        |                      |              | Not required | Required                |
        +                      +              +              +----------+--------------+
        |                      |              |              | cell pin | instance pin |
        +----------------------+--------------+--------------+----------+--------------+
        | VPPERF_M2_M4_1_3_1   | 104.0        | NA           | 435      | NA           |
        | VPPERF_M2_M4_1_2_1   | 88.0         | NA           | 24350    | NA           |
        +----------------------+--------------+--------------+----------+--------------+
        | Total                |              | 0            | 24785    | 0            |
        +----------------------+--------------+--------------+----------+--------------+
```

When no via pillar are found on 2nd PG pin, the table will be replaced by following line:

```
**INFO (OILAM) : Summary number of stack via rule constraint applied on second PG pins:
        No stack via rule found
```

When the `-detailed` parameter is specified while reporting via pillar usage, a new table is generated in the report with the list of secondary PG pins with a via pillar constraint. This is shown below.

```
**INFO (OILAM) : List of second PG pins with stack via rule constraint 'VPPERF_M2_M4_1_2_1':
        +-------+----------------------+--------------+-----------------------------------------+
        | ID    | Stack via rule name  | Rule type    | Instance PG pin name                    |
        +-------+----------------------+--------------+-----------------------------------------+
        | 1     | VPPERF_M2_M4_1_2_1   | Cell Required | FE_OCPC96413_FE_OFN15677_TC_13/TVDD    |
        | 2     | VPPERF_M2_M4_1_2_1   | Cell Required | FE_OCPC96403_TC_447/TVDD               |
        | 3     | VPPERF_M2_M4_1_2_1   | Cell Required | FE_OFC93880_TC_1999/TVDD               |
        | 4     | VPPERF_M2_M4_1_2_1   | Cell Required | FE_OFC10210_TC_1612/TVDD               |
        | 5     | VPPERF_M2_M4_1_2_1   | Cell Required | FE_OFC10209_TC_1612/TVDD               |
        | 6     | VPPERF_M2_M4_1_2_1   | Cell Required | FE_OFC10208_TC_1379/TVDD               |
        | 7     | VPPERF_M2_M4_1_2_1   | Cell Required | FE_OFC10207_TC_1379/TVDD               |
        | 8     | VPPERF_M2_M4_1_2_1   | Cell Required | FE_OFC10206_TC_52/TVDD                 |
        | 9     | VPPERF_M2_M4_1_2_1   | Cell Required | FE_OFC10204_TC_776/TVDD                |
        | 10    | VPPERF_M2_M4_1_2_1   | Cell Required | FE_OFC93879_FE_OFN6183_TC_483/TVDD     |
```

Examples

- The following command prints the summary for the route type constraints:

  ```
  report_route_type_constraints -summary
  ```

  The report below summarizes the number of route type constraints per layer for each category.

```
**INFO (OILAM) : Detailed number of layer constraint usage:

```

- The following command prints the detailed route type constraints information:
  `report_route_type_constraints -detailed`

  The report below summarizes the percentage of respect of the route type constraint (bottom preferred layer) by the current router. For example, in the report below, for the INNOVUS constraints between 90% and 100% respect of the constraint, there are 100.0% of the nets. While INNOVUS_CLK constraints between 90 - 100% respect of the constraint, there are 98.33% of the nets.

```
**INFO (OILAM) : Summary min layer respect by router:

report_threshold_instance_count

```
report_threshold_instance_count
[-help]
[-area]
[-detailed]
[-leakage]
[-out_file file_name]
```

Reports the instance distribution across the VT partitions in the design. By default, the Stylus software partitions the design into either two or three VT buckets. Each library, cell, and instance falls into one of these buckets and is reported by this command.

Parameters

`-help`	Prints a brief description that includes type and default information for each `report_threshold_instance_count` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_threshold_instance_count`
`-area`	Prints the area information across libraries in each VT partition. *Data_type*: bool, optional
`-detailed`	Prints complete details in the specified file. **Note**: Before specifying this parameter, you must specify the file name using the `-out_file` parameter. *Data_type*: bool, optional
`-leakage`	Prints the leakage distribution across the libraries in each VT partition. When you specify this parameter, a complete leakage power analysis is performed on the design, which takes a little long to run. *Data_type*: bool, optional
`-out_file` *file_name*	
	Prints the output in the specified file in the format required for user-defined VT partitioning. **Note**: To print the same report that is output to the log that includes all leakage and instance information, specify the `-detailed` parameter. If you do not specify the `-detailed` parameter, the `-out_file` parameter will only print the VT partitions. *Data_type*: string, optional

Examples

- The following command outputs the Vt partitions to the file `VT_Partitions.rpt`:

  ```
  report_threshold_instance_count -out_file Vt_Partitions.rpt
  ```

  The `Vt_Partitions.rpt` file contains the following information:

```
#####################################################################
#  Generated by:      Cadence Encounter <version>
#  OS:                Linux x86_64(Host ID <machine name>)
#  Generated on:      <date>
#  Design:            <design name>
#  Command:           report_threshold_instance_count -out_file VT_Partitions.rpt
#####################################################################

```

- The following commands output the Vt distribution as well as information on instances and cells. When the output file is not specified, the `report_threshold_instance_count` command outputs only to the log. The second command outputs both to the log and to the output file.

  ```
  report_threshold_instance_count
  report_threshold_instance_count -detailed -out_file VT_detailed.rpt
  ```

  The report will contain the following information:

```
Power view                = MAX1
Number of VT partitions   = 3
Standard cells in design = 1105
Instances in design       = 45515

Instance distribution across the VT partitions:

```

- The following commands output reports with the leakage power numbers included. The first command outputs only to the log. The second command outputs both to the log and to the output file.

  ```
  report_threshold_instance_count -leakage
  report_threshold_instance_count -leakage -detailed -out_file
  VT_detailed_leakage.rpt
  ```

  The report will contain the following information:

```
Power view                = MAX1
Number of VT partitions   = 3
Standard cells in design  = 1105
Instances in design       = 45515
Design leakage power      = 1.041 mW

Instance and leakage distribution across the VT partitions:

reset_path_group_options

```
reset_path_group_options
[-help]
[path_group_name]
[-early]
[-effort_level]
[-late]
[-skewing_slack_constraint]
[-slack_adjustment]
[-slack_adjustment_priority]
[-target_slack]
[-view]
```

Resets the parameters of a specified path group, or of all path groups, to their default values.

- If no group name and no parameters are provided, the command resets all parameters for all path groups to their default values.
- If only the group name is provided, the command resets all parameters of that path group to their default values.
- If a path group and a parameter are provided, then only that parameter of that path group is reset to its default value.

See `set_path_group_options` for parameter descriptions.

Note: This command does not provide the option to reset the weights.
Use `set_path_group_options path_group_name -weight 0` to reset the weights.

Parameters

`-help`	Prints a brief description that includes type and default information for each `reset_path_group_options` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reset_path_group_options`
`path_group_name`	Specifies a path group for which to reset parameters. *Data_type*: string, optional
`parameter_names`	Specifies the parameters to reset to the default value.

Examples

- To reset all parameters of all path groups to the default values, specify the following command:
  ```
  reset_path_group_options
  ```
- To reset all the parameters of the `reg2reg` path group to their default values, but leave the parameters of all other path groups unchanged, specify the following command:
  ```
  reset_path_group_options reg2reg
  ```

Related Commands

route_opt_design

```
route_opt_design

[-help]
[-drv]
[-hold]
[-ideal_clock]
[-num_paths number_of_paths]
[-opt]
[-report_dir directory_name]
[-report_prefix file_name_prefix]
[-route]
[-setup]
[-timing_debug_report]
```

Combines the routing and post-Route optimization flows into a single flow. The benefit of this approach is to interleave the optimization step with routing step. When this command is run, the software performs global and detail routing, setup/hold timing optimization, and DRV fixing. The `route_opt_design` command can be used instead of using two separate commands listed below:

- `route_design`
- `opt_design -post_route -setup -hold`

Note: The `route_opt_design` flow is different from `route_design` followed by `opt_design -post_route -setup -hold` in that the `route_opt_design` command performs more optimization during the routing stage.

The `route_opt_design` command has parameters to split the routing part (`-route`) and the optimization part (`-opt`). When these parameters are specified, the flow exits the interleaved mode, and goes back to the traditional flow with separate commands. This means that `route_opt_design -route` is equivalent to `route_design`, and `route_opt_design -opt` is equivalent to `opt_design -post_route -setup -hold`.

By default, the optimization of `route_opt_design` fixes both setup and hold timing in the interleaved mode with routing. To fix setup timing only, use `route_opt_design -setup`. When the `-setup` parameter is specified, the software performs setup timing optimization, and skips hold timing fixing.

Any partial optimization, using the `-drv` or `-hold` parameters cannot be worked in the interleaved mode. Therefore, if any of these parameters are specified, the software redirects to the `opt_design -post_route` command with the specified option.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `route_opt_design` parameter. For a detailed description of the command and all of its parameters, use the man command: `man route_opt_design`.
`-drv`	Fixes the max_cap and max_tran violations by using the post-Route optimization flow. This is equivalent to `opt_design -post_route -drv`. **Note**: • Ensure that the design is routed before using this parameter. • The `-drv` parameter can only be used with the `-opt` parameter. *Data_type*: bool, optional
`-hold`	When this parameter is specified without `-setup`, the software exits the interleaved mode, and fixes hold timing violations with the post-Route optimization flow. This is equivalent to `opt_design -post_route -hold`. **Note**: Ensure that the design is routed before using this parameter. When this parameter is specified along with the `-setup` parameter, either `-hold -setup` or `-setup -hold`, both the setup and hold timing violations are fixed in the interleaved mode. This is the default behavior of `route_opt_design`. **Note**: • The design should be in the post CTS stage to use `route_opt_design`. • The `-hold` and `-drv` parameters are mutually exclusive. • The `-hold` parameter can only be used with the `-opt` parameter. *Data_type*: bool, optional

`-ideal_clock`	Performs timing optimization using ideal clocks instead of propagated clocks. Using ideal clocks enables you to optimize timing without building a clock tree first, or ignore the existing clock tree, to close ideal timing. If this parameter is not specified, the software assumes the clock tree has been built, and optimizes timing based on propagated clocks. *Data_type*: bool, optional
`-num_paths` *number_of_paths*	Specifies the number of timing paths generated in the timing report. By default, all timing paths are reported. *Data_type*: integer, optional
`-report_dir` *directoryName*	Specifies the directory where the software writes timing reports generated when this command runs. *Default*: `timingReports` *Data_type*: string, optional
`-opt`	When specified, uses the `opt_design -post_route -setup -hold` command and fixes both setup and hold violations for the post-Route optimization flow. The software exits the interleaved mode, and skips routing. **Note**: Ensure that the design is routed before using this parameter. By default, both setup and hold timing violations are fixed. To limit the scope of the optimization, use the `-setup`, `-hold`, and `-drv` parameters along with `-opt` parameter. **Note**: The parameters `-route` and `-opt` are mutually exclusive. *Data_type*: bool, optional
`-report_prefix` *fileNamePrefix*	
	Specifies a prefix for `route_opt_design` report file names. *Default:* *`DesignName_DesignStage`*, where *`DesignStage`* is `post-CTS`, or `post-Route` for `route_opt_design`. *Data_type*: string, optional

`-route`	Specifies that only routing should be done. This is equivalent to `routeDesign` without performing track optimization in the interleaved mode. **Note**: The design should be in the post CTS stage. Note: The -route parameter and the following parameters are mutually exclusive; `-opt`, `-setup`, `-hold`, and `-drv`. *Data_type*: bool, optional
`-setup`	Corrects setup violations in the interleaved mode. When specified without the `-hold` parameter, the software skips the fixing of hold timing violations. **Note**: The design should be in the post CTS stage. **Note**: The `-setup` and `-drv` parameters are mutually exclusive. *Data_type*: bool, optional
`-timing_debug_report`	When specified, generates a machine-readable timing debug report after completing routing and post-route optimization. This report is used for debugging timing results using the timing debug feature in Stylus. **Note**: You can specify the number of paths to be reported using the `-num_paths` parameter. *Data_type*: bool, optional

Examples

- Use the following command to enable interleaved track optimization during the routing stage, for fixing setup violations only:

  ```
  route_opt_design -setup
  ```

- Use the following command to enable interleaved track optimization during the routing stage, for fixing both setup and hold violations:

  ```
  route_opt_design
  ```

  ```
  route_opt_design -setup -hold
  ```

- Use the following command to exit interleaved track optimization mode and perform routing only:

  ```
  route_opt_design -route
  ```

- Use the following command to exit interleaved track optimization mode and perform post-Route optimization only for fixing setup timing:

  ```
  route_opt_design -opt -setup
  ```

  This is equivalent to `opt_design -post_route` or `opt_design -post_route -setup`

- Use the following command to exit interleaved track optimization mode and perform post-Route optimization for fixing both setup and hold timing:

  ```
  route_opt_design -opt
  ```

  This is equivalent to `opt_design -post_route -setup -hold`

set_buffer_footprint

```
set_buffer_footprint
[-help]
names
[-library libName]
```

Sets the buffer cell footprint name. This footprint name is usually assigned during design import. The software uses buffer footprint names during timing optimization and top-level buffer insertion in a partitioned design. You can specify the library that contains the footprint.

Use this command before running timing optimization.

Parameters

`-help`	Prints a brief description that includes type and default information for each `set_buffer_footprint` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_buffer_footprint`
names	Specifies the buffer cell footprint name or a buffer cell name. When you specify a buffer cell name the Innovus software automatically finds the cell footprint name. *Data_type*: string, required
`-library` *lib_name*	Specifies the library that contains the buffer footprint. You must insert a colon (`:`) between the library name and the buffer name when you use this parameter. *Data_type*: string, optional

Example

- The following command sets the buffer cell footprint name to `B_1P`:

  ```
  set_buffer_footprint B_1P
  ```

set_delay_footprint

```
set_delay_footprint
[-help]
[-library lib_name]
names
```

Specifies the delay cell footprint. This footprint name is usually assigned during design import. The delay cells from the cell footprint name are used for inserting delays when you run timing optimization to fix hold-time violations.

Parameters

`-help`	Prints a brief description that includes type and default information for each `set_delay_footprint` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_delay_footprint`
`-library` *lib_name*	Specifies the library name from where the cells will be picked up. *Data_type*: string, optional
names	Specifies the delay cell footprint name or a delay cell name. When you specify a delay cell name, the software automatically finds the cell footprint name. *Data_type*: string, required

Example

The following command sets the delay footprint name to `DEL_1P`:

```
set_delay_footprint DEL_1P
```

    - Using Cell Footprints

set_inverter_footprint

```
set_inverter_footprint
[-help]
[-library lib_name]
names
```

Specifies the inverter cell footprints. The footprint names are usually assigned during design import. The Innovus software uses these inverter footprint names during timing optimization and top-level inverter insertion in a partition design.

Parameters

`-help`	Prints a brief description that includes type and default information for each `set_inverter_footprint` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_inverter_footprint`
names	Specifies the inverter cell footprint names or inverter cell names. When you specify an inverter cell name, the Innovus software automatically finds the cell footprint name. *Data_type*: string, required
`-library` *lib_name*	Specifies the library name from where the cells will be picked up. *Data_type*: string, optional

Guide

- Using Cell Footprints

set_max_cap_per_freq

```
set_max_cap_per_freq
[-help]
-cap {cap1 cap2 …}
[-force]
-freq {freq1 freq2 …}
[-lib lib_name]
-pins {cell pin}
```

Adds a maximum capacitance per frequency table to the existing `max_capacitance` statement in the timing library. Timing analysis uses this table to detect violations, and `opt_design` attempts to repair violations.

The timing engine derives the frequency of an instance from the clock domain to which it is connected (the fastest clock domain, if there is more than one). If the instance is a clock instance (that is, part of the clock tree), the actual clock frequency is used. If the instance is part of the combinational logic (that is, a flip-flop, or the logic connected to the output of a flip-flop), the frequency used equals one-half of the associated clock domain frequency because a flip-flop output can only toggle at one-half the rate of the input clock. For example, a clock of 1.0 Mhz has 1,000,000 rise and fall transitions per second; however the output of a flip-flop connected to a 1.0 Mhz clock can only have 500,000 rise and fall transitions per second.

Timing analysis computes the frequency directly from the timing graph. Use the `check_ac_limits -toggle` command to write the effective frequency onto the associated net in the database.

Note: This command supports MMMC and performs DRV computation as per view frequency. This feature is enabled by setting the below attribute to `true`.

```
set_global timing_report_drv_enable_frequency_per_view true
```

For detailed description of the variable, see the timing Category Attributes chapter.

You can use this command any time after loading the timing library files (that is, after importing or restoring the design).

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_max_cap_per_freq` parameter. For a detailed description of the command and all of its parameters, use `man set_max_cap_per_freq`.

`-cap {`*`cap1 cap2 …`*`}`	
	Specifies a list of capacitance values that must be greater than or equal to 0. You must specify the same number of -freq and -cap values. The software derives the maximum capacitance from a linear interpolation (or extrapolation) for a given frequency value using two frequency values in the table. For interpolation, the software uses the closest value above the frequency, and the closest value below the frequency. For extrapolation, the software uses the two closest values to the frequency. *Type:* Float, specified in units of pF *Data_type*: list, required
`-force`	Computes the maximum capacitance from the interpolated `-freq` and `-cap` values only, and ignores any previously defined `max_capacitance` values for these pins in the library. *Default:* Computes the maximum capacitance using the worst case (minimum value) between the library `max_capacitance` values and the interpolated `-cap` values. *Data_type*: bool, optional
`-freq {`*`freq1 freq2 …`*`}`	
	Specifies a list of at least two frequency values that must be greater than or equal to 0. You must specify the same number of -freq and -cap values, and the frequency values must be specified in ascending order. *Type:* Float, specified in units of Hz *Data_type*: list, required
`-lib` *`libName`*	
	Modifies only the matching cell-pins in the specified library. *Default:* Modifies the matching cell-pins in all libraries *Data_type*: string, optional
`-pins {`*`cell pin`*`}`	

	Adds the new capacitance constraints to the specified set of cells and pins. You can specify output or inout pins. The asterisk (*) wildcard character can be used in a cell or pin name. If a table associated with the pin already exists, it is replaced with the new table. For analysis and optimization, the software uses the most restrictive (the lowest capacitance) value from either the table or the .lib max_capacitance. If you also specify the -force parameter, the max_capacitance value is ignored. The final value can be further modified using .sdc set_max_capacitance statements. *Data_type*: list, required

Examples

Assume all output pins of a library have a `max_capacitance` of 3.5 pF from the library file.

- The following command sets the frequency dependent `max_capacitance` to 3.0 pF at a frequency of 100 Mhz, and to 1.5 pF at a frequency of 200 Mhz, for all output or inout pins for all cells in the library named `fast`:

  ```
  set_max_cap_per_freq -lib fast -freq {100e6 200e6} -cap {3.0 1.5} -pins {* *}
  ```

  As a result, for a net at 300 Mhz, an and2 cell output pin has an extrapolated `max_capacitance` value of 0 pF (which means the cell cannot be used at that frequency). An extrapolation to 50 Mhz results in a `max_capacitance` value of 3.75 pF. However, the 3.75 pF value is greater than the existing `.lib max_capacitance` limit of 3.5 pF; therefore timing analysis uses the 3.5 pF value.

- The following command applies the same constraints to all libraries with cell names matching `dff*` that have a pin named `Qbar`:

  ```
  set_max_cap_per_freq -force -freq {100e6 200e6} -cap {3.0 1.5} -pins {dff* Qbar}
  ```

  Note: The original `.libmax_capacitance` limit is ignored because the `-force` parameter is specified; therefore extrapolation to 50 Mhz results in a final `max_capacitance` constraint value of 3.75 pF.

Related Information

- `check_ac_limits`
- `opt_design`

- timing Category Attributes

set_max_cap_per_freq_transition

```
set_max_cap_per_freq_transition
[-help]
-cap {{cap11 cap12 cap13…} {{cap21 cap22 cap23…}} {{cap31 cap32 cap33…}}}
[-force]
-freq {freq1 freq2 freq3…}
[-input_pin inputpin]
[-lib lib_name]
-pins {cell outputpin}
-transition_time {tran1 tran2 tran3…}
```

Sets the maximum capacitance of a pin in the design. Considers both the input transition time and the output frequency. If the maximum capacitance exceeds this value, the `report_constraint -drv_violation_type max_capacitance` command displays a capacitance violation.

You can use this command any time after loading the timing library files (that is, after importing or restoring the design).

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_max_cap_per_freq_transition` parameter. For a detailed description of the command and all of its parameters, use `man set_max_cap_per_freq_transition`.
`-cap {{cap11 cap12 cap13…} {{cap21 cap22 cap23…}} {{cap31 cap32 cap33…}}}`	

	Specifies a table of capacitance values with the maximum output pin capacitances associated with `-freq` and `-transition_time` values. The total number of `-cap` values must be the total number `-freq` values times the total number of `-transition_time` values. The `-freq` and `-transition_time` values must be specified before `-cap`. The capacitance values are floats in units of pico farad and all values must be greater than or equal to zero. The capacitance table uses frequency as the first index and the input transition as the second index. For example, `cap11`, `cap12`, and `cap13` are for `freq1`, while `c12`, `c22`, and `c32` correspond to the input transition `tran2`. The maximum capacitance is derived from a linear interpolation (or extrapolation) for a given frequency value and a transition value using two frequency values and two transition values n the table (closest above and below for interpolation, the two closest for extrapolation. *Type:* Float, specified in units of pF *Data_type*: list, required
`-force`	Computes the maximum capacitance from the interpolated `-freq, -transition_time,` and `-cap` values only, and ignores any previously defined `max_capacitance` values for these pins in the library. *Default:* (`-force` not specified) Computes the maximum capacitance using the worst case (minimum value) between the library `max_capacitance` values and the interpolated `-cap` values. *Data_type*: bool, optional
`-freq {`*`freq1 freq2 freq3…`*`}`	
	Specifies a list of at least two frequency values with the toggle frequencies at the output pin. Frequency values must be increasing, and the total number of frequency values cannot exceed 255. *Type:* Float, specified in units of Hz. All values must be equal to or greater than `0`. *Data_type*: list, required
`-input_pin` *`inputpin`*	

	Specifies the input pin name corresponding to the input transition values in `-transition_time`. If *`-inputpin`* is not given, `-transition_time` values correspond to all input pins. *Data_type*: string, optional
`-lib` *`lib_name`*	Specifies the library name from inside a `.lib` file to update the cell-pins. *Default:* If a library name is not specified, modifies the matching cell-pins in all libraries *Data_type*: string, optional
`-pins {`*`cell`* `output`*`pin`*`}`	
	Adds the new capacitance constraints to the specified set of cells and pins. You can specify output or inout pins; input pins are ignored. The asterisk (`*`) wildcard character can be used in a cell or pin name. If there is already a table associated with the same input-output pair (input pins are specified using `-input_pin`), it is replaced with the new constraints; otherwise, it is added to the output maximum capacitance table list. For analysis and optimization, the software uses the most restrictive (the lowest capacitance) value from either the table or the `.lib max_capacitance`. If you also specify the `-force` parameter, the `max_capacitance` value is ignored. The final value can be further modified using `.sdc set_max_capacitance` statements. *Data_type*: list, required
`-transition_time {`*`tran1 tran2 tran3…`*`}`	
	Specifies a list of at least two transition values with the input transition times. Transition times must be increasing in value, and the total number of transition times cannot exceed 255. *Type:* Float, specified in units of nanoseconds, and all values must be equal to or greater than `0`. *Data_type*: list, required

Example

The following command establishes a maximum capacitance table for all pins on all cells in all libraries.

```
set_max_cap_per_freq_transition -force -pins {* *} -freq {1e8 1.25e8 1.5e8} -
transition_time {450 475 500} -cap {{0.022 0.017 0.012} {0.02 0.014 0.01} {0.018 0.013
0.008}}
```

The table is shown below:

	450	475	500
1e8	0.022	0.017	0.012
1.25e8	0.02	0.014	0.01
1.5e8	0.018	0.013	0.008

set_max_transition_per_freq

```
set_max_transition_per_freq
[-help]
[-force]
-freq { freq1  freq2 …}
[-lib lib_name]
-pins {cell pin}
-transition {tran1 tran2 ...}
```

Adds a maximum transition per frequency table to the existing `max_transition` statement in the timing library. Timing analysis uses this table to detect violations, and `opt_design` attempts to repair violations.

Use this command any time after loading the timing library files (that is, after importing or restoring the design).

The timing engine derives the frequency of an instance from the clock domain to which it is connected (the fastest clock domain, if there is more than one). If the instance is a clock instance (that is, part of the clock tree), the actual clock frequency is used. If the instance is part of the combinational logic (that is, a flip-flop, or the logic connected to the output of a flip-flop), the frequency used equals one-half of the associated clock domain frequency because a flip-flop output can only toggle at one-half the rate of the input clock. For example, a clock of 1.0 Mhz has 1,000,000 rise and fall transitions per second; however the output of a flip-flop connected to a 1.0 Mhz clock can only have 500,000 rise and fall transitions per second.

Timing analysis computes the frequency directly from the timing graph. Use the `check_ac_limits -toggle` command to write the effective frequency onto the associated net in the database.

Note: This command supports MMMC and performs DRV computation as per view frequency. This feature is enabled by setting the below attribute to `true`.

```
set_global timing_report_drv_enable_frequency_per_view true
```

For detailed description of the variable, see the timing Category Attributes chapter.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_max_transition_per_freq` parameter. For a detailed description of the command and all of its parameters, use `man set_max_transition_per_freq`.
`-force`	Computes the maximum transition from the interpolated `-freq` and `-transition` values only and ignores any previously defined `max_transition` values for these pins in the library. *Default:* Uses the worst case (minimum value) between the `.lib max_transition` values and the interpolated `-transition` values. *Data_type*: bool, optional
`-freq {`*`freq1 freq2 …`*`}`	
	Specifies a list of at least two frequency values that must be greater than or equal to 0. You must specify the same number of `-freq` and `-transition` values, and the frequency values must be specified in ascending order. *Type:* Float, specified in units of Hz *Data_type*: list, required
`-lib` *`lib_name`*	
	Modifies only the matching cell-pins in the specified library. *Default:* Modifies the matching cell-pins in all libraries. *Data_type*: string, optional
`-pins {`*`cell pin`*`}`	

	Adds the new transition constraints to the specified set of cells and pins. You can specify input, output, or inout pins. The asterisk (`*`) wildcard character can be used in a cell or pin name. If a table associated with the pin already exists, it is replaced with the new table. For analysis and optimization, the software uses the most restrictive (the lowest transition) value from either the table or the `.lib max_transition`. If you also specify the -force parameter, the `max_transition` value is ignored. The final value can be further modified by using the `.sdc set_max_transition` statements. *Data_type*: list, required
`-transition {tran1 tran2 …}`	Specifies a list of transition values that must be greater than or equal to 0. You must specify the same number of `-freq` and `-transition` values. The software derives the maximum transition limit from a linear interpolation (or extrapolation) for a given frequency value using two frequency values in the table. For interpolation, the software uses the closest value above the frequency, and the closest value below the frequency. For extrapolation, the software uses the two closest values to the frequency. *Data_type*: list, required

Examples

Assume all output pins of a library have a `max_transition` value of 0.9 ns from the library file.

- The following command sets the frequency dependent `max_transition` to 1.0 ns at a frequency of 100 Mhz, and to 0.7 ns at a frequency of 200 Mhz, for pins matching `in*` of cells matching `*` (that is, all cells) in the library named `slow`:

  ```
  set_max_transition_per_freq -lib slow -freq {100e6 200e6} -transition {1.0 0.7} -pins {* in*}
  ```

  As a result, at 300 Mhz, an `and2` cell input pin named `in1` has an extrapolated `max_transition` value of 0.4ns. An extrapolation to 50 Mhz results in a `max_transition` value of 1.15 ns. However, the 1.15 ns value is greater than the existing `.lib max_transition` value of 0.9 ns; therefore timing analysis uses the 0.9 value.
- The following command applies the same constraints to all libraries with cell names matching `dff*` that have a pin named `clk`:

```
set_max_transition_per_freq -force -freq {100e6 200e6} -transition {1.0 0.7} -pins
{dff* clk}
```

Note: The original `.libmax_transition` value is ignored because the `-force` parameter is specified; therefore an extrapolation to 50 Mhz results in a final `max_transition` limit of 1.15 ns.

set_path_group_options

```
set_path_group_options

[-help]
path_group_name
[-early]
[-effort_level {low | high}]
[-late]
[-skewing_slack_constraint value_in_ns]
[-slack_adjustment float]
[-slack_adjustment_priority integer]
[-target_slack float]
[-view view_names]
[-weight integer]
```

Specifies options to guide timing optimization and timing analysis when path groups are used. To reset parameters to their default value, use `reset_path_group_options`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_path_group_options` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_path_group_options`
`-early`	Specifies early mode. This parameter is used with the `-slack_adjustment` option when you wish to adjust a path groups slack in Hold timing mode only. **Note the following**: • If you do not specify either `-early` or `-late`, then `-late` is implied. • If you specify `-early`, then `-early` is used. • If you specify `-late`, then `-late` is used.

- If you specify both `-early` and `-late`, then both `-early` and `-late` are used, which means the same value of `-early` and `-late` are set at the same time.

For example,

```
set_path_group_options reg2reg -
slack_adjustment -0.3 -early -late

Slack adjustment of -0.3 applied on
reg2reg path_group

**INFO: Setting reg2reg as high effort
level since it has a negative slack
adjustment.

[DEV]innovus 25>
report_path_group_options

|        0   |  2   |        300
|setup_view|
```

Data_type: bool, optional

`-effort_level {low | high}`	Specifies the effort applied to close timing on a specific path group. This parameter is honored by timing optimization (`opt_design`). Select one of the following options: `low`: Specifies that this path group is optimized together with other path groups for best overall slack. low is the default effort value for all user-created path groups. **Note**: Cadence recommends you specify low effort for all path groups except that ones that the tool should focus on most strongly. `high`: Specifies that this path group is optimized separately from the low-effort path groups in order to achieve the best possible WNS for this path group. *Default*: low *Data_type*: enum, optional
path_group_name	Specifies the path group for which to set options. *Data_type*: string, required
`-late`	Specifies late mode. This parameter is used with the `-slack_adjustment` option when you wish to adjust a path groups slack in Setup timing mode only. For usage details, see the description of the `-early` parameter. *Data_type*: bool, optional

`-skewing_slack_constraint` *value_in_ns*	When set, applies the specified skewing slack constraint to the path group. The value specified is in nanoseconds. If not set, no skewing slack constraint is applied to the path group. This parameter provides the ability to control the I/O slack during skewing without degrading the core slack value. The skewing engine skews in a way not to make any already -ve slack path more -ve or not introduce a new -ve slack path. **Examples**: If the following is specified: `set_path_group_options R2O -skewing_slack_constraint 0` *Before skewing*: FF's D slack is `-100 ps`(R2R), Q slack is `-20ps` (R2O) *After skewing*: D slack is `-100ps`, Q slack is `-20ps` *Before skewing*: FF's D slack is `-100 ps`(R2R), Q slack is `30ps` (R2O) *After skewing*: D slack is `-70ps`, Q slack is `0ps` **Note**: • This option can control CCOpt useful skew. If you are running ECF (early clock flow), pre-CTS will use CCOpt useful skew engine to do skewing. in this scenario, this option will take effect. • This option can control post-CTS `opt_clock_skew` behavior. • This option does not impact timing analysis. *Data_type*: float, optional

`-slack_adjustment` *float*	Specifies a positive or negative value used to modify path constraints on all paths that are part of a specific path group. The value is in nanoseconds. To relax the path constraints computed by the timing engine, specify a positive value. To tighten the timing constraints, specify a negative value. This parameter is honored by timing optimization (`opt_design`) and timing analysis (`report_timing`). This means that that the `-slack_adjustment` parameter setting impacts the timing analysis result and all optimization is then performed based on this timing. Using this parameter might have an impact on run time during timing optimization. **Note**: Path groups with negative slack adjustment will be automatically set to high effort, unless the `-effort_level` option is explicitly set to "'`low`". For positive slack adjustment, the effort level will remain the same. This means, if the effort is low before setting a positive slack adjustment, the new effort will be low; if the effort is high before setting a positive slack adjustment, the new effort will be high. **Tip**: Use this parameter together with the `-effort` parameter to direct timing optimization focus. *Data_type*: float, optional

`-slack_adjustment_priority` *integer*	Provides priority to a path group for the slack adjustment feature. The paths that are a part of overlapping path groups get slack adjustment from the path group that has a higher priority value. If the number is higher, the priority is higher. In case of multiple overlapping path groups with different slack adjustment values, the most constraining slack adjustment is applied. *Default*: 0 **Note**: The `-slack_adjustment_priority` parameter is ignored if `-slack_adjustment` is not specified. *Data_type*: unit, optional

`-target_slack` *float*	Specifies a target value for setup slack, in nanoseconds, for all paths that are part of a specific path group. The value can be positive or negative. This parameter is honored by timing optimization (`opt_design`). Using this parameter might have an impact on run time during timing optimization. **Note**: Setting this parameter does not impact the timing analysis results, and only setup optimization considers the target slack as the goal of optimization. The path group target slack (`set_path_group_options -target_slack`) and the global setup target slack (`opt_setup_target_slack`) are cumulative. When both are set, global setup target slack adds on top of what is specified using the `set_path_group_options -target_slack` parameter. The effective number depends upon whether path group target slack number is positive or negative. The global setup target slack is the timing closure target for timing optimization. **Note**: When both, `-slack_adjustment` and `-target_slack` parameters are set, the setup optimization considers the target slack based on slack adjustment timing. *Data_type*: float, optional
`-view` *view_names*	Specifies the view names. This parameter is used when you want to specify different effort levels of the path group for different views. *Default*: `{}` *Data_type*: string, optional

`-weight integer`	Defines the optimization priority. For the default path groups, the software assigns weights in the following manner: For high-effort path groups - the software assigns a weight of "1" to reg2cgate and "2" to reg2reg. All low-effort path groups are assigned a default weight of "0". You can assign any value to this parameter (`0` to `INT_MAX`). There is no upper limit. The software looks at the relative priority of the weights for each path group - the higher the number, the higher the weight. For example, if there are 10 path groups with weights ranging from 1 to 10 and they are all high-effort path groups, the high-effort optimization for all these ten path groups will be started simultaneously. If, however, the optimization is stuck at the path group with the weight 6, the software drops all the path groups that have weights ranging from 1 to 6 and continues to work on the remaining four path groups. **Note**: Use this parameter to control optimization and not `-slack_adjustment_priority`, which only controls the slack adjustment. *Data_type*: unit, optional

Examples

- To add 2 nanoseconds of slack adjustment to all paths belonging to the `PATH_GROUP_A` path group, specify the following command:
  ```
  set_path_group_options PATH_GROUP_A -slack_adjustment 2
  ```
- To subtract 200 picoseconds from all paths belonging to `PATH_GROUP_B` path group, specify the following command:

```
set_path_group_options PATH_GROUP_B -slack_adjustment -0.2
```

- To ensure that the `opt_design` command does not try to achieve a better slack than 2 nanoseconds on path group `PATH_GROUP_A`, specify the following commands:

  ```
  set_path_group_options PATH_GROUP_A -target_slack 2
  opt_design
  ```

  When these commands run, the software internally subtracts 2 nanoseconds of slack adjustment from all paths that belong to `PATH_GROUP_A` path group.

- The following command adds to the slack on all paths inside group `GROUP_1` by 0.2 ns - relaxing the constraints on the paths for Hold timing analysis only:

  ```
  set_path_group_options GROUP_1 -slack_adjustment +0.2 -early
  ```

- The following command subtracts the slack on all paths inside group `GROUP_2` by 0.2 ns - tightening the constraints on the paths for Setup timing analysis only:

  ```
  set_path_group_options GROUP_2 -slack_adjustment -0.2 -late
  ```

- The following commands are used to set the effort level, skewing slack constraint, weight, and views of the two path groups, and generate a report using these parameters:

  ```
  set_path_group_options reg2reg -effort_level low -skewing_slack_constraint 0.3 -
  view AV_HL_FUNC_MIN_RC1
  set_path_group_options reg2cgate -effort_level high-skewing_slack_constraint 0.5 -
  view AV_HL_FUNC_MAX_RC1
  report_path_group_options
  The software prints the following report:
  ------------------------------------------------------------------------------
  -----------------
  |Path Group|Effort|Adjustment(early/late)|Target
  Slack|weight|SkewingSlackCons|view               |
  ------------------------------------------------------------------------------
  -----------------
  |reg2reg   |low   | 0.1     /-0.2        | 0          |   2  |    0.3
   |AV_HL_FUNC_MIN_RC1 |
  |reg2cgate |high  | 0.2    /0            | 0          |   1  |    0.5
   |AV_HL_FUNC_MAX_RC1 |
  ```

  The description of the columns headings and the corresponding parameters to which they map is provided below.

Column Heading	Parameter Name and Description
Path Group	*path_group_name:* Name of the path group for which the options are being set.
Effort	`-effort_level`: Specifies the effort applied to close timing on a specific path group. `low`: Specifies that this path group is optimized together with other path groups for best overall slack. low is the default effort value for all user-created path groups. `high`: Specifies that this path group is optimized separately from the low-effort path groups in order to achieve the best possible WNS for this path group.
Adjustment (early/late)	`-slack_adjustment`: Specifies a positive or negative value used to modify path constraints on all paths that are part of a specific path group. The value is in nanoseconds.
Target Slack	`-target_slack`: Specifies a target value for setup slack, in nanoseconds, for all paths that are part of a specific path group. The value can be positive or negative. **Note**: This column only displays the latest setting, either early or late.
weight	`-weight`: Defines the optimization priority. For the default path groups, the software assigns weights in the following manner: • For high-effort path groups: the software assigns a weight of "1" to reg2cgate and "2" to reg2reg. • All low-effort path groups are assigned a default weight of "0".
Skewing Slack Cons	`-skewing_slack_constraint`: Specifies the skewing slack constraint for the path group. If no constraint is applied to a path group, the column is empty.
view	`-view`: Specifies the view name. It allows you to specify different effort levels of the path group for different views.

set_scheduling_file

```
set_scheduling_file
[-help]
scheduling_file_name
```

Specifies the name of the scheduling file. The file is not taken into account by CTS, but skew clock must have access to the file if it runs several times consecutively.

To see the current setting for the `set_scheduling_file` command, use `get_scheduling_file`.

Parameters

-help	Outputs a brief description that includes type and default information for each set_scheduling_file parameter. For a detailed description of the command and all of its parameters, use the man command: man set_scheduling_file.
scheduling_file_name	Specifies the name of the scheduling file. *Data_type*: string, required

Example

The following command sets the name of the scheduling file to `scheduling_file.cts`:

```
set_scheduling_file scheduling_file.cts
```

For more information about how the scheduling file is used in the pre-CTS flow, see `opt_clock_skew`.

Related Commands

- `opt_clock_skew`
- `set_scheduling_file`

write_multi_bit_flop_mapping_file

```
write_multi_bit_flop_mapping_file
[-help]
[-map_output_pins {false | true | all}]
[-output directory]
[-prefix fileName_prefix]
```

Dumps the multi-bit flip-flop (MBFF) mapping files in the specified directory with the specified prefix name. The following files are dumped:

- `multi_bit_pin_mapping`
  includes multi-bit input pin mapping information by default. In addition, it appends the output pins when the `-map_output_pins` option is specified.
- `multi_bit_mapping`
  includes multi-bit optimization mapping information

The `multi_bit_pin_mapping` file has two columns. The first column provides the full path name of the flop input D pin as it was in the initial netlist. The second column provides the full path name of flop input D pin in the current state of the database that corresponds to the first column. For example, if SBF1, SBF2, SBF3, SBF4 are single-bit flip flops, and MBF1, and MBF2 are two-bit flip flops, then,

The **multi_bit_mapping** file contains the following:

```
SBF1(SBCell1), SBF2(SBCell2) merged to MBF1(MBCell1)

MBF2(MBCell2) split to SBF3(SBCell3), SBF4(SBCell4)
```

The **multi_bit_pin_mapping** file by default contains the following**:**

```
SBF1/D    MBF1/D1

SBF2/D    MBF1/D2

MBF2/D1   SBF3/D

MBF2/D2   SBF4/D
```

Note:

- The `multi_bit_pin_mapping` file contains all information of the flops whose input D pin names have changed. For example, see the "Examples" section below.
- To generate a proper report for merge/split mapping information, the command should be executed as part of the flow in the live session, for example, after running `place_opt_design`. If

the command is run on a restored session, it will generate an empty "`multi_bit_mapping`" file because the merge/split mapping information is not saved while saving the design.

- You can use the `write_do_lec` command to facilitate the Logical Equivalence Checking (LEC) checking of the MBFF instances. This command writes out a `dofile` that contains the name mapping information of the MBIT flops against their split/single bit candidate.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `write_multi_bit_flop_mapping_file` parameter. For a detailed description of the command and all of its parameters, use the man command: `man write_multi_bit_flop_mapping_file`.
`-map_output_pins {false | true | all}`	When set to `true`, the software writes out only the mapped output terms in the MBFF pin mapping file. When set to `false`, the software writes out only input pin mapping in the pin mapping file. This is the default setting. When set to `all`, the software writes out both input and output pin mapping in the pin mapping file. Example of **multi_bit_pin_mapping** file when `-map_output_pins` parameter is set to `false`: MBF1/D1 SBF1/D MBF1/D2 SBF2/D Example of **multi_bit_pin_mapping** file when the `-map_output_pins` parameter is set to `true`: MBF1/D1 SBF1/D MBF1/D2 SBF2/D MBF1/Q1 SBF1/Q MBF1/Q2 SBF2/Q *Default*: `false`
`-output` *`directory`*	Specifies the directory in which to dump the MBFF mapping files. *Default*: ./ *Data_type*: string, optional
`-prefix` *`fileName_prefix`*	Specifies the prefix to the MBFF mapping files. *Default*: without prefix *Data_type*: string, optional

Examples

Consider a scenario in which the original netlist contains the following information:

```
4BitMBF1          (4 bit MBF, D1-4)

SBF1              (single bit FF)
```

Example of merging is as follows:

If the incoming netlist has `4BitMBF1/D4` dangling (no signal attached) and MERGE, merged `SBF1/D` into `4BitMBF1/D4`. The following line will be included in `multi_bit_input_pin_mapping` file:

```
SBF1/D          4BitMBF1/D4
```

Example of splitting is as follows:

If incoming netlist has valid signals for all 4 bits of `4BitMBF1` and splits `4BitMBF1/D4` out to `SDF2/D` leaving `4BitMBF1/D4` dangling, then the following lines will be included in `multi_bit_pin_mapping` file:

```
*VOID*          4BitMBF1/D4

4BitMBF1/D4     SBF2/D
```

write_target_based_opt_file

```
write_target_based_opt_file
[-help]
-bottleneck_instance_number integer
[-early]
[-gtd_file filename]
[-max_paths integer]
[-max_slack float]
[-min_slack float]
-out_file filename
[-path_group groupname_list]
```

This command creates a target-based optimization (TBOpt) file for use with post-route targeted optimization. Once created, this file is passed to the `opt_target_based_opt_file` attribute. You can either provide the command a timing report in a machine-readable format by using the `-gtd_file` parameter or let the command generate the timing report internally by using the values specified for the `-min_slack`, `max_slack`, and -max_paths parameters or the internal default values for these parameters.

Based on this timing report, a bottleneck analysis is performed and the critical instances are stored in a file that is specified using the `-out_file` filename parameter. This file uses the TBOpt format with the INSTS token. The bottleneck analysis computes the number of times an instance appears (on only the failing paths by default) and creates "n" number of path categories for the instances with the highest number of occurrences. Note that "n" is the number you specify using the `-bottleneck_instance_number` parameter of this command.

Also note that by default, multiple instances per path are allowed. This means that if there are multiple critical instances on a path, all of them will be returned, therefore, leading to the generation of the most accurate list of critical instances.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `write_target_based_opt_file` parameter. For a detailed description of the command and all of its parameters, use the man command: `man write_target_based_opt_file`.
`-bottleneck_instance_number integer`	

	Specifies the number of critical bottleneck instances to be generated. This is a required parameter. *Data_type*: int, required

`-early`	Specifies that the TBOpt file will be created based on hold timing's critical nodes. This parameter can be specified along with the following commands to generate and use a hold target file for hold TBOpt. For example:
	`write_target_based_opt_file -early -bottleneck_instance_number 5 -out_file TBOpt_bottleneck_5_hold.txt`
	`set_db opt_target_based_opt_hold_file TBOpt_bottleneck_5_hold.txt`
	`opt_design -post_route -targeted -hold`
	Data_type: bool, optional

`-gtd_file` *filename*	Specifies the name of the machine-readable timing report on which you want to base the critical instance analysis. If this parameter is not specified, the command generates its own file with the `-max_slack` value of `0.0` and `-max_paths` value of `100,000`. *Data_type*: string, optional
`-max_paths` *integer*	Specifies the number of worst paths to be considered, regardless of the endpoint. By default, the value is `100,000`. *Data_type*: int, optional
`-max_slack` *float*	Specifies that only those paths should be considered that have a slack equal to or less than the specified float value in `ns`. By default, the value is `0.0` to ensure that only paths with negative slacks are considered. *Data_type*: float, optional
`-min_slack` *float*	Specifies that only those paths should be considered that have a slack greater than the specified float value in `ns`. *Data_type*: float, optional

`-out_file` *`filename`*	Specifies the name of the TBOpt file that will be generated. This is a required parameter. *Data_type*: string, required
`-path_group` *`groupname_list`*	
	Specifies that only those paths should be considered that are from the specified path groups on which you want to base the critical instance analysis. *Data_type*: string, optional

Example

- The following command generates a TBOpt file with five critical instances using the default values for `-min_slack`, `-max_slack`, and `-max_paths` that will be written to the file, `TBOpt_bottleneck_5.txt`:

  ```
  write_target_based_opt_file -bottleneck_instance_number 5 -out_file
  TBOpt_bottleneck_5.txt
  ```

  The `TBOpt_bottleneck_5.txt` file will contain five critical instances with the appropriate syntax for target-based postRoute optimization.
  For example,

  ```
  INSTS : {mod_i/i_mod_glm_cluster_0/U586} {mod_i/i_mod_glm_cluster_2/U535}
  {mod_i/i_mod_glm_cluster_1/U596} {mod_i/ser_en/U92} {mod_i/ser_en/U101}
  ```

- The following command generates a TBOpt file, `usergenerated.mtarpt` with three critical instances based on a machine-readable timing report generated using the `-machine_readable` parameter of the `report_timing` command:

  ```
  write_target_based_opt_file -bottleneck_instance_number 3 -out_file
  TBOpt_bottleneck_3.txt -gtd_file usergenerated.mtarpt
  ```

- The following command generates a TBOpt file with six critical instances based on only the `reg2reg` path group with the maximum number of worst paths as 3000:

  ```
  write_target_based_opt_file -bottleneck_instance_number 6 -out_file
  TBOpt_bottleneck_6.txt -path_group reg2reg -max_paths 3000
  ```

- The following command generates a TBOpt file with nine critical instances based on a timing analysis of the worst 10,000 paths between `+0.025ns` and `-1.0ns`:

  ```
  write_target_based_opt_file -bottleneck_instance_number 9 -out_file
  TBOpt_bottleneck_9.txt -min_slack -1.0 -max_slack +0.025 -max_paths 10000
  ```

[-feedthru [-cdl_map_file cdl_map_file_name]]
```

Adds shapes on the TSV bumps. You can use this command to add shapes on all the specified TSV bumps or the specified bump. The shape size could be user-defined or same as bump pin on the specified layer.

Parameters

`-help`	Prints a brief description of the `add_obj_on_bump` command usage. For a detailed description of the command, use the `man` command: `man add_obj_on_bump`
`-cdl_map_file` *cdl_map_file_name*	
	Specifies the output cdl map file for LVS. *Data_type*: string, optional
`-cell` *bump_cell_name*	Specifies the name of the bump cell on which the shape is to be added. *Data_type*: string, optional
`-check_only` *bump_name*	Checks if there is a shape on the specified bump and outputs a report file. The `-check_only` option cannot be used with `-write_script`. ⚠ The `-check_only` option can be used only when `-shape` is specified. *Data_type*: string, optional
`-feedthru`	Adds shapes on the bump that contains the TSV layer and whose net is a feedthrough net. *Data_type*: bool, optional

`-incremental`	Adds shapes in the incremental mode. It deletes the shapes without a bump, and adds new shapes on the bumps without shapes. The -incremental parameter only checks the shapes on the same layer.
	In the following sequence of commands, the first command is `add_obj_on_bump -shape M1` and the second command is `add_obj_on_bump -shape M2 -incremental`. In these commands the layers specified are different. Therefore, `add_obj_on_bump` will not delete previously added shapes on `M1`. Also, the result of the command `add_obj_on_bump -shape M2 -incremental` is the same as `add_obj_on_bump -shape M2`.
	`>add_obj_on_bump -shape M1`
	`>add_obj_on_bump -shape M2 -incremental`
	⚠ The `-incremental` option can be used only when `-shape` is specified.
	Data_type: bool, optional

`-shape` *layer+*	Specifies the layer to add new shape. *Data_type*: (layer)+, optional
`-placement_blockage`	Adds a placement blockage on bumps. Only orthogonal polygons are supported. *Data_type*: bool, optional
`-physical_pin` *layer+*	Specifies the layer(s) on which to add physical pins. For a single-pin bump, the name of the physical pin is same as that of the target bump. For a multiple-pin bump, the name of the physical pin is same as that of the bump pin on the same layer. If no bump pin exists on the layer specified for adding the physical pin, the tool chooses the name of any of the pins on the target bump as the pin name of the physical pin. Polygons with non-45-degree edges are supported.
`-polygon {{x1 y1} {x2 y2}...`	
	Specifies the point list of the polygon to add shapes. The center of the specified polygon bounding box aligns with the center of the specified bump cell. *Data_type*: (point)+, optional

`-rect {x1 y1 x2 y2}`	Specifies the rectangle to add shapes. The center of specified rectangle aligns with the center of the specified bump cell. *Data_type*: rect, optional
`-relative_pin_layer` *pin_layer_name*	
	Specifies the pin layer of the pin shape of the specified bump. Adds shapes based on the specified pin shape of the bump. If the `-relative_pin_layer` option is specified while adding objects, the shape of the added object is same as the shape of the relative pin. *Data_type*: (layer), optional
`-routing_blockage` *layer+*	
	Specifies the layer(s) on which to add routing blockages on bumps. Only orthogonal polygons are supported. *Data_type*: (layer)+, optional
`-selected`	Adds shapes on the selected bump. *Data_type*: bool, optional
`-shape_keep_net`	Keeps the net when adding the layer shape. When you specify the `-incremental` option, the tool adds shape with net name if there is no shape with this net on the bump. *Data_type*: bool, optional
`-write_script` *filename*	Specifies the file name to dump a Tcl script for adding objects on bumps. If this option is specified, the tool will not add objects on bumps directly. The `-write_script` option cannot be used with `-check_only`. *Data_type*: string, optional

Example

- The following command adds a shape on layer M1 at the position of the TSV bump whose net is a feedthrough net. The shape on layer M1 is the same as the bump pin shape on layer TSV.

```
add_obj_on_bump -shape M1 -feedthru -relative_pin_layer TSV
```

add_tsv

```
add_tsv
[-help]
[-no_route_blockage]
{[-front_bump  bumpCellName] [-back_bump  bumpCellName] [-tsv_via_name viaName]}
[-front_bump  bumpCellName [-location_type {geometry_center|cell_center} -prefix prefix] [-
stack_via_under_bump stackViaName]]
[-back_bump bumpCellName  [-location_type {geometry_center|cell_center} -prefix prefix]]
[-tsv_via_name viaName [-no_place_blockage  | -spacing s] [[-tsv_feedthru {x y}
     [-stack_via_top_layer layer]] | [-stripe_net pgnetName -stripe_layer layerNum |
     [-stack_via_name stackViaName[-stack_via_marker_layer markerLayerName] -stack_via_array {x
y} -stack_via_pitch {x y}]]]]
{-lower_left_location x y}
[-relative_bump_cell bumpCell | -relative_selected_bump ]} {[-pitch_x_y {x y}] [-
relative_bump_cell bumpCell | -relative_selected_bump ]}
{-upper_right_location x y | -num_x_y x y}
[-relative_bump_cell bumpCell | -relative_selected_bump ]} [{-relative_bump_cell bumpCell | -
relative_selected_bump } [-relative_min_pitch minPitch] [-relative_offset {x y}] [-
relative_bump_type {signal power ground}]]
[-rings n] [-stagger ]
```

Adds TSVs, frontside bumps, and backside bumps under specified conditions. Use this command to create TSVs and bumps after the initial floorplan is loaded.

The command also checks for dummy bump overlaps by default. It checks overlaps between:

- Dummy bumps by checking the OBS overlap.
- Dummy bump and bump by checking the OBS and bump pin overlap.

In case there is dummy bump overlaps, the tool gives a warning message.

Parameters

`-tsv_via_name viaName`

	Specifies the name for TSV via defined in the lef file. If this option is not specified, no TSV will be created. The following arguments are used only with `tsv_via_name`: • `no_place_blockage` • `spacing` • `tsv_feedthru` • `stack_via_top_layer` • `stripe_net` • `stripe_layer` *Data_type*: string, optional
`-front_bump` *bumpCellName*	
	Specifies the name for the frontside bump cell. If this option is not specified, no frontside bump will be created. *Data_type*: string, optional
`-back_bump` *bumpCellName*	
	Specifies the name for the backside bump cell. If this option is not specified, no backside bump will be created. *Data_type*: string, optional
`-location_type {geometry_center cell_center}`	
	Specifies the location type for bump creation. *Data_type*: enum, optional
`-lower_left_location x y`	
	Specifies (in microns) the lower left coordinate of the box in which TSV/Bumps will be created. *Data_type*: point, required
`-num_x_y` x y	Specifies (in microns) the count of the TSV/bump in the horizontal and vertical direction. *Data_type*: point, optional

`-relative_bump_cell` *bumpCell*	Creates TSV or bumps by default at the geometry center of bumps with specified bump cell.
`-relative_bump_type {signal power ground}`	Creates the relative bump type, TSV, or bumps by default at the geometry center of bumps with the specified bump type.
`-relative_min_pitch` *minPitch*	Specifies the minimum pitch between the created bumps/TSVs. The pitch between all the created bumps/TSV should be larger than specified min pitch. The `-relative_min_pitch` option is optional and can be used only if `-relative_bump_cell/-relative_selected_bump` is specified.
`-relative_offset {x y}`	Specifies the offset of created bump/TSV location compared with the relative bump. The geometry center of the created bump/TSV is the geometry center of the relative bumps plus the offset. `-relative_offset` is optional and can be used only if `-relative_bump_cell`/`-relative_selected_bump` is specified.
`-relative_selected_bump`	Creates TSV or bumps by default at the geometry center of the selected bumps.

`-rings` *n*	Creates TSV along rings on the perimeter. If `-rings` is specified, *n* defines the number of rings.
	Data_type: int, optional
	You can create TSV in the following ways:
	• Define the lower left and upper right location of the ring by -`lower_left_location` and `-upper_right_location`, and then the pitch value of x and y direction by -`pitch_x_y`. For example, the following command creates TSV in which the lower-left is at `{x1 y1}` and the upper-right is at `{x2 y2}`
	`add_tsv -lower_left_location {x1 y1} -upper_right_location {x2 y2} -pitch_x_y {px py} -stagger -rings 1`
	`*********`
	`*  *`
	`*  *`

	 • Define the lower left location of the ring by `-lower_left_location`, and then specify the number and pitch value of tsv in x and y directions by `-num_x_y` and `-pitch_x_y`, respectively. For example, the following command creates TSV in which the lower left is at {x1 y1} `-lower_left_location {x1 y1} -num_x_y {12 8} -pitch_x_y {px py} -rings 2`
`-pitch_x_y` *x y*	Specifies (in microns) the distance between TSV centers in the x and y direction. *Data_type*: point, required
`-prefix` *prefix*	Adds a prefix name for bump during bump creation and bump mapping. *Data_type*: string, optional
`-no_place_blockage`	The placement blockage overlapped with TSV cut will be added as default if `-no_place_blockage` is not specified. *Data_type*: bool, optional

`-no_route_blockage`	The routing blockage for each crossing layer will be added if `-noRouteBlkg` is not specified. *Data_type*: bool, optional
`-tsv_feedthru` *`sizex sizey`*	
	Creates the feedthru. `sizeX` and `sizeY` are the dimensions, in microns, for the stack vias aligned with the TSV. *Data_type*: point, optional **Note:** Feedtrhu is a collection of components including TSV, the stacked via (from the first metal to the top metal) aligned with the TSV, and two bumps on the frontside and backside.
`-stack_via_marker_layer` *`markerLayerName`*	Specifies the mark layer name. If cut layers of stack via cell are different, you can use `[-stack_via_marker_layer {`*`markLayerName1 markLayerName2`*`}]` to define different mark layers *Data_type*: string, optional
`-stack_via_name` *`stackViaName`*	Specifies the stack via cell name. The tool automatically adds the specified via cell stacking to the top layer of long TSV. You can add TSV stack vias on both the front-side and back-side layers using `-stack_via_name {`*`stackViaName1 stackViaName2`*`}` *Data_type*: string, optional
`-stack_via_top_layer` *`layer`*	
	Defines the top layer that the TSV structure should connect to. For example, if you specify M5 for this parameter, Innovus will create a structure like `TSV+VIA12+M2+VIA23+M3+…..+M5`. This parameter must be used with `-tsv_feedthru`. *Data_type*: string, optional
`-stack_via_under_bump` *`stackViaName`*	

	Specifies the stack via name under the front bump. *Data_type*: string, optional The tool automatically adds the specified via cell stacking to the bottom layer of front-side bump.
`-stack_via_array {x y}`	Specifies the number of columns and rows for the stack via array. The `-stack_via_array` and `-stack_via_pitch` options can only be specified when `-stack_via_name` is specified. `-stack_via_array` and `-stack_via_pitch` are specified at the same time. The value of `-stack_via_pitch` should be larger than stack via size. Otherwise, the stack via will overlap each other and cause DRC. You can also define different arrays when you add TSV stack via on both the frontside and backside layers with `-stack_via_array {{x1 y1} {x2 y2}}`. If there are two stack vias and only one needs to be defined, you can use `-stack_via_array {{x1 y1} {1 1}}`.
`-stack_via_pitch {x y}`	Specifies the pitch_x and pitch_y of the stack via. The `-stack_via_array` and `-stack_via_pitch` options can only be specified when `-stack_via_name` is specified. `-stack_via_array` and `-stack_via_pitch` are specified at the same time. The value of `-stack_via_pitch` should be larger than stack via size. Otherwise, the stack via will overlap each other and cause DRC. You can also define different pitches when you add TSV stack via on both the frontside and backside layers with `-stack_via_pitch {{x1 y1} {x2 y2}}`

`-stagger`	Staggers (offsets) the TSV/bump array.
	Data_type: bool, optional
	For example:
	without `-stagger` with `-stagger`
	`*****` `*****`
	`*****` `****`
	`*****` `*****`
	`*****` `****`
	`*****` `*****`

`-stripe_net` *pgnetName*	
	Declares that the TSV will be added beneath the power stripe, a stack via will be generated to touch the power stripe, and the new added TSV will be assigned by the power or ground net of the power stripe. *Data_type*: **Note:** This options should be used along with the `-stripe_layer` option. *Data_type*: string, optional
`-stripe_layer` *layerNum*	
	Specifies the layer number or layer name for the stripe net when adding TSV under stripe net. *Data_type*: string, optional **Note:** This option should be used along with `-stripe_net` option.
`-spacing` s	Specifies the placement blockage size. Blockage size = TSV cut size + 2*s. If this option is not specified, "s" will be with the value defined in LAYER TSV session in LEF file. *Data_type*: float, optional
`-upper_right_location x y`	

	Specifies (in microns) the upper right coordinate of the box in which TSV/Bumps will be created. *Data_type*: point, optional

⚠ At least one option of the following arguments is required for the `add_tsv` command:

- `tsv_via_name`
- `front_bump`
- `back_bump`

Examples

- The following command creates a 10 x 10 TSV array with a pitch of 40 microns and the lower left at (300 300):
  ```
  add_tsv -lower_left_location 300 300 -num_x_y 10 10 -pitch_x_y 40 40 -tsv_via_name TSVVIA
  ```
- The following command creates a backside array in box (300 300 700 700) with a pitch of 40 microns:
  ```
  add_tsv -lower_left_location 300 300 -upper_right_location 700 700 -pitch_x_y 40 40 -
  back_bump BUMPCELL
  ```

Related Information

- `assign_tsv`

assign_tsv

```
assign_tsv
[-help]
[-write_down_level_bump]
[-selected_to_net netName | [[-signal | -pg_pad] [-feedthru | -non_feedthru] [-net netlist | -exclude_nets excludeNetList] [-regions {x1 y1 x2 y2 ...] [-exclude_region x1 y1 x2 y2 ...] [-tsv_via_name tsvViaCellName] [-interposer ] ] ]
[{[-back_bump] [-front_bump]} [-force_current_die ]]
```

Assigns nets to TSVs and/or frontside and backside bumps, and/or feedthrus. The command considers all dies in the 3D IC System by using the die abstract files, and optimizes bump assignment for the global nets which connect these dies. If you run the `read_die_abstract` command to import die abstract files of other chips inside the 3D IC System before running the `assign_tsv` command, `assign_tsv` will optimize TSV/bump assignment by considering the whole system.

Note: Use this command after the TSVs and bumps are created and the instances connected with the IO pins are placed.

Parameters

`-help`	Print out the command usage.
`-back_bump`	Declares that the back side bumps and the TSVs will be assigned automatically. *Data_type*: bool, optional
`-force_current_die`	Assigns all IO pins to backside bumps or frontside bump directly without checking the XML file and the top level netlist. You can use `-force_current_die` only if `-back_bump` or `-front_bump` is specified. *Data_type*: bool, optional
`-front_bump`	Declares that the front side bumps will be assigned with the IO pins automatically. *Data_type*: bool, optional
`-tsv_via_name tsvViaCellName`	
	If this option is specified, only the TSV with the VIA cell `tsvViaCellName` will be assigned. Others will be ignored. *Data_type*: string, optional

`-selected_to_net` *netName*	
	Assigns the selected TSVs and bumps with a specified net. *Data_type*: string, optional **Note:** If the selected TSV belongs to a feedthru, the whole feedthru will be assigned with the net. This option is used for manual assignment and is exclusive to any other options for auto assignment.
`-signal`	Declares that only signal will be assigned. *Data_type*: bool, optional
`-pg_pad`	Declares that only power/ground net will be assigned. *Data_type*: bool, optional
`-feedthru`	Declares that the command assigns only the feedthru net. *Data_type*: bool, optional
`-non_feedthru`	Declares that the command assigns only the nonfeedthru signal or power/ground net. *Data_type*: bool, optional
`-nets` *netlist*	Assigns the specified nets to the near TSV/bumps. *Data_type*: string, optional
`-exclude_nets` *excludenetlist*	
	Excludes the nets in the specified boxes. *Data_type*: string, optional
`-regions {`*x1 y1 x2 y2 ...*`}`	
	Assigns the TSV/bump within the box only. *Data_type*: double, optional
`-exclude_regions {`*x1 y1 x2 y2 ...*`}`	
	Excludes the TSV/bumps in the specified boxes. *Data_type*: double, optional
`-interposer`	Declares that the assignment is done in silicon interposer without any instance. *Data_type*: bool, optional

`-write_down_level_bump`	Writes down the level bump file for each hierarchical instance. *Data_type*: bool, optional

Notes:

- If neither `-signal` nor `-pg_pad` is specified, both signal and pgpad will be assigned.
- If neither `-feedthru` nor `-non_feedthru` is specified, both feedthru and non-feedthru net will be assigned.
- If neither `-front_bump` nor `-back_bump` is selected, none of the bumps will be assigned. However, the TSV will still be assigned.

Examples

- The following command assigns the signal IO pins to the frontside bump:
  ```
  assign_tsv -front_bump -signal
  ```
- The following command assigns the selected TSV with net VDD:
  ```
  addTSV -selected_to_net VDD
  ```

Related Information

check_stacked_die

```
check_stacked_die
[-help]
[-check_type type_name]
[-chip_names {chip1 chip2 ...}]
```

Checks die edge violation between adjacent dies. Once you define an OBS layer inside a macro, the adjacent die edge should not overlap this OBS area. If there is any violation between macro OBS and adjacent die edge, it will be marked in the GUI window.

This command must be used after `read_die_abstract` to input adjacent die's die abstract file.

Parameters

`-help`	Prints a brief description of the `check_stacked_die` command usage. For a detailed description of the command, use the `man` command: `man check_stacked_die`
`-check_type type_name`	Specifies the check constrain types. Currently, only the `die_edge` and `bump_keepout` zone checking are supported. *Data_type*: string, optional
`-chip_names {chip1 chip2 ...}`	Specifies the name of the adjacent chip whose edge is to be checked for violation. In a 3D-IC design, there could be more than one top die (in interposer design), so you can specify the chip that needs to be checked. Using this parameter, you can check one or more chips at the same time. *Data_type*: string, optional

Examples

- The following command checks die edge violation between the macro's keep-out area and adjacent die `mother_die`:

  ```
  check_stacked_die -chip_names {mother_die}
  ```

Related Information

- `read_die_abstract`

create_stress_rule

```
create_stress_rule
[-help]
{ {-layer layerName -spacing_table spacing_table [-chip_name chipName]} | [-reset ] }
```

Defines a spacing table for spacing rules. Since the spacing rule varies with the location of the keep out zone in the chip, user can define different spacing tables for different spacing rule. These spacing tables are used by the tool to identify different scenarios and select the correct spacing constraint for a scenario.

Parameters

`-help`	Prints a brief description of the `create_stress_rule` command usage. For a detailed description of the command, use the `man` command: `man create_stress_rule`
`-chip_name` *`chipName`*	Specifies the name of the chip for which the spacing table is used for checking violation. If this option is not specified, the tool applies the spacing rule for all the chips above, below, and current based on the masterslice layer definition in the LEF file *Data_type*: string, optional
`-layer` *`layerName`*	Specifies the name of the stress layer for which the spacing table is used for checking violation. *Data_type*: string, optional
`-reset`	Resets all stress rules. *Data_type*: bool, optional
`-spacing_table` *`spacing_table`*	Specifies the spacing table definition, {x1 y1} {x2 y2}. *Data_type*: string, optional

delete_tsv

```
delete_tsv
{-all | -selected| -unassigned}
```

Deletes the specified TSVs. If the TSV belongs to a feedthru, the entire feedthru will also be deleted.

Parameters

`-all`	Deletes all the TSVs. *Data_type*: bool, required
`-selected`	Deletes the selected TSVs. *Data_type*: bool, required
`-unassigned`	Deletes the unassigned TSVs. *Data_type*: bool, required

Examples

- The following command deletes all the TSVs:
  ```
  delete_tsv -all
  ```

Related Information

- `add_tsv`
- `assign_tsv`
- `unassign_tsv`

read_bump_locations

```
read_bump_locations
-in_file fileName
[-allow_overlap_control {keep_all keep_existing_bumps keep_new_bumps}]
[-die_box]
[-force_current_die]
[-ignore_route_blockages]
[{-back_bump_cell bumpCellName | -bump_cell_from_bump_file } [-rotate_bump  -
prefix prefixName]]
[{-front_bump_cell bumpCellName | -bump_cell_from_bump_file } [-rotate_bump  -prefix prefixName]
[-stack_via_under_bump stackViaName]]
[-prefix prefixName | -bump_name_from_bump_file ]
[-check_alignment ] [
-non_feedthru ]
[-feedthru ]
[-tsv_master viaCellName
  [-feedthru_size {x y}]
  [-offset {x y}]]
```

The command creates or assigns objects on the current die according to the bumps on the adjacent die. In a TSV design, the micro bumps on the adjacent die should be aligned, and the aligned micro bumps should be with the same signal. Specify this command to sync-up the micro bump between dies. Firstly, the command tries to find the front side bump/back side bump/TSV at the location aligned to the bump on the adjacent dies. If all the specified bumps/TSVs are found on the current die, the command will assign the found bump/TSV with the same signal as the bump on the adjacent die; if none of the specified bumps/TSV are found, the command will create the specified bump/TSV with the same signal at the aligned position.

This command supports the combo bump and embedded bump flows.

Use this command after reading the stacked die config file (XML), by using `read_tsv_config`, as the die configuration is required for the bump alignment.

The command also checks for dummy bump overlaps by default. It checks overlaps between:

- Dummy bumps by checking the OBS overlap.
- Dummy bump and bump by checking the OBS and bump pin overlap.

In case there is dummy bump overlaps, the tool gives a warning message.

Note: A combo bump is a group of bumps that are treated as one bump, which means all bumps in the same combo bump will be created, assigned, unassigned, and manipulated at the same time. This command synchronizes the combo bump information between adjacent chips automatically. All bumps belonging to the same combo bump will be treated as one unit. Embedded bump is the bump at the block-level, and the information of these bumps can be exchanged between chips at the top-level.

Parameters

`-allow_overlap_control {keep_all keep_existing_bumps keep_new_bumps}`	Specifies the overlap control type. The allowed values for the `-allow_overlap_control` parameter are: • `keep_all`: Keeps all overlapping bumps. • `keep_existing_bumps`: Keeps the existing bumps before calling `read_bump_locations` if there is an overlap. If this option is specified, `read_bump_locations` keeps creating a bump if there is an overlap and continues creating the remaining bumps. A warning message is displayed when bump creation is skipped to avoid overlap. • `keep_new_bumps`: Removes the existing bumps before calling `read_bump_locations`, places the newly created bump if there is overlap, and then continues creating the remaining bumps. A warning message is displayed when deleting the existing bumps to avoid overlap. If the status of the existing bumps to be deleted is covered or fixed, a warning is displayed and the new bumps overlapping with the covered or fixed old bump are not kept.
`-back_bump_cell` *`bumpCellName`*	Creates or assigns the backside bumps at the location aligned with the bumps on the adjacent die. *Data_type*: string, optional
`-bump_cell_from_bump_file`	Creates bumps with the same bump cell defined in the bump file. *Data_type*: bool, optional
`-bump_name_from_bump_file`	Creates bumps with the same bump name defined in bump file. *Data_type*: bool, optional
`-check_alignment`	Use this parameter to check the alignment between current die and the adjacent dies. It also checks the overlap between the OBS layer and bumps (both front and back bumps). When this parameter is specified, all other parameters are ineffective. *Data_type*: bool, optional
`-die_box`	Draws the die bounding box based on the DieBox value in the bump file. *Data_type*: bool, optional
`-feedthru`	Creates or assigns the bump with feedthru net only. If `-feedthru_size` and `-tsv_master` are specified, the TSV and the stacked via of the feedthru will also be created. *Data_type*: bool, optional

`-feedthru_size` *sizex sizey*	
	Specifies the size for feedthru. This option is exclusive with the `-non_feedthru` option. *Data_type*: point, optional
`-force_current_die`	Specifies to consider the bump file as the current die bump file. Skip to check if the specified bump file is for current die or adjacent die or a block.
`-front_bump_cell` *bumpCellName*	
	Creates or assigns the frontside bumps at the location aligned with the bumps on the adjacent die. *Data_type*: string, optional
`-ignore_route_blockages`	Allows creation of bumps on route blockages. When this option is specified, the tool ignores checking route blockages when creating bumps. *Data_type*: bool, optional
`-in_file` *fileName*	Specifies the name of the bump location file of the adjacent die. *Data_type*: string, required
`-non_feedthru`	Creates or assigns the bump with normal net only. *Data_type*: bool, optional
`-offset x y`	Specifies the offset from the TSV to the corresponding bump. *Data_type*: point, optional **Note:** You can also specify the offset in the bump file by appending `-offset x y` to the line. The offset in the bump file has higher priority than the offset specified in the command line. If `-offset` is specified at both command line and bump file, the program will follow the offset specified in the bump file.
`-prefix` *prefixName*	Adds a prefix name for bump during bump creation and bump mapping. *Data_type*: string, optional The default name of bumps are `frontBump_*` or `backBump_*` with serial numbers. If `-prefix` *prefixName* is applied, created bump names are `prefixName_frontBump_*` or `prefixName_backBump_*`.

`-rotate_bump`	Rotates bumps during bump mapping according to the chip and bump orientation information of the adjacent die. *Data_type*: bool, optional
`-stack_via_under_bump` *stackViaName*	Specifies the stack via name under the front bump. The tool automatically adds the specified via cell stacking to the bottom layer of front-side bump. *Data_type*: string, optional
`-tsv_master` *viaCellName*	Creates or assigns the TSV at the location aligned (or with offset if `-offset` is specified) to the bumps on the adjacent die. *Data_type*: string, optional

Note: If neither `-feedthru` nor `-non_feedthru` is specified, the bump/TSV with both feedthru net and non-feedthru net will be created and assigned.

Examples

- The following command reads a bump file and creates the corresponding frontside bump on current die:

  ```
  read_bump_locations bumpfile -front_bump_cell front_bump_cell
  ```

- The following command reads a bump file and creates the corresponding backside bump and TSV current die:

  ```
  read_bump_locations bumpfile -back_bump_cell back_bump_cell -tsv_master tsv_via
  ```

Related Information

- `write_bump_locations`
- `read_tsv_config`

read_codesign_die_abstract

```
read_codesign_die_abstract
[-help]
file_name
[-check_only]
[-no_different_views]
```

Reads the die abstract directly to update Innovus. The command provides flexibility in terms of what is read and the elimination of the I/O Update file and TCL code.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `read_codesign_die_abstract` parameter. For a detailed description of the command and all of its parameters, use the man command: `man read_codesign_die_abstract`
`file_name`	Specifies the name of the die abstract file.
`-check_only`	This is only valid with the `-no_different_views` option. If these two options are given, then the difference viewer will not be used, and the Innovus db will not be updated.
`-no_different_views`	When the `-no_different_views` option is used, the difference viewer will not be utilized. The die abstract will be read and the Innovus db will be updated with all the changes unless the `-check_only` option is provided.

Related Information

- `write_codesign_die_abstract`

read_die_abstract

```
read_die_abstract
DIEABSTRACTFILE
```

Reads the die abstract of the adjacent die. With this command, the abstract of the adjacent die is imported and displayed overlapped with the current design.

This command supports the embedded bump flow for hierarchical designs.

The `read_die_abstract` command is used after reading the stacked die config file (XML) by using `read_tsv_config` because the die configuration is required for die alignment. You can turn off the import adjacent die objects by changing the visibility of abs* layers in the *Custom* tab of the *Color Preferences* form.

Parameters

DIEABSTRACTFILE	Specifies the name of the die abstract file. *Data_type*: string, required

Examples

- The following command reads a die abstract file `die1.abs`:

  ```
  read_die_abstract die1.abs
  ```

Related Information

- `read_tsv_config`
- `write_die_abstract`
- The *Color Preferences* section of the The Main Window chapter in *Innovus Stylus Common UI Menu Reference*.

read_tsv_config

```
read_tsv_config
{[-stacked_die_file filename] [-power_file filename]}
[-chip_name chipName]
[-top_netlist topLevelNetlist ]
```

Imports 3D IC configuration files of the whole design, including the stack die configuration file, power net configuration file and top-level netlist.

Parameters

-stacked_die_file filename	
	Reads the stack die configuration file. *Data_type*: string, optional
-power_file *filename*	Imports the power net configuration file. *Data_type*: string, optional
-chip_name *name*	Specifies the hierarchical instance name (chip) name of the current design in the top-level netlist. *Data_type*: string, optional
-top_netlist *topLevelNetlist*	Imports the top level netlist to support 3D IC design in OA mode. *Data_type*: string, optional

Examples

- The following command reads the stacked die configuration file and power configuration file and specifies that the current design is named `mem_1`:

  ```
  read_tsv_config -stacked_die_file stacked_die.xml -power_file power.side -chip_name mem_1
  ```

- Below is the example of a stack die configuration file:

```
<StackChip>
  <TopDesign name="top" />
  <Tier number=1>
    <Chip name="i_asic_entity" orientation="R0" faceUp="Yes" llx=0 lly=0 sizeX=6000.0
sizeY=6000.0 scaleFactor=1 />
  </Tier>
  <Tier number=2>
```

```
    <Chip name="i_ramextra" orientation="R0" faceUp="Yes" llx=1500.0 lly=1250.0 sizeX=3500.0
sizeY=3000.0 scaleFactor=1 />
  </Tier>
</StackChip>
```

- Below is the example of a power net configuration file:

```
VDD i_asic_entity   sharable

VDD i_ramextra       backside

VSS i_asic_entity   sharable

VSS i_ramextra      backside

Alias:

i_asic_entity/VDD i_ramextra/VDD

i_asic_entity/VSS i_ramextra/VSS
```

unassign_tsv

```
unassign_tsv
{-net_name netname| -all |-signal | -power | -ground | -selected}
```

Unassigns the specified TSV. This command is used for manual operating on TSV or iteration between TSV assignment and instance placement.

Parameters

`-net_name` *netname*	Unassigns the specified net from TSVs. *Data_type*: string, required
`-all`	Unassigns all the TSVs. *Data_type*: bool, required
`-signal`	Unassigns the signal net from TSVs. *Data_type*: bool, required
`-power`	Unassigns the power net from TSVs. *Data_type*: bool, required
`-ground`	Unassigns the ground net from TSVs. *Data_type*: bool, required
`-selected`	Unassigns selected TSVs. *Data_type*: bool, required

Examples

- The following command reads unassign all the TSVs with power net:
  ```
  unassign_tsv -power
  ```

Related Information

- `add_tsv`
- `assign_tsv`
- Design Methodology for 3D IC with Through Silicon Via chapter in *Innovus Stylus Common UI User Guide*.

write_bump_locations

```
write_bump_locations
out_file
[-selected]
```

Writes the bump information to a file. It also writes the bump keep-out area information to the bump file. Specify this command after the bumps are created and/or assigned.

This command supports the combo bump and embedded bump flows.

Parameters

out_file	Specifies the file name. *Data_type*: string, required
-selected	Specifies to output information related to selected bumps to the bump file. Select the required bumps in the GUI or on the command line, and specify this parameter to output the bump information. You can use this parameter when you want to output bump information that is related to a specific block in hierarchical designs. *Data_type*: bool, optional

Examples

- The following command create a bump information file `die1.bump`:

  ```
  write_bump_locations die1.bump
  ```

- The below example shows a sample a bump information file:

  ```
  === die1.bump ===

        ChipName: ramextra

        DieBox: 0.000000 0.000000 3500.000000 2999.910000

        OBS: BumpKOZ -poly 906.030 1047.445 906.030 100.000 100.000 100.000 100.000 1047.445
  -spacing 0.000 -backSide

        OBS: BumpKOZ -poly 906.030 1952.465 906.030 2899.910 100.000 2899.910 100.000
  1952.465 -spacing 0.000 -backSide

        OBS: BumpKOZ -poly 2593.970 1047.445 2593.970 100.000 3400.000 100.000 3400.000
  1047.445 -spacing 0.000 -backSide

[-seal_ring_east distance_in_microns]
[-seal_ring_north distance_in_microns]
[-seal_ring_south distance_in_microns]
[-seal_ring_west distance_in_microns]
[-version {4.0}]
```

Writes the abstract of current die to a file. It also writes the OBS for die edge checking to the die abstract file. Specify this command after the initial floorplan is loaded. The file will be imported by the adjacent die and therefore the current design will be honored by the adjacent die. The write_codesign_die_abstract

command is similar to the writeDieAbstract except that the write_codesign_die_abstract command provides options for filtering portions of the abstract which may not be required for some flows. It also provides the option to write out a third-party die abstract for ICs that do not have TSVs.

This command supports the embedded bump flow for hierarchical designs.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_codesign_die_abstract` parameter. For a detailed description of the command and all of its parameters, use the man command: `man write_codesign_die_abstract`
`out_file`	Specifies the name of the die abstract file. *Data_type*: string, required
`-block_pin_layer_bottom` *`layer_name`*	Specifies the name of the legal routing layer for block macros. If specified, the layers below the mentioned layer should not be the output to the die abstract. *Data_type*: string, optional
`-block_pin_layer_top` *`layer_name`*	Specifies the name of the legal routing layer for block macros. If given, the layers above the mentioned layer should not be the output to the die abstract. *Data_type*: string, optional
`-block_pin_min_size` *`x y`*	Defines the minimum size of the pin that will be output to the die abstract. *Data_type*: float, optional
`-block_pin_name_includes` *`pin_name`*	Specifies that only pins that contain the mentioned value will be in the output. *Data_type*: string, optional
`-bump_pin_layer_bottom` *`layer_name`*	Specifies the legal routing layers name for bump macros. If given, the layers below the specified layer are not to be output to the die abstract. *Data_type*: string, optional

`-bump_pin_layer_top` *layer_name*	Specifies the legal routing layer name; used for bump macros. If given, the layers above the specified layer are not to be output to the die abstract. *Data_type*: string, optional
`-constraints` *file_name*	Specifies the name of the file that lists the constraints. This file will be read and the constraints will be applied to the design. *Data_type*: string, optional
`-die_shrink_by` *num*	Specifies the percentage by which the die should be shrunk. A typical shrink value is 10 (for a 10% optical shrink). Default: `0` The default value, `0`, indicates no shrink. *Data_type*: float, optional
`-die_thickness` *num*	Specifies the die thickness. Default: `0` *Data_type*: float, optional
`-include_macro_obstruction`	Specifies to give LEF macro OBS shapes in the output to the die abstract. By default, OBS obstructions are not included. *Data_type*: bool, optional
`-io_macros` *macro_names*	Identifies the I/O macros that are to be written to the die abstract. If a macro is not specified, co-design is done at the bump level. *Data_type*: string, optional
`-io_pin_layer_bottom` *layer_name*	Specifies the legal routing layer name; used for I/O macros. If given, the layers below is not to be output to the die abstract. *Data_type*: string, optional
`-io_pin_layer_top` *layer_name*	Specifies the legal routing layers' name; used for I/O macros. If given, the layers above is not to be output to the die abstract. *Data_type*: string, optional

`-io_pin_min_size` *pin_size*	This parameter defines the minimum size of pin that will be output to the die abstract. The pin's x and y dimensions must be at least this value. *Data_type*: float, optional
`-io_pin_name_includes` *pin_name*	This string indicates that only pins that contain the string value will be output. *Data_type*: string, optional
`-layer_detail`	when given, indicates that the layer_details is to be output to the die. *Data_type*: bool, optional
`-macro_obstruction_layer_bottom` *layer_name*	If specified, identifies the bottom layer for which OBS shapes are exported to the die abstract. The default value for this option is the top metal layer. *Data_type*: string, optional
`-macro_obstruction_layer_top` *layer_name*	If specified, identifies the top layer for which OBS shapes are exported to the die abstract. *Data_type*: string, optional
`-no_block_macros`	Indicates that block macros should not be the output to the die abstract. *Data_type*: bool, optional
`-no_blockages`	Indicates that blockages should not be the output to the die abstract. *Data_type*: bool, optional
`-no_rdl_routing`	Indicates that the rdl routing should not be the output to the die abstract. *Data_type*: bool, optional
`-power_routing`	Indicates that the power routing should not be the output to the die abstract. *Data_type*: bool, optional

`-power_routing_layer_bottom` *layer_name*	Specifies the names of the legal routing layers for power routing. If given, the layers below are not to be output to the die abstract. *Data_type*: string, optional
`-power_routing_layer_top` *layer_name*	Specifies the names of legal routing layers for power routing. If given, the layers above are not output to the die abstract. *Data_type*: string, optional
`-rdl_routing_layer_bottom` *layer_name*	Specifies the names of legal routing layers for rdl routing. If given, the layers below are not to be output to the die abstract. *Data_type*: string, optional
`-rdl_routing_layer_top` *layer_name*	Specifies the names of legal routing layers for rdl routing. If given, the layers above are not to be output to the die abstract. *Data_type*: string, optional
`-scribe_all` *distance_in_microns*	Specifies the distance in microns from the die boundary to the edge of the silicon after being cut from the wafer from all sides. *Data_type*: float, optional
`-scribe_east` *distance_in_microns*	Specifies the distance in microns from the die boundary to the edge of the silicon after being cut from the wafer from the East side. *Data_type*: float, optional
`-scribe_north` *distance_in_microns*	Specifies the distance in microns from the die boundary to the edge of the silicon after being cut from the wafer from the North side. *Data_type*: float, optional
`-scribe_south` *distance_in_microns*	Specifies the distance in microns from the die boundary to the edge of the silicon after being cut from the wafer from the South side. *Data_type*: float, optional
`-scribe_west` *distance_in_microns*	Specifies the distance in microns from the die boundary to the edge of the silicon after being cut from the wafer from the West side. *Data_type*: float, optional

`-seal_ring_all` *distance_in_microns*	Species the distance of the seal ring from the die boundary on all sides. Seal ring is a border around the die boundary that is put in pre-shrink. *Data_type*: float, optional
`-seal_ring_east` *distance_in_microns*	Species the distance of the seal ring from the die boundary from the East side. *Data_type*: float, optional
`-seal_ring_north` *distance_in_microns*	Species the distance of the seal ring from the die boundary from the North side. *Data_type*: float, optional
`-seal_ring_south` *distance_in_microns*	Species the distance of the seal ring from the die boundary from the South side. *Data_type*: float, optional
`-seal_ring_west` *distance_in_microns*	Species the distance of the seal ring from the die boundary from the West side. *Data_type*: float, optional
`-version {4.0}`	Specifies the version number of die abstract. *Data_type*: enum, optional

Related Information

- `read_codesign_die_abstract`

write_die_abstract

```
write_die_abstract
out_file
[-no_filter]
```

Writes the abstract of current die to a file. It also writes the OBS for die edge checking to the die abstract file. Specify this command after the initial floorplan is loaded. The file will be imported by the adjacent die and therefore the current design will be honored by the adjacent die.

This command supports the embedded bump flow for hierarchical designs.

Note: By default, the proposed behavior for `write_die_abstract` is:

- For MACRO pin geometries, output ports on top metal layer in all MACROS of all classes.
- For routing, output routing for all top level Verilog ports, and for power and ground, output only those wires with a SHAPE of IOWIRE.

Parameters

out_file	Specifies the file name. *Data_type*: string, required
-no_filter	Turn off to filter the die abstract contents. *Data_type*: bool, optional

Examples

- The following command creates a die abstract file `die1.abs`:

  ```
  write_die_abstract die1.abs
  ```

Related Information

- `read_die_abstract`
- Design Methodology for 3D IC with Through Silicon Via chapter in *Innovus Stylus Common UI User Guide*.

write_micro_bump_mapping_file

```
write_micro_bump_mapping_file
[-help]
bump_map_file
[-merge_with {filename1, filename2,...}]
```

Writes the micro bump mapping file for Quantus and Voltus use. Use this command after the aligned bump pair is created by `read_bump_locations` command. This command supports the embedded bump flow for hierarchical designs.

Parameters

`-help`	Prints a brief description of the `write_micro_bump_mapping_file` command usage. For a detailed description of the command, use the `man` command: `man write_micro_bump_mapping_file`
bump_map_file	Specifies the file name. *Data_type*: string, required
`-merge_with {filename1, filename2,...}`	
	If there are more than two dies in the design, this command may be called more than one time. This option should be specified at the last time to merge the previously generated files. *Data_type*: string, optional

Examples

- The following command creates a bump mapping file:
  `write_micro_bump_mapping_file bump.map`

  Here is an example of a bump mapping file, `bump.map`:

```

```

Related Information

- read_bump_locations

write_spef_between_tsv_dies

```
write_spef_between_tsv_dies
out_file
```

Creates a top-level spef that describes the connectivity between dies. The RC is `0` in this SPEF file, but only inter-die connectivity is written. This spef file, together with the spef for each die, is the input of Tempus for static timing analysis.

This command is used after reading the stacked die config file (XML) using `read_tsv_config` as the die configuration is required to detect the connectivity between dies.

Parameters

out_file	Specifies the file name. *Data_type*: string, optional

Examples

- The following command creates a `0` load top-level spef file:

  ```
  write_spef_between_tsv_dies top.spef
  ```

Related Information

- `read_tsv_config`

write_design_stack_config

```
write_design_stack_config
[-help]
{[-xml StackedDieFileName] [-power_config_file PowerConnectionFile]}
```

Saves the xml file and power config file in the specified path.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_design_stack_config` parameter. For a detailed description of the command and all of its parameters, use the man command: `man write_design_stack_config`
`-power_config_file` *`PowerConnectionFile`*	Specifies the file name of the power connection.
`-xml` *`StackedDieFileName`*	Specifies the file name of the stacked die.

Related Information

- `read_design_stack_config`

read_design_stack_config

```
read_design_stack_config
[-help]
[-avoid_floorplan_change]
[-chip_name NameOfChip]
[-manufacturing_grid grid]
[-power_config_file PowerConnectionFile]
[-top_netlist VerilogFileName]
[-xml StackedDieFileName]
```

Loads the die stacking config file (*.xml) for Innovus to understand the 3D-IC top-level structure.

You can use this command before or after the `init_design` command. When you use `read_design_stack_config` before `init_design`, in addition to loading the die stacking information into the memory, it patches up the virtual techLEF of the 3DIC top cell and the Verilog netlist if the `init_lef_file` attribute is not set before `init_design`. If you use `read_design_stack_config` after `init_design`, when the top design (Netlist, tech LEF) has already been loaded into Innovus, but without XML. Without the XML, Innovus does not know that the top cell is the top of a 3DIC design. Therefore, XML is required to let Innovus know the vertical position and face up/down information of the dies for the GUI display and the contact layer mapping relationship.

When the top-level netlist is missing, `read_design_stack_config` can help generate a virtual netlist, but the pins are floating so that you can still load the 3D-IC design into Innovus with iHDB. Only top is in the virtual netlist. `read_design_stack_config` internally calls addInst to add other dies.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `read_design_stack_config` parameter. For a detailed description of the command and all of its parameters, use the man command: `man rread_design_stack_config`
`-avoid_floorplan_change`	When you specify this option, the floorplan and die instances will not be created.
`-chip_name` *`NameOfChip`*	Specifies the name to be used when the current die is instantiated.
`-manufacturing_grid` *`grid`*	Specifies the manufacturing grid.
`-power_config_file` *`PowerConnectionFile`*	Specifies the file name of the power connection.
`-top_netlist` *`VerilogFileName`*	Specifies the file name of the top-level netlist verilog.
`-xml` *`StackedDieFileName`*	Specifies the file name of the stacked die.

44

Unix Commands

- flowtool
- innovus
- lef2oa
- nagelfar
- oa2lef

flowtool

```
  flowtool
[-db "type location [name] [view]"]
[-dir run_dir]
[-display {all | trunk}]
[-dist path_to_script]
[-enabled list_of_features]
[-files list_of_files]
[-from flow_or_flow_step]
[-inject_tcl tcl_code]
[-isolate]
[-jobs integer]
[-predict {summary | verbose | tcl | script}]
[-ref_run path_to_refernce_run]
[-reset]
[-run_tag name_of_run]
[-status]
[-to flow_or_flow_step]
```

Provides a way to run flows from the command line. In addition to providing another interface to existing Flowkit functionality, it enables multi-session, multi-tool and branching flows.

Note: TCL 8.5 or higher is required to run flowtool.

Parameters

`-db "type location [name] [view]"`	Specifies the database to be used to start the run. Flowtool distinguishes between the multiple DB types (such as OA and script) and tools (such as Innovus, Tempus, and Genus). This information is stored in four ways to determine how the DB will be read. The four values of the `-db` parameter specify those four ways of reading the DB. The `type` value refers to the supported DB types, which are mentioned below:
	• **TCL**
	Expanded form:
	`{tcl path_to_file null null}`
	Simplified form:
	`{file_that_ends_with.tcl}`
	• **ENC**
	Expanded form:
	`{enc path_to_enc.dat_dir null null}`
	Simplified form:
	`{path_to_dir_that_ends_with.dat}`
	• **RC**
	Expanded form:
	`{rc path_to_genus_db null null}`
	Simplified form:
	`{file_that_ends_with.db}`
	• **OA**
	Expanded form:
	`{oa path_to_cds.lib_location design view}`
	Simplified form:
	`{NONE}` since all four fields are required.

`-dir run_dir`	Changes to the named directory before doing anything else (including looking for starting scripts).
`-display {all | trunk}`	Filters the output to various types of flows.
`-dist path_to_script`	Specifies the distribution script and arguments to be pretended to the command line when executing tools. Type: `string`
`-enabled list_of_features`	Enables the specified features. Type: `string`
-files *list_of_files*	Specifies one or more files that describe the flow and flow steps. These files can be in the TCL or YAML syntax. When this parameter is used, `flowtool` searches for the default directory and master flow file name used for each flow type. *Default:* • `./scripts/run_flow.tcl`, when the TCL-based flow scripts are used. • `./scripts/flow.yaml`, when the YAML-based flow scripts are used.
`-from flow_or_flow_step`	Specifies the `flow` or `flow_step` name (inclusive) to start running the flow accepting a full dotted, comma-separated, and case-insensitive canonical path to a flow step object. Type: `string`
`-inject_tcl tcl_code`	Injects the specified TCL into every step. Type: `string`
`-isolate`	Runs each step in its own tool session.
`-jobs integer`	Specifies the maximum number of tasks to run in parallel. If this parameter is not specified, there is no limit to the number of flows, which can run simultaneously.
`-predict {summary | verbose | tcl | script}`	Specifies the prediction of the flow that will run (before executing the flow).

`-ref_run` *`path_to_refernce_run`*	If `-from` is specified, the `-ref_run` option points to a working directory/database of a previous run. Type: `string`
`-reset`	While trying to run a completed flow, this parameter starts it again from the beginning.
`-run_tag` *`name_of_run`*	Sets the `-dir` option to the same as the *`run_tag_value`*, if the `-dir` option is not specified. Additionally, it updates the tool startup code to include: `set_db flow_run_tag <value>` Type: `string`
`-status`	Prints the execution status (completed steps) of a run.
`-to` *`flow_or_flow_step`*	Specifies the `flow` or `flow_step` name (inclusive) to stop running the flow accepting a full dotted, comma-separated, and case-insensitive canonical path to a flow step object. Type: `string`

[-overwrite]
[-stylus]
[-version]
[-wait minutes]
```

Launches an Innovus™ Implementation System session. The `innovus` command starts one of the following products:

- Innovus Implementation System
- Innovus Implementation System Basic
- Virtuoso® Digital Implementation
- Virtuoso® Digital Implementation XL
- First Encounter® L
- First Encounter® XL

For an overview of the products and product licensing, see Product and Licensing Information chapter in the *Innovus Stylus Common UI User Guide.*

To start an Innovus session, type the `innovus` command with the appropriate parameters on the UNIX/Linux command line. If you type the command without parameters, the software starts in GUI mode and creates a log file and a command file. The system attempts to check out the license with the most functionality, then the license with the next most functionality, and so on.

Parameters

`-help`	Writes out the usage and options with brief descriptions.
`-abort_on_error`	Exits if an error is detected at any point. If any Tcl command returns `TCL_ERROR` to the top level, or any `Error (XXX): ...` message occurs, the process will exit.
`-batch`	Runs without interactive prompt. After all the options, including `-execute` and `-files`, are processed, the job exits.
`-cds_lib_file in_file`	
	Loads the specified file instead of the default `cds.lib` file in the current directory to obtain the names and locations of OpenAccess libraries. The `cds.lib` file is used to list the OpenAccess library names, and their physical locations.
`-cpus value`	Specifies the number of CPUs to be used for multi-threading on current host. This calls the appropriate Tcl command to set the local cpu count. This happens before any `-execute` or `-files` commands are processed. This may require extra multi-CPU licenses to be checked out (see `-lic_multi_cpu`).

`-db dir`	Specifies the DB directory to be read. This option calls `read_db` internally. Example: `innovus -db path/dbName.enc.dat` The specified DB directory is read before `-execute` or `-files` is invoked. **Note**: The database being restored with `-db` should not be an Integrated Hierarchical Database (iHDB). If you want to restore an iHDB database, use `-ihdb dir` instead. The `-db` and `-ihdb` options cannot be used together.
`-disable_user_startup`	Reads only the init file in the installation hierarchy. Does not read init files in the home or current directory. This option suppresses the default loading from the home and current directory, which can be used to guarantee there are no local over-rides to various project settings. See the "*Initialization Files*" section for the init files that are loaded by default.
`-execute list_of_Tcl_commands`	
	Specifies the Tcl commands to be executed at startup, as a quoted string.
`-files in_file_list`	Specifies one or more Tcl files to be sourced at startup, after `-execute` commands are processed. Set the shell envar `CDS_STYLUS_SOURCE_VERBOSE` to `0` if you don't want the `source` command output to default to verbose.
`-lic_multi_cpu lic_list`	
	Controls which licenses are to be used for higher multi-CPU usage in priority order from left to right. The allowed license names are: `invs_cpu`: Innovus CPU Accelerator Option `invs` - Innovus Implementation System `invsb` - Innovus Implementation System Basic `fel`: First Encounter® L `fexl`: First Encounter® XL For example, `-lic_multi_cpu "fel fexl"` will try to check out `fel` first, and then `fexl`. The licenses will not be checked out until a Tcl command tries to use extra cpus that require more licenses.
`-lic_options lic_list`	

	Specifies the order for dynamic checkout of extra option licenses when needed by a specific command. In some cases, more than one option license can be used to enable a given feature. You can control which options are allowed to be checked out, and in what priority (from left to right) when required during the run. The allowed license names are: `invs_hier` – Innovus Hierarchical Design Option `invs_ms` - Innovus Mixed Signal Option `invs_3d_ic` - Innovus 3D-IC Option `invs_3nm` - Innovus 3nm Option `invs_5nm` - Innovus 5nm Option `invs_7nm` - Innovus 7nm Option `invs_20nm` - Innovus 20nm Option `invs_10nm` - Innovus 10nm Option `invs_hfr` - Innovus HFR Option `invs_gigaplace` - Innovus GigaPlace XL Option `invs_gigaplace_gxl` - Innovus GigaPlace GXL Option `qrcaa` - Quantus Advanced Analysis GXL Option `enclp` - Encounter Low Power GXL Option `encan` - Encounter Advanced Node GXL Option `enccco` - Encounter Clock Concurrent Opt GXL Option `encng` - Encounter Next Generation (This license is used to enable beta features.) `vdixl_capacity` - VDI-XL Block Capacity Option `invs_pi` - Innovus Power Integrity Option `invs_ml` - Innovus Machine Learning Implementation Option `invs_ehfs` - Innovus Early Hierarchical Floorplan Synthesis Option `invs_dfm` - Innovus DFM Option `invs_sc` - Innovus Superconducting Option `invs_automotive` - Innovus Automotive Option `tpsxl` - Tempus Timing Signoff Solution XL `tpsl` - Tempus Timing Signoff Solution L `vtsxl` - Voltus IC Power Integrity Solution XL `vtsl` - Voltus IC Power Integrity Solution L `vtsxm` - Voltus IC Power Integrity Solution - XM `vtsesd` - Voltus IC Power Integrity Solution - ESD `vtsaa` - Voltus IC Power Integrity Solution Advanced Analysis GXL Option Option licenses can be checked out dynamically when a specific Tcl command requires it. This may cause the Tcl script to stall and wait for a license, or to exit if the wait period expires. For example, `-lic_options "encan encng enccco"` will only allow those three options to be checked-out dynamically, and in that priority order.
`-lic_startup` *`lic_list`*	

	Requests one of these licenses at startup in priority order from left to right. The supported licenses are: `invs` - Innovus Implementation System `invsb` - Innovus Implementation System Basic `fexl` - First Encounter® XL `vdixl` - Virtuoso® Digital Implementation XL. `vdi` - Virtuoso® Digital Implementation `fel`: First Encounter® L For example, `-lic_startup "fexl fel"` will try to check out `fexl` first, and then `fel`. The checkouts will be attempted repeatedly until one succeeds or the `-wait` period expires.
`-lic_startup_options` *`lic_list`*	

	Specifies additional option licenses needed at startup. If not provided, they will be checked out when needed during the run. The allowed license names are: `invs_hier` – Innovus Hierarchical Design Option `invs_ms` - Innovus Mixed Signal Option `invs_3d_ic` - Innovus 3D-IC Option `invs_3nm` - Innovus 3nm Option `invs_5nm` - Innovus 5nm Option `invs_7nm` - Innovus 7nm Option `invs_20nm` - Innovus 20nm Option `invs_10nm` - Innovus 10nm Option `invs_hfr` - Innovus HFR Option `invs_gigaplace` - Innovus GigaPlace XL Option `invs_gigaplace_gxl` - Innovus GigaPlace GXL Option `qrcaa` - Quantus Advanced Analysis GXL Option `enclp` - Encounter Low Power GXL Option `encan` - Encounter Advanced Node GXL Option `enccco` - Encounter Clock Concurrent Opt GXL Option `encng` - Encounter Next Generation (This license is used to enable beta features.) `vdixl_capacity` - VDI-XL Block Capacity Option `invs_pi` - Innovus Power Integrity Option `invs_ml` - Innovus Machine Learning Implementation Option `invs_ehfs` - Innovus Early Hierarchical Floorplan Synthesis Option `invs_dfm` - Innovus DFM Option `invs_sc` - Innovus Superconducting Option `invs_automotive` - Innovus Automotive Option `tpsxl` - Tempus Timing Signoff Solution XL `tpsl` - Tempus Timing Signoff Solution L `vtsxl` - Voltus IC Power Integrity Solution XL `vtsl` - Voltus IC Power Integrity Solution L `vtsxm` - Voltus IC Power Integrity Solution - XM `vtsesd` - Voltus IC Power Integrity Solution - ESD `vtsaa` - Voltus IC Power Integrity Solution Advanced Analysis GXL Option For example, `-lic_startup_options "enccco encan"` will try to check out both `enccco and encan` when Innovus starts up. The checkouts will be attempted repeatedly until it succeeds or the `-wait` period expires.
`-lic_stack {1 | 2}`	Specifies the number of licenses to stack for stackable licenses. Some startup licenses that have limited instance counts can be stacked so that multiple licenses can be checked-out to increase the instance limit. Innovus allows stacking of two `vdi` or `vdixl` licenses to increase the instance limit from 50,000 to 100,000. For example, `-lic_stack 2` combined with `-lic_startup vdi` would check out two vdi licenses to allow 100,000 instances. *Default*: `1`

`-log prefix`	Specifies the prefix for the `.log`, `.cmd`, and `.logv` files. If three arguments are given, such as `-log "a b c"`, then the three names are used exactly without any extension added. So, `-log "mylog mycmd mylogv"` will result in `mylog mycmd mylogv` files. The default for *prefix* is `innovus`. So if `-log` is not specified, `innovus.log`, `innovus.cmd`, and `innovus.logv` files will be created. If you specify `-log test`, the tool creates `test.log`, `test.cmd` and `test.logv` files. The `.log` file contains the normal logging output, the `.cmd` file contains the Tcl commands that were executed, and the `.logv` file contains a super-set of the .log output plus "verbose" debugging output that is needed only for detailed debugging. If the `.log` file already exists, an integer is added to the end of all the files to make them unique. This means if `-log test` is specified, the tool will create `test.log test.cmd test.logv` for the first run, `test.log1 test.cmd1 test.logv1` for the next run, and so on. Only the existence of .log is checked, the existence of the .cmd or .logv files is not checked. The `-overwrite` option can be used to disable this behavior and overwrite an existing .log file. If the *prefix* value has a period in it, the last extension is stripped off for the `.cmd` and `.logv` usage. For example, `-log out.log` will result in `out.log out.cmd out.logv` files, and `-log out.a.log` will result in `out.a.log out.a.cmd out.a.logv` files. However, if the last extension in the *prefix* value is `.gz`, it will be retained. For example, if you specify `-log test.gz`, the tool will create `test.log.gz`, `test.cmd.gz`, and `test.logv.gz` files. If you specify `-log "test.log.gz test.cmd test.logv.gz"`, the tool will not gzip all files but will create files exactly as specified: `test.log.gz`, `test.cmd`, and `test.logv.gz`. If `test.log` or `test.log.gz` already exists, an integer is added to make the new files unique: `test.log1.gz`, `test.cmd1`, and `test.logv1.gz`. If there is an additional extension before `.gz` , it is stripped off. You can disable any given file by using `/dev/null`. For example, `-log "my.log /dev/null /dev/null"` will only create `my.log`. *Default*: `innovus.log` **Note**: If you provide the log file name under a directory path and the directory path does not exist, Innovus will create the directory path and save the log file under the directory.
`-no_cmd`	Specifies that the `.cmd` file should not be created.
`-no_gui`	Prevents the GUI and Tk from initializing at startup so only the user type-in window, such as xterm, is visible. You can start the GUI later in the session with the command `gui_show`.
`-no_logv`	Specifies that verbose log file should not be created.
`-overwrite`	Overwrites an existing .log file (and associated `.cmd` and `.logv` files) instead of adding an integer to make the files unique.
`-ihdb dir`	Specifies that the Integrated Hierarchical Database (iHDB) directory is to be read, such as `xxx/my_design/placed`. This option calls `read_module_model` internally. Example: `innovus -ihdb iHDB_path/cell/tag` The specified iHDB directory is read before `-execute` or `-files` is invoked. The specified iHDB should already have been created with `write_module_model`. To learn more about the iHDB flow, refer to the "*Integrated Hierarchical Database*" section in the Hierarchical and Prototyping Flow chapter of the *Innovus Stylus Common UI User Guide* **Note**: If you want to restore a non-iHDB database, use the `-db dir` option instead. The `-db` and `-ihdb` options cannot be used together.
`-stylus`	Launches the Innovus Stylus Common UI interface. This changes the Tcl commands to the Stylus Common UI interface described in the Innovus Stylus Common UI Text Reference Manual and the Stylus Common UI Database Object Information manuals. See the Innovus Stylus Common UI Migration Guide for a summary of the changes.
`-version`	Returns the program version information.
`-wait minutes`	Specifies the number of minutes the system waits for a license to become available before exiting. *Default:* 0 (no wait time) *Value range:* 0 to 10,000

Initialization Files

By default, various initialization files are loaded at startup, if they exist. They can be used to configure the GUI, load utility Tcl files, or configure Innovus settings. The initialization files are read in the following sequence:

1. `~/.cadence/innovus/{gui.pref.tcl, gui.color.tcl, workspaces}` in the home directory if the GUI is enabled. These files are intended to be created by *View -> Set Preference* and *View -> All Colors -> Save* options for a specific user.

2. `.cadence/innovus/{gui.pref.tcl, gui.color.tcl, workspaces/}` in the current directory if the GUI is enabled. These files are intended to be created by *View -> Set Preference* and V*iew -> All Colors -> Save* options for any user working in this directory.
3. `<install_dir>/etc/innovus/enc.tcl` in the installation directory. This is intended for CAD teams that want to set Tcl parameters, customize the GUI, or add user-defined Tcl commands that affect all users of this release.
4. `~/enc.tcl` in the home directory. This is intended for user-specific setting that should affect only one user.
5. `./enc.tcl` in the current directory. This is intended for design-specific setting that should affect only designs in this directory.

Note: The GUI files are not loaded in the non-GUI mode.

If the `-stylus` parameter is specified, the initialization files are loaded in the following order instead:

1. `~/.cadence/innovus/{gui.pref.tcl, gui.color.tcl, workspaces}` in the home directory if the GUI is enabled
2. `.cadence/innovus/{gui.pref.tcl, gui.color.tcl, workspaces/}` in the current directory if the GUI is enabled.
3. `<install_dir>/etc/innovus/innovus.tcl` in the installation directory.
4. `~/.cadence/innovus/innovus.tcl` in the home directory.
5. `./.cadence/innovus/innovus.tcl` in the current directory.
6. `./innovus_startup.tcl` in the current directory.

Note: The `-stylus` usage sets the `source_verbose` root attribute to `true` at startup. The GUI preference init files (1 and 2 above) ignore this setting, but the non-GUI preference initialization files above (3, 4, 5, and 6) will use verbose logging by default. If the shell envar `CDS_STYLUS_SOURCE_VERBOSE` exists and has a boolean value, then the `source_verbose` attribute will be set to the envar value at startup. So you can turn off verbose logging at startup by using the following command:

```
setenv CDS_STYLUS_SOURCE_VERBOSE 0
```

Setting Up the Run-Time Environment

If *`install_dir`* is the location of your Innovus installation, you should set up your run-time environment like this:

- Add the *`install_dir`*`/bin` directory to your path. The `bin` directory has links to all the public executables in the install hierarchy.
- If you want the Innovus Stylus Common UI man pages to be available from the Unix `man` command, you can add *`install_dir`*`/share/innovus/stylus/man` to your `MANPATH` envar.
- If you want the Tcl man pages to be available from the Unix `man` command, you can add *`install_dir`*`/share/tcltools/man` to your `MANPATH` envar.

For example, you might add this to your startup shell script:

```
set install_dir = /tools/innovus16.2/lnx86

set path = ($install_dir/bin $path)

setenv MANPATH $install_dir/share/innovus/stylus/man:$install_dir/share/tcltools/man:$MANPATH
```

Note: When Innovus launches, it automatically adds either the legacy or the Innovus Stylus Common UI man pages (depending on the `-stylus` option) and the Tcl man pages to the beginning of the current `MANPATH` inside Innovus. Therefore, from within Innovus, the `man` command will see both sets of man pages before any other man pages.

Temporary File Locations

Each Innovus session creates its own temporary directory to store temporary files at the beginning of the run.

If you have the write permission, the tool creates `tmp_dir` under the current directory (.). If not, `tmp_dir` is created in `/tmp`. If the Unix envar `TMPDIR` is set, then the `tmp_dir` directory is created inside `$TMPDIR`.

The name of the `tmp_dir` directory will look like:

```
innovus_temp_[pid]_[hostname]_[user]_xxxxxx
```

Where `_xxxxxx` is a string added to make the directory unique. For example:

```
innovus_temp_10233_farm254_bob_nfp9ez
```

The temporary directory is automatically removed on exit or if the run terminated with a catchable signal (e.g. `SIGSEGV`).

```

The LEF to OpenAccess (`lef2oa`) translator can be used to convert LEF files into equivalent OpenAccess data. It supports three main styles of use:

1. Converting the technology information, such as layers, DRC rules, via rules, vias, and so on, into an OA tech file. This OA techfile is sufficient for Innovus use but is not really usable for Virtuoso because it does not contain information about custom layers below `metal1`, pcells, and so on. This techfile can be read by `techLoadDump` to create an ASCII techfile and then users can cut-and-paste the necessary information, such as DRC rules, into a Virtuoso OA PDK ASCII techfile to create a merged OA techfile.
2. Creating an incremental techfile using the `-pnrLibDataOnly` option that only has technology data that is dependent on the standard cell library, such as default routing rule (`LEFDefaultRouteSpec`), non-default rules (NDRs), sites, and so on.
3. Converting the LEF macros into OA abstract cellviews.

Innovus uses a Cadence version of the LEF to OpenAccess translator that does more than the public domain `lef2oa` executable. The main difference is that many DRC rules that are expressed as properties that begin with `LEF58_` (for example, `PROPERTY LEF58_SPACING "..." ;`) are understood and mapped directly to the correct OA foundry constraints. In general, the rules needed for 28nm nodes and older are supported, while newer rules for 20nm and smaller are not supported. If you have any unsupported LEF property rules, they can be translated using Innovus commands instead. To do so, read the LEF into Innovus and use the `write_oa_techfile` Innovus command.

Parameters

`-commentChar char`	Identifies the comment character. *Default*: `#`
`-compress`	Allows libraries to be compressed.

`-compressLevel` *zLevel*	Defines the compression level to be used. *Default*: 1
`-createFixedViaDefs`	Allows the creation of fixed via definitions.
`-dataModel` *version*	
	Specifies a data model value of 0, 1, 2, or 3, which determines the data model for the OpenAccess database and determines how option is omitted, the default data model value of 4 is used unless the OA_DATAMODEL environment variable is set or a file nam directory of your OpenAccess installation hierarchy. *Default*: `4`
`-defaultRuleName` *name*	
	Specifies the name of the constraint group (default: `LEFDefaultRouteSpec`) to generate in the technology database. If a constraint exists in a technology database being modified, the translation fails unless the `-overwrite` option is used. *Default*: `LEFDefaultRouteSpec`
`-DMAttributes` *attributeList*	
	Specifies a list of design management (DM) attributes that are associated with every library that this application creates. Attributes be no space on either side of the equal sign, two or more pairs must be space-separated, and the list must be enclosed in quotes.
`-DMSystem` *sysName*	Specifies the DM system to be used for the library, which can be any DM plug-in available to the user. The DM plug-ins included The default DM system is `oaDMSystem`, which automatically selects between `oaDMTurbo` or `oaDMFileSys`. Use of the `oaDMTurbo` plug
`-h | -help`	Displays usage information.
`-layerMap` *filelist*	Specifies a quoted, space-separated list of one or more layer mapping files to be used during translation. You must specify the co
`-layoutView` *viewName*	Specifies the view name used for FOREIGN container views. *Default:* `layout`
`-lef` *file*	Specifies the LEF file to import into the OpenAccess database.
`-lib` *library*	Specifies the name of the destination library. If the library exists, the library must contain a technology database or refer to a librar library exists, new designs are created for macro definitions. If you redefine a macro in the file, a new design is created by overwri exist, a library is created in the current working directory and will contain a technology database.
`-libDefFile` *fileList*	
	Specifies the library definitions (`lib.defs`) file to load. The path to the `lib.defs` file can be a full or relative path. If this option is on system is used to find and load the `lib.defs` file.
`-libPath` *path*	Specifies the path to the output library.
`-logFile` *file*	Specifies the log filename. If this option is omitted, the log filename defaults to `lef2oaCDS.log`.
`-lockColors`	Specifies that all shapes created from `PORT` and `PIN` definitions that have a `MASK` construct associated with them will have their lock color set.
`-mapConflicts`	Maps certain conflicts between incremental and base technologies to constraints and constraint parameter definitions.
`-noInfo` *msgIds*	Suppresses the specified INFO messages. *msgIds* is a quoted, space separated list of numbers. Each number in the list represer message you want to suppress. None of the numbers in the list may be zero. Suppressed messages do not appear on the termina
`-noWarning` *msgIds*	Suppresses the specified WARNING messages. *msgIds* is a quoted, space separated list of numbers. Each number in the list rep message you want to suppress. None of the numbers in the list may be zero. Suppressed messages do not appear on the termina total of WARNING messages displayed in the summary.
`-overwrite`	Replaces MACROS in an existing design with the translated data. If this option is omitted, the default behavior is to update the ex DBU value in an existing technology database.
`-pinLabels`	Creates pin labels in designs by using OpenAccess `oaAttrDisplay` objects on `oaTerms`. Labels are added on the `oaTerm` for each figure. See also the `-textLayer` and `-textHeight` options.

`-pnrLibDataOnly`	Maps only library-specific place and route information to an incremental tech, ignoring foundry rules. Recommended for convertin database that references a technology database that has complete foundry information. LEF constructs `DIRECTION` and `PITCH`, alo specified) are mapped to constraints in the `LEFDefaultRouteSpec` type constraint group. `VIAS` and `VIARULES` defined are added to t `NONDEFAULTRULES` are mapped to OA constraint groups, `SITES` are mapped to `oaSiteDefs`, and `MACROS` are mapped to abstract `oaDe`
`-shared`	Allows other applications to access the output library while this application is running.
`-suffix` *string*	Adds the specified suffix to the constraint group definition names.
`-techDMAttributes` *attrList*	Specifies a list of DM attributes to be associated with every technology library created.
`-techDMSystem` *sysName*	Specifies the DM system to be used for the technology library, which is either `oaDMTurbo` or `oaDMFileSys`. The default is `oaDMTurbo`
`-techLib` *library*	Specifies the name of a technology library to use when creating a new cell library. If the specified technology library does not exis information in the LEF file.
`-techLibPath` *path*	Specifies the path to be used for creating a technology library specified by the `-techLib` argument. The is only used when the libr exist.
`-techRefs` *libList*	Specifies the list of libraries that contain the master technology databases.
`-templateFile` *file*	Specifies a file containing arguments to `lef2oa`. You can specify a template file instead of entering a string of arguments on the co
`-textHeight` *value*	Specifies an integer value for the pin label text height in database units (DBU). The DBU value is set by `lef2oa` by using the DAT used, and this option is omitted, the pin label text height defaults to the DBU value in the technology database for maskLayout vie
`-textLayer` *value*	Specifies the layer used for pin label text. If `-pinLabels` is used, and this option is not specified, the pin label text layer defaults to technology database, it is added.
`-useFoundryInnovus`	Specifies that the LEF LAYER LEF58 properties constraints will be placed into the `foundry_innovus` constraint group. This optior tech files for use by the mixed signal flow. For more information on Rapid MSOA PDKs, refer to the Technology Data Preparation *Guide*.
`-view` *viewName*	Specifies the output view name. The default view name is `abstract`.
`-v`	Prints tool, format and library version information
`-version`	Prints tool and format version information

nagelfar

```
nagelfar
[<nagelfar.tcl options>]
[file1.tcl file2.tcl …]
```

Does the “lint type” checking of Innovus Tcl script files.

It finds many common Tcl errors, such as misspelled commands, using a Tcl variable before setting it.

The check-syntax command is a wrapper around the public-domain Tcl linter named nagelfar. Nagelfar automatically loads the Innovus syntax and plugin files and is therefore aware of Innovus commands and options. Nagelfar is available from http://sourceforge.net/projects/nagelfar. A recent version of nagelfar is included in the installation hierarchy at: `<install_dir>/share/nagelfar`.

Nagelfar is a wrapper around `<install_dir>/share/nagelfar/nagelfar.tcl`

The wrapper automatically loads the correct Innovus nagelfar legacy syntax file and plugin file so that Innovus commands and options are understood by nagelfar. The files are loaded from:

```
<install_dir>/share/innovus/nagelfar/innovus.syntaxdb.tcl
<install_dir>/share/innovus/nagelfar/innovus.plugin.tcl
```

If you want to check the Stylus Common UI command syntax, you need use the nagelfar files from here:

```
<install_dir>/share/commonui/nagelfar/innovus.commonui.syntaxdb.tcl
<install_dir>/share/commonui/nagelfar/innovus.commonui.plugin.tcl
```

and call negalfar.tcl directly from the Linux prompt to avoid loading the legacy files like this:

```
set install_dir = <install_dir>

set nag_dir = $install_dir/share/nagelfar

set cui_dir = $install_dir/share/commonui/nagelfar

$nag_dir/nagelfar.tcl \

-s $cui_dir/innovus.commonui.syntaxdb.tcl \

-plugin $cui_dir/innovus.commonui.plugin.tcl \

<other nagelfar options> [file1.tcl file2.tcl …]
```

You can check the nagelfar documentation in the installation directory for details about its options, the checks it performs, and the steps to turn on or off various checks.

To run this command, you must have tclsh in your search path.

You can type `nagelfar -help` to see all the nagelfar.tcl options.

Options	Description
`-encoding <enc>`	Reads script with this encoding.
`-exitcode`	Returns status code 2 for any error or 1 for warning.
`-filter <p>`	Specifies to suppress any message that matches the global pattern.
`-glob <pattern>`	Adds matching files to scriptfiles to check.
`-gui`	Starts with GUI even when files are specified.
`-H`	Specifies a prefix each error line with file name.
`header <file>`	Creates a "header" file with syntax info for scriptfiles.
`-html`	Generates html-output.
`-instrument`	Instruments source file for code coverage.
`-markup`	Markup source file with code coverage result.
`-novar`	Disables variable checking.
`-prefix <pref>`	Specifies the prefix for line anchors (html output)
`-quiet`	Suppresses non-syntax output.

`-s <dbfile>`	Includes a database file. You can include more than one database file. If <dbfile> is "_", it adds the default database.
`-severity <level>`	Sets severity level filter to N/W/E (default N).
`-strictappend`	Enforces having an initialized variable in (l)append.
`-tab <size>`	Specifies the Tab size, default is 8.
`-WelseN`	Enforces else keyword. Default 1.
`-WexprN`	Sets expression warning level to N.
`-WsubN`	Sets subcommand warning level to N.
`1`	Does not warn on single commands. "if [apa] {...}" is ok.
`1 (def)`	Warns about shortened subcommands.
`2 (def)`	Warns about any unbraced expression.

Example

- The following example show the usage of `nagelfar` for file `a.tcl`:

```
linux> nagelfar -H a.tcl
Checking file a.tcl
a.tcl: 2: W Unknown command "typo_in_cmd_name"
a.tcl: 3: E Bad option -typo_in_opt_name to "routeDesign"
```

Related Information

- `check_syntax` is the corresponding Tcl command that can be used directly inside Innovus.

oa2lef

```
oa2lef
-lef file
-lib library
[-cell cells]
[-h | -help]
[-libDefFile filename]
[-lockedColorsOnly]
[-logFile file]
[-noInfo msgIds]
[-noTech]
[-noWarning msgIds]
[-templateFile file]
[-useFoundryInnovus]
[-views viewName]
[-v]
[-ver version]
[-version]
```

This translator can be used to convert OpenAccess data into equivalent LEF data.

Innovus uses a Cadence version of `oa2lef` that does more than the public domain `oa2lef` executable. The main difference is that many DRC rules that are expressed as properties that begin with `LEF58_` (for example, `PROPERTY LEF58_SPACING "..." ;`) are understood and mapped to the correct LEF syntax. In general, the rules needed for 28nm nodes and older are supported, while newer rules for 20nm and smaller are not supported. If you have any unsupported LEF property rules, they can be translated into LEF using Innovus commands instead. To do so, read the OA techfile into Innovus, and use the Innovus `write_lef_library` command.

Parameters

`-cell` *cells*	Specifies a space-separated list of cells to translate.
`-help or -h`	Displays usage information.
`-lef` *file*	Specifies the output LEF file name.
`-lib` *library*	Specifies the name of the source library, containing a technology database.
`-libDefFile` *filename*	Specifies the `lib.defs` file to load. The path to the `lib.defs` file can be a full or relative path. If this option is omitted, the default search mechanism of the DM system is used to find and load the `lib.defs` file.
`-lockedColorsOnly`	Prints the colors of only the shapes with a locked state of `true` when mapping the oaFigs or oaVias belonging to oaPins to the LEF PINs and PORTs.
`-logFile` *file*	Specifies the log filename. If this option is omitted, the log filename defaults to `oa2lef.log`.
`-noInfo` *msgIds*	Suppresses the specified INFO messages. msgIds is a quoted, space-separated list of numbers. Each number in the list represents the numerical portion of the ID for the message you want to suppress. None of the numbers in the list may be zero. Suppressed messages do not appear on the terminal or in the log file.
`-noTech`	Specifies that the technology information is not output.
`-noWarning` *msgIds*	Suppresses the specified WARNING messages. *msgIds* is a quoted, space-separated list of numbers. Each number in the list represents the numerical portion of the ID for the message you want to suppress. None of the numbers in the list may be zero. Suppressed messages do not appear on the terminal or in the log file and are not included in the total of WARNING messages displayed in the summary.
`-templateFile` *file*	Specifies a file containing arguments to `oa2lef`. You can specify a template file instead of entering a string of arguments on the command line.
`-useFoundryInnovus`	Prints the `foundry_innovus` constraint group as LEF LAYER LEF58 properties. These constraints are found only in Rapid MSOA tech files that are used for the Cadence mixed signal implementation solution. For more information on Rapid MSOA PDKs, refer to the Technology Data Preparation chapter in the *Mixed Signal (MS) Interoperability Guide*.
`-v`	Prints tool, format, and library version information.
`-ver` *version*	Specifies the LEF version to write, which can be 5.3, 5.4, 5.5, 5.6, 5.7 or 5.8. The default version is 5.7.
`-version`	Prints tool and format version information
`-views` *viewName*	Specifies a space-separated list of views to translate. Only the first view name for a particular cell is used; all others are ignored.

Unified Safety Format Commands

Midas Unified Safety Format (USF) Physical is loaded at startup. To enable USF in Innovus, you must set the `safety_midas_enable` attribute to `physical`.

```
set_db safety_midas_enable physical
```

You will see a message like this:

```
Cadence Midas USF - Physical
Copyright 2022 Cadence Design Systems, Inc. All rights reserved worldwide.
Cadence and the Cadence logo are registered trademarks of Cadence Design Systems Inc.
in the United States and other countries.
Midas USF - Physical Version: 22.03.002
1 physical
```

ⓘ Once USF Physical is loaded, it is not possible to disable or reload it in the current session.

- USF File Commands
- USF Support Commands

USF File Commands

- apply_safety_mechanism
- create_esubpart
- create_failure_mode
- create_safety_mechanism
- set_safety_mechanism_rules_dcls
- set_safety_mechanism_rules_tmr

apply_safety_mechanism

```
apply_safety_mechanism
[-help]
safety_mechanism
[-generated]
-to failure_mode
```

Maps a safety mechanism to one or more failure modes.

This command should be applied only via a USF file that is read in using `read_usf`.

Parameters

`-help`	Prints a brief description of the `apply_safety_mechanism` command. For a detailed description of the command, use the `man` command: `man apply_safety_mechanism`.
safety_mechanism	Specifies the safety mechanism identifier. *Data_type*: string, required
`-generated`	Specifies that the additional logic required to create this safety mechanism has already been inserted into the design. *Data_type*: bool, optional
`-to` *failure_mode*	Specifies the failure mode identifier to which the specified safety mechanism should be associated. **Note**: One safety mechanism can be mapped to multiple failure modes. *Data_type*: string, required

Example

- The following command applies the `SM_TMR` safety mechanism to the `FM_22` failure mode:

  ```
  apply_safety_mechanism SM_TMR -to FM_22
  ```

Related Information

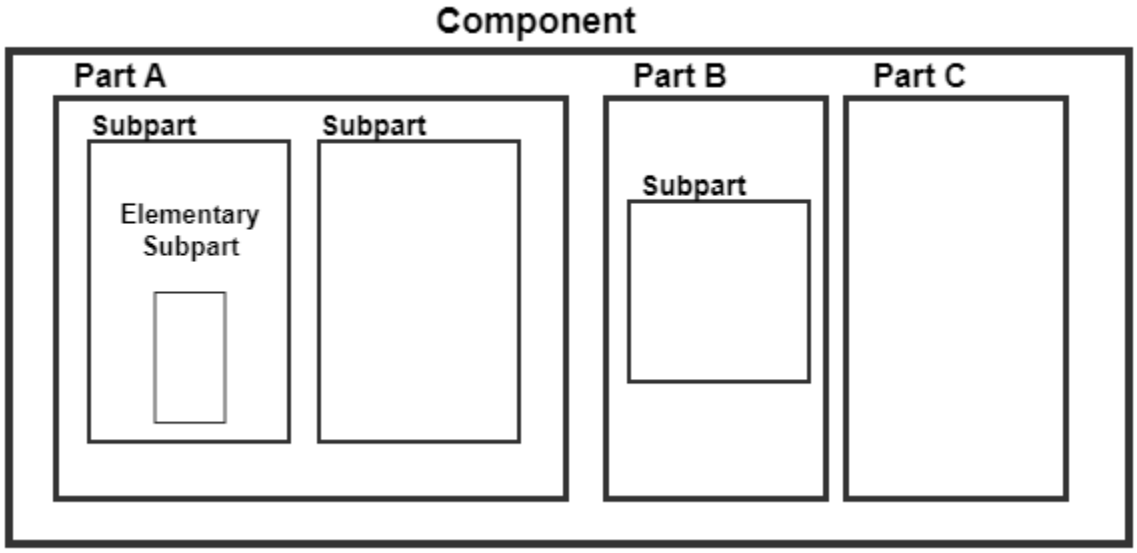
- check_safety_mechanism
- create_esubpart
- create_failure_mode
- create_safety_mechanism
- read_usf
- safety Category Attributes
- set_safety_mechanism_rules_dcls
- set_safety_mechanism_rules_tmr

create_esubpart

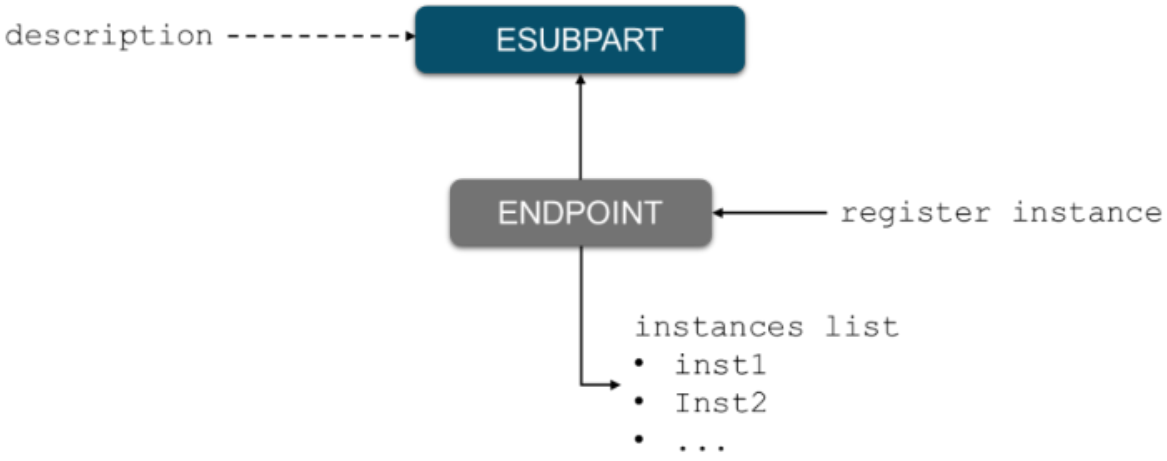
```
create_esubpart
[-help]
esp
[-description description]
-inst string
-register_endpoint string
```

Creates an elementary subpart, which is the smallest hardware subpart considered in safety analysis.

The diagram below represents a component with its parts, subparts, and elementary subparts.



An elementary subpart is a group of instances identified with a descriptor. The instances are associated to reference an endpoint. In the current implementation, the endpoint can only be a register.



The `create_esubpart` command should be applied only via a USF file that is read in using `read_usf`.

Parameters

`-help`	Prints a brief description of the `create_esubpart` command. For a detailed description of the command, use the `man` command: `man create_esubpart`.
esp	Specifies the identifier to be associated with the elementary subpart being created. *Data_type*: string, required
`-description` *description*	
	Specifies a textual description for the elementary subpart being created. *Data_type*: string, optional
`-inst` *string*	Specifies the instances to be mapped to the elementary subpart. *Data_type*: string, required
`-register_endpoint` *string*	
	Specifies a reference instance for the endpoint. *Data_type*: string, required

Example

- The following command creates an elementary subpart named with the specified description, endpoint, and instances:

```
create_esbupart ESP_VOT_0 -description "automatically generated elementary subpart"
 -register_endpoint { xsv_fpga_top/or1200_top/or1200_cpu/or1200_fpu/s_exp_diff_reg\[5\] }
 -inst { xsv_fpga_top/or1200_top/or1200_cpu/or1200_fpu/s_exp_diff_reg\[5\]_tv_an1
         xsv_fpga_top/or1200_top/or1200_cpu/or1200_fpu/s_exp_diff_reg\[5\]_tv_an2
         xsv_fpga_top/or1200_top/or1200_cpu/or1200_fpu/s_exp_diff_reg\[5\]_tv_or1
         xsv_fpga_top/or1200_top/or1200_cpu/or1200_fpu/s_exp_diff_reg\[5\]_tv_or2
 }
```

Related Information

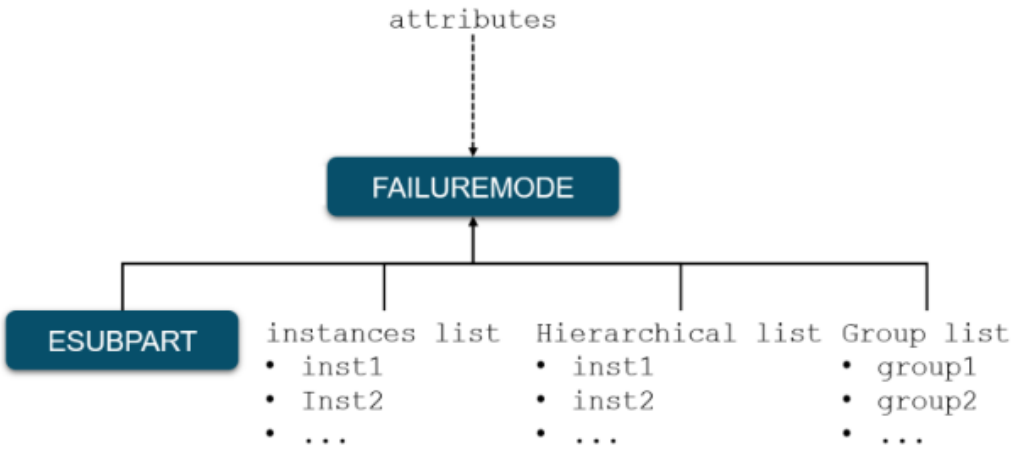
- check_safety_mechanism
- create_failure_mode
- create_safety_mechanism
- read_usf
- safety Category Attributes
- set_safety_mechanism_rules_dcls
- set_safety_mechanism_rules_tmr

create_failure_mode

```
create_failure_mode
[-help]
failuremode
[-attributes string]
[-description description]
{-hinst string | -inst string | -esubpart string | -group string}
```

Defines a failure mode. The failure mode groups a given set of logic that is relevant from the safety point of view. For example, it could be the logic that needs to be protected by one or more safety mechanisms or the logic that is describing a safety mechanism that has already been implemented.



The `create_failure_mode` command should be applied only via a USF file that is read in using `read_usf`.

Parameters

`-help`	Prints a brief description of the `create_failure_mode` command. For a detailed description of the command, use the `man` command: `man create_failure_mode`.
`failuremode`	Specifies the identifier to be associated to the failure mode being created. *Data_type*: string, required
`-attributes` *`string`*	Specifies the optional attributes attached to the failure mode. *Data_type*: string, optional
`-description` *`description`*	Specifies a textual description for the failure mode being created. *Data_type*: string, optional
`-esubpart` *`string`*	Specifies a list of elementary subparts. *Data_type*: string, required
`-group` *`string`*	Specifies the groups to be mapped to the failure mode. *Data_type*: string, required
`-hinst` *`string`*	Specifies the hierarchical instance(s) to be mapped to the failure mode. *Data_type*: string, required
`-inst` *`string`*	Specifies the instances to be mapped to the failure mode. *Data_type*: string, required

Example

- The following command creates a failure mode named `FM_22` with the specified description and hierarchical instance:

```
create_failure_mode FM_22 -description "FPU Adder produces incorrect data due to
fault into the FPU prenorm addsubtracter"
     -hinst
xsv_fpga_top/or1200_top/or1200_cpu/or1200_fpu/fpu_arith/fpu_prenorm_addsub
```

Related Information

- set_safety_mechanism_rules_tmr

create_safety_mechanism

```
create_safety_mechanism
[-help]
safety_mechanism
[-class {aou hw sw aou_hw aou_sw}]
[-description description]
[-type {tmr dcls}]
```

Defines a new safety mechanism. A safety mechanism is extra hardware inserted into your design to bypass, detect, or correct faults.

This command should be applied only via a USF file that is read in using `read_usf`.

Parameters

`-help`	Prints a brief description of the `create_safety_mechanism` command. For a detailed description of the command, use the `man` command: `man create_safety_mechanism`.
`safety_mechanism`	Specifies a name for the safety mechanism being defined. *Data_type*: string, required
`-class {aou hw sw aou_hw aou_sw}`	Specifies the supported safety mechanism classes. The possible values are: • `aou`: assumption of use • `hw`: hardware • `sw`: software • `aou_hw`: assumption of use hardware • `aou_sw`: assumption of use software *Default*: `hw` *Data_type*: enum, optional
`-description` *`description`*	Specifies a description for the safety mechanism being defined. *Data_type*: string, optional
`-type {tmr dcls}`	Specifies the type of the safety mechanism being defined. The options are: • `tmr` - triple modular redundancy • `dcls` - dual-core lockstep *Default*: `tmr` *Data_type*: enum, optional

Example

- The following command creates a safety mechanism named, `SM_TMR`, of the specified class and type:

```
create_safety_mechanism SM_TMR -description "Triple Modular Redundant Flip Flops" -type tmr -class hw
```

Related Information

- `apply_safety_mechanism`
- `check_safety_mechanism`
- `create_esubpart`
- `create_failure_mode`
- `read_usf`
- `safety` Category Attributes
- `set_safety_mechanism_rules_dcls`
- `set_safety_mechanism_rules_tmr`

set_safety_mechanism_rules_dcls

```
set_safety_mechanism_rules_dcls
[-help]
[-exclusive_groups {{group_A1 {group_A2 group_A3 ...}} {group_B1 group_B2
group_B3 ...} ... }]
[-isolate_clock {* | group_A1 group_A2 ...}]
[-spacing d]
```

Defines the separation rules to be applied to the dual core lockstep (DCLS) groups in the design.

Each time the `set_safety_mechansim_rules_dcls` command is issued, the tool clears any previously set DCLS-associated attributes across all groups prior to setting them in the way the latest command dictates. Therefore, this command cannot be used multiple times to accumulate a set of rules.

This `set_safety_mechansim_rules_dcls` command may be interactively applied at the command line. That is, it is not restricted to be read in as part of a USF file using `read_usf`. However, if the command is not in a USF file that is being read, it must be applied only after DCLS-related USF information has been read because it depends on this information to function correctly.

Attempting to use this command before a design is loaded or before the groups listed in arguments are defined will cause an error to be issued. In addition, any groups mentioned in this command must already be defined as DCLS groups using a combination of the `create_failure_mode`, `create_safety_mechanism` (with type `dcls`), and `apply_safety_mechanism` commands.

Parameters

`-help`	Prints a brief description of the `set_safety_mechanism_rules_dcls` command. For a detailed description of the command, use the `man` command: `man set_safety_mechanism_rules_dcls`.
`-exclusive_groups {{group_A1 {group_A2 group_A3 ...}} {group_B1 group_B2 group_B3 ...} ... }`	

	Specifies a list of mutually exclusive DCLS group lists. This parameter is mandatory if the `-spacing` parameter is being used. Wildcards are not allowed in the `-exclusive_groups` arguments. If a group is referenced more than once in the `-exclusive_groups` arguments, an error will be issued. In the argument string above, `{group_A1 {group_A2 group_A3 ...}` is a master/checker arrangement, where *group_A1* is the "master" group and *group_A2* and *group_A3* are the "checker" groups. This means that the checker groups must be separated from the master group by a distance of at least *d* as specified with the `-spacing` parameter. However, a checker group may overlap other checker groups. When a master/checker arrangement is specified, there can be only one master and there must be at least two checkers. In the `{group_B1 group_B2 group_B3 ...}` part of the argument string, *group_B1*, *group_B2*, and *group_B3* are all mutually exclusive. This means that they must all be separated from one another by a distance of at least *d* specified with the `-spacing` parameter. Each list of mutually exclusive groups must have at least two members or else an error will be issued.
`-isolate_clock {* | group_A1 group_A2 ...}`	

	Specifies a list of groups where clock isolation is required. This argument is optional. Clock isolation is specific to each listed group. If specified for a group, it isolates that group from the rest of the clock network in the design. Clock isolation is not just about separating two groups. For example, in the diagram below, the path shown in red will not occur for the groups with isolated clocking.  If * is specified, clock isolation is enacted for all the DCLS groups in the design.
`-spacing` *d*	Defines in microns the minimum spacing between exclusive DCLS groups. This parameter is mandatory if the `-exclusive_groups` parameter is used. The distance `d` here is expected to be a positive rational number. The specified distance is rounded to the nearest 0.001 value. If the distance specified is a negative number, a warning is issued and the setting is changed to `0`.

Examples

- The following command specifies that groups `A` and `B` are mutually exclusive to one another. The group boundaries must be at least 5 microns apart:
  ```
  set_safety_mechanism_rules_dcls -exclusive_groups { {A B} } -spacing 5
  ```
- The following command specifies that groups `A`, `B`, and `C` are mutually exclusive. These groups must be at least 10 microns apart:
  ```
  set_safety_mechanism_rules_dcls -exclusive_groups { {A B C} } -spacing 10
  ```
- The following command specifies that group `W` must be at least 5 microns from groups `X`, `Y`, and `Z`. However, `X`, `Y`, and `Z` may overlap one another:
  ```
  set_safety_mechanism_rules_dcls -exclusive_groups { {W {X Y Z}} } -spacing 5
  ```
- The following command specifies that groups `A`, `B`, and `C` must be at least 5 microns apart from one another and group `W` must be at least 5 microns from groups `X`, `Y`, and `Z`. However, `X`, `Y`, and `Z` may overlap one another. In addition, groups `A`, `B`,`C`, `W`, `X`, `Y`, and `Z` are to have isolated clocks:
  ```
  set_safety_mechanism_rules_dcls -exclusive_groups { {A B C} {W {X Y Z}} } -spacing 5
  -isolate_clock { * }
  ```

Related Information

- `apply_safety_mechanism`
- `check_safety_mechanism`
- `create_esubpart`
- `create_failure_mode`
- `create_safety_mechanism`
- `read_usf`
- `safety` Category Attributes
- `set_safety_mechanism_rules_tmr`

set_safety_mechanism_rules_tmr

```
set_safety_mechanism_rules_tmr
[-help]
{[-spacing double] [-spacing_x dx] [-spacing_y dy] [-isolate_clock {none unique_driver}] }
[-spacing double | -spacing_x dx]
[-spacing double | -spacing_y dy]
```

Defines the triple modular redundancy (TMR) safety-mechanism rules that need to be enforced during implementation.

The rules concern the physical spacing between TMR flip-flops and clock isolation of TMR flip-flops. The `set_safety_mechanism_rules_tmr` command may be applied interactively at the command line. That is, it is not restricted to be read in as part of a USF file using `read_usf`.

Each time the `set_safety_mechansim_rules_tmr` command is issued, the tool first clears any previously set TMR rules. This means that the `set_safety_mechansim_rules_tmr` command cannot be used multiple times to accumulate a set of rules.

One of the following parameters must be specified with the command:

- `-spacing`
- `-spacing_x` and/or `-spacing_y`
- `-isolate_clock`

Additionally, the `-spacing` parameter is mutually exclusive to the `-spacing_x` and `-spacing_y` parameters.

Parameters

`-help`	Prints a brief description of the `set_safety_mechanism_rules_tmr` command. For a detailed description of the command, use the `man` command: `man set_safety_mechanism_rules_tmr`.
`-isolate_clock {none unique_driver}`	

	Controls whether or not the three flops in a TMR group may share the same leaf clock buffer. Supported values are: • `none` - Specifies that the three flops in a TMR group may also share the same leaf clock buffer. • `unique_driver` - Specifies that the clock pin of every TMR flop should be directly driven by its own unique clock cell with fanout equal to `1`. *Default*: `none` *Data_type*: enum, required
`-spacing` *double*	Specifies the minimum radial spacing in µm between a group of TMR flip-flops sharing the same parent. This parameter is mutually exclusive to the `-spacing_x` and `-spacing_y` parameters. The spacing is expected to be a positive rational number. The specified value is rounded to the nearest 0.001. If a negative number is given, a warning is issued and the `spacing` value is set as `0`. *Data_type*: double, required
`-spacing_x` *dx*	Specifies the minimum spacing in the X dimension in µm between a group of TMR flip-flops sharing the same parent. This parameter is mutually exclusive to the `-spacing` parameter. The specified value is rounded to the nearest 0.001. If a negative number is given, a warning is issued and the `-spacing_x` value is set as `0`. *Data_type*: double, required
`-spacing_y` *dy*	Specifies the minimum spacing in the Y dimension in µm between a group of TMR flip-flops sharing the same parent. This parameter is mutually exclusive to the `-spacing` parameter. The specified value is rounded to the nearest 0.001. If a negative number is given, a warning is issued and the `-spacing_y` value is set as `0`. *Data_type*: double, required

Example

- The following command specifies a 5µm radial spacing between TMR flip-flops and requires isolation of clock pins.

```
set_safety_mechansim_rules_tmr -spacing 5 -isolate_clock unique_driver
```

Related Information

- read_usf
- reset_usf
- usf_version
- write_usf

check_safety_mechanism

```
check_safety_mechanism
[-help]
[-out_file file_name]
```

Checks all the safety mechanisms and prints a report, optionally writing it to the specified file as well.

The report contains a list of:

- All the safety mechanisms
- The safety mechanism violations found for each safety mechanism, grouped by type

See Report Content for details.

Parameters

`-help`	Prints a brief description of the `check_safety_mechanism` command. For a detailed description of the command, use the `man` command: `man check_safety_mechanism`.
`-out_file` *file_name*	Writes the report to the specified file. If omitted, no report file is generated. *Data_type*: string, optional

Report Content

The report contains one section per safety mechanism, listing all violations (if any) of that safety mechanism, grouped by type.

Safety mechanisms of type `dcls` (dual-core lockstep) have the following violation types:

- dcls group overlap violations: Two exclusive dcls groups overlap.
- dcls group spacing violations: Two exclusive dcls groups are closer than permitted.
- dcls inst placement violations: An inst belonging to a dcls group is placed outside of that group's boundary.
- dcls internal net routing violations: A net connected only to the insts inside a single dcls group is routed outside that group's boundary.
- dcls interface net routing violations: A net connected to insts both inside and outside a dcls group is routed inside the boundary of an exclusive group.
- dcls clock isolation violations: A clock net connected to a dcls group is driving loads outside that group.

Safety mechanisms of type `tmr` (triple modular redundancy) have the following violation types:

- tmr spacing violations: Two tmr insts from the same safety mechanism are placed closer than permitted.
- tmr clock isolation violations: A clock net driving a tmr inst is also driving other insts.

Example

- The following command checks all the safety mechanisms and writes the report to the `safety_report.rpt` file:

  ```
  check_safety_mechanism -out_file safety_report.rpt
  ```

Related Information

- create_safety_mechanism
- read_safety_tmr
- read_usf
- reset_usf
- safety Category Attributes
- usf_version
- write_usf

read_safety_tmr

```
read_safety_tmr
[-help]
tmr_info_file
-failure_mode failure_mode_name
-safety_mechanism safety_mechanism_name
```

Reads the triple modular redundancy (TMR) information file. For designs with TMR logic already inserted, either in the register-transfer level (RTL) or with third party tools, this command identifies the existing TMR logic and assimilates it into the Unified Safety Format (USF).

You can issue the `read_safety_tmr` command multiple times to build up information in cases where there are multiple different safety mechanism names or failure mode names. However, this may be done only for new safety mechanism and failure mode names. You cannot accumulate TMR information by reusing a safety mechanism or failure mode name that has been already read in with the `read_safety_tmr` command.

Parameters

`-help`	Prints a brief description of the `read_safety_tmr` command. For a detailed description of the command, use the `man` command: `man read_safety_tmr`.

tmr_info_file	Specifies the name of the TMR information file. This is a text file listing each flip-flop and its accompanying cloned flip-flops where TMR has already been applied. Optionally, the file may also list the names of the voter cells that are used.
	
	The TMR information file has the following format:
	
	`<parent_FF1> <clone_FF1A> <clone_FF1B> <voter1A> <voter1B>`
	`...`
	`<parent_FF2> <clone_FF2A> <clone_FF2B> <voter2A> <voter2B>`
	`...`
	`...`
	
	The instance names may be supplied with the full path including the design name at the root. If the design name is not given at the root of the instance path for a given instance, that instance is assumed to be in the current design. The instance names are separated by white space.
	
	Comments are allowed in this file and must be preceded by #.
	
	Blank lines are also allowed.
	
	Data_type: string, required

`-failure_mode` *failure_mode_name*	
	Specifies the name of the failure mode for parent flops. The failure mode for clone flops will be *<failure_mode_name>*`_clones`. The failure mode for voter cells will be *<failure_mode_name>*`_voters`. *Data_type*: string, required
`-safety_mechanism` *safety_mechanism_name*	
	Specifies the name of the safety mechanism for the TMR logic. *Data_type*: string, required

read_usf

```
read_usf
[-help]
USF_file
```

Reads in a Unified Safety Format (USF) file specifying the safety intent of your design.

Parameters

`-help`	Prints a brief description of the `read_usf` command. For a detailed description of the command, use the `man` command: `man read_usf`.
`USF_file`	Specifies the name of the USF file to be read. *Data_type*: string, required

Example

- The following command reads in the USF file named `myFile.usf`:

  ```
  read_usf myFile.usf
  ```

Related Information

- `check_safety_mechanism`
- `read_safety_tmr`
- `reset_usf`
- `safety` Category Attributes
- `usf_version`
- `write_usf`

reset_usf

```
reset_usf
[-help]
```

Resets the Unified Safety Format (USF) Physical safety information and related database attributes completely.

Parameters

`-help`	Prints a brief description of the `reset_usf` command. For a detailed description of the command, use the `man` command: `man reset_usf`.

Related Information

- `check_safety_mechanism`
- `read_safety_tmr`
- `read_usf`
- `safety` Category Attributes
- `usf_version`
- `write_usf`

usf_version

```
usf_version
[-help]
```

Retrieves the version of the USF Physical being used to interpret the USF commands.

Parameters

`-help`	Prints a brief description of the `usf_version` command. For a detailed description of the command, use the `man` command: `man usf_version`.

Related Information

- `check_safety_mechanism`
- `read_safety_tmr`
- `read_usf`
- `reset_usf`
- `safety` Category Attributes
- `write_usf`

write_usf

```
write_usf
[-help]
USF_file
```

Writes the safety intent of your design to the specified Unified Safety Format (USF) file.

Parameters

`-help`	Prints a brief description of the `write_usf` command. For a detailed description of the command, use the `man` command: `man write_usf`.
`USF_file`	Specifies the name of the USF file to be saved. *Data_type*: string, required

Example

- The following command saves the USF information in the `myFile.usf` file.

  ```
  write_usf myFile.usf
  ```

Related Information

convert_special_routes_for_eco

```
convert_special_routes_for_eco
[-help]
[-exclude_nets nets]
[-nets nets]
```

Converts special nets to geometrically equivalent regular nets. You can convert all special nets, named special nets, or all special nets except those you specify. The `convert_special_routes_for_eco` command supports polygon shapes as well.

Notes

- If you do not specify any parameters, this command converts all special nets to signal nets.
- This command does not work for PG nets.

Parameters

`-help`	Prints a brief description that includes type and default information for each `convert_special_routes_for_eco` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man convert_special_routes_for_eco`
`-exclude_nets` *nets*	Specifies nets you do not want to convert. You can use wildcards. • If a name contains a special character, enclose it in braces (`{}`). • If you specify multiple net names, enclose the names in braces (`{}`). *Data_type*: (net)*, optional
`-nets` *nets*	Specifies the nets to convert. You can use wildcards. • If a name contains a special character, enclose it in braces (`{}`). • If you specify multiple net names, enclose the names in braces (`{}`). *Data_type*: (net)*, optional

Note: For backward compatibility, this command also supports the following syntax for nets to convert:

`convert_special_routes_for_eco` *netName* [*netName2 netName3 ...*]

Examples

- The following command converts special nets named `clk*` to regular nets:
  `convert_special_routes_for_eco -nets clk*`
- The following command converts all special nets, except those named `clk1*`, to regular nets:
  `convert_special_routes_for_eco -exclude_nets clk1*`
- The following command converts special nets named `clk*` to regular nets, except nets named `clk1*`:
  `convert_special_routes_for_eco -nets clk* -exclude_nets clk1*`
- The following command converts all special nets named `clk*`, `a2`, and `s2[1]`, except for nets `clk1` and `clk2`, to regular nets:
  `convert_special_routes_for_eco -nets {clk* a2 s2[1]} -exclude_nets {clk1 clk2}`

create_fillet

```
create_fillet [-help]
```

Adds a tear-drop fillet between a wire and bump connection. A teardrop fillet is used to reinforce the mechanical strength of the connection to the bump. This applies to all bumps in the design. If the connected wire is too short to create the fillet, a marker is created to indicate the failure.

Parameters

`-help`	Prints a brief description that includes type and default information for each `create_fillet` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man create_fillet`

delete_fillet

```
delete_fillet [-help]
```

Deletes the tear-drop fillet that was added between a wire and bump connection with the `create_fillet` command.

Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man delete_fillet`

Related Information

delete_routes

```
delete_routes
[-help]
[-area {x1 y1 x2 y2}]
[-direction {h | v | 45 | 135}]
[-floating_via]
[-layer {list_of_layers}]
[-net net*]
[-parallel_routing]
[-physical_pin_only]
[-obj_type {wire via}]
[-regular_wire_with_drc]
[-selected]
[-shapes  {ring stripe followpin iowire corewire blockwire padring blockring fillwire fillwireopc
drcfill none}]
[-shield]
[-shield_only]
[-status {fixed noshield routed shield unknown}]
[-sub_class sublass_name]
[-trim_metal]
[-type {regular | special | patch}]
[-use {clock | power | signal} ]
[-via_cell cell_name_list]
[-with_edit_flag {0 | 1}]
```

Deletes physical wires, any vias connected to the wires, and violation markers associated with the wires.
Use `delete_routes -physical_pin_only` to delete physical pins in the design.

By default, when you delete a wire or via with delete_routes, the tool searches and deletes all related DRC markers. If you do not want the related DRC markers to be cleared when you delete a wire or via, set the `edit_wire_drc_on` root attribute to `false` before using `delete_routes`. This can improve the run time if have to delete a large number of wires and vias.

By default, the `delete_routes` command retains TSVs and deletes only the real routing layers and vias. You can change this behavior by setting the `edit_wire_delete_tsv` parameter to `true` before using `delete_routes`.

Note: The `delete_routes` command deletes only those vias that are connected to wires. To delete vias that are not connected to wires, use the `delete_metal_fill` command.

The `delete_routes` command deletes physical wires. The `delete_nets` command deletes logical nets. For more information, see `delete_nets`.

Parameters

`-help`	Prints a brief description that includes type and default information for each `delete_routes` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_routes`
`-area {x1 y1 x2 y2}`	Specifies the coordinates for the area from which to delete the wires. *Default:* Deletes all wires. *Data_type*: rect, optional
`-direction {h | v | 45 | 135}`	Specifies the orientation of the wires to delete. *Default:* If you do not specify this parameter, deletes wires with either orientations. `h`: Specifies that only horizontal wires are to be deleted. `v`: Specifies that only vertical wires are to be deleted. `45`: Specifies that only 45-degree wires are to be deleted. `135`: Specifies that only 135-degree wires are to be deleted. *Data_type*: enum, optional
`-floating_via`	Specifies that only floating vias should be deleted. *Data_type*: bool, optional
`-layer {list_of_layers}`	Specifies the layers from which to delete wires. You must specify layers by using their LEF names. You must use LEF layer names or a routing layer index value (1 for the first routing layer, 2 for the second routing layer, and so on). This option supports backside and Through Silicon Via (TSV) layers as well. *Default:* If you do not specify this parameter, deletes wires from all layers. *Data_type*: string, optional

`-net net*`	Specifies the net or list of nets from which to delete wires. You can use wildcard values in this field. For example, if you specify `V*`, deletes wires from nets `VDD` and `VSS`. If you are specifying multiple nets, enclose them in braces. **Note**: By default, the wires and vias shielding the nets specified with `delete_routes -net` are not deleted. If you want to delete the shielding as well, specify `-shield` along with `-net`.  *Data_type*: (net)*, optional
`-obj_type {wire via}`	Specifies whether wires or vias should be deleted. You can specify both as well. If `-obj_type` is not specified, `editDelete` deletes both wires and vias by default. *Data_type*: (enum)+, optional
`-parallel_routing`	Specifies that the wires created by NanoRoute parallel routing are to be deleted. *Data_type*: bool, optional
`-physical_pin_only`	Specifies that the physical pins in the design are to be deleted. You can use filter options, such as `-net`, `-layer`, `-area`, and `-selected` along with `-physical_pin_only` to delete specific physical pins. *Data_type*: bool, optional
`-regular_wire_with_drc`	Deletes the regular wires with violation markers. This parameter works only when `-net` or `-status` are specified as filters. *Data_type*: bool, optional
`-selected`	Deletes selected wires, vias, and physical pins. **Note**: Only physically selected objects are deleted. If you want to delete all wires from a net, use `select_routes -net` to ensure the wires of the net are physically selected. *Data_type*: bool, optional
`-shapes {ring stripe followpin iowire corewire blockwire padring blockring fillwire fillwireopc drcfill none}`	

	Specifies the shapes of the wires to delete. The status must be in all upper-case letters. If you specify multiple shapes, enclose the shapes in braces. For shape definitions, see *Shapes,* in the "DEF Syntax" chapter of the LEF/DEF Language Reference. *Default:* If you do not specify this parameter, deletes wires of all shapes. *Data_type*: (enum)+, optional
`-shield`	Deletes the wires and vias of the nets specified with the `-net` parameter, along with the wires and vias shielding the specified nets. **Note**: This parameter cannot be used with `-shield_only`. *Data_type*: bool, optional
`-shield_only`	Deletes only the wires and vias shielding the nets specified with the `-net` parameter. The signal nets being shielded are retained.  **Note**: This parameter cannot be used with `-shield`. *Data_type*: bool, optional
`-status {fixed noshield routed shield unknown}`	
	Specifies the status of wires to delete. If you specify more than one status, enclose the status list in curly braces. **Note:** If you select `-type special -status noshield` or `-type regular -status shield` the software generates an error message. *Data_type*: (enum)+, optional
`-sub_class` *`sublass_name`*	Specifies the subclass name of the wires to be deleted. Use this parameter if you want to delete rings, stripes, or other wires belonging to a specific subclass. **Note:** You can use wildcards in *`subclass_name`*. Only special wire is supported by this option. *Data_type*: string, optional

`-trim_metal`	Deletes the trim metal attached to all patch wires, without deleting the patch wires. If `-selected` is also specified, deletes only the trim metal attached to the selected patch wire without deleting the patch wire. *Data_type*: bool, optional
`-type {regular | special | patch}`	Specifies whether to delete regular wires, special wires, or patch wires. **Note:** If you specify `regular`, omit the `-shapes` parameter or specify `-shapes none`. *Data_type*: enum, optional
`-use {clock | power | signal}`	
	Indicates that wires will be deleted on the basis of the specified use: `clock`: Specifies that only wires for clock nets will be deleted. `power`: Specifies that only wires for power nets will be deleted. `signal`: Specifies that only wires for general signal nets will be deleted. *Data_type*: enum, optional
`-via_cell` *cell_name_list*	
	Specifies the via cells of the vias to be deleted. You can use wildcards while specifying the via cell names. If you are specifying multiple cell names, enclose them in braces.
`-with_edit_flag {0 | 1}`	Deletes all modified wires, that is wires with value `1` for the `isEdit` property on the net. **Notes** • As the `isEdit` property is added on the whole net, all the wires on the net with `isEdit` value set to `1` will be deleted. • The `isEdit` property is used to flag nets with modified wires and vias. This is useful when evaluating how many objects need to be modified for fixing DRC violations and then deciding whether to fix the violations manually or through ECO routing. The `isEdit` property is controlled through the `edit_wire_create_is_edit_flag` root attribute in the `edit_wire` category. By default, this attribute is set to `false`. If you set the value of this attribute to `true`, the `isEdit` property is set to `1` for nets with modified wires or vias. *Data_type*: enum, optional

Examples

- The following command removes wires from the *METAL1* and *METAL2* layers:
  ```
  delete_routes -layer {METAL1 METAL2}
  ```
- The following command removes horizontal fillwires from the *METAL1* layer:
  ```
  delete_routes -layer METAL1 -direction h -shapes fillwire
  ```
- The following command removes wires from the specified area:
  ```
  delete_routes -area 100 100 200 200
  ```
- The following command removes the selected wires and vias from the specified area:
  ```
  delete_routes -area 100 100 200 200 -selected
  ```
- The following command only deletes the special wires that belong to the net `carry4` leaving the vias untouched:
  ```
  delete_routes -type special -net carry4 -obj_type {wire}
  ```
- The following command deletes all physical pins:
  ```
  delete_routes -physical_pin_only
  ```
- The following command deletes all physical pins from net VSS:
  ```
  delete_routes -net VSS -physical_pin_only
  ```
- The following command deletes all physical pins from nets VSS and VDD:
  ```
  delete_routes -net {VDD VSS} -physical_pin_only
  ```
- The following command deletes all physical pins from layer METAL2:
  ```
  delete_routes -layer METAL2 -physical_pin_only
  ```
- The following command deletes all physical pins from the specified area:
  ```
  delete_routes -area {26 0 31 4} -physical_pin_only
  ```
- The following set of commands deletes the selected physical pin:
  ```
  select_obj <ptr of layerShape> #Selects the pointer of the layer shape
                                 #belonging to a physical pin
  delete_routes -selected
  ```
- The following command deletes the regular wires with violation markers from only the specified net:
  ```
  delete_routes -net B -regular_wire_with_drc
  ```

- The following command deletes only routed regular wires with violation markers from the specified net:

```
delete_routes -net B -regular_wire_with_drc -status routed
```

delete_secondary_pg_net

```
delete_secondary_pg_net
[-help]
-insts inst+
-net net
```

Deletes Power/Ground (P/G) net wire segments from specified instances. This command provides an easy way delete the routing from specific instance P/G pins to stripes.

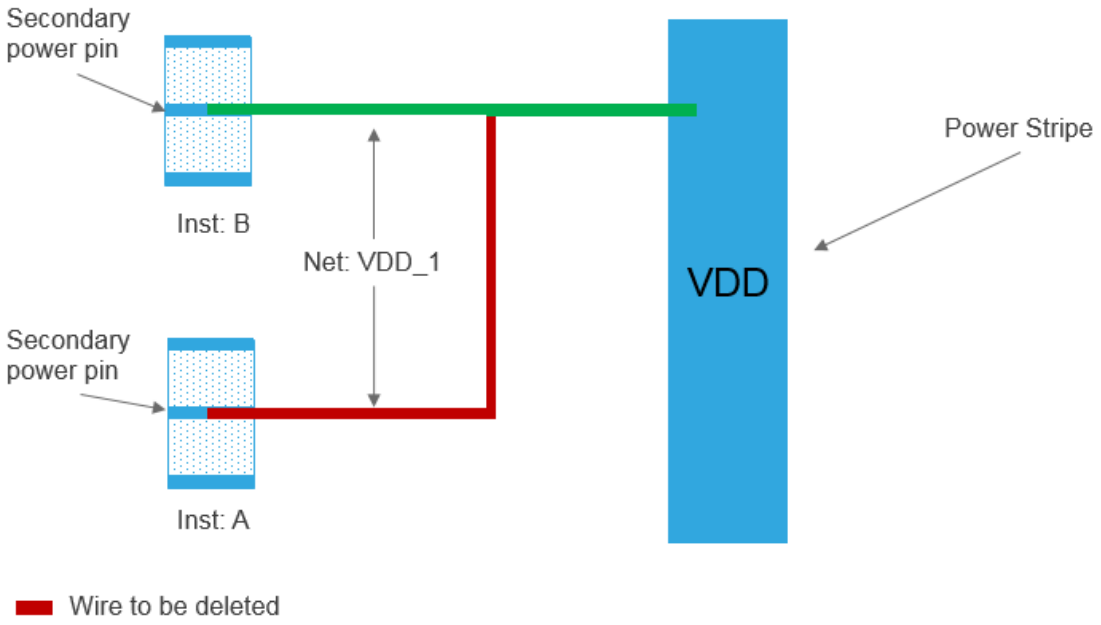
Note: This command does not support dangling secondary P/G nets.

Parameters

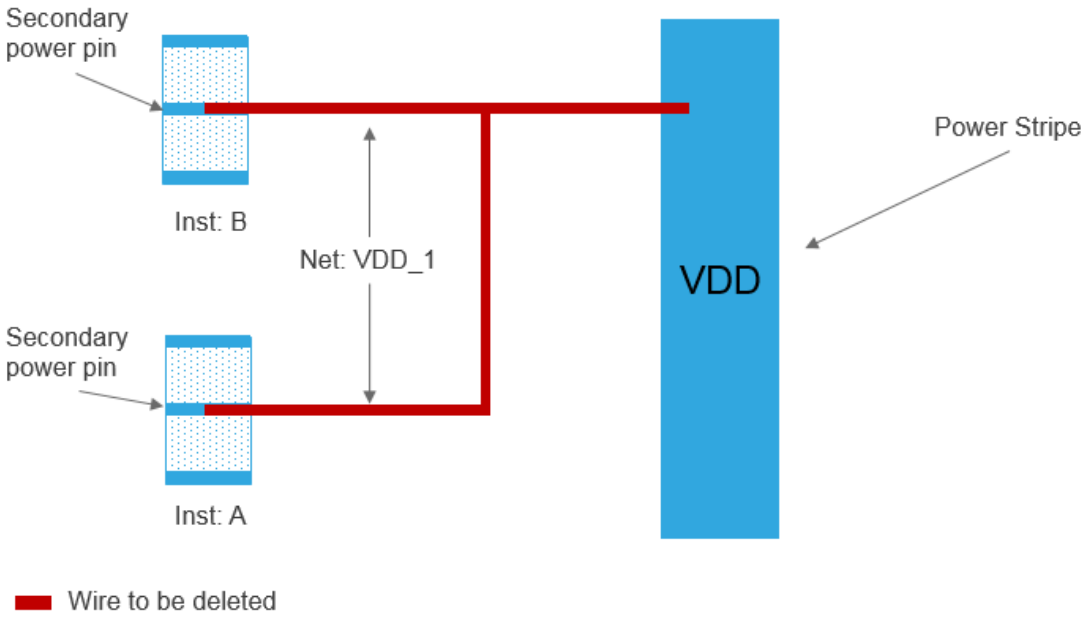
`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man delete_secondary_pg_net`
`-insts inst+`	Specifies the list of instances that have a secondary PG pin. Wildcards are supported in instance names. If one or more specified instances does not connect with the specified net, the tool displays a warning and ignores those instances. *Data_type*: (inst)+, required
`-net net_name`	Specifies the net name. **Note**: *net_name* does not take any wildcard values. *Data_type*: (net), required

Examples

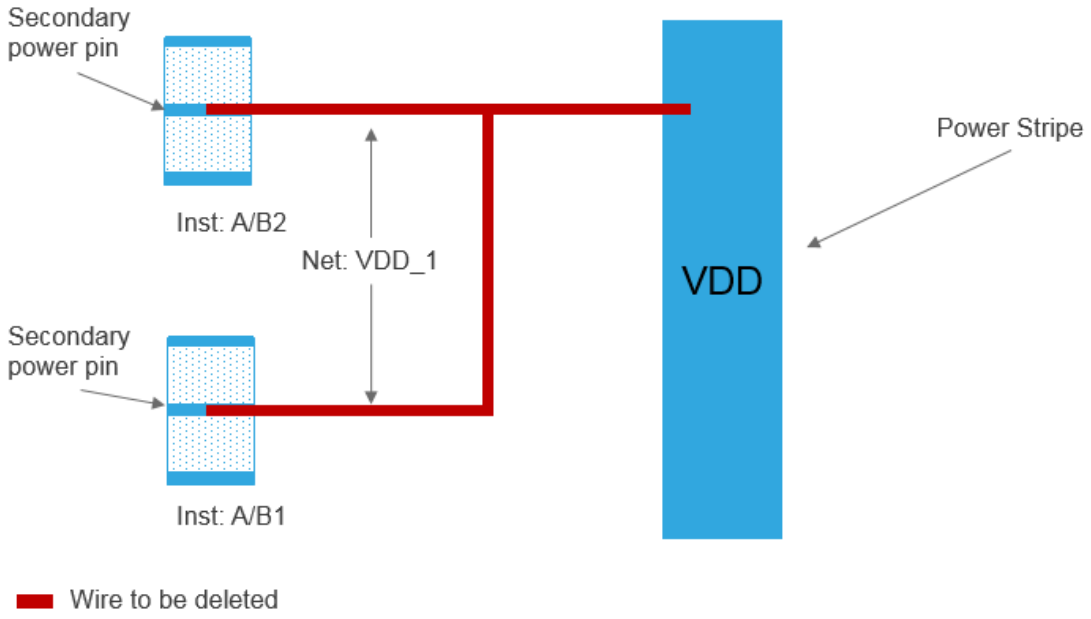
- The following command deletes the routing from the instance `A` P/G pin in net `VDD_1` to the power stripe:
  ```
  delete_secondary_pg_net -net VDD_1 -insts {A}
  ```



- The following command selects the routing from the P/G pins in instances `A` and `B` in net `VDD_1` to the power stripe:
```
delete_secondary_pg_net -net VDD_1 -insts {A B}
```



- The following command selects the routing from the P/G pins in instances `A/B1` and A/B2 in net `VDD_1` to the power stripe:
```
delete_secondary_pg_net -net VDD_1 -insts {A/*}
```



Related Information

deselect_routes

```
deselect_routes
[-help]
[-area {x1 y1 x2 y2}]
[-direction {h | v | 45 | 135}]
[-floating_via]
[-layer list_of_layers]
[-nets net*]
[-physical_pin_only]
[-regular_wire_with_drc]
[-shapes {ring stripe followpin iowire corewire blockwire padring blockring fillwire fillwireopc
drcfill none}]
[-shield]
[-shield_only]
[-status {cover fixed noshield routed shield}]
[-sub_class sublass_name]
[-type {regular special patch}]
[-use {clock power signal}]
[-via_cell cell_name_list]
[-with_edit_flag {0 | 1}]
[-obj_type {wire via} ]
[-from_pin pin_name -to_pin pin_name]
```

Deselects wires and vias based on specified parameters. Use this command when nets are selected.

Note - You can use this command to deselect nets by property. For example, to delete all signal nets except clock nets, select all signal nets with `select_routes`, deselect the clock nets with this command, then delete the selected nets with `delete_routes`.

Parameters

`-help`	Prints a brief description that includes type and default information for each `deselect_routes` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man deselect_routes`
`-area {x1 y1 x2 y2}`	Specifies the coordinates for the area from which to deselect wires and vias. *Data_type*: rect, optional

`-direction {h | v | 45 | 135}`	Specifies the orientation of the wires to deselect. *Default:* If you do not specify this parameter, deselects wires in any orientation. • `h`: Specifies that horizontal wires are to be deselected. • `v`: Specifies that vertical wires are to be deselected. • 45: Specifies that 45-degree wires are to be deselected. • 135: Specifies that 135-degree wires are to be deselected. *Data_type*: enum, optional
`-floating_via`	Specifies that only floating vias are to be deselected. A via, or a stack of vias, is floating, if it is not connected to another object, wire, pin, or via, on either its top or bottom metal layer or on both these layers. *Data_type*: bool, optional
`-from_pin` *pin_name*	Specifies the name of the starting pin of the wire to be deselected. The starting pin you specify should be connected to the same net as the ending pin specified with `-to_pin`. If they connect to different nets, the tool reports an error. **Note**: Deselection of wires between specified pins is supported only for signal and clock nets. *Data_type*: string, optional
`-layer` *list_of_layers*	Specifies the layers from which to deselect wires and vias. If you specify multiple layers, enclose the layer names in braces. *Default:* If you do not specify this parameter, deselects wires and vias from all layers. *Data_type*: string, optional
`-nets` *net**	Specifies the net names from which to deselect wires and vias. This option supports backside and Through Silicon Via (TSV) layers as well. **Note:** You can use wildcard values in this field. For example, if you specify `V*`, deselects wires and vias from nets `VDD` and `VSS`. *Data_type*: (net)*, optional
`-obj_type {wire via}`	Specifies whether wires or vias or both should be deselected. If the parameter is not specified, only wires are deselected. *Default*: `wire` *Data_type*: (enum)+, optional

`-physical_pin_only`	Specifies that physical pins are to be deselected. By default, `deselect_routes` does not deselect physical pins. You can use the `-physical_pin_only` parameter along with `-area`, `-layer`, or `-nets` to deselect the physical pins in the specified area, layer, or net, respectively. *Data_type*: bool, optional
`-regular_wire_with_drc`	Deselects regular wires with violation markers. *Data_type*: bool, optional
`-shapes {ring stripe followpin iowire corewire blockwire padring blockring fillwire fillwireopc drcfill none}`	
	Specifies the shapes of the wires and vias to be deselected. If you specify multiple shapes, enclose the list of shapes in braces. For shape definitions, see *Shapes,* in the "DEF Syntax" chapter of theLEF/DEF Language Reference. *Default:* If you do not specify this parameter, deselects wires of all shapes. *Data_type*: (enum)+, optional
`-shield`	Deselects the wires and vias of the nets specified with the `-nets` parameter, along with the wires and vias shielding the specified nets. **Note**: This parameter cannot be used with `-shield_only`. *Data_type*: bool, optional
`-shield_only`	Deselects only the shield wires associated with the nets specified using the `-nets` parameter. The signal nets being shielded are remain selected. **Note**: This parameter cannot be used with `-shield`. *Data_type*: bool, optional
`-status {cover fixed noshield routed shield unknown}`	
	Specifies the status of the wires and vias to be deselected. Use all upper-case letters for the status. If you specify more than one status, enclose the status list in curly braces. **Note:** If you select `-type special -status noshield` or `-type signal -status shield` the software generates an error message. *Data_type*: (enum)+, optional

`-sub_class` *`sublass_name`*	Specifies the subclass name of the wires to be deselected. Use this parameter if you want to deselect wires or vias belonging to a specific subclass. Here, *`subclass_name`* is a user-defined attribute that has been previously defined using the `-user_class` parameter of the `add_split_power_vias`, `add_rings`, `add_stripes`, or `route_special` command. For wires, use this parameter if you want to deselect rings, stripes, or other wires belonging to a specific subclass. **Note:** You can use wildcards in *`subclass_name`*. *Data_type*: string, optional
`-to_pin` *`pin_name`*	Specifies the name of the ending pin of the wire to be deselected. The ending pin you specify should be connected to the same net as the starting pin specified with `-from_pin`. If they connect to different nets, the tool reports an error. In addition, the from and to pins you specify should be connected to the same wire. If there there are more than one wire or via between the specified starting and ending pins, the command is not able to deselect the wire path and returns an error. The `-from_pin` and `-to_pin` parameters are compatible with only the `-direction`, `-layer`, `-object_type`, and `-status` options of the `deselect_routes` command. If you use `-from_pin` and `-to_pin` with any other `deselect_routes` parameters, the tool returns an error. **Note**: Deselection of wires between specified pins is supported only for signal and clock nets. *Data_type*: string, optional
`-type {regular special patch}`	Specifies whether to deselect regular wires and vias, special wires and vias, or patch wires. **Note:** If you specify `regular`, you must omit the `-shapes` parameter or specify `-shapes none`. *Data_type*: enum, optional
`-use {clock power signal}`	Specifies whether to select only CLOCK wires/vias, POWER wires, or SIGNAL wires. *Data_type*: enum, optional
`-via_cell` *`cell_name_list`*	Specifies the via cells of the vias to be deselected. You can use wildcards while specifying via cell names. If you are specifying multiple cell names, enclose them in braces. *Data_type*: string, optional

`-with_edit_flag {0 | 1}`	Deselects all modified wires and vias, that is wires and vias with value `1` for the `isEdit` property on the net. **Notes** • As the `isEdit` property is added on the whole net, all the wires and vias on the net with `isEdit` value set to `1` will be deselected. • The `isEdit` property is used to flag nets with modified wires and vias. This is useful when evaluating how many objects need to be modified for fixing DRC violations and then deciding whether to fix the violations manually or through ECO routing. The `isEdit` property is controlled through the `edit_wire_create_is_edit_flag` root attribute in the `edit_wire` category. By default, this attribute is set to `false`. If you set the value of this attribute to `true`, the `isEdit` property is set to `1` for nets with modified wires or vias. *Data_type*: enum, optional

Examples

- The following command deselects all horizontal fillwires on the *METAL1* layer:
  ```
  deselect_routes -layers METAL1 -direction h -shapes fillwire
  ```
- The following command deselects all vias:
  ```
  deselect_routes -obj_type via
  ```
- The following command deselects all wires:
  ```
  deselect_routes
  ```
- The following command deselects all wires and vias:
  ```
  deselect_routes -obj_type {wire via}
  ```

deselect_secondary_pg_net

```
deselect_secondary_pg_net
[-help]
-insts inst+
-net net
```

Deselects Power/Ground (P/G) net wire segments from specified instances. This command provides an easy way to deselect the routing from specific instance P/G pins to stripes.

Note: This command does not support dangling secondary P/G nets.

Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man deselect_secondary_pg_net`
`-insts inst+`	Specifies the list of instances that have a secondary PG pin. Wildcards are supported in instance names. If one or more specified instances does not connect with the specified net, the tool displays a warning and ignores those instances. *Data_type*: (inst)+, required
`-net net_name`	Specifies the net name. **Note**: *net_name* does not take any wildcard values. *Data_type*: (net), required

Examples

- The following command deselects the routing from the P/G pin in instance `A` of net `VDD_1` to the power stripe:
  ```
  deselect_secondary_pg_net -net VDD_1 -insts {A}
  ```
- The following command deselects the routing from the P/G pins in instances `A` and `B` in net `VDD_1` to the power stripe:
  ```
  deselect_secondary_pg_net -net VDD_1 -insts {A B}
  ```
- The following command deselects the routing from the P/G pins in instances `A/B1` and A/B2 in net `VDD_1` to the power stripe:
  ```
  deselect_secondary_pg_net -net VDD_1 -insts {A/*}
  ```

edit_add_polygon_point

```
edit_add_polygon_point
[-help]
point
```

Defines a vertex or corner of a polygon. By issuing the `edit_add_polygon_point` command `n` times, you can create a polygon with `n+1` sides. You can then specify the `edit_end_polygon_point` command to end the polygon at the specified coordinates. `edit_add_polygon_point` honors the `edit_wire_shape` root attribute. This means if you want to create a polygon of a specific shape, you can first use `edit_wire_shape` to specify the required shape and then use `edit_add_polygon_point` and `edit_end_polygon_point` to create the polygon.

The `edit_add_polygon_point` command is DRC aware. When you create a polygon shape using this command, the tool marks any DRC violations in the shape during creation, provided that `edit_wire_drc_on` is set to `true` (default).

Parameters

`-help`	Prints a brief description that includes type and default information for each `edit_add_polygon_point` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man edit_add_polygon_point`
`point`	Specifies the `x` and `y` coordinates of a corner of a wire polygon. *Data_type*: point, required

Example

- The following commands create three-sided wire polygon that ends at the point specified by `edit_end_polygon_point`.

  ```
  edit_add_polygon_point 700 300
  edit_add_polygon_point 700 500
  edit_end_polygon_point 200 400
  ```

  The first side of the wire polygon starts at `700, 300` and ends at `700, 500`. The second side starts at `700, 500` and ends at `200, 400`. The third side is formed by joining the starting point of the polygon (`700,300`) and the ending point specified by `edit_end_polygon_point` (`200,400`).

  - *Wire* section

edit_add_route_point

```
edit_add_route_point
[-help]
point
```

Creates a wire segment that starts or ends at the specified coordinates. Splits diagonal wires whose width is greater than the LEF `MAXWIDTH` parameter for that layer as they are drawn.

If required, the tool allows you to change the net order while adding wire segments. Check the **Examples** sections for details.

If you do not want to view flight lines between Power and Ground (PG) wires and pins when drawing PG nets, use `set_layer_preference flightLine -is_visible 0` to turn off the display of these flightlines. `edit_add_route_point` as well as `edit_end_route_point` honor this setting.

Parameters

`-help`	Prints a brief description that includes type and default information for each `edit_add_route_point` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man edit_add_route_point`
`point`	Specifies the `x` and `y` coordinates for the start point or end point of the wire segment. Note that if the points you specify with each successive `edit_add_route_point` command are not aligned vertically or horizontally, the tool adjusts the coordinates to align the end point of one segment with the start point of the next segment. *Data_type*: point, required

Examples

- The following commands create wire segments that start and stop at the specified points. The complete wire ends at the point specified by `edit_end_route_point`.

```
edit_add_route_point 33.392 36.831    #Start of first wire segment
edit_add_route_point 32.985 32.766    #End of first wire segment, start of second
edit_add_route_point 18.064 32.115    #End of second wire segment
edit_add_route_point 20.951 27.073    #End of third wire segment
edit_end_route_point 20.992 27.114 #End of wire
```

- Use the following set of commands to add wire segments with different orders of nets:

```
gui_set_tool addWire
set_db edit_wire_layer_horizontal M10
set_db edit_wire_nets { a b c d e f}
set_db edit_wire_wire_override_spec {{1 0.062 0.128} {2 0.062 0.1900} {3 0.062 0.128} {4 0.062
0.1900} {5 0.062 0.128} {6 0.062 0.1900} }
edit_add_route_point {1000 2500}
edit_add_route_point {1100 2500}

set_db edit_wire_layer_vertical M9
#Change Net Order
set_db edit_wire_nets { a c b d f e}
set_db edit_wire_wire_override_spec {{1 0.082 0.228} {2 0.082 0.2900} {3 0.082 0.228} {4 0.082
0.6680} {5 0.082 0.228} {6 0.082 0.2900} }
edit_add_route_point {1100 2600}
edit_end_route_point {1100 2600}
```

edit_add_trim_metal

```
edit_add_trim_metal
[-help]
[-layer string]
-location {x y}
[-mask integer]
[-snap_to_end]
```

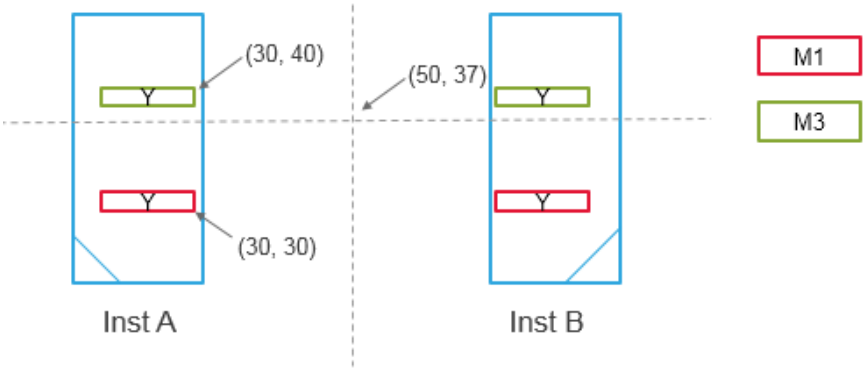
Adds trim metal at the specified location.

Parameters

`-help`	Prints a brief description that includes type and default information for each `edit_add_trim_metal` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man edit_add_trim_metal`
`-layer string`	Specifies the layer on which the trim metal is to be added. The layer name should be a routing layer defined in the LEF file. Note that you can specify only one valid layer name. That is, a layer name list is not supported. If the `-layer` option is not specified, `editAddTrimMetal` adds the trim metal on the nearest object. Check the **Examples** section below to see how to use this option. *Data_type*: string, optional
`-location {x y}`	Specifies the coordinates for the center point of the trim metal. The tool may adjust automatically to the closest location that is best for the trim metal. *Data_type*: point, required
`-mask integer`	Specifies the mask value for the trim metal. However, if `USEMETALMASK` is already defined for the trim layer in the tech LEF, you cannot define the mask value here. *Data_type*: int, optional
`-snap_to_end`	Specifies that the trim metal should be snapped to the closest end of the selected pin or wire. *Data_type*: bool, optional

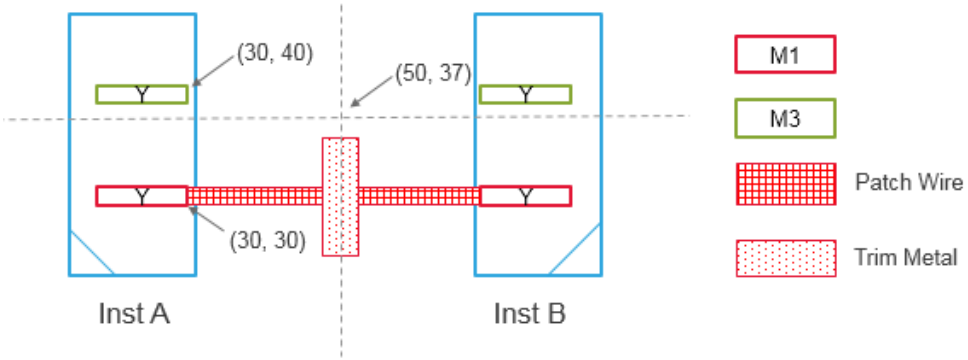
Examples

In the following illustration, the pin Y has two pin shapes, one on `M1` and the other on `M3`. The Pin Y on Inst A is selected.



- If you add trim metal with the `-layer` option (as specified below), the tool will add the trim metal on the pin shape that is on layer `M1`.

  ```
  edit_add_trim_metal -layer M1 -location {50 37}
  ```



- If you add trim metal without the `-layer` option (as shown in the command below), the tool will add the trim metal on the nearest pin, which in this case is on `M3`.

  ```
  edit_add_trim_metal -location {50 37}
  ```

edit_adjust_routes

```
edit_adjust_routes
[-help]
[-adjust_size]
-refer_obj {top bottom left right}
{[-align_edge {left center right top middle bottom diag45_top diag45_middle diag45_bottom diag135_top
diag135_middle diag135_bottom}]
 [-space_mode {horizontal vertical dist_horizontal dist_vertical diag45 diag135 dist_diag45
dist_diag135}
   [-space float_value]]}
```

Aligns wires and pins on the basis of the specified options. The following objects can be aligned using this command:

- Regular, special, and patch wires
- Physical pins
- Macro pins

The `edit_adjust_routes` command enables you to align objects in one or both of the following modes:

- Align by edge: Use the `-align_edge` parameter to align objects with the reference object by the specified edge.
- Align with spacing: Use the `-space_mode` parameter to adjust the spacing between objects.

Parameters

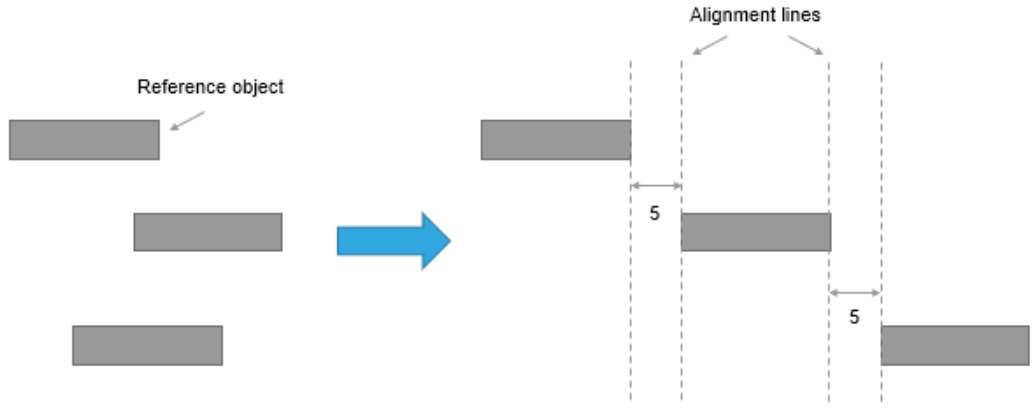
`-help`	Prints a brief description that includes type and default information for each `edit_adjust_routes` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man edit_adjust_routes`
`-adjust_size`	Resizes the objects being aligned to match the reference object. If `-align_edge` is specified, the specified edge of the objects is stretched or shrunk to align with the edge of the reference object. If `-space_mode` is specified, the objects being aligned are resized to be equal to the reference object. *Data_type*: bool, optional
`-align_edge {left center right top middle bottom diag45_top diag45_middle diag45_bottom diag135_top diag135_middle diag135_bottom}`	
	Specifies the edge by which the objects should be aligned with the reference object. *Data_type*: enum, optional
`-refer_obj {top bottom left right}`	

	Specifies the object of reference for alignment. For example, `-refer_obj left` means that objects should be aligned with reference to the leftmost object. This option is mandatory. *Data_type*: enum, required
`-space` *`float_value`*	Specifies the spacing value for aligning objects in the space mode. This option can be specified only if `-space_mode` is specified. *Data_type*: float, optional
`-space_mode {horizontal vertical dist_horizontal dist_vertical diag45 diag135 dist_diag45 dist_diag135}`	
	Specifies that objects should be aligned in the space mode. In this mode, the objects are aligned such that there is equal spacing between them. You can specify one of the following space mode options: • `horizontal` - Aligns the objects such that the horizontal spacing between them is equal to the value specified with `-space`. • `vertical` - Aligns the objects such that the vertical spacing between them is equal to the value specified with `-space`. • `dist_horizontal` - Distributes the objects horizontally. • `dist_vertical` - Distributes the objects vertically. • `diag45` - Aligns the objects in the 45-degree direction such that the spacing between them is equal to the value specified with `-space`. • `diag135` - Aligns the objects in the 135-degree direction such that the spacing between them is equal to the value specified with `-space`. • `dist_diag45` - Distributes the objects in the 45-degree direction. • `dist_diag135` - Distributes the objects in the 135-degree direction. *Data_type*: enum, optional

Example

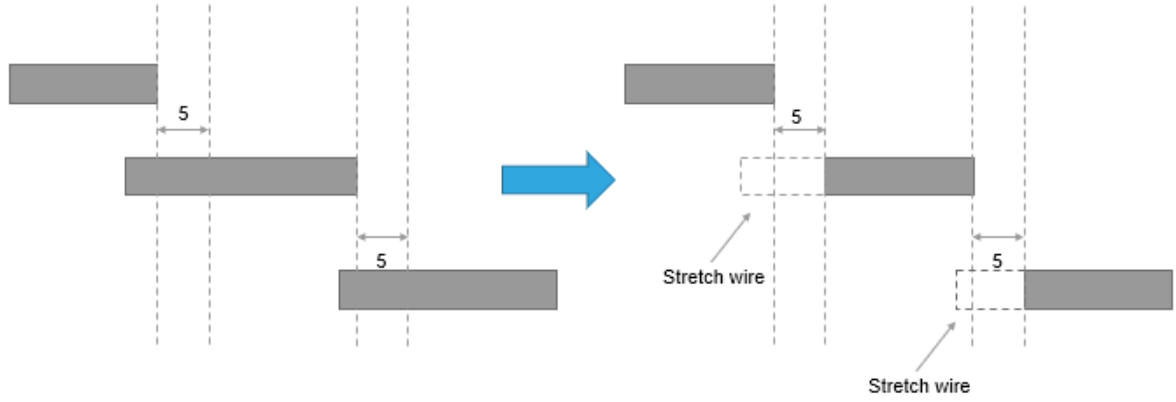
- The following command uses the leftmost object as reference and aligns the wires in the horizontal direction in the space mode with a spacing of 5 units:

```
edit_adjust_routes -space_mode horizontal -spacing 5 -refer_obj left
```



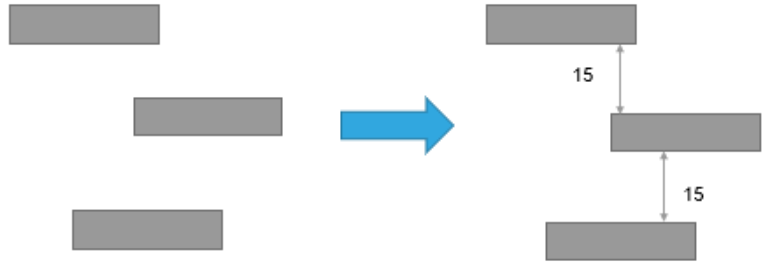
- The following command uses the leftmost object as reference and aligns the wires in the horizontal direction in the space mode with a spacing of 5 units. The command also resizes the objects being aligned to match the reference object:

```
edit_adjust_routes -space_mode horizontal -spacing 5 -refer_obj left -adjust_size
```



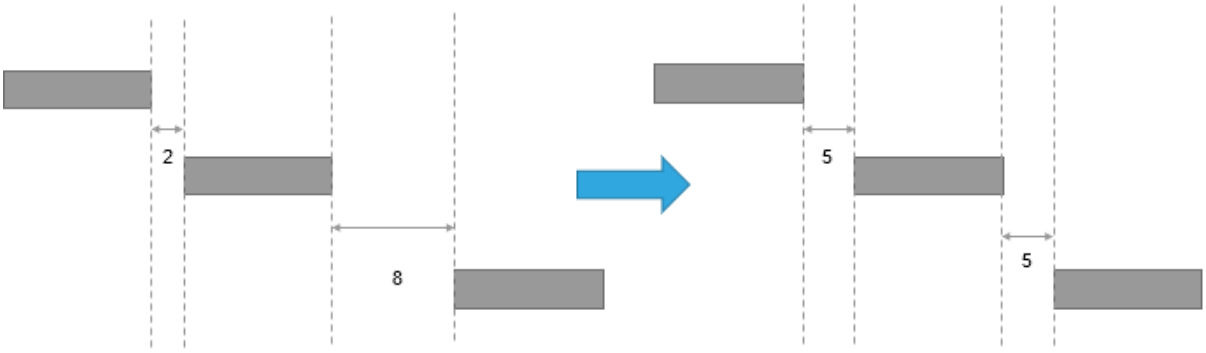
- The following command uses the leftmost object as reference and aligns the wires in the vertical direction in the space mode with a spacing of 15 units:

```
edit_adjust_routes -space_mode vertical -spacing 15 -refer_obj left
```

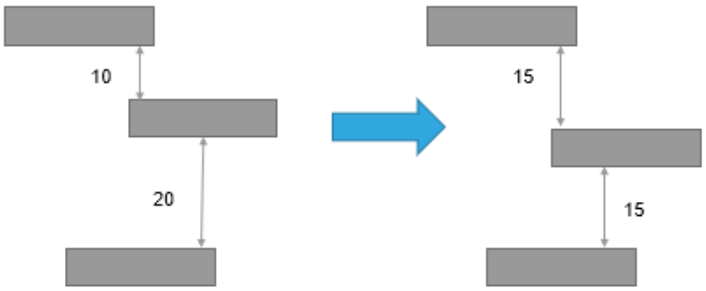


- The following command uses the leftmost object as reference and distributes the wires horizontally:

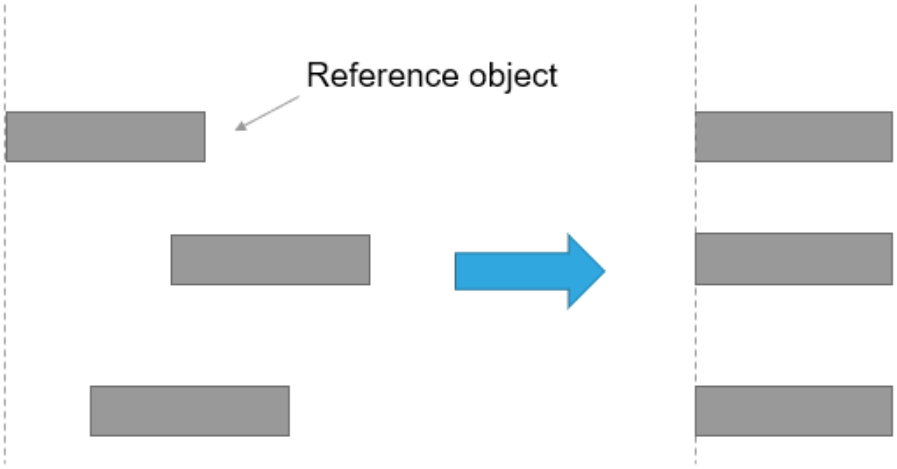
```
edit_adjust_routes -space_mode dist_horizontal -refer_obj left
```



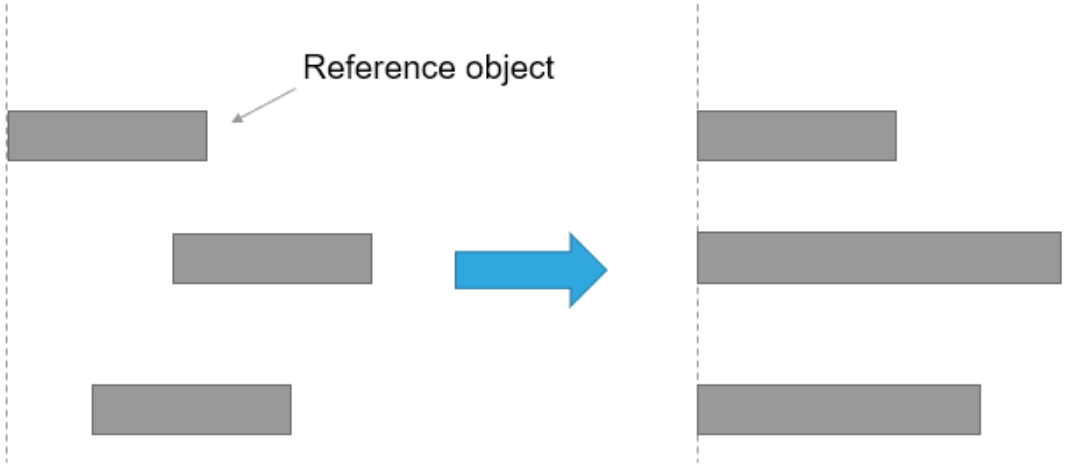
- The following command uses the leftmost object as reference and distributes the wires vertically:
  ```
  edit_adjust_routes -space_mode dist_vertical -refer_obj left
  ```



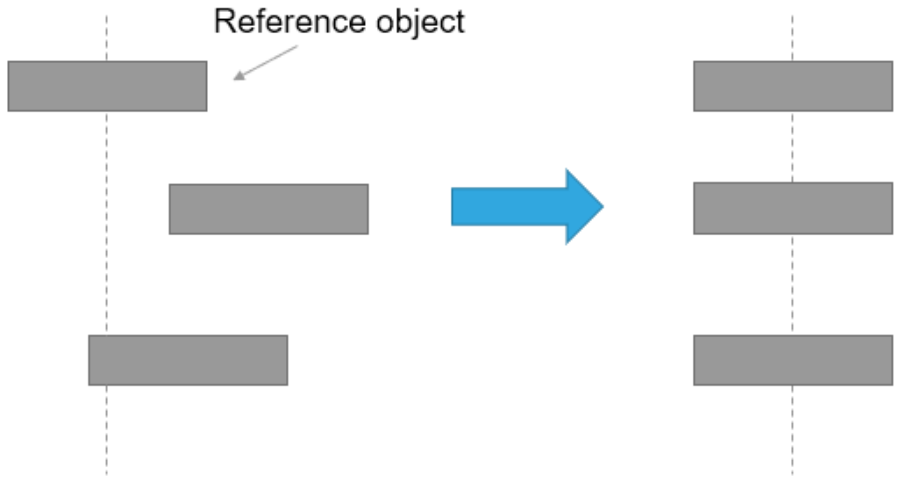
- The following command aligns the left edge of all the wires using the leftmost object as reference:
  ```
  edit_adjust_routes -align_edge left -refer_obj left
  ```



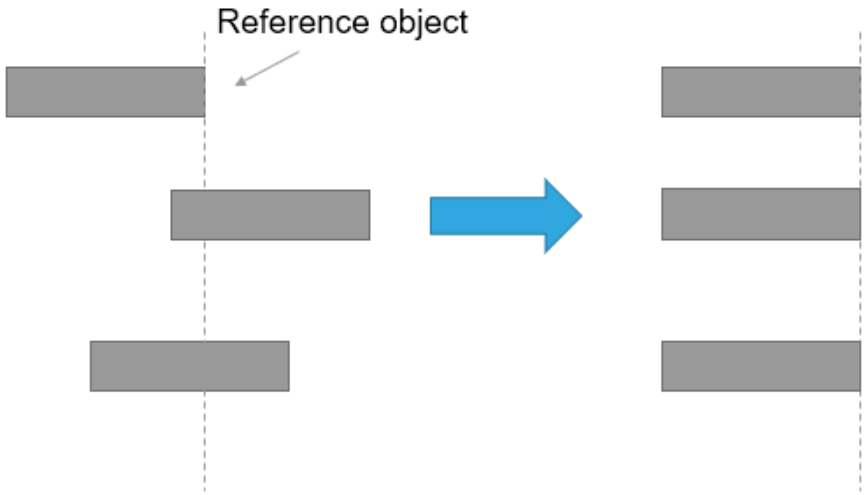
- The following command uses the leftmost wire as reference and resizes the other wires so that their left edges align with the left edge of the reference wire:
  ```
  edit_adjust_routes -align_edge left -refer_obj left -adjust_size
  ```



- The following command aligns the center of all the wires using the leftmost object as reference:
  ```
  edit_adjust_routes -align_edge center -refer_obj left
  ```

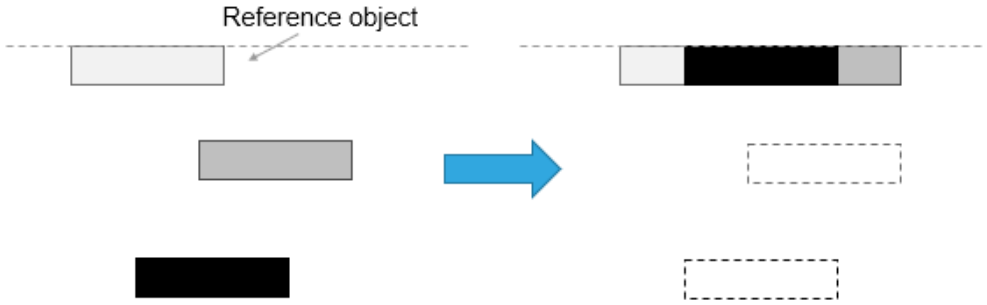


- The following command aligns the right edge of all the wires using the leftmost object as reference:
  ```
  edit_adjust_routes -align_edge right -refer_obj left
  ```



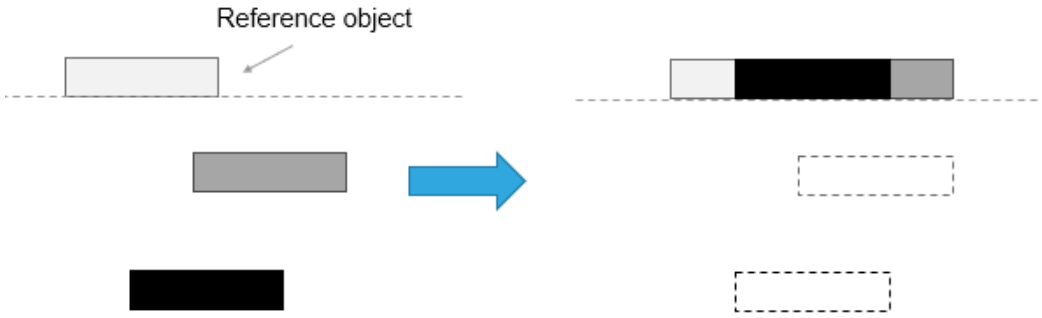
- The following command aligns the top edge of all the wires using the leftmost object as reference:

```
edit_adjust_routes -align_edge top -refer_obj left
```



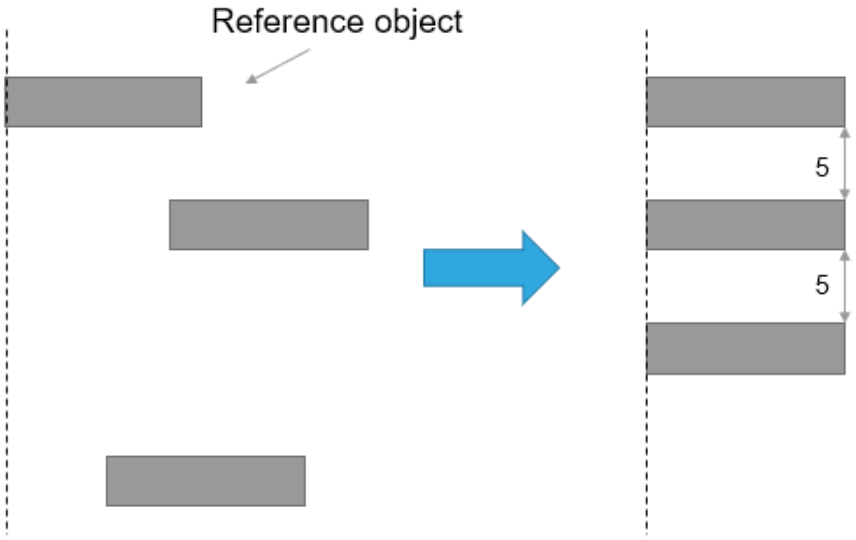
- The following command aligns the bottom edge of all the wires using the leftmost object as reference:

```
edit_adjust_routes -align_edge bottom -refer_obj left
```



- The following command uses the leftmost object as reference and aligns the left edge of all the wires, keeping a spacing of 5 units between the wires in the vertical direction:

```
edit_adjust_routes -align_edge left -space_mode vertical -spacing 5 -refer_obj left
```



- The following command uses the leftmost object as reference and aligns the wires in the 135-degree direction in the space mode with a spacing of 5 units:

```
edit_adjust_routes -space_mode diag135 -space 5.0 -refer_obj left
```

edit_create_via

```
edit_create_via
[-help]
point
```

Creates a via instance and places the origin at the specified coordinates. The origin of the instance's via cell may or may not be at its center. Specify the via parameters with the attributes in the `edit_wire_via` category.

Parameters

`-help`	Prints a brief description that includes type and default information for each `edit_create_via` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man edit_create_via`
point	Specifies the `x` and `y` coordinates of the via origin. *Data_type*: point, required

Example

- The following command adds a via with origin at coordinates `550, 675`:
  ```
  edit_create_via 550 675
  ```

edit_cut_route

```
edit_cut_route
[-help]
[-only_visible_wires]
[-selected]
{-lines {x1 y1 x2 y2 ...} | -box {x1 y1 x2 y2} }
```

Cuts wires, bus guides, or rectangles at the specified location. You can choose to cut by line (using the `-lines` parameter) or by box (using the `-box` parameter. `edit_cut_route` honors `edit_wire_cut_wire_overlap` settings.

Patch wires are also supported.

Parameters

`-help`	Prints a brief description that includes type and default information for each `edit_cut_route` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man edit_cut_route`
`-box {x1 y1 x2 y2}`	Specifies the lower-left and upper-right coordinates of the box for cutting wires, bus guides, or rectangles. The `-box` option currently has the following limitations: • The cut-box must be a rectangle (or square). A polygon shape will be ignored. • Only the wires that are perpendicular to the cut-box edge are cut. In addition, the cut-box edge must pass across the wire, bus guide, or rectangle completely. • This option can be used to cut only horizontal and vertical wires. 45-degree wires are not yet supported. *Data_type*: rect, optional
`-lines {x1 y1 x2 y2 ...}`	Specifies the start and end coordinates of one or more line segments for cutting wires, bus guides, or rectangles. If you specify multiple cut-line segments, they should be parallel to each other. For instance, you cannot specify one horizontal cut-line and one vertical cut-line with the `-lines` parameter. If you do, the tool reports the following error: `Cut lines are not parallel.` In addition, a cut-line must cut across the wire, bus guide, or rectangle

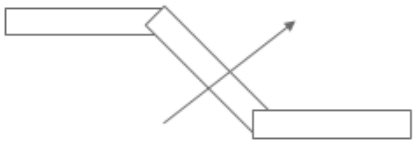
from one edge to the other. Once cut, the signal wire pieces maintain a one-half wire-width extension. Special wires do not maintain an extension.

When you run `edit_cut_route`, the tool snaps the cut-line to the manufacturing grid automatically. The change in coordinates is displayed at the prompt as a warning such as follows:

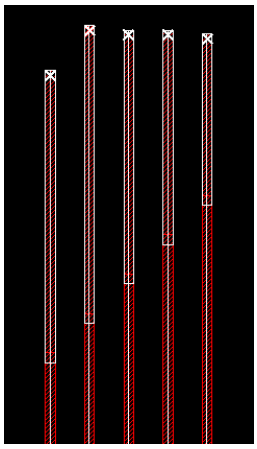
```
WARNING: Cut-line is auto-snapped from (966.343500 1227.245500
966.811500 1227.245500) to (966.345000 1227.245000 966.810000
1227.245000).
```

Note that the tool records only the cut-line coordinate before snapping in the log file.

Note: The `-lines` option supports 45-degree wire edits.



In addition, you can also draw a 45-degree cut-line to cut a group of wires in a stair pattern as shown below:



Both regular and special wires can be cut with a 45-degree cut-line. However, patch wires cannot be cut in this way. When you use a 45-degree cut-line, the wires are cut from the touch point of the center line. You can use a single 45-degree cut-line to cut wires in different directions as shown below:

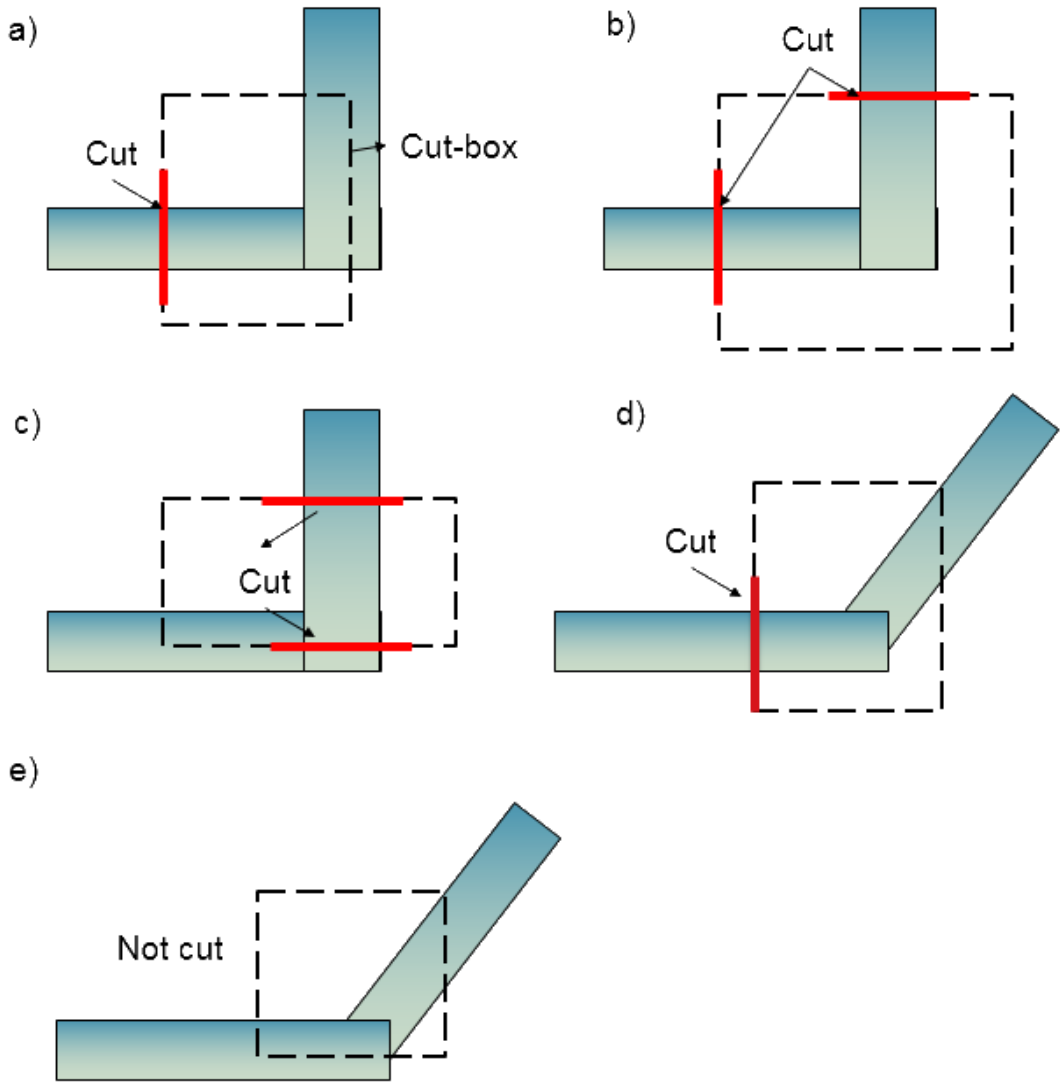
	 *Data_type*: (rect)+, optional
`-only_visible_wires`	Specifies that only the wires on the visible layers are cut. If this parameter is not specified, the tool cuts all the wires overlapping with the cut-line or box. *Data_type*: bool, optional
`-selected`	Specifies that only the selected wires, bus guides, or rectangles should be cut. *Data_type*: bool, optional

Examples

- The following command cuts the wires through which the specified cut-line passes:
  ```
  edit_cut_route -lines {200 300 200 310}
  ```
- Consider the wire depicted below:

  
  The following command cuts the wire, along the specified 45-degree cut-line segments, `{95.30 -641.16 95.39 -641.08}` and `{95.69 -641.17 95.78 -641.08}`:
  ```
  edit_cut_route -lines {95.30 -641.16 95.39 -641.08 95.69 -641.17 95.78 -641.08}
  ```

- The following diagrams show examples of using a cut-box to cut wires:
  - In a), the horizontal wire is cut. The vertical wire is not cut because the cut-box edges that are perpendicular to the wire do not pass through it completely.
  - In b), both the horizontal and vertical wires are cut.
  - In c), the vertical wire is cut at the two places where the perpendicular edges of the cut-box pass through it completely. The horizontal wire is not cut.
  - In d), the horizontal wire is cut. The 45-degree wire is not cut because 45-degree wire edits are not yet supported while cutting by box.
  - In e), no cuts are made.



a)
Cut
Cut-box
b)
Cut
c)

edit_duplicate_routes

```
edit_duplicate_routes
[-help]
[-layer_horizontal layer]
[-layer_vertical layer]
```

Copies the geometry of selected special wires and pastes them at the same coordinates. If you do not specify a layer, the software pastes them onto the same layer. If you specify a layer, the software copies them to the specified layer and generates vias to maintain connectivity for the duplicated wire.

After duplicating the wires, the software selects the new wires and deselects the original wires. Use the `edit_move_routes` command to move duplicated wires to new locations.

Note: Use the `select_routes` command to select wires.

Parameters

`-help`	Prints a brief description that includes type and default information for each `edit_duplicate_routes` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man edit_duplicate_routes`
`-layer_horizontal` *layer*	Specifies the new layer for duplicated horizontal wires. *Data_type*: string, optional
`-layer_vertical` *layer*	Specifies the new layer for duplicated vertical wires. *Data_type*: string, optional

Example

- The following command duplicates selected horizontal wires and places them on the *METAL3* layer and duplicates selected vertical wires and places them on the *METAL4* layer. It generates vias for the new wires.
  ```
  edit_duplicate_routes -layer_horizontal METAL3 -layer_vertical METAL4
  ```

    - *Wire* section

edit_end_polygon_point

```
edit_end_polygon_point
[-help]
point
```

Ends a newly created polygon at the specified coordinates. Use this command after at least one `edit_add_polygon_point` command has been issued.

Parameters

`-help`	Prints a brief description that includes type and default information for each `edit_end_polygon_point` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man edit_end_polygon_point`
point	Specifies the `x` and `y` coordinates for the end point of a newly created wire polygon. *Data_type*: point, required

Example

- The following commands create three-sided wire polygon that ends at the point specified by `edit_end_polygon_point`.

  ```
  edit_add_polygon_point 700 300
  edit_add_polygon_point 700 500
  edit_end_polygon_point 200 400
  ```

  The first side of the wire polygon starts at `700, 300` and ends at `700, 500`. The second side starts at `700, 500` and ends at `200, 400`. The third side is formed by joining the starting point of the polygon (`700,300`) and the ending point specified by `edit_end_polygon_point` (`200,400`).

edit_end_route_point

```
edit_end_route_point
[-help]
point
```

Ends a newly created wire segment at the specified coordinates. Splits diagonal wires whose width is greater than the LEF `MAXWIDTH` parameter for that layer as they are drawn. Use this command after at least one `edit_add_route_point` command has been issued.

Parameters

`-help`	Prints a brief description that includes type and default information for each `edit_end_route_point` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man edit_end_route_point`
`point`	Specifies the `x` and `y` coordinates for the end point of a newly created wire segment. *Data_type*: point, required

Example

- The following commands create a wire that ends at the point specified by `edit_end_route_point`:

```
edit_add_route_point 33.392 36.831
edit_add_route_point 32.985 32.766
edit_add_route_point 18.064 32.115
edit_add_route_point 20.951 27.073
edit_end_route_point 20.992 27.114
```

edit_merge_routes

```
edit_merge_routes [-help]
```

Merges all wires of the same width, layer, and net that are colinear with and electrically connected to a selected wire. Does not merge signal wires that contain branches. This command also supports 45-degree wire edits.

This command can also be used to merge selected bus guides.

Note: Use the `select_routes` command to select the wire. Use the `select_obj` command to select bus guides or segments.

Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man edit_merge_routes`

edit_move_routes

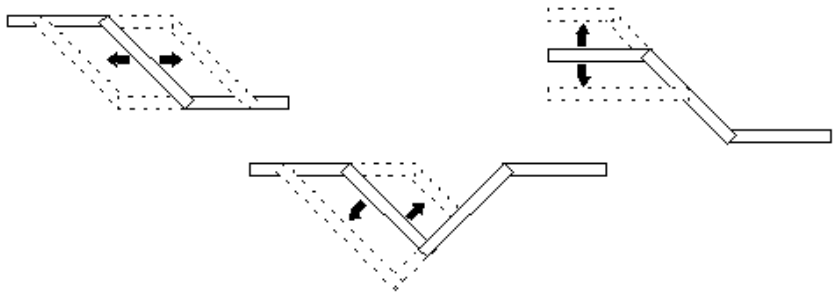
```
edit_move_routes
[-help]
{[[-direction {x y diag45 diag135} -distance double ] | [-dx double -dy double] | -to {x y}] }
```

Moves selected wires or boundary pins.

Moving Wires

`edit_move_routes` moves selected wires in the orthogonal direction. When used with the `-direction` and `-distance` or `-dx` and `-dy` combination, `edit_move_routes` maintains connectivity by stretching connected wires in the orthogonal direction. This command also supports 45 and 135-degree wire edits.

Move 45-degree wire segments while maintaining connectivity



Use the `edit_wire_connect_with_specified_layer` root attribute to control whether layer preference settings are honored when wires are moved. The default value of this parameter is `false`. If you set this parameter to `true`, `edit_move_route` honors the `edit_wire_layer_horizontal` and `edit_wire_layer_vertical` settings while jogging metal layers. For instance, if you cut a vertical wire on `M4` by using `edit_cut_route` such that the wire is divided into three wire segments and then move the wire segment in the middle in the horizontal direction, the tool automatically creates new connecting wires on the layer defined by `edit_wire_layer_horizontal` and drops vias correctly. This means you no longer need to perform the additional step for layer change (`edit_update_route_layer` or `Shift+L`) while moving wires to create a jog. This feature is applicable for both regular and special wires.

To get the current value of the `edit_wire_connect_with_specified_layer` parameter, you can use the `get_db` command.

Note: You can use the `set_db edit_wire_snap_end_to track_regular` and `set_db edit_wire_snap_end_to track_special` commands to specify whether or not to snap wires to the track. To get the current values of these attributes, use `get_db`.

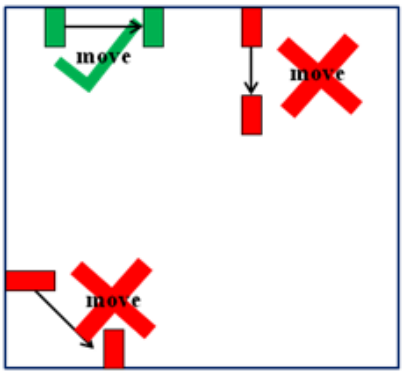
Moving Physical Pins

`edit_move_routes` moves selected physical pins along with connected wires.

Keep the following considerations in mind while trying to move a physical pin with `edit_move_routes`:

- `edit_move_routes` can be used to move only the physical pins on the design boundary. Pins inside the design cannot be moved with this command.

- A pin can be moved only along a boundary.
- It cannot be moved between design boundaries.



- Pins on the top or bottom boundary can be moved only horizontally.
- Pins on the left or right boundary can be moved only vertically.

Note: You can use the `set_db edit_wire_snap_objects_to_track pin` command to snap moved pins to the track. This attribute is set to `true` by default. To get the current value of this attribute, use get_db edit_wire_`snap_objects_to_track pin`.

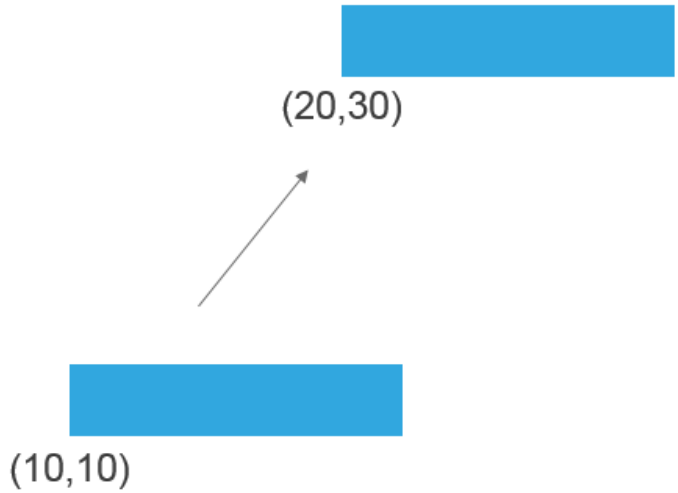
Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man edit_move_routes`
`-direction {x y diag45 diag135}`	
	Specifies the direction of movement. Use one of the following options: • `diag45` - Moves selected wires the specified *`-distance`* in a 45-degree direction. This option cannot be used for moving physical pins. • `diag135` - Moves selected wires the specified *`-distance`* in a 135-degree direction. This option cannot be used for moving physical pins. • `x` - Moves selected vertical wires or pins to the right (if you specify a positive value for *`-distance`*) or left (if you specify a negative value for *`-distance`*). • `y` - Moves selected horizontal wires or pins up (if you specify a positive value for *`-distance`*) or down (if you specify a negative value for *`-distance`*). *Data_type*: enum, optional
`-distance` *`double`*	Specifies the distance to move the wire or pin in microns. *Data_type*: double, optional
`-dx` *`double`*	Specifies the distance in microns by which the selected wire should be moved in the x direction. You must specify the `-dy` value along with it. For example, if you want to move the wire in the x direction by 0.2 microns, specify the following command: `edit_move_routes -dx 0.2 -dy 0` *Data_type*: double, optional
`-dy` *`double`*	Specifies the distance in microns by which the selected wire should be moved in the y direction. You must specify the `-dx` value along with it. For example, if you want to move the wire in the y direction by 0.2 microns, specify the following command: `edit_move_routes -dx 0 -dy 0.2` *Data_type*: double, optional
`-to {x y}`	Specifies the coordinates of the new location to which the selected wire or via is to be moved. If you are moving a via, the `x` and `y`values specify the new coordinates of the via origin. In the case of a wire, the `x` and `y` values specify the new coordinates of the lower left corner of the wire. See Examples. When you move the selected wire or via with `editMove -to`, connected wires are not moved. *Data_type*: point, optional

Examples

- The following command moves the selected wire such that its lower-left corner lies on the coordinates {`20, 30`} after the move:

```
edit_move_routes -to {20 30}
```



- The following command moves the selected via such that its original lies on the coordinates {`20, 30`} after the move:

```
edit_move_routes -to {20 30}
```

edit_resize_routes

```
edit_resize_routes
[-help]
[-keep_center_line {0 1 auto}]
[-no_connection]
[-polygon_edge_start {x y} | -to float_value]
{[[-direction {x y diag45 diag135} -side {high low}] | [-polygon_edge_start {x y} -polygon_edge_end
{x y}]] [-offset float_value | -to float_value]] | [-corner {low_left low_right up_left up_right} -
dx float_value -dy float_value]}
```

Resizes wires and pins. The `edit_resize_routes` command can be used to:

- Change the length of wires.
- Change the width of wires.
- Enlarge or shrink wires by changing both the length and width of a wire simultaneously.
- Change the width of physical pins.

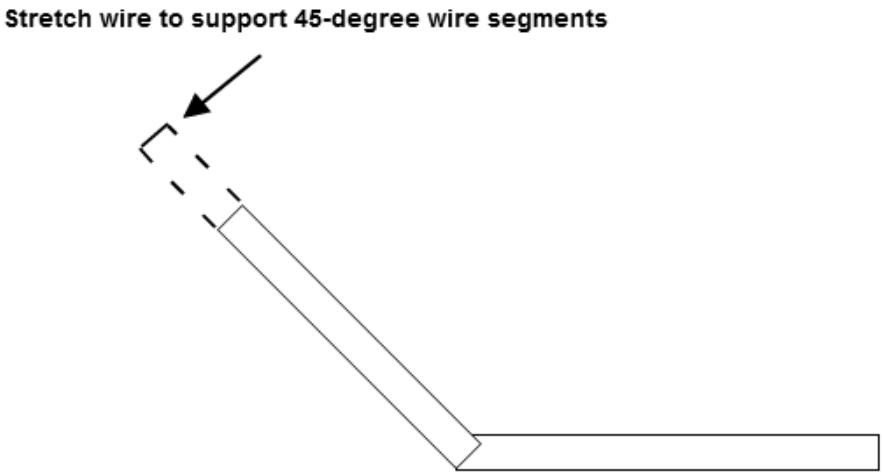
> While changing the wire width to fix EM violations, apply the following setting before invoking the `edit_resize_routes` command:
>
> ```
> set_db edit_wire_unrestricted_regular_wire_width true
> ```
>
> By default, when you are changing the width of a wire, it snaps to the closest non-default route (NDR) available. If you set the `edit_wire_unrestricted_regular_wire_width` attribute to `true`, a wire can be stretched to any width without any restrictions.

Typically, the `edit_resize_routes` command can be used in two modes:

Mode 1 - Change the size of a wire or pin in only one direction at a time

If `-direction` is specified, the tool changes the size in the specified direction only. In this mode, the `edit_resize_routes` command can be used to:

- Change the length of selected regular and special wires by stretching or shrinking them and then snapping them to the closest manufacturing grid point. The `edit_resize_routes` command also supports the stretching/shrinking of 45 and 135-degree wires.



Note: Use the `select_routes` command to select the wires.

- Change the width of selected wires and update vias connected to the changed wires to maintain the via-to-wire dimension ratio. `edit_resize_routes` can be used to change the width of regular as well as special wires:
  - For regular wires, if the width value you specified is not defined in the tech LEF, the tool snaps the width of the regular wire to the closest value defined in the default or non-default rule and prints the following message in the log file:

    ```
    WARNING: The wire width is not defined in default or non default rule, snap wire width to the closest value defined in LEF file
    ```

    The tool also selects a suitable via cell defined in the tech LEF file. If a suitable via cell is not available, the tool does not drop any via.

    When you change the width of a regular wire, the center line is still connected with the neighboring wires after the change:

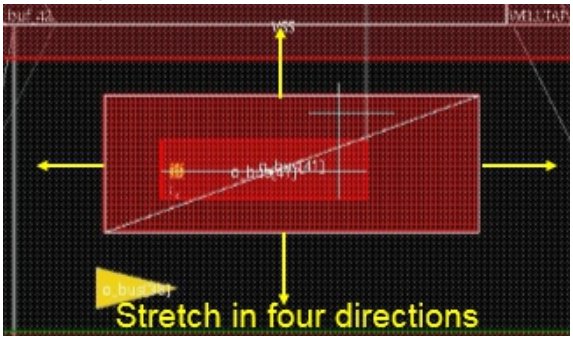
  - For a special wire, you can change the wire width freely by specifying an incremental value. The tool uses viagen to generate a via after the width change of a special wire.

Note: Use the `select_routes` command to select the wires.

If you change the width of a wire, and then change it back to the original width, you might see a discrepancy

due to rounding.
Note: If you specify a width value that is not an even multiple of the manufacturing grid value, the software displays a warning.

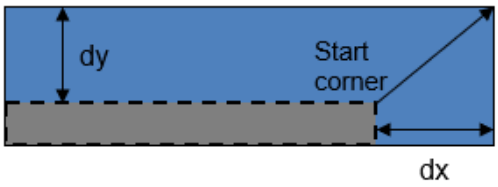
- Resize patch wires. Patch wires can be stretched in four directions:



- Change the width of physical pins. While using the `edit_resize_routes` command to change the pin width, keep the following points in mind:
  - If `set_db edit_wire_drc_on true` has been specified before modifying the pin width, the tool follows the rules from the LEF file while changing pin width.
  - The pin width, whether vertical or horizontal, should not be less than the minimum width defined in the LEF file.
  - If you specify a value less than minimum width for a pin, the tool uses the minimum width for that pin.

Mode 2 - Change the size of a wire in both the x and y directions simultaneously

If `-direction` is not specified, the tool changes both the width and height of the selected wire at the same time. You can use `-corner` to specify the start corner from which to stretch or shrink the wire. This mode works for only horizontal or vertical special wires in the no_connection mode. Use `-dx` and `-dy` to specify the distance to stretch the wire in x and y directions, respectively.



Parameters

`-help`	Prints a brief description that includes type and default information for each `edit_resize_routes` parameter. For a detailed description of the command, use the `man` command: `man edit_resize_routes`
`-corner {low_left low_right up_left up_right}`	

	Specifies the starting corner from which the wire should be stretched. *Data_type*: enum, optional
`-direction {x y diag45 diag135}`	
	Specifies the direction in which the wire or pin is to be stretched or shrunk: ◦ `x` - Resizes wires or pins horizontally. For a horizontal wire, specify the direction as `x` if you want to modify the length of the wire (i.e stretch or shrink the horizontal wire). For a vertical wire, specify the direction as `x` if you want to modify the width of the wire. ◦ `y` - Resizes wires or pins vertically. For a horizontal wire, specify the direction as `y` if you want to modify the width of the wire. For a vertical wire, specify the direction as `y` if you want to modify the length of the wire (i.e stretch or shrink the vertical wire). ◦ `diag45` - Resizes the selected wires in the 45-degree direction by the specified offset value. **Note**: This parameter can be used only for wires. ◦ `diag135` - Resizes the selected wires in the 135-degree direction by the specified offset value. **Note**: This parameter can be used only for wires. *Data_type*: enum, optional
`-dx` *`float_value`*	Specifies the distance to which the wire should be stretched in the x direction. *Data_type*: float, optional
`-dy` *`float_value`*	Specifies the distance to which the wire should be stretched in the y direction. *Data_type*: float, optional
`-keep_center_line {0 1 auto}`	

	Controls whether the wire or physical pin is resized with the center line unchanged: • `0` - Resizes the wire or pin from the specified side only. This option works in both the connection and no_connection modes.  This setting cannot be used for changing the width of signal wires. • `1` - Resizes the wire or pin from both the low and high sides, even if you are stretching it from only one side. This is done to keep the center line unchanged.  This option works in both the connection and no_connection modes for wires. However, a physical pin can keep the center line unchanged during a resize in the no-connection mode only. • `auto` - When set to `auto`, the software automatically detects when to keep the center line unchanged. *Default*: `auto` *Data_type*: enum, optional
`-no_connection`	Resizes the wire without auto via/wire creation and DRC checking. If `-no_connection` is not specified, the tool will reprocess the via and do basic DRC checking:  **Note:** Patch wires are resized without auto via/wire creation and DRC checking even if `-no_connection` is not specified. *Data_type*: bool, optional

`-offset` *float_value*	Specifies, in microns, the distance to which the wires or pins should be stretched or shrunk. *Data_type*: float, optional
`-polygon_edge_end {x y}`	Specifies the end point for a polygon edge {x y}. This option is used only to resize a polygon. *Data_type*: point, optional
`-polygon_edge_start {x y}`	Specifies the start point for a polygon edge {x y}. This option is used only to resize a polygon. *Data_type*: point, optional
`-side {high low}`	Specifies the side from which the wire or pin is to be stretched or shrunk: • `high` - Stretches or shrinks wires or pins from the top or the right. • `low` - Stretches or shrinks the wires or pins from the bottom or the left. *Data_type*: enum, optional
`-to` *float_value*	Specifies, in microns, the new height for selected horizontal wires or the new width for selected vertical wires. *Data_type*: float, optional

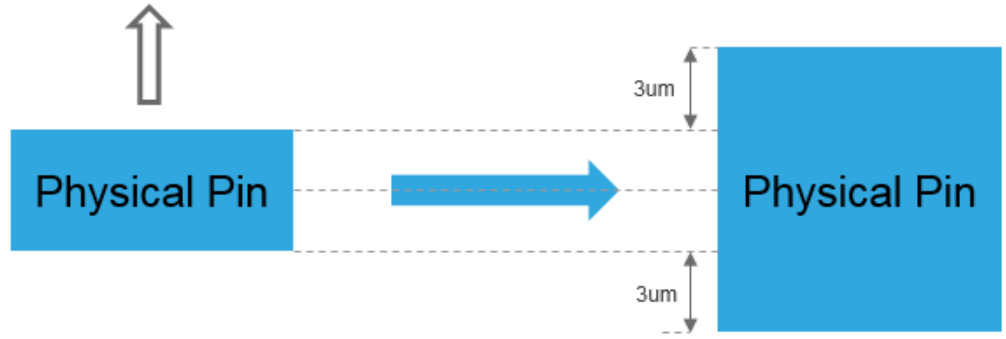
Examples

- The following command stretches the selected vertical wire from the top by 8.5 µm.
  ```
  edit_resize_routes -direction y -offset 8.5 -side high
  ```
- The following command stretches the selected vertical wire from the bottom by 0.511 µm.
  ```
  edit_resize_routes -direction y -offset -0.511 -side low
  ```
- The following command shrinks the selected vertical wire from the bottom by 0.619 µm.
  ```
  edit_resize_routes -direction y -offset 0.619 -side low
  ```
- The following command stretches a horizontal wire from the right by 1.27 µm.
  ```
  edit_resize_routes -direction x -offset 1.27 -side high
  ```
- The following command shrinks a horizontal wire from the left by 0.443 µm.
  ```
  edit_resize_routes -direction x -offset 0.443 -side low
  ```
- The following command stretches a horizontal wire from the left by 0.86 µm.
  ```
  edit_resize_routes -direction x -offset -0.86 -side low
  ```
- The following command increases the width of the selected horizontal special wire by 0.01 µm:
  ```
  edit_resize_routes -direction y -offset 0.01 -side high
  ```
- The following command changes the width of the selected horizontal regular wire to 0.48 µm:
  ```
  edit_resize_routes -to 0.48 -direction y -side high
  ```

If 0.48 is not defined in the NDR, the tool snaps the width to the closest value defined in the NDR.

- The following command increases the vertical width of the selected physical pin by 3 µm each from both top and bottom, keeping the center line unchanged:

```
edit_resize_routes -direction y -offset -3 -side high -no_connection -keep_center_line 1
```



- The following command reduces the horizontal width of the selected physical pin by 3 µm each from both left and right, keeping the center line unchanged:

```
edit_resize_routes -direction x -offset 3 -side low -no_connection -keep_center_line 1
```

edit_rotate

```
edit_rotate
[-help]
[-mode {group | single}]
[-rotate_point {x y}]
{-flip {mx my} | -rotate {r90 r180 r270}}
```

Flips or rotates selected wires and vias. Use this command for more flexible custom routing and fixing DRC violations using existing wires. Using the `editRotate` command, you can:

- Flip selected wires or vias on the X or Y axis (`MX` or `MY`)
- Rotate the selected wires or vias by 90, 180, or 270 degrees (`R90`, `R180`, or `R270`).

The selected object is rotated or flipped based on current orientation, and the lower-left coordinate of the wire/via remains the same after rotation or flip.

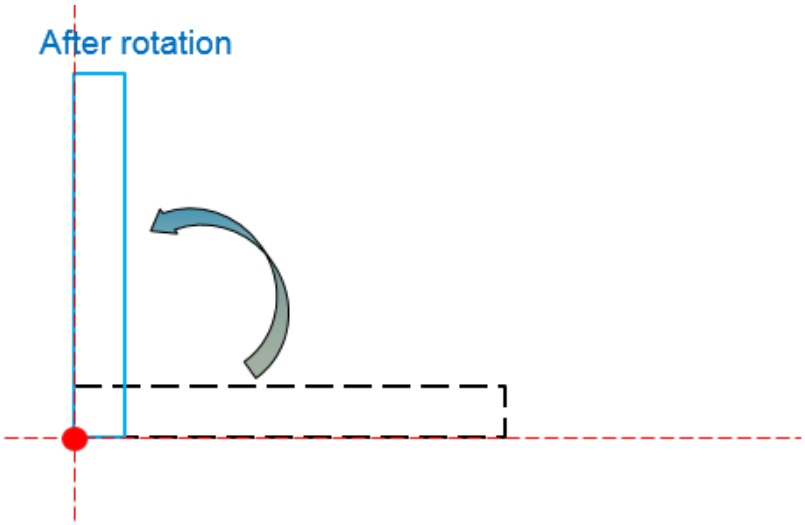
You can also flip or rotate multiple objects simultaneously as one group.

Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man editRotate`
`-flip {mx my}`	Flips a wire or via. If you specify `mx`, the selected object is flipped on the X axis. If you specify my, the object is flipped on the Y axis. *Data_type*: enum, optional
`-mode {group single}`	Rotates multiple selected wires and vias at the same time using the specified mode: • `group` - Flips or rotates the selected objects as a group. This is the default mode when multiple objects are selected. In this mode, the tool flips or rotates the bounding box which encloses all the selected objects. • `single` - Flips or rotates the selected objects individually. *Data_type*: enum, optional
`-rotate {r90 r180 r270}`	Rotates wires or vias by 90, 180, or 270 degrees, as specified. *Data_type*: enum, optional
`-rotate_point {x y}`	Specifies the point around which the wire should be rotated. If this option is not specified, the selected wires/vias are rotated around the lower-left corner of bounding box of wires/vias. *Data_type*: point, optional

Examples

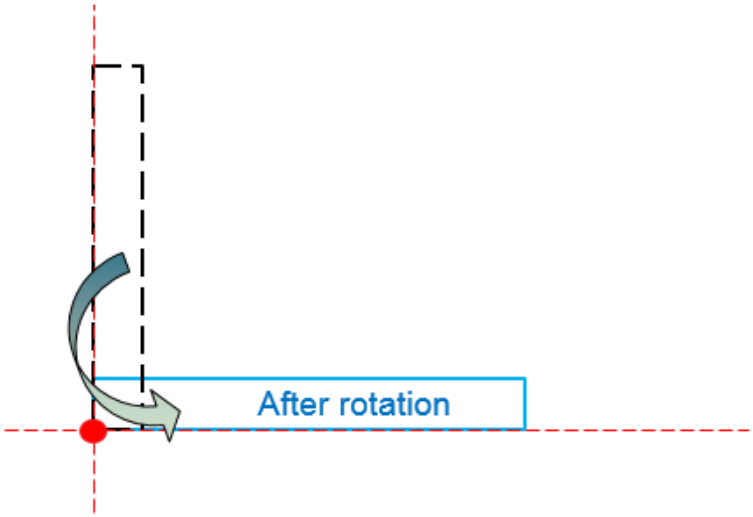
- The following command rotates the selected wire by 90 degrees:
  ```
  edit_rotate -rotate r90
  ```



- The following command rotates the selected object, which originally has `r90` as its original orientation by 90 degrees:

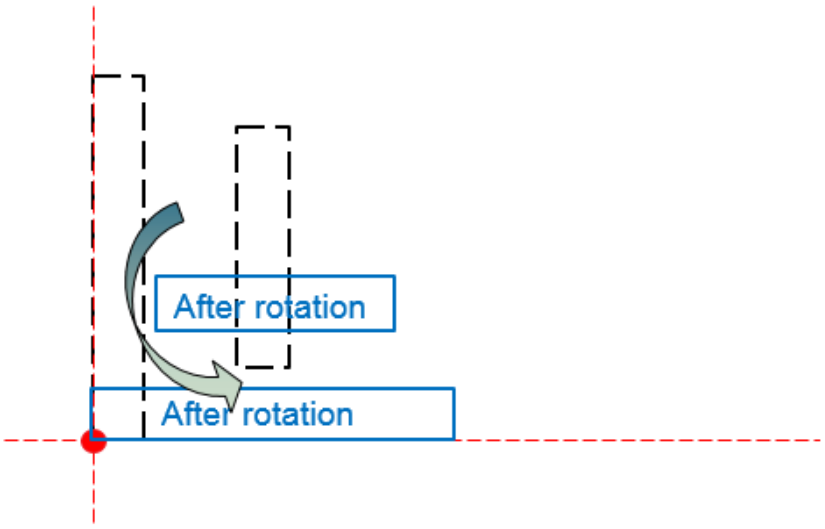
  ```
  edit_rotate -rotate r90
  ```

  The final orientation of the object will be `r180` as shown below:



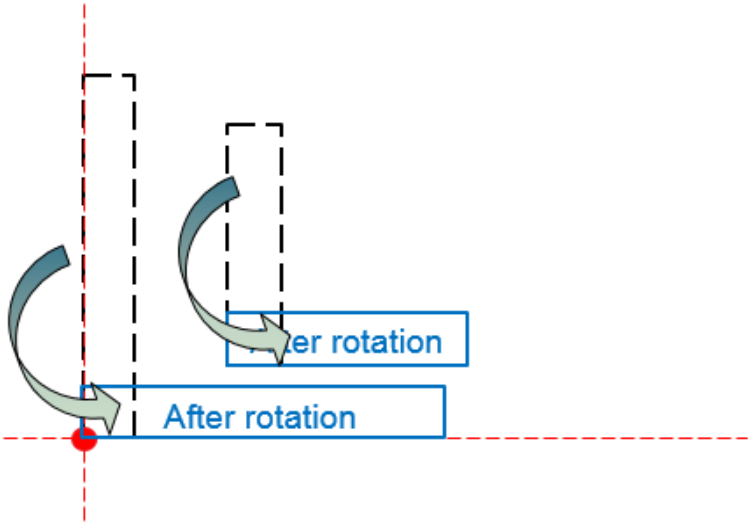
- The following command rotates the bounding box of the selected wires by 90 degrees to rotate the wires as one group:

  ```
  edit_rotate -rotate r90 -mode group
  ```



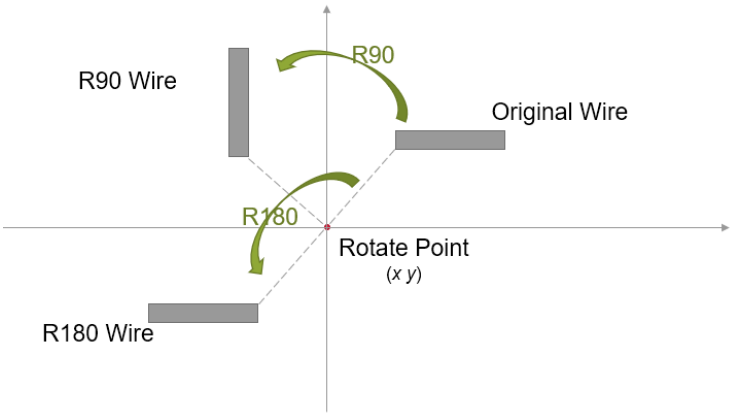
- The following command rotates the selected wires individually by 90 degrees:

```
edit_rotate -rotate r90 -mode single
```



- The following commands rotate the selected wire by 90 and 180 degrees, respectively, around the specified rotation point, *x y*:

```
edit_rotate -rotate r90 -rotate_point x y
edit_rotate -rotate r180 -rotate_point x y
```



- The following commands rotate the selected group of wires by 90 and 180 degrees, respectively, around the specified rotation point, *x y*:

```
edit_rotate -rotate r90 -mode group -rotate_point x y
edit_rotate  -rotate r180 -mode group -rotate_point x y
```

edit_split_routes

```
edit_split_routes [-help]
```

Splits selected special wires at connection points with orthogonal wires. This command can also be used to split selected bus guides.

Note: Use the `select_routes` command to select the wires. Use the `select_obj` command to select bus guides or bus guide segments

Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man edit_split_routes`

edit_split_wide_routes

```
edit_split_wide_routes [-help]
```

Splits wires that violate the MAXWIDTH value in the LEF LAYER (Routing) statement. Also splits diagonal wires whose width is greater than the MAXWIDTH value as they are drawn.

Parameters

-help	Prints the usage of the command. For a detailed description of the command, use the man command: `man edit_split_wide_routes`

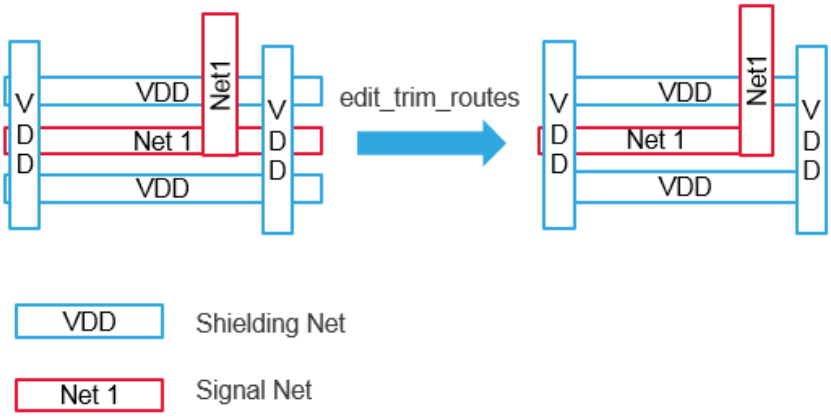
edit_trim_routes

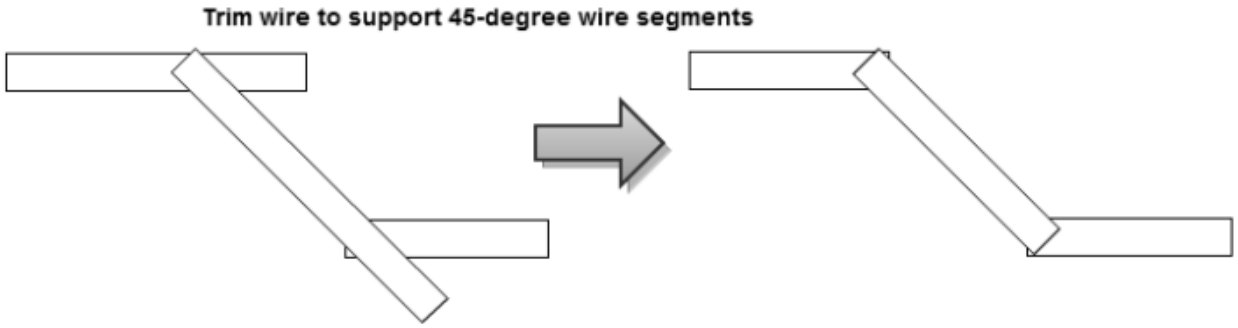
```
edit_trim_routes
[-help]
[-keep_floating_stubs]
[-status {cover fixed noshield routed shield}]
[-type {float}]
[-all  | -selected  | -nets netNames]
[-all  | -selected  | -layers layer_names]
[-all  | -selected  | -area {x1 y1 x2 y2}]
```

Removes or trims wires. Wires are trimmed or removed as follows:

- Trims floating stubs of wires back to the closest connection point.
- Removes wires that do not have electrical connections to other wires or pins (floating wires).
- Removes wires with only one connection to another wire or pin, along with connecting vias. Removing a wire with one connection might cause the wire to which the just-removed wire is connected to change from being a wire with two connections to a wire with one connection and thus it will also be removed. This process is repeated until no wires with one connection are left.
  Note: The `edit_trim_routes` command recognizes patch wires and detects the patch wire connection with the via. Therefore, it does not delete patch wires even if they are connected from only one side.
- Trims shield wires along with signal wires.

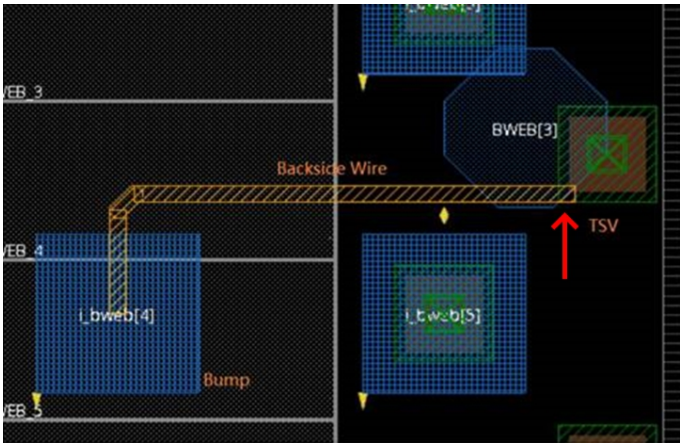


- Trims wires to support 45-degree wire segments.



Notes

- The `edit_trim_routes` command recognizes Through Silicon Via (TSV) connections and detects the backside wire connection with the TSV so it does not remove the backside routes connected to TSV.



- The `edit_trim_routes` command does not trim metal fill segments. To trim metal fill segments use the `trim_metal_fill` command.

Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man edit_trim_routes`
`-all`	Trims all special wires and floating stubs. *Data_type*: bool, optional

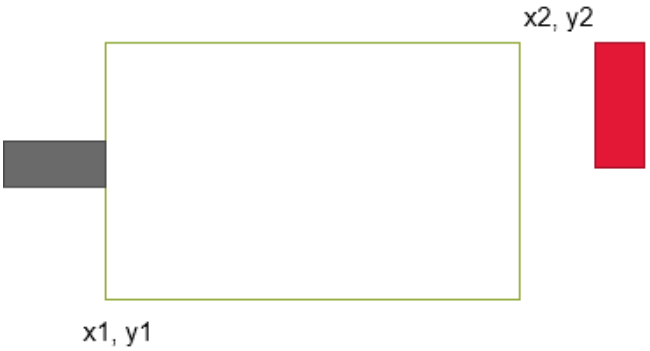
`-area {x1 y1 x2 y2}`	Specifies the coordinates for the box area from which to trim the wires. Here: • `x1` - Specifies the lower left x coordinate. • `y1` - Specifies the lower left y coordinate. • `x2` - Specifies the upper right x coordinate. • `y2` - Specifies the upper right y coordinate. Only the wires that overlap with the specified box area are trimmed. The wires that just touch the box area are not trimmed. *Data_type*: rect, optional
`-keep_floating_stubs`	Selects the floating wires but does not remove the floating stubs. Use this parameter if you want to assess the impact before actually trimming. *Data_type*: bool, optional
`-layers layer_names`	Specifies the layers from which to trim wires. If you are specifying multiple layers, enclose the layer names in braces. *Default*: If you do not specify this parameter, the command trims wires on all layers. *Data_type*: string, optional
`-nets net*`	Trims wires on the nets you specify. You can use wildcards to specify the nets. *Data_type*: (net)*, optional
`-selected`	Trims selected wires. Use the `select_routes` command to select the wires. This is the default value. *Data_type*: bool, optional
`-status {cover fixed noshield routed shield}`	
	Specifies the status of wires to trim. *Data_type*: enum, optional
`-type {float}`	Removes only wires that do not have electrical connections to other wires or pins (floating wires). The tool will not trim the wire with connection to other wires at one end if this option is specified. *Data_type*: enum, optional

Examples

- The following command trims the wires overlapping the box area specified by the coordinates `{x1 y1 x2 y2}`:
  `edit_trim_routes -area {x1 y1 x2 y2}`

  Before

  After



- The following command trims the wires in the specified layers:
  `edit_trim_routes -layers {Metal1 Metal3}`

edit_update_route_layer

```
edit_update_route_layer
[-help]
[-layer_horizontal layer]
[-layer_vertical layer]
```

Changes the layer of selected wires and updates vias connecting to the wires that change layers.

Note: Use the `select_routes` command to select the wires.

Parameters

`-help`	Prints a brief description that includes type and default information for each `edit_update_route_layer` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man edit_update_route_layer`
`-layer_horizontal` *layer*	Specifies the new layer for the selected horizontal wires. *Data_type*: string, optional
`-layer_vertical` *layer*	Specifies the new layer for the selected vertical wires. *Data_type*: string, optional

Example

- The following command moves all selected horizontal wires to the *METAL3* layer and all selected vertical wires to the *METAL4* layer:
  ```
  edit_update_route_layer -layer_horizontal METAL3 -layer_vertical METAL4
  ```

Related Information

edit_update_route_mask

```
edit_update_route_mask
[-help]
{-to {0 1 2} | [[-top {0 1 2}] [-bottom {0 1 2}] [-cut {0 1 2}]] | -trim_metal {0 1 2}}
```

Changes the mask for the selected wires, vias, physical pins, or trim metal to the specified color.

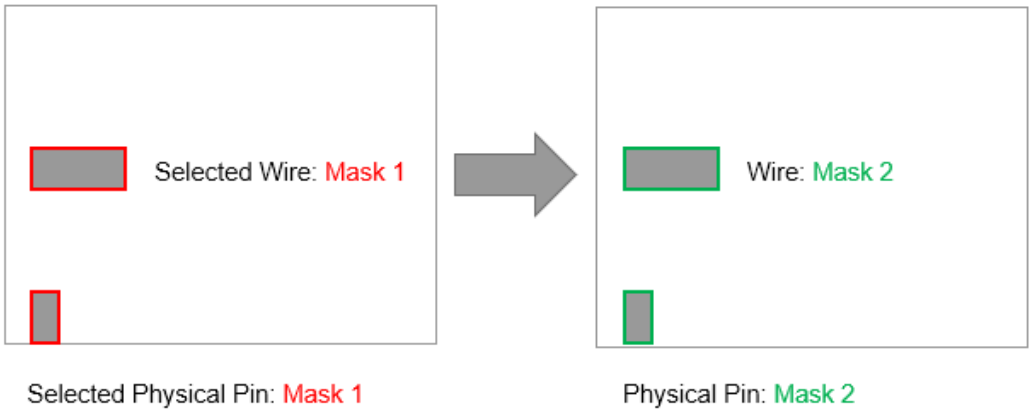
Parameters

`-help`	Prints a brief description that includes type and default information for each `edit_update_route_mask` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man edit_update_route_mask`
`-bottom {0 1 2}`	Changes the mask for the bottom layer of the selected vias to the specified color. *Data_type*: enum, optional
`-cut {0 1 2}`	Changes the mask for the cut layer of the selected vias to the specified color. *Data_type*: enum, optional
`-to {0 1 2}`	Changes the mask for the selected wires and physical pins to the specified color. *Data_type*: enum, optional
`-top {0 1 2}`	Changes the mask for the bottom layer of the selected vias to the specified color. *Data_type*: enum, optional
`-trim_metal {0 1 2}`	Changes the mask for the trim metal of the selected patch wires to the specified color. If the trim metal being edited completely covers another trim metal, the mask of the covered trim metal is also changed simultaneously. *Data_type*: enum, optional

Examples

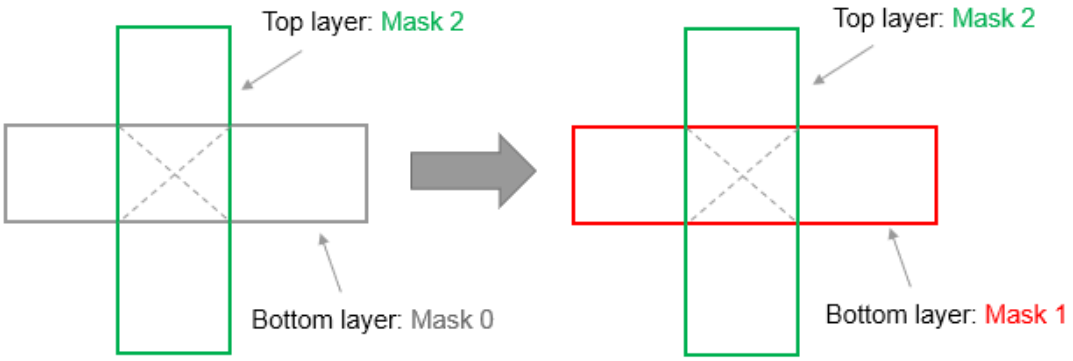
- The following command changes the mask for the selected wire and physical pin to `2`:

  ```
  edit_update_route_mask -to {2}
  ```



- The following command changes the mask for the bottom layer of the selected via to `1`:

  ```
  edit_update_route_mask -bottom {1}
  ```



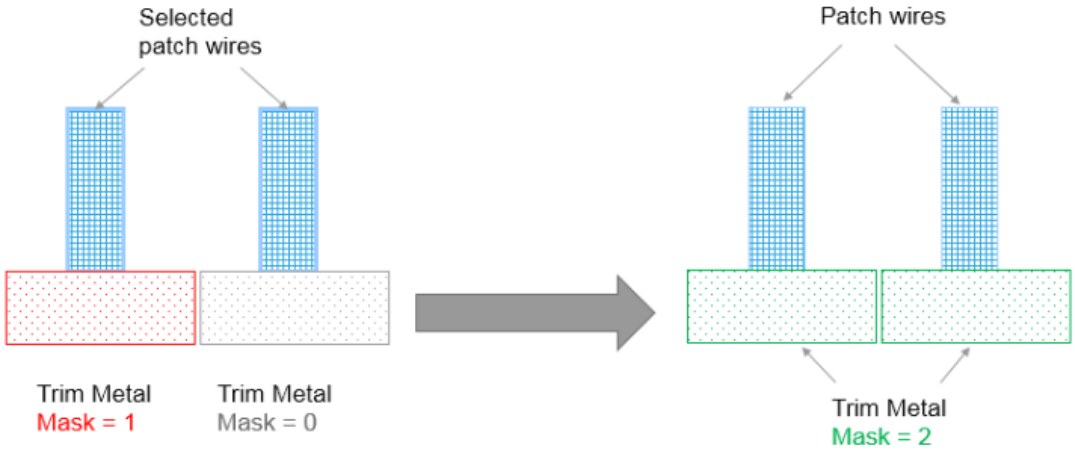
- The following command changes the mask for the trim metal of the selected patch wires to `2`:

  ```
  edit_update_route_mask -trim_metal {2}
  ```

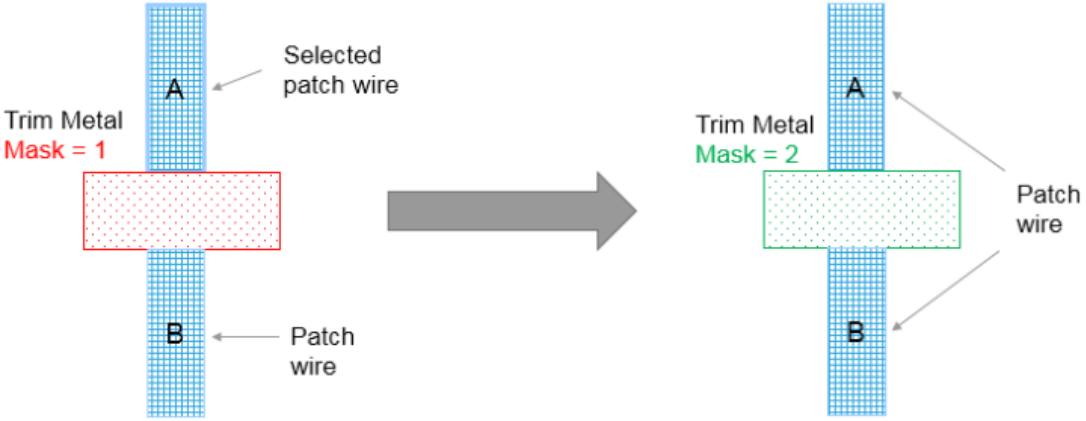
  Given below are the results of running this command in various situations:

  - If a single patch wire was selected before running the command:

  - If multiple patch wires were selected before running the command:



- If the trim metal for the selected patch wire (Patch Wire A) completely overlaps the trim metal for another patch wire that is not selected (Patch Wire B):



- If the trim metal for the selected patch wire (Patch Wire A) partially overlaps the trim metal for another patch wire that is not selected (Patch Wire B):

- Edit Menu chapter in the *Menu Reference*
  - *Wire* section

edit_update_route_net

```
edit_update_route_net
[-help]
-to netName
```

Changes the net associated with selected physical pins, wires, and vias.

You can also use `edit_update_route_net` to change the net name of the patch wire (pWire) generated by NanoRoute.

Parameters

`-help`	Prints a brief description that includes type and default information for each `edit_update_route_net` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man edit_update_route_net`
`-to`	Specifies the name of the net to which to assign the selected physical pins, wires and vias. *Data_type*: (net), required

Example

- The following set of commands selects the physical pins, wires, and vias that belong to net `VDD1` and reassigns them to net `VDD2`:

  ```
  select_routes -nets VDD1
  edit_update_route_net -to VDD2
  ```

Related Information

edit_update_route_rule

```
edit_update_route_rule
[-help]
[-from old_rule]
-to new_rule
```

Changes the LEF rule associated with selected wire segments from the *old_rule* to the *new_rule*. You must select the wires for which the rule needs to be changed before running edit_update_route_rule. You can select wires either using the GUI or by using the select_routes command.

Note: This command does not change the routing rule for the net. If the net is re-routed by NanoRoute, these changes will be lost. To change the routing rule, use set_route_attributes -nets -route_rule. For more information, see set_route_attributes.

Parameters

-help	Prints a brief description that includes type and default information for each edit_update_route_rule parameter. For a detailed description of the command and all of its parameters, use the man command: man edit_update_route_rule
-from *old_rule*	Specifies the qualifying rule. Only wire segments whose associated rule matches *old_rule* are changed. If you do not specify this parameter, the tool will change the rule of all selected wires. *Data_type*: string, optional
-to *new_rule*	Specifies the destination rule. Wire segments originally associated with *old_rule* are associated with *new_rule* after this command runs. Specify one of the following: • A nondefault rule defined in the LEF LAYER (Routing) section • default (applies the default routing rule) *Data_type*: string, required

Example

- The following command changes the wire segments that are associated with rule SP to the default rule. If the wire width or extension of SP is different from its counterpart in the default rule, the wire geometry is changed accordingly.
  ```
  edit_update_route_rule -from SP -to default
  ```

edit_update_route_status

```
edit_update_route_status
[-help]
[shield_net_name]
[-nets <net>+]
-to {routed fixed cover shield noshield}
```

Changes the DEF status of selected wires or vias to the specified status. Use this command to change the net status of the selected net. If `-nets` is specified with `edit_update_route_status`, the tool changes the status of all the objects belonging to the specified nets to the status specified with the `-to` parameter.

Note: Before using this command to change the status of a wire, you must select the wire by either clicking it or using the `select_routes` command.

Parameters

`-help`	Prints a brief description that includes type and default information for each `edit_update_route_status` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man edit_update_route_status`
`shield_net_name`	Specifies the name of the net to be shielded by the selected wire. Use this parameter if you want to change the selected wire to a `shield` for the specified net. **Note**: You can use this parameter only if you have specified `-to shield`. *Data_type*: string, optional
`-nets <net>+`	Specifies the names of the nets for which the object status is to be changed. If `-nets` is specified with `edit_update_route_status`, the tool changes the status of all the objects (regular wires, special wires, regular vias, and special vias) belonging to the specified nets to the status specified with the `-to` parameter. *Data_type*: (net), optional
`-to {routed fixed cover shield noshield}`	
	Specifies the DEF status of the selected wires or vias after you issue this command. **Note:** You cannot change a special wire to `noshield` status or change a signal wire to `shield` status. *Data_type*: enum, required

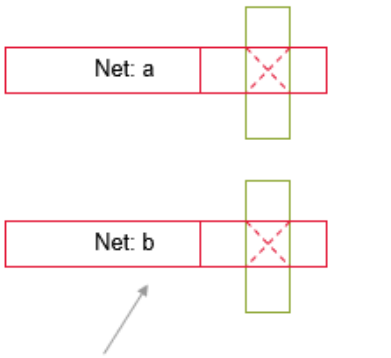
Examples

- The following commands select and then freeze the wires and vias on the `METAL1` and `METAL2` layers by

changing their status to `cover`. Innovus does not delete wires or vias with status `cover`:

```
select_routes -layer {METAL1 METAL2}
edit_update_route_status -to cover
```

- Consider the nets depicted below:



The wire/via under net b is **selected**

  - The following command changes the status of only the wire and via under net `a` to `fixed`. The status of the wire and via under net `b` is not changed even though net `b` is selected:

    ```
    edit_update_route_status -nets a -to fixed
    ```

  - The following command changes the status of the wires and vias under both nets `a` and `b` to `fixed`:

    ```
    edit_update_route_status -nets {a b} -to fixed
    ```

    - *Wire* section

edit_update_via

```
edit_update_via
[-help]
[-net net_name]
[-signal_only {0 | 1}]
{[-from string [-area {x1 y1 x2 y2} | -at {x y} ]] | [-selected]}
{-to string | [-via_columns integer -via_rows integer [-cut_class class_name]]}
```

Replaces the selected vias or the vias listed in `-from` with the specified vias or with vias having the specified cut class and pattern.

While modifying a via with `edit_update_via`, the tool behavior varies depending on your `edit_wire_drc_on` and `edit_wire_keep_via` attribute settings:

- `set_db edit_wire_drc_on false`
  With this setting, the tool does not check for Design Rule Check (DRC) violations when you modify a via using the `edit_update_via` command.
- `set_db edit_wire_drc_on true`
  `set_db edit_wire_keep_via false`
  With these settings, the tool checks for DRC violations and allows you to replace the via even if the new via is generating violations. The DRC violations are displayed on the layout.
- `set_db edit_wire_drc_on true`
  `set_db edit_wire_keep_via true`
  With these settings, the tool checks for DRC violations and retains the original via if the new one is generating violations.

The behavior defined above applies for all via modifications with `edit_update_via`, irrespective of whether you use the `-to string` option or the `-via_columns integer -via_rows integer` options.

Note that the `edit_wire_drc_on true` setting does not check cut spacing, enclosure spacing, or other geometry of the via cell itself.

Parameters

`-help`	Prints a brief description that includes type and default information for each `edit_update_via` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man edit_update_via`
`-area {x1 y1 x2 y2}`	Specifies an area in which to replace vias. If a via indicated by the `-from` parameter is in this area, replaces the via with the via indicated by the `-to` parameter. *Data_type*: rect, required

`-at {x y}`	Specifies the coordinates for the origin of a via to replace. The via at this location is replaced by the via indicated by the `-to` parameter. *Data_type*: point, required
`-cut_class class_name`	Specifies the cut class of the replacement vias. *Data_type*: string, optional
`-from string`	Specifies a via or list of vias to replace. Enclose the via names on the list in curly braces and separate each name with a space. Vias whose masters are not specified in `string` are not changed. **Notes:** • You must specify the `-from` or the `-selected` parameter. If you do not specify at least one of these parameters, the software does not change any vias. • The number of via names on the `-from` list must be equal to the number of via names on the `-to` list. In addition, the corresponding pair of vias in each list must be on the same layer. *Data_type*: string, required
`-net net_name`	Specifies the net name on which to change vias. *Data_type*: (net), optional
`-selected`	Replace vias for selected ones only. **Note:** You must specify either the `-from` or the `-selected` parameter. If you do not specify at least one of these parameters, the software does not change any vias. *Data_type*: bool, optional
`-signal_only {1 | 0}`	Specifies whether signal vias only or signal and special vias are changed. Specify `1` to change signal via only. Specify `0` to change signal and special vias. *Default:* `0` *Data_type*: enum, optional
`-to string`	Specifies a via or a list of vias to replace the vias indicated by the `-from` parameter. If you specify more than one via, enclose the via list in curly braces and separate each via name with a space. **Note:** The number of via names on the list must be the equal to the number of via names on the list for the `-from` parameter. In addition, the corresponding pair of vias in each list must be on the same layer. *Data_type*: string, required
`-via_columns integer`	Specifies the number of columns in the replacement vias. *Data_type*: int, optional

`-via_rows` *integer*	Specifies the number of rows in the replacement vias. *Data_type*: int, optional

Example

- The following command changes all `VIA_XX` vias of the net `VDD1` located within a specified region to `VIA_YY` vias:
  ```
  edit_update_via -net VDD1 -area {x1 y1 x2 y2} -from VIA_XX -to VIA_YY
  ```
- The following command changes the selected vias with vias having a cut pattern of 3 by 3:
  ```
  edit_update_via -selected -via_columns 3 -via_rows 3
  ```

edit_wire_via Category Attributes

The root attributes in the `edit_wire` category are:

- edit_wire_via_allow_geometry_drc
- edit_wire_via_auto_snap
- edit_wire_via_auto_update
- edit_wire_via_cell_name
- edit_wire_via_create_by
- edit_wire_via_cut_layer
- edit_wire_via_snap_honor_color
- edit_wire_via_type

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `edit_wire` category, use the following command:

```
get_db -category edit_wire
```

The following set of commands add a via with the same geometry as the cell specified by the `edit_wire_via_cell_name` attribute. The origin of the via is at coordinates `550`, `675`:

```
set_db edit_wire_via_create_by viacell

edit_create_via 550 675
```

For more help on editing wires, see the Editing Wires chapter in the *User Guide.*

edit_wire_via_allow_geometry_drc

```
edit_wire_via_allow_geometry_drc {true|false}
```

Default: `true`

Data_type: bool, read/write

Checks geometry DRC.

Related Commands

To review global controls that affect wire editing, see `edit_wire Category Attributes` in the *Text Command Reference*. Other related commands are:

- `delete_routes`

- edit_create_via
- edit_move_routes

- edit_update_route_layer
- edit_update_route_net
- edit_update_route_rule
- edit_update_route_status
- edit_update_via
- select_routes
- edit_trim_routes

edit_wire_via_auto_snap

```
edit_wire_via_auto_snap {true|false}
```

Default: `true`

Data_type: bool, read/write

Controls whether to snap vias to the intersection of tracks or to the manufacturing grid.

- Specify `true` to snap the via to the center of the intersection of tracks.
- Specify `false` to keep the via in the location where it is added or moved, snapping only to the manufacturing grid.

Related Commands

To review global controls that affect wire editing, see `edit_wire Category Attributes` in the *Text Command Reference*. Other related commands are:

- edit_update_route_status

- edit_update_via
- select_routes
- edit_trim_routes

edit_wire_via_auto_update

```
edit_wire_via_auto_update {true|false}
```

Default: `true`

Data_type: bool, read/write

Determines whether existing vias are replaced with new ones in case of overlap.

- Specify `true` to replace existing vias with the new ones added with `edit_create_via` in case of any overlap.
- Specify `false` if you want to retain existing vias even if there is some overlap with the new vias being added.

Related Commands

- edit_update_route_status
- edit_update_via
- select_routes
- edit_trim_routes

edit_wire_via_cell_name

```
edit_wire_via_cell_name cellname
```

Default: `""`

Data_type: string, read/write

Specifies the name of the via cell from the LEF or DEF file.

Related Commands

To review global controls that affect wire editing, see `edit_wire Category Attributes` in the *Text Command Reference*. Other related commands are:

- `edit_trim_routes`

edit_wire_via_create_by

`edit_wire_via_create_by {viacell|parameters}`

Default: `parameters`

Data_type: enum {viacell parameters}, read/write

Controls whether the tool creates vias based on the `edit_wire_via_cell_name` attribute or the cut class name.

- Specify `viacell` to create the via with the same geometry as the cell specified by the `edit_wire_via_cell_name` attribute.
- Specify `parameters` to create the via cell based on the cut class parameters.

Related Commands

To review global controls that affect wire editing, see `edit_wire Category Attributes` in the *Text Command Reference*. Other related commands are:

- edit_update_via
- select_routes
- edit_trim_routes

edit_wire_via_cut_layer

`edit_wire_via_cut_layer` *cellname*

Default: `V12`

Data_type: string, read/write

Specifies the via layer name for the via to be created or modified.

Related Commands

To review global controls that affect wire editing, see `edit_wire Category Attributes` in the *Text Command Reference*. Other related commands are:

- edit_update_route_status
- edit_update_via
- select_routes
- edit_trim_routes

edit_wire_via_snap_honor_color

`edit_wire_via_snap_honor_color {true|false}`

Default: `true`

Data_type: bool, read/write

Specifies whether or not to snap via to the track with the same color automatically.

Related Commands

To review global controls that affect wire editing, see `edit_wire Category Attributes` in the *Text Command Reference*. Other related commands are:

- `edit_update_route_rule`
- `edit_update_route_status`
- `edit_update_via`
- `select_routes`
- `edit_trim_routes`

edit_wire_via_type

`edit_wire_via_type {auto|regular|special}`

Default: `auto`

Data_type: enum {auto regular special}, read/write

Specifies the type of the via to be created:

- `auto` - Assigns the correct via type based on the type of connected wire.
- `regular` - Creates regular vias
- `special` - Creates special vias

For example, if you specify the type as `regular` by using the following command and then run the `edit_create_via` command, the tool will create a regular via even if there are PG shapes on other layers

overlapping the area:

```
set_db edit_wire_via_type regular
```

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `edit_wire` category, use the following command:

```
get_db -category edit_wire
```

For more help on editing wires, see the Editing Wires chapter in the *User Guide.*

edit_wire_align

```
edit_wire_align {true | false}
```

Default: `true`

Data_type: bool, read/write

Specifies whether or not to support alignment of objects during interactive edits using the GUI.

Related Commands

- select_routes

edit_wire_allow_45_degree

```
edit_wire_allow_45_degree {true | false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether to allow the creation of a 45-degree wire.

Related Commands

- delete_routes
- edit_add_route_point

edit_wire_arrow_incremental

`edit_wire_arrow_incremental` *value*

Default: `1.0`

Data_type: double, read/write

Specifies the step increments in microns to move wires with the arrow keys.

Related Commands

- delete_routes
- edit_add_route_point
- edit_merge_routes
- edit_move_routes
- edit_resize_routes
- edit_trim_routes

edit_wire_assign_multi_pattern_color

```
edit_wire_assign_multi_pattern_color {auto mask1 mask2 mask3}
```

Default: `auto`

Data_type: enum {auto mask1 mask2 mask3}, read/write

Specifies how to assign mask color on the double patterning technology (DPT) layer of the wire segment to be created. Select one of the following:

- `auto`: Mask color is assigned automatically.
- `mask1`: Assigns `mask1` color to the added wire segment.
- `mask2`: Assigns `mask2` color to the added wire segment.
- `mask3`: Assigns `mask3` color to the added wire segment.

edit_wire_auto_distribute_bus

```
edit_wire_auto_distribute_bus {true | false}
```

Default: `false`

Data_type: bool, read/write

Auto-distributes a group of wires, and sets the same spacing based on option `-bus_total_width_vertical` or `-bus_total_width_horizontal`.

If `-auto_distribute_bus` is set to `true`, the tool ignores the `-spacing_horizontal` and `-spacing_vertical` settings.

While drawing a bus, the tool auto-sets spacing as:
`wire spacing = (total bus width - total wire width)/ (wire number - 1)`

If the spacing is less than the minimum spacing, the tool auto-sets it to min spacing.

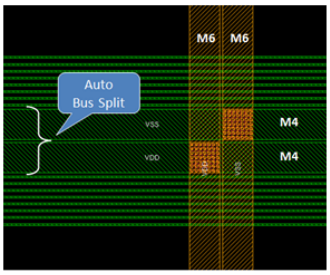
edit_wire_auto_split_bus

```
edit_wire_auto_split_bus {true | false}
```

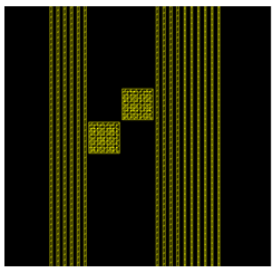
Default: `false`

Data_type: bool, read/write

Specifies whether or not Wire Editor should split buses automatically around power structures to avoid DRC violations.



Auto bus split around power trunk



Auto bus split around power vias

By default, there is no detour around via array and anchor wires of the bus being drawn always snap to the routing tracks.

`edit_wire_auto_split_bus` also supports busses of special wires with different widths.

- `select_routes`

edit_wire_bus_honor_start_parameters

```
edit_wire_bus_honor_start_parameters {true | false}
```

Default: `false`

Data_type: bool, read/write

Specifies that the wire width and spacing of the start points (pins) should be honored when drawing routes for a bus. The following diagram depicts how the width and spacing of the bus is maintained through turns for the the 2nd to N-1 wire segment, if you set `edit_wire_bus_honor_start_parameters` to `true`:

edit_wire_bus_honor_width_setting

`edit_wire_bus_honor_width_setting {true | false}`

Default: `false` (Pin width is used if `edit_wire_snap_bus_to_pin` is set to `true`)

Data_type: bool, read/write

Specifies whether or not the tool should adjust the wire width when snapping bus wires to pin. By default, if `edit_wire_snap_bus_to_pin` is set to `true`, the tool adjusts the wire width to be the same as the macro or IO pin width. If you do not want the width to be adjusted to match the pin width,

set `edit_wire_bus_honor_width_setting` to `true`. In this case, the tool uses the width value defined by `edit_wire_width_horizontal` or `edit_wire_width_vertical` when snapping bus to pin.

edit_wire_bus_total_width_horizontal

`edit_wire_bus_total_width_horizontal` *`value`*

Default: `0.0`

Data_type: double, read/write

Specifies the total width of a horizontal bus.

While drawing a bus, the tool auto-sets spacing as:
`wire spacing = (total bus width - total wire width)/ (wire number - 1)`

Related Commands

edit_wire_bus_total_width_vertical

```
edit_wire_bus_total_width_vertical value
```

Default: 0.0

Data_type: double, read/write

Specifies the total width of a vertical bus.

While drawing a bus, the tool auto-sets spacing as:
```
wire spacing = (total bus width - total wire width)/ (wire number - 1)
```

Related Commands

- select_routes

edit_wire_change_order_at_turn

```
edit_wire_change_order_at_turn {reverse_order|keep_order}
```

Default: `keep_order`

Data_type: string, read/write

Specifies whether the order of the wires changes (`reverse_order`) or stays the same (`keep_order`) when the wire makes a 90-degree turn.

Related Commands

- delete_routes
- edit_add_route_point
- edit_merge_routes

edit_wire_check_design_boundary

```
edit_wire_check_design_boundary {true|false}
```

Default: `false`

Data_type: bool, read/write

Specifies that wires and vias are to be made inside the design boundary. If `edit_wire_check_design_boundary` is set to `true`, you cannot manually stretch a wire into the area defined by the `edit_wire_pull_back_distance` attribute.

Note: 45-degree wires do not follow this rule.

- select_routes

edit_wire_close_polygons

```
edit_wire_close_polygons {true|false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether to close a special route structure toward itself, using the `Escape` key. For the route closure to complete, the ending wire segments must be drawn towards the start wire segments, but do not have to touch them. If you specify this attribute, the software ignores the `edit_wire_extend_wires` attribute.

- select_routes

edit_wire_color_align_with_track

```
edit_wire_color_align_with_track {true|false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether the wire color is to be changed to match the track color during a move or copy operation. If you set the `edit_wire_color_align_with_track` attribute to `true` and move or copy a wire to snap it to a track, the track color is automatically assigned to the wire. Note that if the wire does not snap to a track or if the wire covers more than one track, this attribute will not have any effect.

This attribute is turned off by default. This means when you move or copy a wire, the wire color is retained by default.

edit_wire_connect_pin

```
edit_wire_connect_pin {in|out|inout|nodir}
```

Default: `in out inout nodir`

Data_type: enum* {in out inout nodir}, read/write

Specifies the type of pin on which a via should be generated. You can specify the following pin types with this attribute:

- `in` - Generates a via on an input pin.
- `out` - Generates a via on an output pin.
- `inout` - Generates a via on an inout pin.
- `nodir` - Generates a via on a pin for which no direction is specified.

- select_routes

edit_wire_connect_with_specified_layer

```
edit_wire_connect_with_specified_layer {true|false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether or not the layer of connecting wires should be changed as per the `edit_wire_layer_horizontal` or `edit_wire_layer_vertical` settings when moving wires with the `edit_move_routes` command. If you set this attribute to `true`, `edit_move_routes` honors the `edit_wire_layer_horizontal` or `edit_wire_layer_vertical` settings while jogging metal layers. For instance, suppose you cut a vertical wire on `M4` by using `edit_cut_route` such that the wire is divided into three wire segments. Now, if you select the wire segment in the middle and move it in the horizontal direction, the tool automatically creates new connecting wires on the layer defined by `edit_wire_layer_horizontal` and drops vias correctly. This feature is applicable for both regular and special wires.

edit_wire_create_crossover_vias

```
edit_wire_create_crossover_vias {true|false}
```

Default: `true`

Data_type: bool, read/write

Specifies whether the software creates a via when you draw a wire that crosses a wire or pin of the same net that is on a different layer. Does not create vias if minimum or maximum layer constraints prevent the creation of vias. If you draw a wire between two pins, the software creates vias on the pins as needed, regardless of whether this option is selected or deselected.

If you set this attribute to `false`, the software does not create vias at crossovers. For example, if you draw a wire from left to right, the software begins creating a via at the left edge of the vertical target. This via is removed as soon as the drawing wire moves past the right edge of the vertical target.

edit_wire_create_is_edit_flag

```
edit_wire_create_is_edit_flag {true|false}
```

Default: false

Data_type: bool, read/write

Specifies whether to create the db property is_edit for wire edit. This property is used to flag nets with modified wires and vias. This is useful when evaluating how many objects need to be modified for fixing DRC violations and then deciding whether to fix the violations manually or through ECO routing. This property is written to the DEF file.

By default, this attribute is set to false. If you set the value of this attribute to true, the is_edit property is set to 1 for nets with modified wires or vias. The following type of modifications can cause is_edit to be set to 1:

- Drawing a new wire through edit_add_route_point and edit_end_route_point
- Moving a wire/via with edit_move_routes
- Stretching a wire/via with edit_resize_routes

You can reset the is_edit property with set_db.

Note: The is_edit property is independent of edit_wire_keep_status true.

edit_wire_create_via_on_pin

```
edit_wire_create_via_on_pin {true|false}
```

Default: `true`

Data_type: bool, read/write

Specifies whether the software creates vias at pins. Specify `false` to prevent the software from creating vias at pins. A value of `false` might be needed for bump pins that are not square-shaped.

Related Commands

edit_wire_cut_wire_overlap

```
edit_wire_cut_wire_overlap {regular|special}
```

Default: `regular`, which means that regular wires are cut with an overlap while special wires are cut without an overlap

Data_type: enum* {regular special}, read/write

Creates overlaps while cutting specified type of wires. The supported values are:

- `regular` - Cuts regular wires with an overlap
- `special` - Cuts special wires with an overlap

If this attribute is not specified, all wires are cut without overlap. This is equivalent to setting `edit_wire_cut_wire_overlap` to `""`.

edit_wire_debug_file

`edit_wire_debug_file` *`output_file`*

Default: `""`

Data_type: string, read/write

Specifies the file name for reporting untrimmed wires and vias if `edit_wire_verbose` is set to `true`. If you don't specify a name but `edit_wire_verbose` is set to `true`, the file is named `editTrim_debug.rpt`. If the tool finds the same file in the saved directory, the new file replaces the old one.

Related Commands

- edit_trim_routes
- edit_update_route_status

edit_wire_delete_tsv

`edit_wire_delete_tsv {true|false}`

Default: `false`

Data_type: bool, read/write

Specifies whether or not `delete_routes` deletes the items on a Through-Silicon Via (TSV) layer.

- `true` - The tool deletes the items on TSV layers if `delete_routes` is used without `-layer` or `-selected`.
- `false` - The tool does not delete the items on TSV layers if `delete_routes` is used without `-layer` or `-selected`.

Default: `false`

The `delete_routes` command observes the layer range setting specified by the `edit_wire_layer_min` and `edit_wire_layer_max` attributes, which specify the minimum and maximum routing layers, respectively. If `-layer` is specified with `delete_routes`, the tool ignores the range setting from the `edit_wire_layer_min` and `edit_wire_layer_max` attributes and deletes items only from the specified layers. If `-selected` is specified with `delete_routes`, the tool deletes only the selected wires and vias.

Related Command

- `delete_routes`

edit_wire_delete_pin_with_wire

`edit_wire_delete_pin_with_wire {true|false}`

Default: `true`

Data_type: bool, read/write

Deletes the pin with the wire.

Related Commands

- `delete_routes`
- `edit_add_route_point`
- `edit_merge_routes`
- `edit_move_routes`
- `edit_resize_routes`
- `edit_trim_routes`

- `edit_update_via`
- `select_routes`

edit_wire_delete_wire_via_through_layers

```
edit_wire_delete_wire_via_through_layers {true|false}
```

Default: `false`

Data_type: bool, read/write

Deletes wire via in the deep through mode, when set to `true`.

For instance, assume you have two vertical wires `M3` and `M5` at the same location. The tool will not drop vias between these two wires when you draw `M5` because both the wires have the same direction. However, when you draw the horizontal `M6` wire, the tool will drop the vias from `M3` to `M6`. All the three wires have the same net. Now, if you delete the `M6` wire, the setting for `edit_wire_delete_wire_via_through` determines which vias are removed.
If `edit_wire_delete_wire_via_through` is set to `true`, the tool deletes the via from `M3` to `M6`. However, if it is set to `false`, the tool only deletes the via from `M5` to `M6`.

- `edit_update_route_status`
- `edit_update_via`
- `select_routes`

edit_wire_display_wire_length_with_cursor

```
edit_wire_display_wire_length_with_cursor {true|false}
```

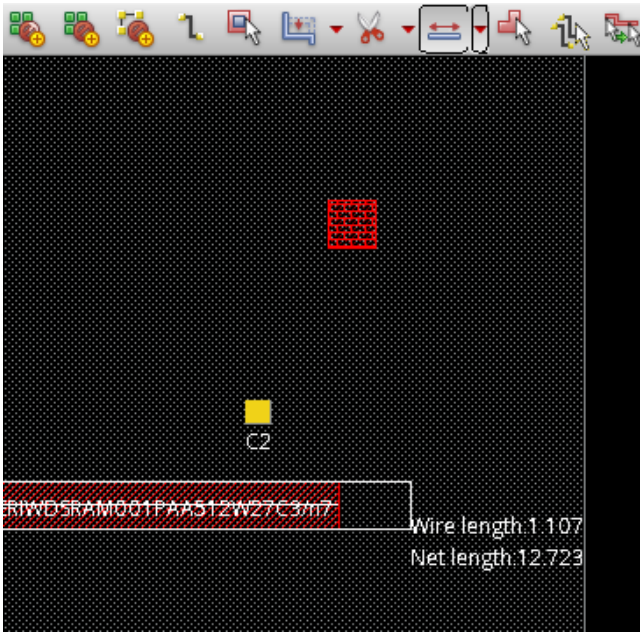
Default: `true`

Data_type: bool, read/write

Specifies whether or not to display the total and current wire length while editing wires by using the mouse. When this parameter is set to `true`, the tool displays the total and current wire length during the following wire edit

operations:

- Adding a new regular, special, or patch wire
- Stretching the length of a regular or special wire
- Resizing a patch wire



edit_wire_draw_shield

```
edit_wire_draw_shield {true|false}
```

Default: `false`

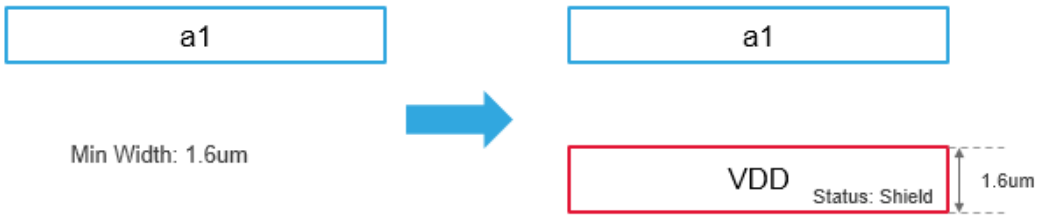
Data_type: bool, read/write

Specifies whether the wire being created is a shield wire.

When `edit_wire_draw_shield` is set to `true`, the wire editor creates a wire with the net name specified using the `shielding_nets` attribute. The newly created wire/via has its status set to `shield` and its shield signal net set to the net name specified with the `edit_wire_nets` attribute. Note that you can specify only one net with the `edit_wire_nets` attribute when drawing a shield wire. The new shield wire/via also has its shape set to `None`. The shield wire defaults to the minimum width and spacing, unless explicitly set to other values. Note that NanoRoute supports only minimum width and minimum spacing.

For example, If you want to draw a shield wire for the wire a1, set the following attributes before drawing the wire:

```
set_db edit_wire_nets a1
set_db edit_wire_shielding_nets VDD
set_db edit_wire_draw_shield true
set_db edit_wire_shape none
set_db edit_wire_width_horizontal 2
```



When `edit_wire_draw_shield` is set to `true`, the tool automatically sets the status of the new wire to `shield` and its width to the minimum width (1.6um). If you also want to change the shield net attribute for the net, set the `edit_wire_update_shield_net` parameter to `true` as well before drawing the wire.

When `edit_wire_draw_shield` is set to `false`, the wire editor reverts to its original behavior and draws a wire/via with the net specified using the `edit_wire_nets` attribute.

Notes:

When `edit_wire_draw_shield` is set to `true`, the following `edit_wire` attributes are ignored:

- `edit_wire_shield`
- `edit_wire_shield_shape`

- `select_routes`

edit_wire_draw_with_group_centerline

```
edit_wire_draw_with_group_centerline {true|false}
```

Default: `false`

Data_type: bool, read/write

Draws the bus along the center-line of whole wires when set to `true`.

Enable this option if you set `edit_wire_auto_distribute_bus` to `true`.

If `edit_wire_draw_with_group_centerline` is set to `true`, the tool ignores the `edit_wire_drawing_wire` setting.

- `edit_update_route_rule`
- `edit_update_route_status`
- `edit_update_via`
- `select_routes`

edit_wire_drawing_wire

`edit_wire_drawing_wire` *`value`*

Default: `1`

Data_type: int, read/write

Specifies which of the nets used with the `edit_wire_nets` attribute corresponds to the mouse pointer location when adding an array of wires. For horizontal wires, a value of `1` indicates the bottom-most net. For vertical wires, a value of `1` indicates the left-most net. The *`value`* is an integer of the same or lower value as the number of nets. For example, if you specify 5 nets, you can specify `1`, `2`, `3`, `4`, or `5` as the value for this parameter.

This net is also used as the reference net when changing direction. All other nets around this net are lengthened or shortened accordingly.

edit_wire_drc_aware_cross_metal

```
edit_wire_drc_aware_cross_metal {true|false}
```

Default: `true, read/write`

Data_type: bool

Specifies whether or not to stretch or move a wire back to the closest location available before a violation occurs with the crossing metal. This option works only if `edit_wire_stop_at_drc` is set to `true`:

- If both `edit_wire_stop_at_drc` and `edit_wire_drc_aware_cross_metal` are set to `true`, the tool stops moving or stretching the wire at the closest location available before a spacing violation occurs with the crossing metal.
- If `edit_wire_stop_at_drc` is set to `true` but `edit_wire_drc_aware_cross_metal` is set to `false`, the tool moves or stretches the wire to the desired location across the crossing metal even if it results in a spacing DRC violation.

This attribute impacts the following type of modifications:

- Drawing a new wire through `edit_add_route_point` and `edit_end_route_point`
- Moving a wire/via with `edit_move_routes`
- Stretching a wire/via with `edit_resize_routes`

Related Commands

- edit_add_route_point
- edit_end_route_point
- edit_move_routes
- edit_resize_routes

edit_wire_drc_on

```
edit_wire_drc_on {true|false}
```

Default: `true`

Data_type: bool, read/write

Specifies whether design rule checking (DRC) should be performed during wire and via editing.

While modifying a via with edit_update_via, the `edit_wire_drc_on` and `edit_wire_keep_via` settings are used in combination to decide whether or not a via should be replaced if the new via cell results in DRC violations. For more details, see edit_update_via.

edit_wire_drc_use_non_default_spacing

```
edit_wire_drc_use_non_default_spacing {true|false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether non-default spacing defined in the non-default rule (NDR) of the editing net should be used for spacing check during wire editing.

Note

- By default (`false`), the Wire Editor DRC check honors the default/minimum spacing.
- If the net or via has an NDR with the `HARDSPACING` keyword, the Wire Editor DRC check honors the non-default spacing even if `edit_wire_use_non_default_spacing` is set to `false`.
- After `edit_wire_use_non_default_spacing 1` is set, all subsequent wire editing commands honor the non-default spacing during the geometry check on the net/via if the NDR is defined.

edit_wire_extend_wires

```
edit_wire_extend_wires {start|end|start_cell_boundary|end_cell_boundary}
```

Default: `""`

Data_type: enum* {start end start_cell_boundary end_cell_boundary}, read/write

Specifies which boundary of the wire segment extends and connects to the first logical target, after completing a signal or power route. You can specify the following boundary options with this parameter:

- `start` - Specifies that the startpoint of the route segment extends and connects to the first logical target, after

completing a signal or power route. If there is no logical target, the startpoint is not changed.

- `end` - Specifies that the endpoint of the route segment extends and connects to the first logical target, after completing a signal or power route. If there is no logical target, the endpoint is not changed.
- `start_cell_boundary` - Specifies that the startpoint of the segment always extends to the cell boundary, after completing a special route. If the segment is extended to the boundary and crosses the wires on the same net, the tool makes a via connection to the wires. In addition, the tool creates pins at the boundary. This parameter can only be used in conjunction with `-extend_wires start`.
- `end_cell_boundary` - Specifies that the endpoint of the segment always extends to the cell boundary, after completing a special route. If the segment is extended to the boundary and crosses wires on the same net, the tool makes a via connection to the wires. In addition, the tool creates pins at the boundary. This parameter can only be used in conjunction with `-extend_wires end`.

Note: If you do not want the wire segment to be extended, set `edit_wire_extend_wires` to `""`.

edit_wire_final_check_with_verify

```
edit_wire_final_check_with_verify {true|false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether to do final checks with verify.

When `edit_wire_final_check_with_verify` is set to `true`, Wire Editor calls the Full Geometry Checker (FGC) engine for the final DRC check on the bounding box of changed area after commits. This ensures that the final wire editing result is DRC clean as per FGC. Specify this attribute if you are using advanced rules, such as 20nm and 14nm.

- `select_routes`

edit_wire_ignore_drc

`edit_wire_ignore_drc {conn_antenna|max_via_stack|min_cut|min_enclosed_area|min_step|protrusion}`

Default: `""`

Data_type: enum* {conn_antenna max_via_stack min_cut min_enclosed_area min_step protrusion}, read/write

Specifies which violation type should be ignored during wire editing. You can specify the following options:

- `conn_antenna` - Does not check the connection antenna for DRC violations.
- `max_via_stack` - Does not check maximum via stack DRC violations during wire editing.
- `min_cut` - Does not check for minimum cut DRC during wire editing.
- `min_enclosed_area` - Does not perform minimum enclosed area DRC during wire editing.
- `min_step` - Does not perform minimum step DRC during wire editing.
- `protrusion` - Does not perform protrusion DRC during wire editing.

Note: If you do not want to ignore any violation type, set `edit_wire_ignore_drc` to `""`.

edit_wire_jog_connect_layer

`edit_wire_jog_connect_layer` *value*

Default: `0`

Data_type: int, read/write

Specifies the number of layers by which the new jog wire segments created on moving a wire should be moved up or down. Note that the `edit_wire_jog_connect_layer` attribute will have no impact if you have set the `edit_wire_connect_with_specified_layer` attribute to `true`.

- The following example uses the `edit_wirejog_connect_layer` attribute to specify that the tool should automatically move up new jog wires created on moving a wire segment by 1 layer:

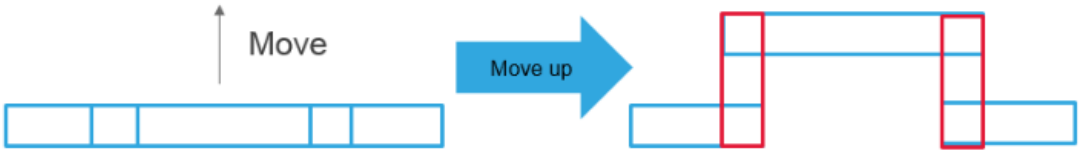
  ```
  set_db edit_wire_connect_with_specified_layer false
  set_db edit_wire_jog_connect_layer 1
  ```

  
  Here, the blue wire segments are on layer `M2` while the red jog wire segments are on the `M3` layer.

- In the following example, as the `edit_wire_jog_connect_layer` parameter is set to -1, the tool automatically moves down the new jog wires by 1 layer:

  ```
  set_db edit_wire_connect_with_specified_layer false
  ```

```
set_db edit_wire_jog_connect_layer -1
```



In this case, the blue wire segments are on layer M2 while the red jog wire segments are on the M1 layer.

edit_wire_keep_floating_via

```
edit_wire_keep_floating_via {true|false}
```

Default: `false`

Data_type: bool, read/write

Controls whether or not floating vias are retained when wires are deleted. By default, floating vias are deleted when you delete a wire.

Set the `edit_wire_keep_floating_via` attribute to `true` if you want to retain floating vias when you delete wires.

- edit_update_via
- select_routes

edit_wire_keep_status

```
edit_wire_keep_status {true|false}
```

Default: `true`

Data_type: bool, read/write

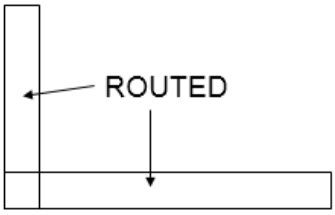
Specifies whether or not the object status should be changed during editing. This option is set to `true` by default, which means wire status is not changed after editing. If this option is set to `false`, the wire status is changed to `FIXED` automatically after `edit_move_routes` and `edit_resize_routes`.

Notes:

This option has an impact on both regular and special wires and vias. The tool only changes the status of the wire segment that is modified.

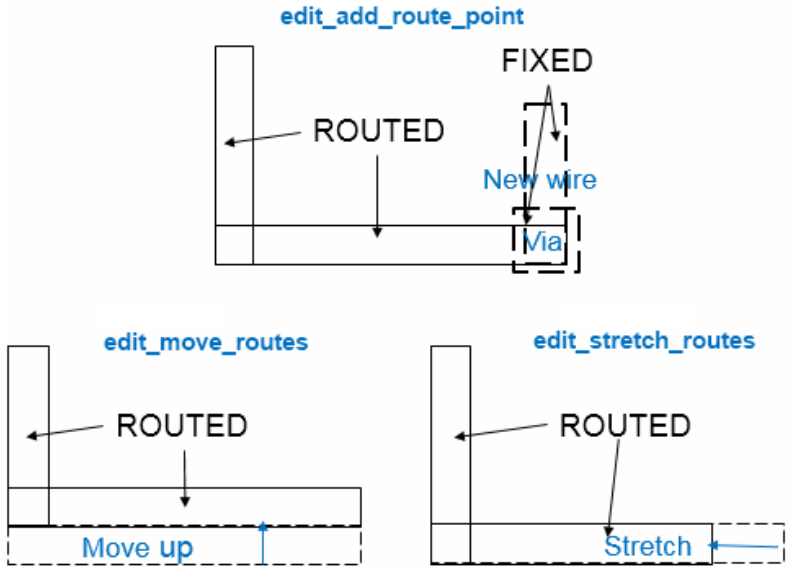
Use the `set_db edit_wire_status FIXED` command to set the status of newly drawn wires to `FIXED` after `edit_add_route_point`.

Consider the wire segment shown in the figure below:



- The following command specifies that the status of the modified wire segment should be retained after `edit_move_routes` and `edit_resize_routes`:

  ```
  set_db edit_wire_status FIXED
  set_db edit_wire_keep_status true
  ```



- The following command specifies that the status of the modified wire segment should be changed to `FIXED` after `edit_move_routes` and `edit_resize_routes`:

  ```
  set_db edit_wire_status FIXED
  set_db edit_wire_keep_status false
  ```

- edit_update_route_status
- edit_update_via
- select_routes

edit_wire_keep_via

```
edit_wire_keep_via {true|false}
```

Default: `false`

Data_type: bool, read/write

Controls whether or not the original via is retained in a wire move or stretch. If this attribute is set to `true`, the tool keeps the via unchanged if there is no DRC violation as a result of the move or stretch. However, the tool can change the via if a DRC violation occurs. Set the `edit_wire_keep_via` attribute to `false` if you do not want the original via to be retained when a wire is moved or stretched. This attribute is applicable for both regular and special vias.

While modifying a via with `edit_update_via`, the `edit_wire_keep_via` and `edit_wire_drc_on` settings are used in combination to decide whether or not a via should be replaced if the new via cell results in DRC violations. For more details, see `edit_update_via`.

edit_wire_lateral_movement_range

`edit_wire_lateral_movement_range` *value*

Default: `0.0`

Data_type: double, read/write

Specifies how much the wire you are adding or stretching can be moved laterally to avoid potential DRC violations with existing wires, nets, or blockages. The preferred lateral movement direction is up for horizontal wires and left for vertical wires, provided this movement does not result in a new violation.

If a violation cannot be avoided even by moving the new wire within the specified lateral movement range, the tool obeys other specified wire edit settings. For example, if the `edit_wire_stop_at_drc 1` setting is specified, the tool moves or stretches the new wire up till the closest location available before the DRC violation occurs.

Notes:

- The `edit_wire_lateral_movement_range` attribute works only if `edit_wire_drc_on` is set to `1`.
  If `edit_wire_drc_on` is set to `0`, the tool ignores the `edit_wire_lateral_movement_range` setting.
- The `edit_wire_lateral_movement_range` attribute can support multiple nets.
- The `edit_wire_lateral_movement_range` attribute is relevant only for avoiding violations with wires and vias. If the wire being added crosses a routing blockage or cell OBS, the `edit_wire_lateral_movement_range` setting is ignored.

See the examples below to understand how the `edit_wire_lateral_movement_range` attribute works:

In the following examples, the blue wire is being moved or stretched from left to right. See how the tool behavior changes with the various edit_wire attribute settings given below:

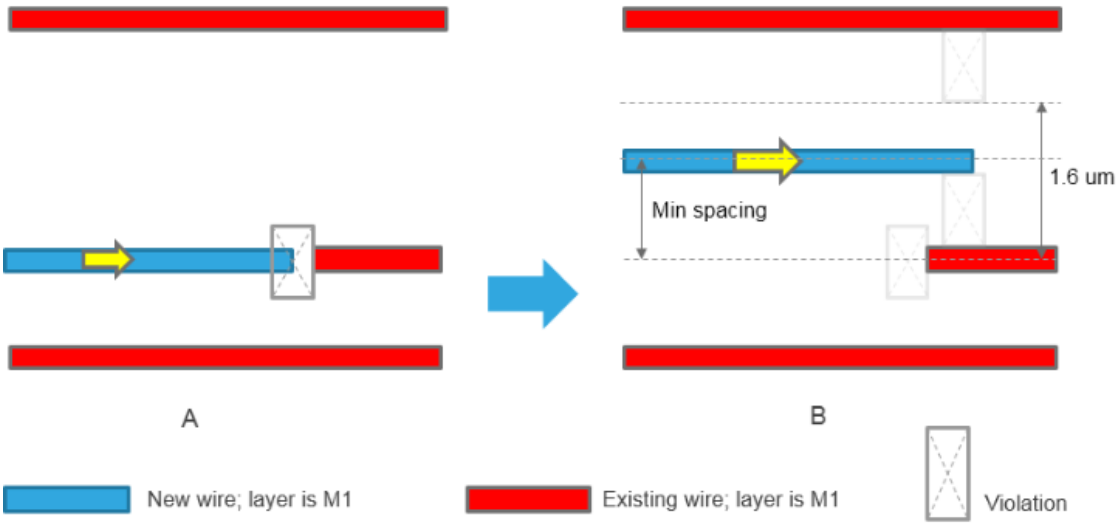
- ```
  set_db edit_wire_drc_on 1
  set_db edit_wire_lateral_movement_range 0
  set_db edit_wire_stop_at_drc 1
  ```

  This wire edit will generate a violation with an existing wire (see A), so the tool shrinks the new wire to a distance such that there is no violation (see B).

- ```
  set_db edit_wire_drc_on 1
  set_db edit_wire_lateral_movement_range 0
  set_db edit_wire_stop_at_drc 0
  ```

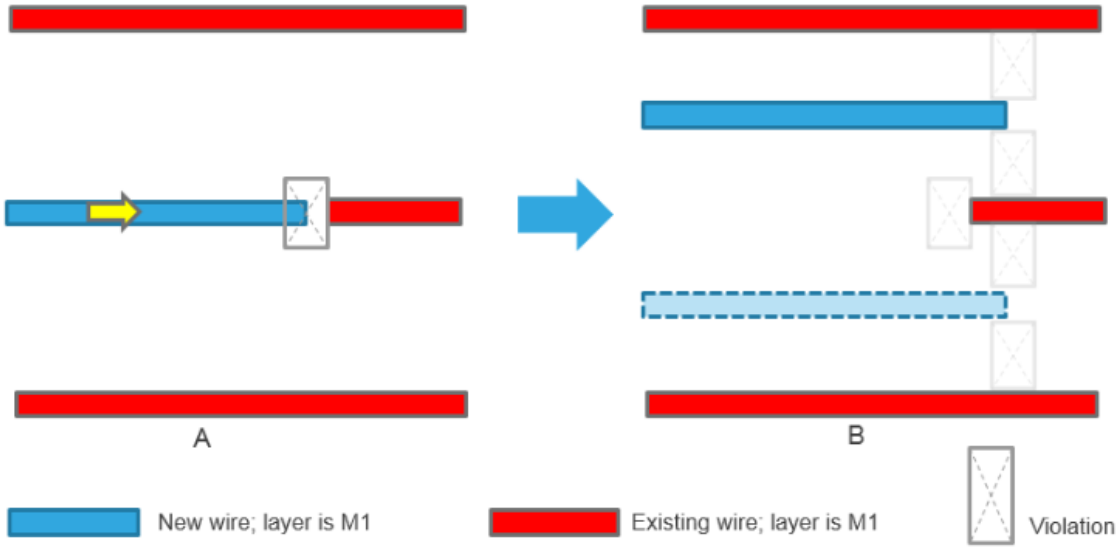
  This wire edit will generate a violation with an existing wire (see A). However, the tool allows the new wire to be moved or stretched to any length and reports a violation because of the `edit_wire_stop_at_drc 0` setting (see B).

- ```
  set_db edit_wire_drc_on 1
  set_db edit_wire_lateral_movement_range 1.6
  set_db edit_wire_stop_at_drc 1
  ```
  ```



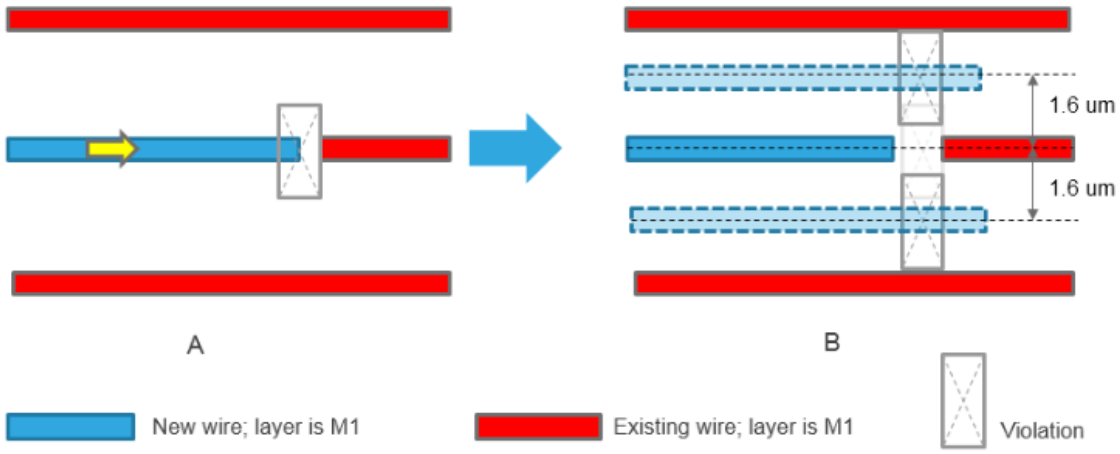
This wire edit will generate a violation with an existing wire (see A). So, the tool moves the new wire up by a minimum distance to avoid generating a violation (see B).

- ```
  set_db edit_wire_drc_on 1
  set_db edit_wire_lateral_movement_range 1.6
  set_db edit_wire_stop_at_drc 1
  ```



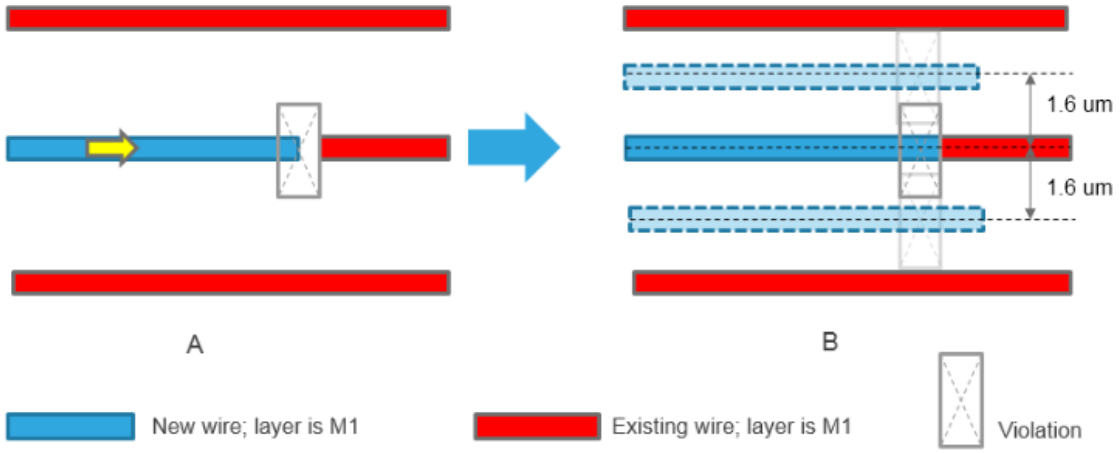
This wire edit will generate a violation with an existing wire (see A). The blue wire can be moved either up or down to avoid the violation. In this case, the tool moves the wire up, which is the preferred direction for horizontal wires (see B).

- ```
  set_db edit_wire_drc_on 1
  set_db edit_wire_lateral_movement_range 1.6
  set_db edit_wire_stop_at_drc 1
  ```



This wire edit will generate a violation with an existing wire (see A). However, even if the blue wire is moved up or down within the specified lateral movement range, the tool still cannot avoid a violation. Therefore, the tool obeys other specified wire edit settings. In this example, the tool obeys the `-stop_at_drc 1` setting and moves or stretches the blue wire up till the closest location available before the DRC violation occurs (see B).

- ```
  set_db edit_wire_drc_on 1
  set_db edit_wire_lateral_movement_range 1.6
  set_db edit_wire_stop_at_drc 0
  ```



This wire edit will generate a violation with an existing wire (see A). However, even if the blue wire is moved up or down within the specified lateral movement range, the tool still cannot avoid a violation. Therefore, the tool obeys other specified wire edit settings. In this example, the tool obeys the `-stop_at_drc 0` setting and allows you to move or stretch the wire even though it results in a DRC violation. (see B).
  ```

edit_wire_max_pointer_number

edit_wire_max_pointer_number *integer*

Default: 100

Data_type: int, read/write

Specifies the maximum number of pointers to be returned by wire edit commands. Use this attribute along with edit_wire_return_obj_pointer to control object pointers returned by wire edit commands. The returned pointers make it possible for you to select and further edit the newly created or modified wire or via.

- select_routes

edit_wire_mirror_bus_route

```
edit_wire_mirror_bus_route {true|false}
```

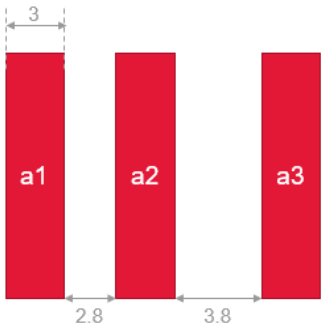
Default: `false`

Data_type: bool, read/write

Specifies whether or not to reverse the net order for the bus route. When this attribute is specified, the definition of the wire override spec is reversed. For example, suppose you have drawn a bus route with the following settings:

```
set_db edit_wire_nets {a1 a2 a3}
set_db edit_wire_override true
set_db edit_wire_wire_override_spec {{1 3 2.8} {2 3 3.8} {3 3 4.8}}
```

The bus is drawn as follows, with nets counted from left to right:



Now, by setting `edit_wire_mirror_bus_route` to `true`, you can draw a mirror bus route with nets counted from right to

left:

```
set_db edit_wire_nets {a1 a2 a3}
set_db edit_wire_override true
set_db edit_wire_wire_override_spec {{1 3 2.8} {2 3 3.8} {3 3 4.8}}
set_db edit_wire_mirror_bus_route true
```

- select_routes

edit_wire_nets

`edit_wire_nets` *nets*

Default: ""

Data_type: string, read/write

Specifies one or more nets for editing. If you specify multiple nets, separate each net name with a space and enclose the names in curly braces.

You can use the following format to specify a bus:

netName`[`*x*`:`*y*`]`

For example, to draw eight wires for a bus, type the following:

`edit_wire_nets` *netName*`[7:0]`

This is equivalent to specifying *netName*`[7], `*netName*`[6], ... `*netName*`[0]`. Specifying `edit_wire_nets` *netName*`[0:7]` reverses the order.

The order in which you specify the nets determines the drawing arrangement of the wires.

- For horizontally drawn wires, the first net specified is drawn as the bottom-most wire, followed by the next net on its top side, and so on. The last net specified is drawn as the top-most wire.
- For vertically drawn wires, the first net specified is drawn as the left-most wire, followed by the next net, and so on. The last net specified is drawn as the right-most wire.

edit_wire_no_merge_special_wire

`edit_wire_no_merge_special_wire {true|false}`

Default: `false`

Data_type: bool, read/write

Specifies whether or not a wire being added should be merged automatically with any existing wire at that point. Set this attribute to true, if you want to disable the auto merge feature.

Related Commands

edit_wire_only_show_edit_layer

```
edit_wire_only_show_edit_layer {true|false}
```

Default: `true`

Data_type: bool, read/write

Specifies that only the layer with the objects being edited should be shown and other layers and objects should be dimmed out during the following wire/via edit operations:

- Add
- Resize
- Copy/Move

Related Commands

edit_wire_orthogonal_connection_only

```
edit_wire_orthogonal_connection_only {true|false}
```

Default: `true`

Data_type: bool, read/write

Specifies whether to consider wires and pins that are in the same direction as a target for connection. For example, if you extend a wire to the left, any horizontal wire it meets is not considered for a target if the value of this attribute is set to `true`. However, a vertical wire is considered a target.

edit_wire_outer_shield_width

`edit_wire_outer_shield_width` *value*

Default: `0.0` (minimum wire width on the layer)

Data_type: double, read/write

Specifies a width value in microns to be used for outer shield(s) depending on the setting of the `edit_wire_shield` attribute.

Note: You must define the outer shield first. The outer shield is the shielding wire beyond the first or the last wire being created manually.

edit_wire_partial_overlap_threshold

`edit_wire_partial_overlap_threshold` *value*

Default: `0`

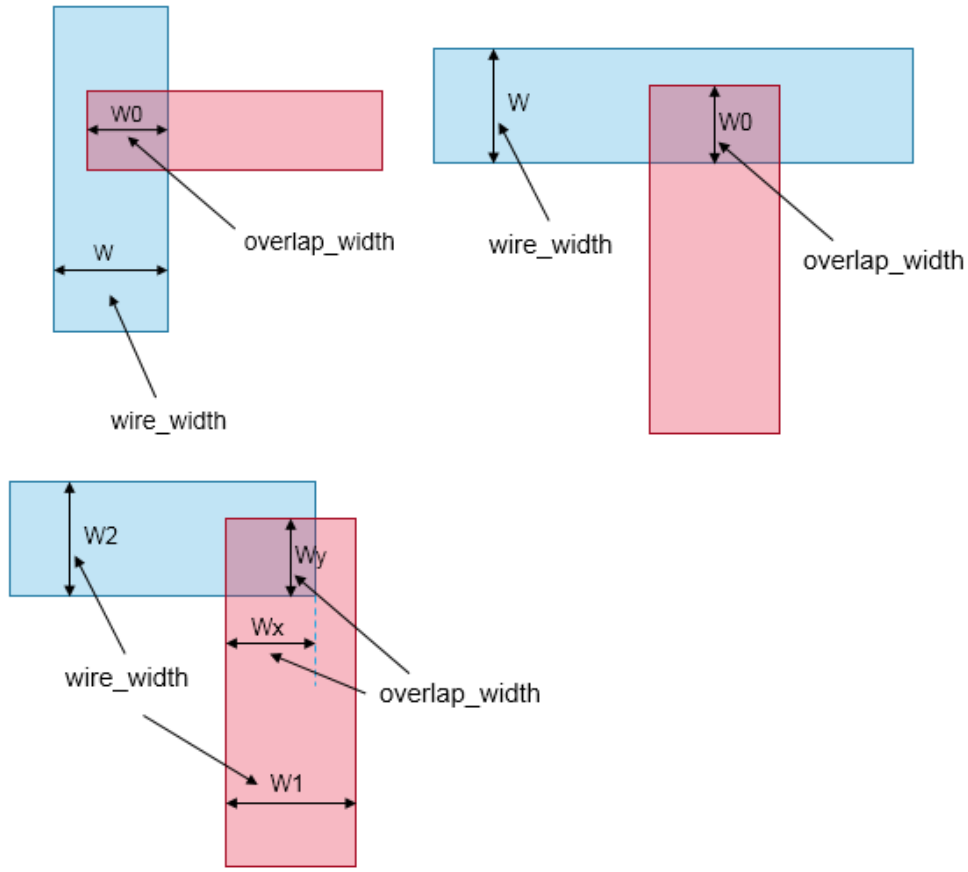
Data_type: int, read/write

Specifies the ratio threshold for special via creation on partially overlapping wires. The threshold value may range from `0` to `100`, with a value of `100` specifying that no via is dropped on a partial overlap intersection. The tool drops a via only when the `overlap_width` to `wire_width` ratio percentage is greater than or equal to the specified threshold value.

For example, suppose the threshold value is set to `100`. Now consider the following cases in which the pink wire is being drawn over the existing blue wire:

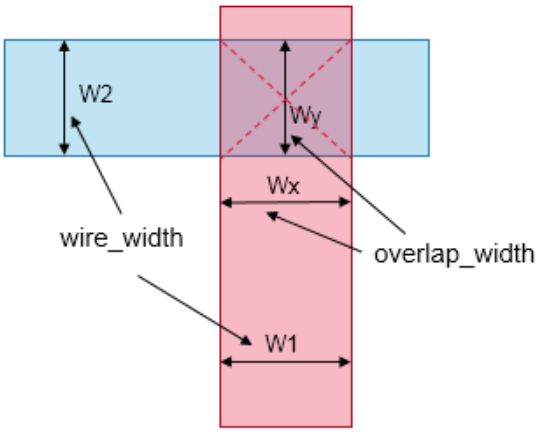
Case 1 - Overlap width less than wire width

In each of the cases depicted below, the `overlap_width` is less than the corresponding `wire_width`. As the `overlap_width` to `wire_width` ratio percentage is less than `100`, which is the specified threshold value, the tool does not drop a via on the partial overlap area:



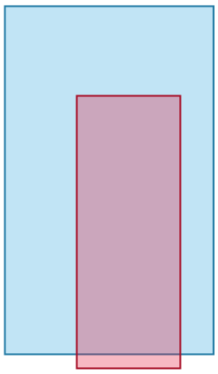
Case 2 - Overlap width equal to wire width

In the following case, the `overlap_width` is equal to the corresponding `wire_width`. As the `overlap_width` to `wire_width` ratio percentage is equal to `100`, which is the specified threshold value, the tool drops a via on the overlap area.



Notes:

- The `partial_overlap_threshold` attribute value is applicable only if the new wire is crossing an existing wire in a different direction. If the new wire being drawn is overlapping an existing wire in the same direction, the tool does not create a via:



- If the `edit_wire_create_crossover_vias` attribute is set to `false`, the tool ignores the setting of the `edit_wire_partial_overlap_threshold` attribute and does not create any via on the overlap area.

edit_wire_pull_back_distance

`edit_wire_pull_back_distance` *`string`*

Default: `auto`, which means the tool uses the largest min spacing of the layer as the forbidden distance.

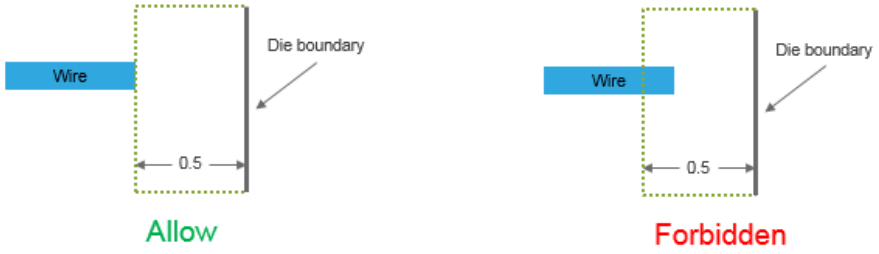
Data_type: string, read/write

Specifies the value for forbidden distance. If the `edit_wire_check_design_boundary` attribute is set to `true`, the tool takes into account the settings of the `edit_wire_pull_back_distance` attribute during wire edit operations.

If the `edit_wire_pull_back_distance` value is positive, the tool marks the corresponding area inside the boundary as an extra keep-out area. For example, if you specify the following command, the tool marks 0.5 distance inside the die boundary on all edges as an extra keep-out area and does not allow you to stretch a wire into this area. You are allowed to stretch the wire only up till the forbidden line.

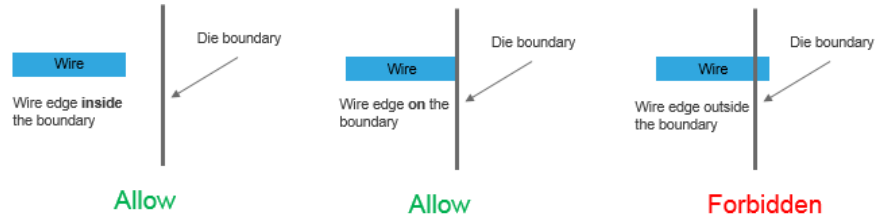
```
set_db edit_wire_check_design_boundary true

set_db edit_wire_pull_back_distance 0.5
```



If the `edit_wire_pull_back_distance` value is `0`, the tool does not allow you to manually stretch a wire beyond the die boundary. If you try to stretch the wire edge beyond the boundary, the tool stops the wire edge at the boundary and prints a warning.

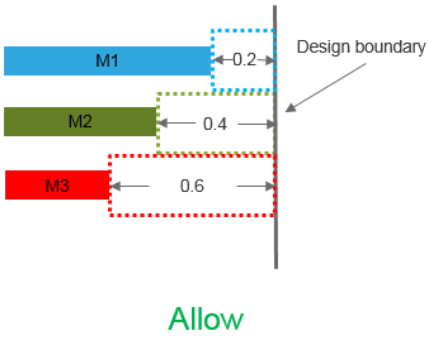
```
set_db edit_wire_check_design_boundary true
set_db edit_wire_pull_back_distance 0
```



If the edge of a wire is already beyond the boundary (with `set_db edit_wire_check_design_boundary true` and `set_db edit_wire_pull_back_distance 0`) and you attempt to stretch it further, the wire remains in the current location and the tool does not allow further stretching.

If you stretch multiple wires with `edit_wire_pull_back_distance` set to `auto`, the tool uses the largest spacing value of each layer as the pull back distance for related wire. For example, the diagram below illustrates pull back distances if the spacing for different layers is set as follows:

```
M1: 0.2      M2: 0.4      M3: 0.6
```



If you do not need the `edit_wire_pull_back_distance` constraint, set `edit_wire_check_design_boundary` to `0`.

Note: 45-degree wires do not follow this rule

edit_wire_return_obj_pointer

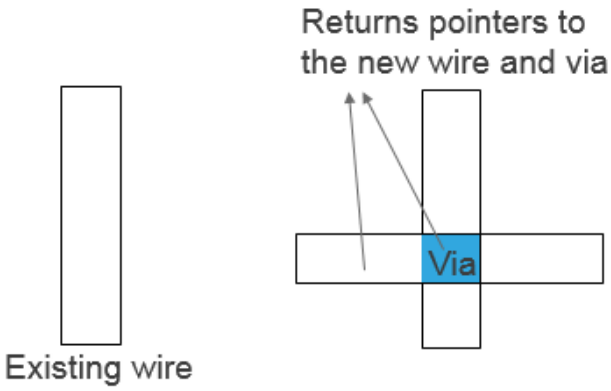
```
edit_wire_return_obj_pointer {true|false}
```

Default: `false`

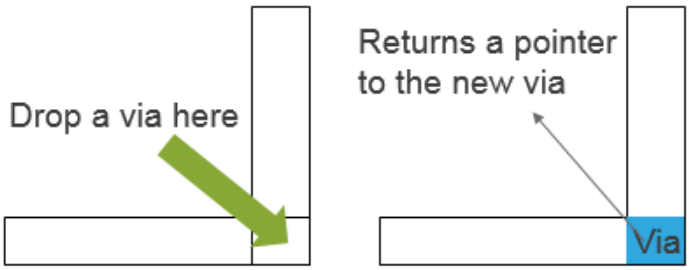
Data_type: bool, read/write

Specifies whether or not pointers are returned after wire edit operations. This attribute is set to `false` by default. When set to `true`, the wire edit commands mentioned in Related Commands return pointers for new or modified wires and vias. The returned pointers make it possible for you to select and further edit the newly created or modified wire or via. The diagrams below illustrate the pointers that are returned after some common wire edit operations:

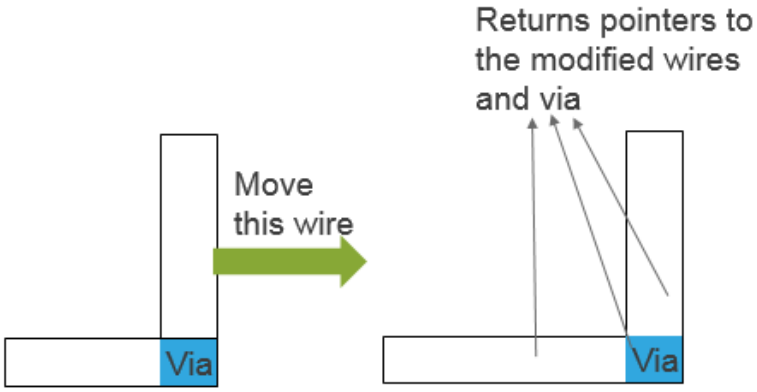
Case 1: Draw a wire

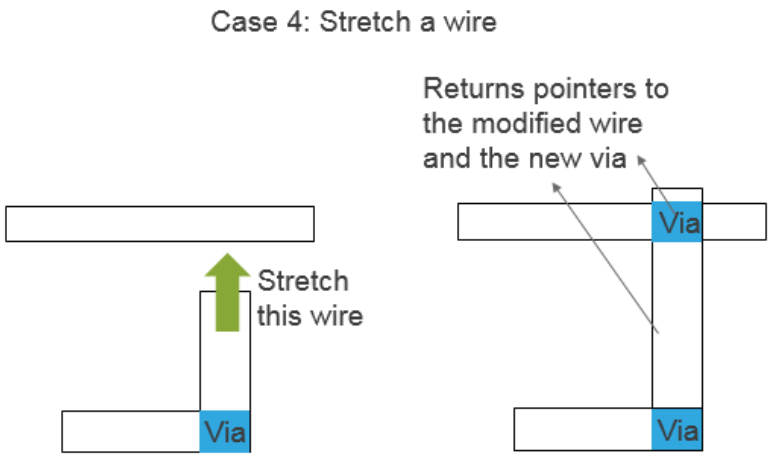


Case 2: Add a via



Case 3: Move a wire





Related Commands

The following wire edit commands return pointers for new or modified wires and vias when the `edit_wire_return_obj_pointer` attribute is set to `true`:

- `edit_create_via`
- `edit_copy`
- `edit_cut_route`
- `edit_duplicate_routes`
- `edit_end_route_point`
- `edit_merge_routes`
- `edit_move_routes`
- `edit_resize_routes`
- `edit_rotate`
- `edit_split_routes`
- `edit_trim_routes`
- `edit_update_route_layer`
- `edit_update_via`

edit_wire_rule

`edit_wire_rule` *`rule`*

Default: `default`

Data_type: string, read/write

Uses the specified LEF rule for regular wires.

Related Commands

- `delete_routes`
- `edit_add_route_point`
- `edit_merge_routes`
- `edit_move_routes`
- `edit_resize_routes`
- `edit_trim_routes`

- `edit_update_route_net`
- `edit_update_route_rule`
- `edit_update_route_status`
- `edit_update_via`
- `select_routes`

edit_wire_search_route_rule_vias_only

```
edit_wire_search_route_rule_vias_only {true|false}
```

Default: `false`

Data_type: bool, read/write

Specifies that when the *Shift + N* bindkey is used, the Wire Editor should circle through NDR vias only.

Related Commands

- delete_routes
- edit_add_route_point
- edit_merge_routes
- edit_move_routes
- edit_resize_routes

- edit_update_via
- select_routes

edit_wire_shape

```
edit_wire_shape {ring stripe followpin iowire corewire blockwire padring blockring fillwire
fillwireopc drcfill none}
```

Default: `stripe`

Data_type: enum {ring stripe followpin iowire corewire blockwire padring blockring fillwire fillwireopc drcfill none}, read/write

Specifies the shape associated with the wire you draw.

Related Commands

edit_wire_shield

`edit_wire_shield {high|low|adjacent}`

Default: `""`

Data_type: enum* {high low adjacent}, read/write

Specifies the side to which a minimum width shield wire should be added. Use the following options to specify the side:

- `adjacent` - Specifies that a minimum width shield wire(s) should be added centered between two adjacent wires.
- `high` - Specifies that minimum width shield wires should be added at the top (High) side of horizontal routes or at the right side of vertical routes. The spacing of the added shield wire is determined by the value of the `edit_wire_outer_shield_spacing` attribute. If this value is `0`, the spacing is determined by the minimum spacing rule in the technology file.
- `low` - Specifies that minimum width shield wires should be added at the bottom (Low) side of horizontal routes or at the left side of vertical routes. The spacing of the added shield wire is determined by the value of the `edit_wire_outer_shield_spacing` attribute. If this value is `0`, the spacing is determined by the minimum spacing rule in the technology file.

Note: If you do not want to specify the side to which the minimum width shield wire should be added, set `edit_wire_shield` to `""`.

edit_wire_show_drc_info_for_edit_shape

```
edit_wire_show_drc_info_for_edit_shape {true|false}
```

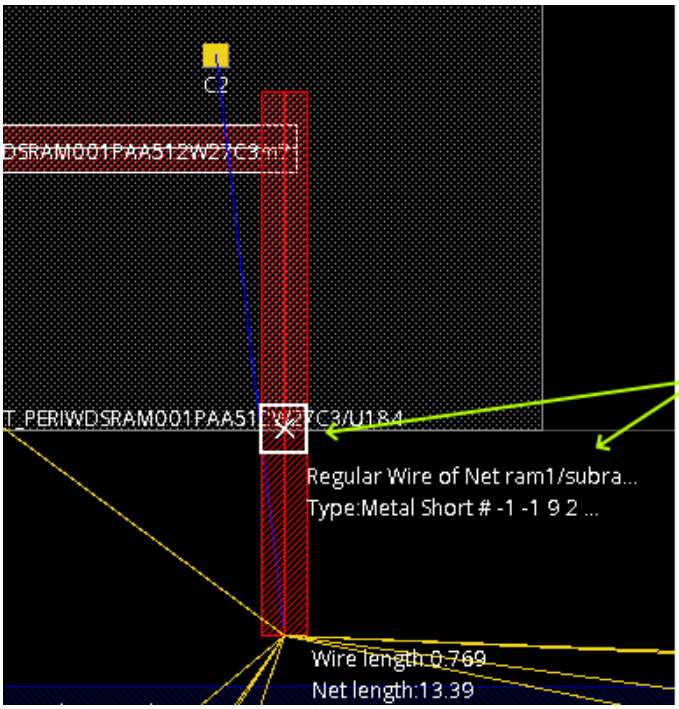
Default: `true`

Data_type: bool, read/write

Specifies that the tool should display the detailed DRC information in a violation marker nearby if a violation is generated during the following wire/via edit operations:

- Add
- Resize
- Move

In the example below, the wire being added will cause a Metal Short violation as mentioned in the DRC information displayed near the violation marker:



You can address the DRC issues displayed by either:

- Cancelling the edit operation causing the DRC violation.
- Adjusting the edit operation to meet the DRC requirement. For instance, in the example shown below, the wire being added is causing a Parallel Run Length spacing violation:

  In this case, you can move the right edge to save spacing. The DRC violation and related information will disappear:

Note: If there are any existing violation markers, they are dimmed out so that the latest marker is more clearly visible.

edit_wire_snap_align_to

```
edit_wire_snap_align_to {center low high auto}
```

Default: `auto`

Data_type: enum {center low high auto}, read/write

Specifies how to align with a pin when ending a route. To ensure the proper alignment, do not specify `edit_wire_snap_objects_to_track` with this attribute. Select one of the following:

- `center`: Snaps wires to the center of the pin.
- `low`: Snaps wires to the bottom of vertical pins or to the left side of horizontal pins.
- `high`: Snaps wires to the top of vertical pins or to the right side of horizontal pins.
- `auto`: The software determines alignment automatically.

edit_wire_snap_bus_to_pin

```
edit_wire_snap_bus_to_pin {true|false}
```

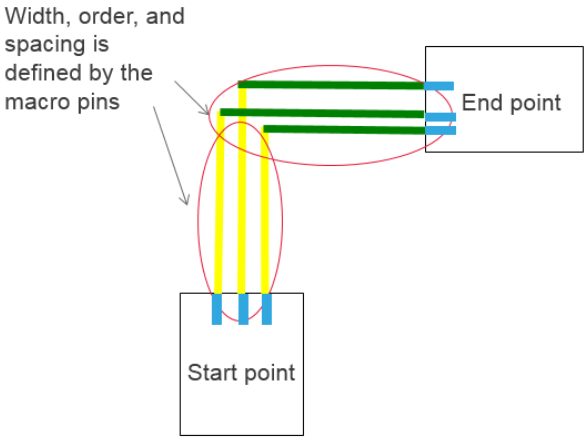
Default: `false`, which means the tool does not snap each wire of the bus to the macro pin automatically.

Data_type: bool, read/write

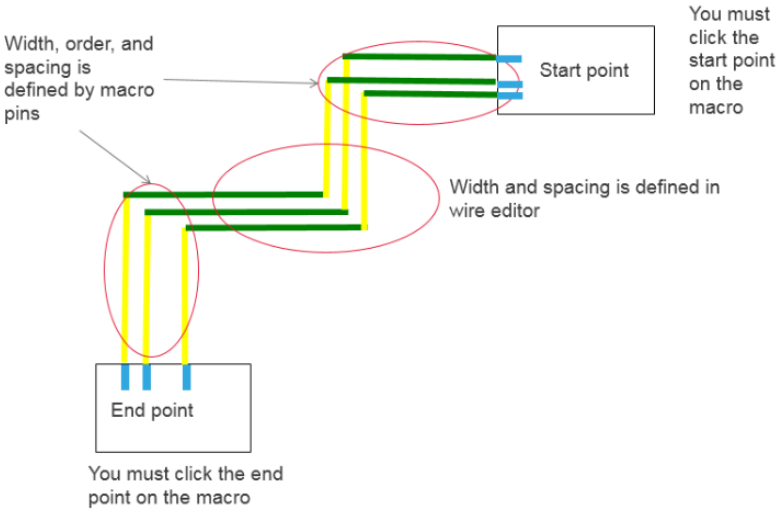
Specifies whether or not to change wire width, spacing, and order according to the connected pin.
The `edit_wire_snap_bus_to_pin` attribute supports macro to IO pin snapping as well as IO pin to IO pin snapping.

When you set the `edit_wire_snap_bus_to_pin` option to `true`:

- You do not have to align the pins at the start/end macro. Just start drawing the bus from the start macro and draw the subsequent wire segments until you arrive at the end macro. When you double-click to end the bus, all the start and end segments of the bus snap to their respective pins automatically.
- The tool gets the pin width and spacing information, and changes the wire width, spacing, and order according to the connected pins for the start and end segments of the bus.

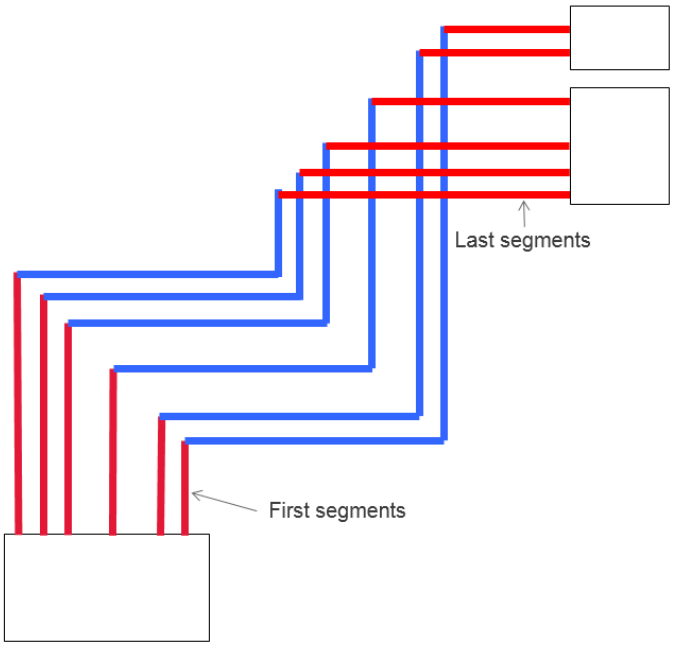


- If the bus has multiple corners, the tool uses the width and spacing value defined by the wire edit options for the middle segments of the bus.



- The tool also changes the wire segment layer according to the pin layer when accessing the pins. If the connecting pin is on a single layer, such as M4, the tool changes the wire segment layer to M4 when accessing pins. If the connecting pin is on multiple layers, the tool changes layers as follows:
    - If the pin is on M2, M3, and M4, but you have defined M5 and M6 for wire edit, the tool uses M4 for the first wire segment. In that way, wire edit has minimum via when connecting the first and second wire segment.
    - If the pin is on M2, M3, and M4, but you have defined M2 and M3 for wire edit, tool uses M3 for the first wire segment when connecting to the pin in the vertical direction (Wire edit sets M2 as the horizontal layer and M3 as the vertical layer).

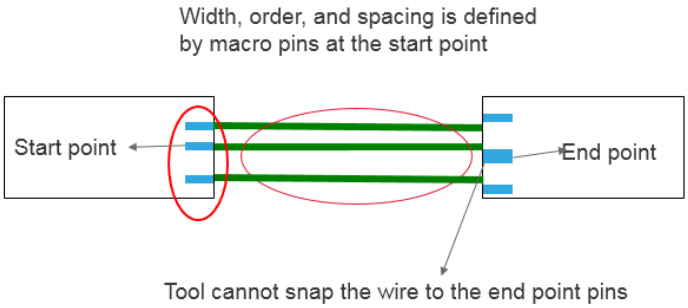
  For middle segments of the bus, the tool still uses the wire edit layer setting.
- `snap_bus_to_pin` supports snapping from one to multiple (1->N) macros for bus. When drawing the bus, the end points could be the pins on different macros. As long as the end point is inside a macro, the tool is able to auto snap to these IO cell pins. The following diagram depicts how `edit_wire_snap_bus_to_pin`, when enabled, supports 1->N macros.



- When you click outside the design core area after drawing a bus, the wires of the bus are snapped to the IO pin.

When using the `edit_wire_snap_bus_to_pin` option, keep the following limitations in mind:

- The bus routing pattern must have at least one corner. Otherwise, the tool cannot snap the bus to both the start and end target pins.



- You must click at the macros with target pins for the start and end points of the bus. The tool searches only the specified macros for the connected pins.
- For a regular wire, the tool creates an NDR for each pin width automatically (the width is not defined in tech LEF), but you cannot delete the NDR from the database.

Both regular and special wires support this feature.

Note: The `edit_wire_snap_bus_to_pin` option is exclusive to the `set_db edit_wire_snap_to pin` option. When `set_db edit_wire_snap_to pin` is set, the tool uses the original snapping behavior in which only the first drawing wire is snapped to the pin without any wire width and spacing change.

edit_wire_snap_end_to

```
edit_wire_snap_end_to {track_regular|track_special|manufacturing_grid}
```

Default: ""

Data_type: enum* {track_regular track_special manufacturing_grid}, read/write

Snaps the end of the wire being drawn to the specified object. You can specify the following options:

- `manufacturing_grid` - Specifies that the end of an off-grid wire should be snapped to the manufacturing grid.
- `track_regular` - Snaps the end of regular wires to track. For a long multi-pin net, you might want to draw the trunk wire first and then draw the branch wires along the trunk wire. The start/end points of the trunk wire are usually not on pins. So if the trunk wire start/end points do not snap to the track, it will leave an off-grid wire segment. To prevent this, snap the end of regular wires to track by setting `set_db edit_wire_snap_end_to track_regular`. The start/end points of the regular wire will snap to the closest orthogonal layer preferred track.
- `track_special` - Snaps the end of special routes to track. For a long multi-pin net, you might want to draw the trunk wire first and then draw the branch wires along the trunk wire. The start/end points of the trunk wire are usually not on pins. So if the trunk wire start/end points do not snap to the track, it will leave an off-grid wire segment. To prevent this, snap the end of special routes to track by setting `set_db edit_wire_snap_end_to track_special`. The start/end points of the special route will snap to the closest orthogonal layer preferred track.

Note: If you do not want to snap the end of the wire to any object, use `set_db edit_wire_snap_end_to ""`.

edit_wire_snap_objects_to_track

```
edit_wire_snap_objects_to_track {special|regular|patch|pin}
```

Default: `regular patch`

Data_type: enum* {special regular patch pin}, read/write

Snaps the center line of the wires being added or moved to the closest routing track in the preferred direction for the layer automatically. You can specify the following options:

- `special` - Snaps added or moved special wires to the closest routing track in the preferred direction for the layer automatically. This parameter also controls whether to cut special wires on the routing track.
  Note: See `edit_wire_snap_to pin` for a description of the software's behavior when both `edit_wire_snap_objects_to_track special` and `edit_wire_snap_to pin` are specified.
- `regular` - Snaps added or moved signal wires to the closest routing track in the preferred direction for the layer automatically. This parameter also controls whether to cut signal wires on the routing track.
  Note: See `edit_wire_snap_to pin` for a description of the software's behavior when both `edit_wire_snap_objects_to_track regular` and `edit_wire_snap_to pin` are specified.
- `patch` - Snaps patch wires automatically to the closest routing track for the layer as the wires are drawn, copied, or moved.
- `pin` - Snaps a moved physical pin to the closest routing track in the preferred direction for the layer automatically.

Note: If you do not want to snap any object to track, use `set_db edit_wire_snap_objects_to_track ""` to disable all track snap.

- `select_routes`

edit_wire_snap_to

`edit_wire_snap_to {special|pg|pin|row}`

Default: `special pg pin`

Data_type: enum* {special pg pin row}, read/write

Snaps the end of the wires being added or moved to the specified object. You can specify the following objects:

- `special` - Automatically extends a special wire for maximum via coverage when crossing over a same-net wire on an adjacent layer.
- `pg` - Snaps new wires whose start point is within a "snap region" to the closest end of a power or ground wire on the same net. The snap region is one-half the width of the target wire.
  - The snap region for orthogonal wires forms a square with the width of the power or ground wire.
  - The snap region for wires at 45-degree angles to the power or ground wire forms a square from the point where the wire will connect. Each side of the square is the width of the power or ground wire.
  - The snap region for wires that are parallel to power or ground wires is the full power or ground wire.
- `pin` - Snaps added or moved wires to a pin automatically. If you double-click at a pin, it snaps the wire to the pin. To ensure the wire is snapped to the center of the pin, specify `edit_wire_snap_objects_to_track`

`special` (or `edit_wire_snap_objects_to_track regular`) and specify a value for `edit_wire_snap_align_to`.

When you specify both `edit_wire_snap_objects_to_track special` (or `edit_wire_snap_objects_to_track regular`) and `edit_wire_snap_to pin`, the software has the following behavior:

- If the wire will fall partially outside the pin when snapped to a track, it snaps to the pin.
- If the wire will fall inside the pin when snapped to a track, it snaps to both the pin and a track.
- If there is no track on the pin, the wire snaps to the pin.

- `row` - Snaps added or moved wires to the nearest standard cell row. Use this parameter to create followpins. This parameter supports both horizontal and vertical rows.

For example, if you want to snap a wire to a pin automatically, specify `set_db edit_wire_snap_to pin` instead.

Note: If you do not want to snap wires to any object, use `set_db edit_wire_snap_to ""` to disable all object snap.

- `select_routes`

edit_wire_snap_to_track_honor_color

`edit_wire_snap_to_track_honor_color {true|false}`

Default: `true`

Data_type: bool, read/write

Specifies whether to snap wires to a track with the same color automatically. This option is on by default. If you need to move a wire to a track with a different color, set this option to `false`.

Notes:

This is a global setting and can be used to control all the snapping behavior in wire edit commands.

This command has no impact on `edit_add_route_point`. When drawing wires, the tool honors the color setting specified by `set_db edit_wire_assign_multi_pattern_color`.

edit_wire_snap_trim_metal_to_trim_grid

`edit_wire_snap_trim_metal_to_trim_grid {true|false}`

Default: `true`

Data_type: bool, read/write

Specifies whether or not the trim metal should snap to the closest trim track during trim-metal editing.

If you set this attribute to `false`, the trim metal is drawn on the location specified by `edit_add_trim_metal -location`.

Note: `edit_move_routes` does not follow the setting specified
by the edit_wire_snap_trim_metal_to_trim_grid attribute.

- edit_update_route_status
- edit_update_via
- select_routes

edit_wire_status

```
edit_wire_status {cover fixed noshield routed shield auto}
```

Default: `fixed`

Data_type: enum {cover fixed noshield routed shield auto}, read/write

Specifies the status associated with the wire you draw. By default, when you add special wires manually using the GUI, the tool creates crossover vias with `fixed` status. Use the `edit_wire_status` attribute to draw wires and vias with the specified status.

If the value is specified as `auto`, the tool sets the status of wires drawn on signal and power nets to `routed` and that for wires drawn on clock nets to `fixed`.

Note:

- For a special wire, `noshield` is not supported. If you specify this value for a special wire, the tool gives a warning message and keeps the status as `fixed`.
- For a regular wire, `shield` is not supported. If you specify this value for a regular wire, the tool gives a warning message and keeps the status as `fixed`.

edit_wire_stop_at_drc

```
edit_wire_stop_at_drc {true|false}
```

Default: `true`

Data_type: bool, read/write

Checks DRC rules and stops moving or stretching wires before causing a violation.

- Specify `true` to stop moving or stretching the wire at the closest location available before a violation occurs. In this case, you cannot move a wire to the desired destination if that wire passes through a location where a DRC violation occurs.
- Specify `false` to ignore DRC rules when moving or stretching wires. The software moves or stretches a wire to the desired location even if it results in a DRC violation.

edit_wire_stretch_end

```
edit_wire_stretch_end {high|low}
```

Default: `high`

Data_type: enum {high low}, read/write

Specifies the direction in which to stretch or reduce wires.

- `high` - Stretches or reduces wires from the top for vertical wires or from the right for horizontal wires.
- `low` - Stretches or reduces wires from the bottom for vertical wires or from the left for horizontal wires.

edit_wire_turn_at

```
edit_wire_turn_at {center_line|wire_edge}
```

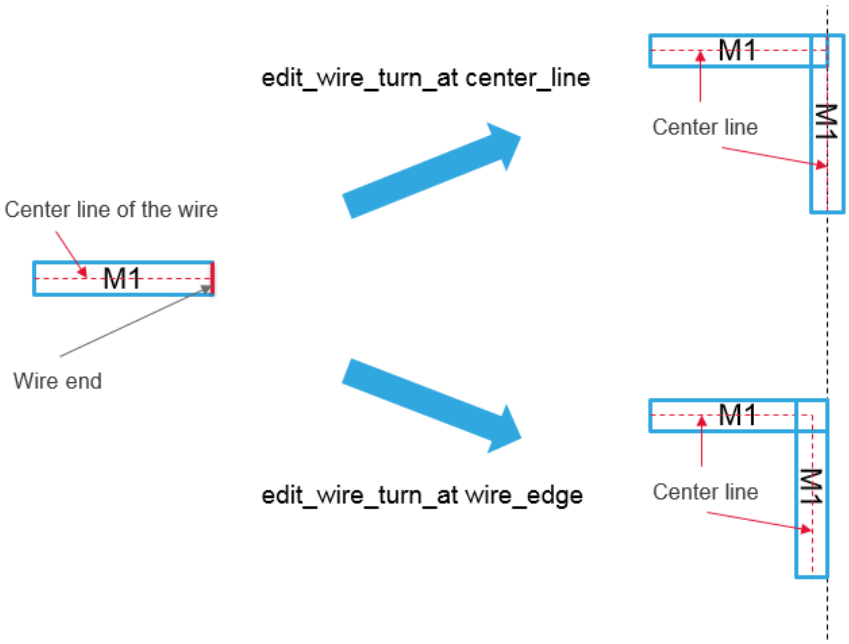
Default: `center_line`

Data_type: enum* {center_line wire_edge}, read/write

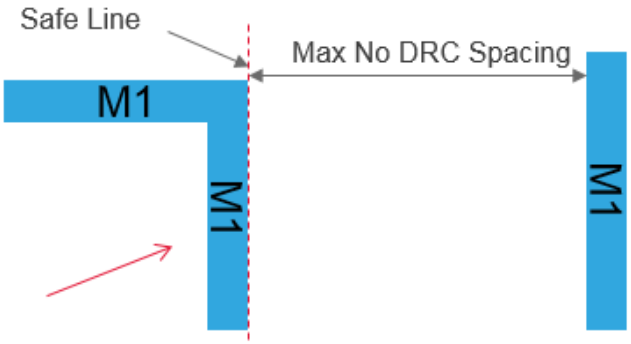
Specifies the start location of the new wire segment when a wire is turned. This attribute can be used for both regular and special wires. You can specify one of the following values for `edit_wire_turn_at`:

- `center_line` - When you turn a wire, the center line of the new wire segment aligns to the end of the old wire segment.
- `wire_edge` - When you turn a wire, the long edge of the new wire segment aligns to the end of the old wire segment.

The diagram below depicts the tool behavior for both options:



Use the `wire_edge` option when turning a wire at the *Safe Line* for an adjacent wire. With this option, the tool turns the wire without extending it beyond the *Safe Line* to avoid a minumum spacing rule violation with the adjacent wire:



You can use the default `edit_wire_turn_at center_line` option if there is no adjacent wire.

edit_wire_type

```
edit_wire_type {regular|special|patch}
```

Default: ""

Data_type: enum {regular special patch}, read/write

Specifies the type of the wire being created. You can specify one of the following options:

- `regular` - Creates regular wires and vias.
- `special` - Creates special wires and vias.
- `patch` - Creates patch wires.

Related Commands

- delete_routes

edit_wire_unrestricted_regular_wire_width

```
edit_wire_unrestricted_regular_wire_width {true|false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether the widening of a regular wire is unrestricted. By default, when you are changing the width of a wire, it snaps to the closest non-default route (NDR) available. If you set the `edit_wire_unrestricted_regular_wire_width` parameter to `true`, a wire can be stretched to any width without any restrictions.

- select_routes

edit_wire_update_shield_net

```
edit_wire_update_shield_net {true|false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether the shield net attribute on a signal net should be automatically updated. Use this attribute if you want Nanoroute to recognize the net as a shield net and not remove it during routing.

If you set the `edit_wire_update_shield_net` attribute to `true` before drawing a signal net, for example `net11`, the shield net attribute is automatically set on that signal net. You can verify this by using the `get_route_attributes` command as follows:

```
> get_route_attributes -nets net11
```

The result is:

```
#NET net11 attributes:
# weight = 2 (default)
# non_default_rule = default (default)
# non_default_rule_effort = auto (default)
# shield_net = VDD
```

If you now run `route_design`, NanoRoute recognizes the net as a shield net and does not remove it.

edit_wire_use_fix_via

```
edit_wire_use_fix_via {true|false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether to use fixVia for special via with minStep DRC violation.

Note: If a design is under 20nm, the tool turns on fixVia integration by default:
`set_db edit_wire_use_fix_via true`

To turn off the setting, use `set_db edit_wire_use_fix_via false`.

edit_wire_use_interleaving_wire_group

`edit_wire_use_interleaving_wire_group {true|false}`

Default: `false`

Data_type: bool, read/write

Alternates the specified wires in the wire group. For example, if you specify `set_db edit_wire_nets VDD VSS` and `set_db edit_wire_use_interleaving_wire_group true`, the software alternates the power and ground wires in the wire group.

When `edit_wire_use_interleaving_wire_group` is set to `true`, the software draws a wire group like the following:

edit_wire_use_wire_group

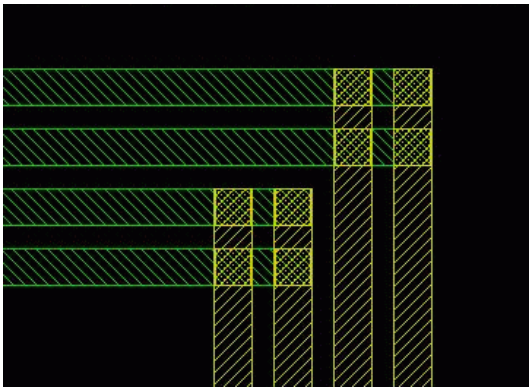
```
edit_wire_use_wire_group {true|false}
```

Default: `false` (The wire editor does not use wire groups.)

Data_type: bool, read/write

Groups multiple wires from the same net. Specify this attribute to decrease resistance and provide stronger connections.

The following figure shows power and ground wires that form a wire group.



Related Commands

edit_wire_use_wire_group_bits

`edit_wire_use_wire_group_bits` *`number_of_bits`*

Default: `0` (disabled)

Data_type: int, read/write

Specifies the number of times to replicate a wire in the wire group. For example, if you specify `VSS` and `VDD` nets, and specify `2` for this attribute, the software creates a wire group with two power wires and two ground wires.

Note - The value of this attribute must be greater than `1` to enable wire groups.

When `edit_wire_use_wire_group_bits 2` is specified, Innovus draws a wire group like the following:

edit_wire_use_wire_group_reinforcement

```
edit_wire_use_wire_group_reinforcement {true|false}
```

Default: `false`

Data_type: bool, read/write

Creates slots in the wire group by creating wires that connect the wires in the wire group, but are orthogonal to them. Slots help to reduce resistance in power networks. Specifying both this attribute and `edit_wire_use_interleaving_wire_group` creates shorts in the wire group.

When `edit_wire_use_wire_group_reinforcement true` is specified, Innovus draws a wire group like the following:

edit_wire_use_wire_group_reinforcement_group_via

```
edit_wire_use_wire_group_reinforcement_group_via {true|false}
```

Default: `false`

Data_type: bool, read/write

Specifies that the wire group uses group vias. Group vias are connected vias in a wire group. Using group vias ensures that the contact is maintained if one of the vias in the wire group produces a void.

In the following figure, the wire group has group vias:

edit_wire_use_wire_group_reinforcement_spacing

```
edit_wire_use_wire_group_reinforcement_spacing spacing
```

Default: `0.0`

Data_type: double, read/write

Specifies the spacing for the orthogonal wires in the wire groups.

Related Commands

edit_wire_verbose

```
edit_wire_verbose {true|false}
```

Default: `false`

Data_type: bool, read/write

Reports untrimmed wires/vias that cannot be trimmed because either they are connected to a patch wire or their status is `cover`. Set this parameter to `true` before running `edit_trim_routes` if you want untrimmed wires/vias to be reported. You can additionally use `edit_wire_debug_file` to specify the name for the report. The default report file name is `editTrim_debug.rpt`.

For example, the following set of commands report untrimmed wires and vias with connectivity issues in a file named `wireTest.rpt`:

```
set_db edit_wire_verbose true
set_db edit_wire_debug_file wireTest.rpt
edit_trim_routes
```

The report (sample) is as follows:

```
############################################################
# Generated by: Cadence Innovus 20.10-b015_1
# OS: Linux x86_64(Host ID noi-leenap1)
# Generated on: Mon Feb 10 13:50:19 2020
# Design: carve
# Command: edit_trim_routes
############################################################
```

```
Removed 0 wires and 0 vias.
1 wire can't be trimmed, because it connect a patch wire or the status is Cover.

The wires status is Cover:
Wire: ram1/subram02_lower/TESTACT_INST_PERIWDSRAM001PAA512W27C3/n7 M2 97845,-642213,100551,-642147
```

Note: Only wires and vias that have connectivity issues are reported.

Related Commands

- edit_trim_routes
- edit_update_route_status

edit_wire_via_columns

edit_wire_via_columns *integer*

Default: 0

Data_type: int, read/write

Specifies the number of columns in a via cut. This parameter works only if -use_via_gen is set to 1 for special vias.

Related Commands

- delete_routes
- edit_add_route_point
- edit_merge_routes
- edit_move_routes

- edit_update_route_status
- edit_update_via
- select_routes

edit_wire_via_exclude_spec

`edit_wire_via_exclude_spec` *value*

Default: `""`

Data_type: string, read/write

Specifies the list of vias to be ignored by the wire editor. You can define the list of vias in the *exclude_list* as follows:

```
set_db edit_wire_via_exclude_spec {{default via0} {rule1 via2} {rule2 {via2 via3}}}
```

For example, the wire editor will ignore the `V1L2LVH` via with the following command:

```
set_db edit_wire_via_exclude_spec {{default V1L2LVH}}
```

Related Commands

- `edit_update_via`
- `select_routes`

edit_wire_via_override_spec

`edit_wire_via_override_spec` *value*

Default: `""`

Data_type: string, read/write

Specifies the default vias to be used by wire editor. You can use this attribute if you do not want wire editor to select vias automatically.

`edit_wire_via_override_spec` allows a regular via on NDR nets. You can define the via in the via spec as follows:

```
set_db edit_wire_via_override_spec {{default via0} {rule1 via2} {rule2 via1}}
```

Here, if you draw a wire with NDR name `rule1`, the tool will always drop `via2` in the wire intersection area. The tool will not check whether `via2` belongs to NDR rule `rule1` in the Tech Lef.

You can define the full set of required vias for regular as well as NDR nets in one command with the `edit_wire_via_override_spec` attribute. For example:

```
set_db edit_wire_via_override_spec { {default via0 via1 via2 via3 via4 via5 via6 via7 via8} {NDR_rule1
via2 via3 via4 via5 via6 via7 NDR_rule1_via2 NDR_rule1_via3 NDR_rule1_via4 NDR_rule1_via5
NDR_rule1_via6 NDR_rule1_via7}  {NDR_rule2 via2 via3 via4 via5 via6 via7 NDR_rule1_via2 NDR_rule1_via3
NDR_rule1_via4 NDR_rule1_via5 NDR_rule2_via2 NDR_rule2_via3 NDR_rule2_via4 NDR_rule1_via5
NDR_rule2_via6 NDR_rule2_via7} }
```

This use model reduces the runtime for via selection during Wire Edit.

When you perform wire edit operations, via selection happens as follows for the above definition:

- For regular wire edit, the tool always picks a via from the `default` list specified with the `edit_wire_via_override_spec` option.
- For editing nets with the `NDR_rule1` rule, the tool picks any via from the list defined under the rule `NDR_rule1` in the above example.
- For editing nets with `NDR_rule2`, the tool picks any via from the list defined under the rule `NDR_rule2`.

During wire edit for DRC fixing on both regular and NDR wires, the tool always picks a via that is DRC clean after any wire edit operation, from the above definition.

The following command uses the `edit_wire_via_override_spec` attribute to specify via selections for the default rule as well as for the nondefault rule `SP`:

```
set_db edit_wire_via_override_spec {{default via12 via23 via45} {SP spvia12}}
```

As specified in the command, wire editor makes via selections for layers as follows:

- For the default rule:
  - `via12` for layer `V12`
  - `via23` for layer `V23`
  - `via45` for layer `V45`
- For the nondefault rule `SP`:
  - `spvia12` for layer `V12`

Note: Wire editor automatically selects best vias for the layers that are not specified with `edit_wire_via_override_spec`.

edit_wire_via_rows

`edit_wire_via_rows` *integer*

Default: `0`

Data_type: int, read/write

Specifies the number of rows in a via cut. This parameter works only if `-use_via_gen` is set to `1` for special vias.

edit_wire_via_scale_height

`edit_wire_via_scale_height` *value*

Default: `100`

Data_type: int, read/write

Specifies the absolute height of the special vias added when drawing wires. For example, the following commands scale the via added while drawing a wire to 80% height and width:

```
set_db edit_wire_via_scale_height 80
set_db edit_wire_via_scale_width 80
```

edit_wire_wire_override_spec

edit_wire_wire_override_spec {*specification*}

Default: ""

Data_type: string, read/write

Contains the details of the override specification. The specification has the following format:

{{*wire_index width spacing layer ndr_name*} {...}}

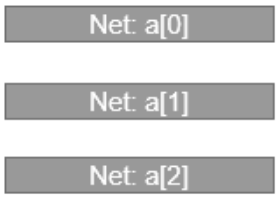
Specify the net numbers, followed by the override width, the override spacing to the next net, layer, or override NDR name for the specified nets.

The net number is the position of the net specified by the -nets parameter. If you specify more than one net, separate net numbers with commas.

For example, the following specification indicates that the first and second nets should have a width of 10.0 and a spacing of 3.0:

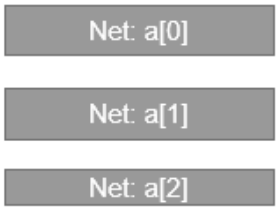
1,2 10.0 3.0

Now, consider the addition of a bus a[0] a[1] a[2]. The NDR name is default, and the metal layer name is M0.



- The following command reassigns the first and second nets to a new NDR, `2_wide`:

  ```
  set_db edit_wire_wire_override_spec {1,2 "" "" "" 2_wide}
  ```

- The following command assigns the `M2` layer to the first wire and the `M4` layer to the third wire.:

  ```
  set_db edit_wire_wire_override_spec {{1 "" M2} {3 "" M4}}
  ```

end_parallel_edit

```
end_parallel_edit
[-help]
-out_file parallel_edit_file_name
```

Ends parallel editing. The conmmand:

- compares the data in memory with the original data saved in binary files by `start_parallel_edit`
- saves the parallel edit file with the specified name

Multiple `end_parallel_edit` commands are allowed after one `start_parallel_edit`.

Parameters

`-help`	Prints a brief description that includes type and default information for each `end_parallel_edit` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man end_parallel_edit`
`-out_file` *`parallel_edit_file_name`*	Specifies the name of the parallel edit file. *Data_type*: string, required

Example

- The following command compares the data in memory with the data saved in the binary files and writes the parallel edit information to `PE1.txt` file: :

```
innovus 8> end_parallel_edit -out_file PE1.txt
Start saving parallel edit information to PE1.txt
************************************************************************
Comparing net attribute and regular wire/via with reference DB
Comparing instance with reference DB
Comparing physical pin with reference DB
Comparing NDR rule with reference DB
Comparing routing blockage with reference DB
Comparing placement blockage with reference DB
Comparing via cell with reference DB
Comparing special wire/via with reference DB
************************************************************************
End saving parallel edit information
```

Related Information

read_parallel_edit_files

```
read_parallel_edit_files
[-help]
[-check]
[-conflict_mode {only_one stop_all}]
-files list_of_files
[-ignore_error]
[-report_file file_name]
```

Loads all the specified parallel edit files and implements the editing changes recorded in them.

During parallel editing, there is a possibility of a conflict if the same attribute of an object is changed in different parallel edit files. Some cases in which a conflict can occur are listed below:

- Two users edit the layer of the same wire segment.
- Two users edit the width of the same NDR rule.
- One user cuts the wire segment, and another user changes the status of the same wire.

In the following examples of parallel edits, there is no conflict:

- One user edits the layer of wire, and another user edits its mask.
- One user edits the width of an NDR rule, and another user edits its spacing.

In case of any conflict in the parallel edit files, the tool implements changes as per the specified conflict mode and writes the conflicting information to a report file.

For information on the parallel edit flow, format of a parallel edit file, and conflict handling examples see the "Parallel Editing Capability" section in the Editing Wires chapter of the *User Guide.*

Parameters

`-help`	Prints a brief description that includes type and default information for each `read_parallel_edit_files` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man read_parallel_edit_files`
`-check`	Specifies that the tool should only check the syntax and conflict of the files but should not actually implement the changes. *Data_type*: bool, optional
`-conflict_mode {only_one stop_all}`	Specifies the conflict mode. The two possible modes are: • `only_one` - In case of conflicting commands, the first read command is implemented and the other command is recorded in the conflict report. • `stop_all` - In case of conflicting commands, the tool implements neither of the conflicting commands and records both of them in the conflict report. *Data_type*: enum, optional
`-files` *list_of_files*	Specifies the list of parallel editing files. *Data_type*: string, required
`-ignore_error`	Specifies whether errors in files should be ignored. When this option is specified, the tool skips lines with issues in the files but continues to read the other wires on the same net. *Data_type*: bool, optional
`-report_file` *file_name*	Specifies the name of the conflict report. *Data_type*: string, optional

report_legal_wire_width_for_bump

```
report_legal_wire_width_for_bump
[-help]
-location x y
-width value
```

Reports two legal widths for a 45-degree wire to connect to the 45-degree side of an octagon-shaped bump in the wire editor.

Parameters

`-help`	Prints out the command usage.
`-location x y`	Specifies the location inside the bump near the (45-degree) side of the connection. *Data_type*: point, required
`-width value`	Sets the initial width value of the 45-degree wire in microns. *Data_type*: float, required

Example

- The following command reports two legal widths for a 45-degree wire to connect to the 45-degree side of an octagon-shaped bump at the specified location with the specified initial width:

  ```
  report_legal_wire_width_for_bump -location 681.83 777.28 -width 9.25
  ```

  The reported values are:

  ```
  9.230000 9.260000
  ```

[-use {clock power signal}]
[-via_cell cell_name_list]
[-obj_type {wire via}]
[-with_edit_flag {0 | 1}
[-from_pin pin_name -to_pin pin_name]
```

Selects wires and vias using the specified parameters. The wires and vias are updated by subsequent wire editing commands.

Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man select_routes`
`-area {x1 y1 x2 y2}`	Specifies the coordinates for the area from which to select wires and vias. *Default:* Entire area *x1*: Specifies the lower left x coordinate. *y1*: Specifies the lower left y coordinate. *x2*: Specifies the upper right x coordinate. *y2*: Specifies the upper right y coordinate. *Data_type*: rect, optional

`-direction {h | v | 45 | 135}`	Specifies the orientation of the wires to be selected. *Default:* If you do not specify this parameter, selects wires with any orientation. `h`: Specifies that horizontal wires are to be selected. `v`: Specifies that vertical wires are to be selected. 45: Specifies that 45-degree wires are to be selected. 135: Specifies that 135-degree wires are to be selected. *Data_type*: enum, optional
`-floating_via`	Specifies that only floating vias are to be selected. A via, or a stack of vias, is floating, if it is not connected to another object, wire, pin, or via, on either its top or bottom metal layer or on both these layers. *Data_type*: bool, optional
`-from_pin` *pin_name*	Specifies the name of the starting pin of the wire to be selected. The starting pin you specify should be connected to the same net as the ending pin specified with `-to_pin`. If they connect to different nets, the tool reports an error. In addition, the from and to pins you specify should be connected to the same wire. **Note**: Selection of wires between specified pins is supported only for signal and clock nets. *Data_type*: string, optional
`-layer` *list_of_layers*	Specifies the layers from which to select wires and vias. This option supports backside and Through Silicon Via (TSV) layers as well. If you are specifying multiple layers, enclose them in braces. *Default:* If you do not specify this parameter, selects wires and vias on all layers. *Data_type*: string, optional
`-nets` *net**	Specifies the net names from which to select wires and vias. You can use wildcard values in this field. For example, if you specify `V*`, selects wires/vias from nets `VDD` and `VSS`. *Data_type*: (net)*, optional
`-obj_type {wire via}`	Specifies whether wires or vias or both should be selected. If the parameter is not specified, only wires are selected. *Default*: `wire` *Data_type*: (enum)+, optional

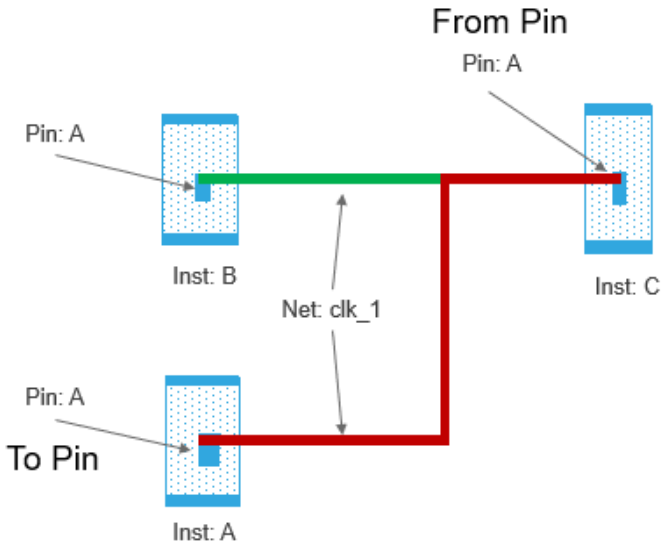
`-physical_pin_only`	Specifies that physical pins are to be selected. By default, `select_routes` does not select physical pins. You can use the `-physical_pin_only` parameter along with `-area`, `-layer`, or `-nets` to select the physical pins in the specified area, layer, or net, respectively. *Data_type*: bool, optional
`-regular_wire_with_drc`	Selects regular wires with violation markers. Clock nets are also selected. *Data_type*: bool, optional
`-shapes {ring stripe followpin iowire corewire blockwire padring blockring fillwire fillwireopc drcfill none}`	
	Specifies the shapes of the wires and vias to be selected. If you specify multiple shapes, enclose the list of shapes in braces. For shape definitions, see *Shapes,* in the "DEF Syntax" chapter of the LEF/DEF Language Reference. *Default:* If you do not specify this parameter, selects all shapes. *Data_type*: (enum)+, optional
`-shield`	Selects the wires and vias of the nets specified with the `-nets` parameter, along with the wires and vias shielding the specified nets. **Note**: This parameter cannot be used with `-shield_only`. *Data_type*: bool, optional
`-shield_only`	Selects only the shield wires associated with the nets specified using the `-nets` parameter. The signal nets being shielded are not selected. **Note**: This parameter cannot be used with `-shield`. *Data_type*: bool, optional
`-status {cover fixed noshield routed shield unknown}`	
	Specifies the status of the wires and vias to be selected. If you specify more than one status, enclose the status list in curly braces. **Note:** If you select `-type special -status noshield` or `-type signal -status shield`, the software generates an error message. *Data_type*: (enum)+, optional

`-sub_class` *`sublass_name`*	Specifies the subclass name of the wires and vias to be selected. Use this parameter if you want to select wires or vias belonging to a specific subclass. Here, *`subclass_name`* is a user-defined attribute that has been previously defined using the `-user_class` parameter of the `add_split_power_vias`, `add_rings`, `add_stripes`, or `route_special` command. For wires, use this parameter if you want to select or delete rings, stripes, or other wires belonging to a specific subclass. Only special wire is supported by this option. **Note:** You can use wildcards in *`subclass_name`*. *Data_type*: string, optional
`-to_pin` *`pin_name`*	Specifies the name of the ending pin of the wire to be selected. The ending pin you specify should be connected to the same net as the starting pin specified with `-from_pin`. If they connect to different nets, the tool reports an error. In addition, the from and to pins you specify should be connected to the same wire. If there there are more than one wire or via between the specified starting and ending pins, the command is not able to select the wire path and returns an error. The `-from_pin` and `-to_pin` parameters are compatible with only the `-direction`, `-layer`, `-object_type`, and `-status` options of the `select_routes` command. If you use `-from_pin` and `-to_pin` with any other `select_routes` parameters, the tool returns an error. **Note**: Selection of wires between specified pins is supported only for signal and clock nets. *Data_type*: string, optional
`-type {regular special patch}`	
	Specifies whether to select regular wires and vias, special wires and vias, or patch wires. **Note:** If you specify `regular`, you must omit the `-shapes` parameter or specify `-shapes none`. *Data_type*: enum, optional
`-use {clock power signal}`	Specifies whether to select only CLOCK wires/vias, POWER wires, or SIGNAL wires. *Data_type*: enum, optional
`-via_cell` *`cell_name_list`*	Specifies the via cells of the vias to be selected. You can use wildcards while specifying via cell names. If you are specifying multiple cell names, enclose them in braces. *Data_type*: string, optional

`-with_edit_flag {0 | 1}`	Selects all modified wires and vias, that is wires and vias with value `1` for the `is_edit` property on the net. **Notes** • As the `is_edit` property is added on the whole net, all the wires and vias on the net with `is_edit` value set to `1` will be selected. • The `is_edit` property is used to flag nets with modified wires and vias. This is useful when evaluating how many objects need to be modified for fixing DRC violations and then deciding whether to fix the violations manually or through ECO routing. The `is_edit` property is controlled through the `edit_wire create_is_edit_flag` root attribute in the `edit_wire` category. By default, this parameter is set to `false`. If you set the value of this attribute to `true`, the `is_edit` property is set to `1` for nets with modified wires or vias. *Data_type*: enum, optional

Examples

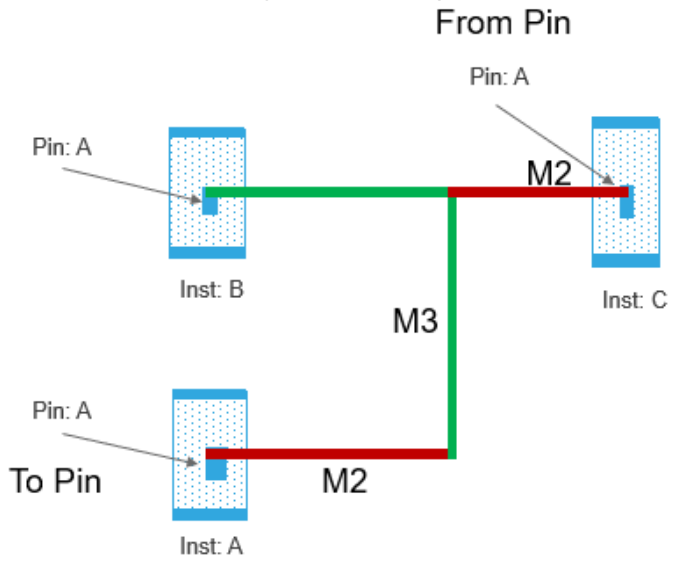
- The following command selects all wires on the *METAL1* and *METAL2* layers:
  ```
  select_routes -layer {METAL1 METAL2}
  ```
- The following command selects all vias on the cut layer `VIA12`:
  ```
  select_routes -layer VIA12 -obj_type via
  ```
- The following command selects all vias on the cut layers `VIA12` and `VIA23`:
  ```
  select_routes -layer {VIA12 VIA23} -obj_type via
  ```
- The following command selects all wires on the *METAL1* and *METAL2* layers and vias on the cut layer `VIA12`:
  ```
  select_routes -layer {METAL1 METAL2 VIA12} -obj_type {wire via}
  ```
- The following command selects all horizontal fillwires on the *METAL1* layer:
  ```
  select_routes -layer METAL1 -direction h -shapes fillwire
  ```
- The following command selects VDD STRIPEs with subclass "stripe_A":
  ```
  select_routes -nets VDD -shapes stripe -type special -sub_class stripe_A
  ```
- The following command selects all vias of shape `FOLLOWPIN` with names that match the pattern `tapcellvia_VIA1_RUL*`:
  ```
  select_routes -shapes followpin -via_cell tapcellvia_VIA1_RUL* -obj_type via
  ```
- The following command selects all the modified wires and vias:
  ```
  select_routes -with_edit_flag 1 -obj_type {wire via}
  ```
- The following command selects the complete wire between the specified from and to pins:
  ```
  select_routes -from_pin C/A -to_pin A/A
  ```
  The selected wire is depicted in red in the diagram below:



- The following command selects only the wire segments on the `M2` layer between the specified from and to pins:

  ```
  select_routes -from_pin C/A -to_pin A/A -layer M2
  ```

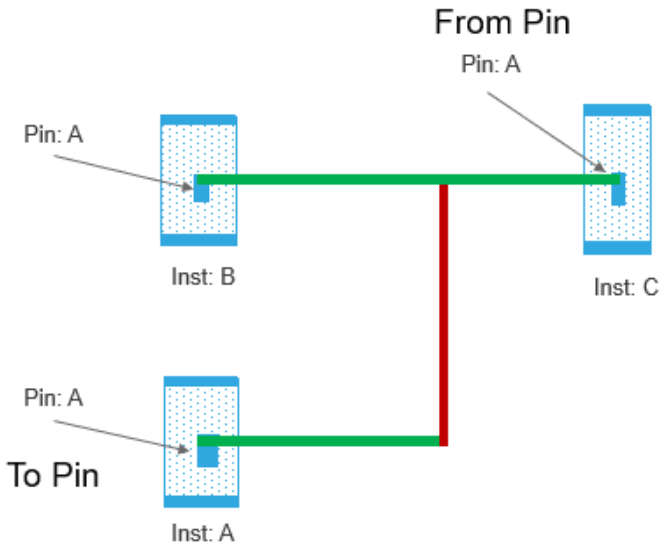
  The selected wire segments are depicted in red in the diagram below:



- The following command only the vertical wire segments between the specified from and to pins:

  ```
  select_routes -from_pin C/A -to_pin A/A -direction V
  ```

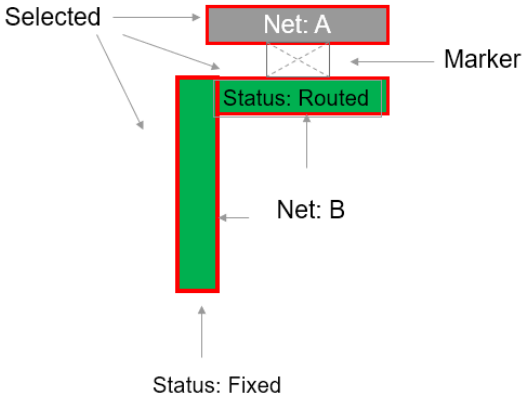
  The selected wire segment is depicted in red in the diagram below:



- Consider the example below:

  - The following command selects all nets that have DRC markers:

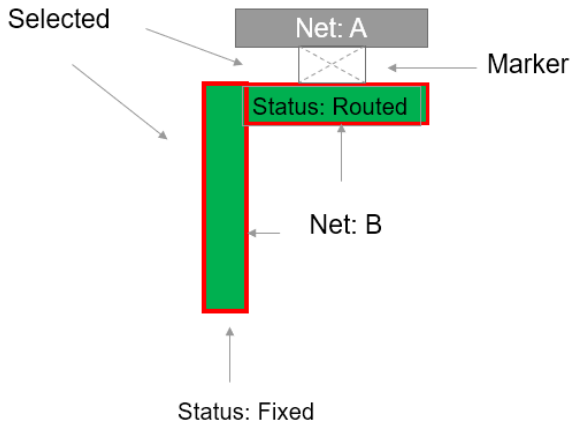
```
select_routes -regular_wire_with_drc
```



Both nets A and B are selected.

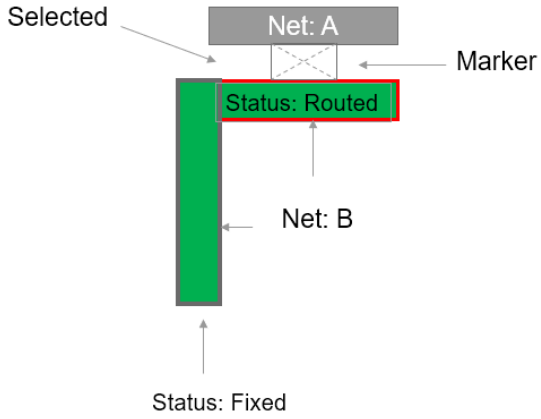
- The following command selects wires with DRC markers from only Net B:

  ```
  select_routes -nets B -regular_wire_with_drc
  ```



- The following command selects only routed wires with DRC markers from Net B:

  ```
  select_routes -nets B -regular_wire_with_drc -status ROUTED
  ```



- The following set of commands select and delete nets with DRC markers while excluding clock nets:

  ```
  select_routes -regular_wire_with_drc
  deselect_routes -use clock
  delete_routes -selected
  ```

select_secondary_pg_net

```
select_secondary_pg_net
[-help]
-insts inst+
{-net net | -pin pin_name}
```

Selects Power/Ground (P/G) net wire segments from specified instances. The wire segments are selected from the instance P/G pins to stripes (swire targets). This provides an easy way to select and delete routing from specific instance P/G pins to stripes.

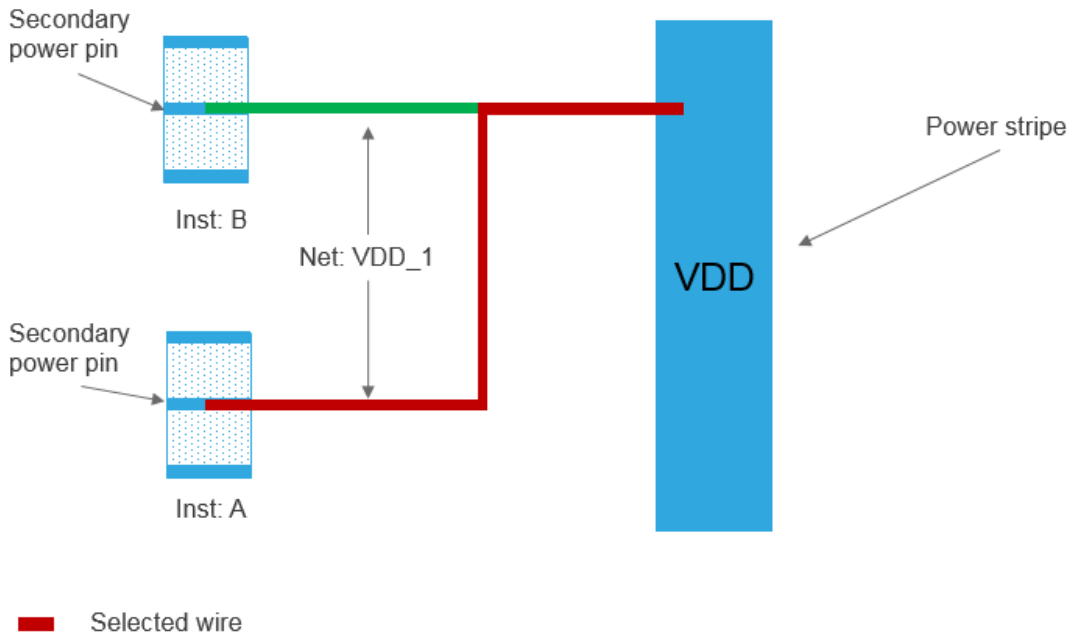
Note: This command does not support dangling secondary P/G nets.

Parameters

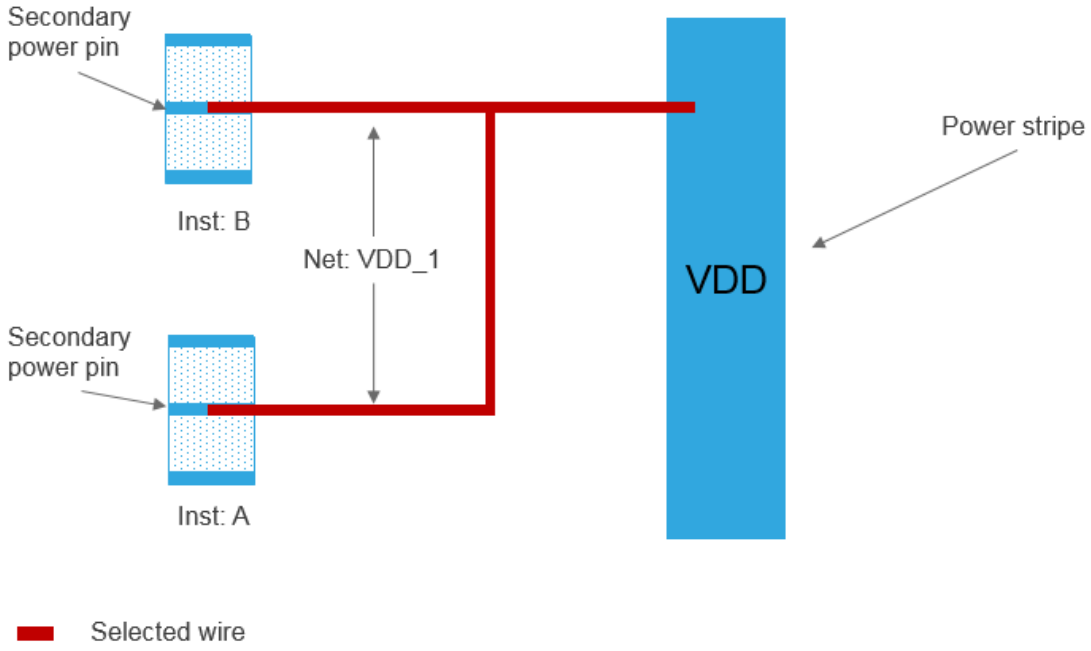
`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man select_secondary_pg_net`
`-insts inst+`	Specifies the list of instances that have a secondary PG pin. Wildcards are supported in instance names. If one or more specified instances does not connect with the specified net, the tool displays a warning and ignores those instances. *Data_type*: (inst)+, required
`-net net_name`	Specifies the net name. **Note**: *net_name* does not take any wildcard values. This parameter cannot be used with `-pin`. *Data_type*: (net), optional
`-pin pin_name`	Specifies the pin name. This parameter cannot be used with `-net`. *Data_type*: string, optional

Examples

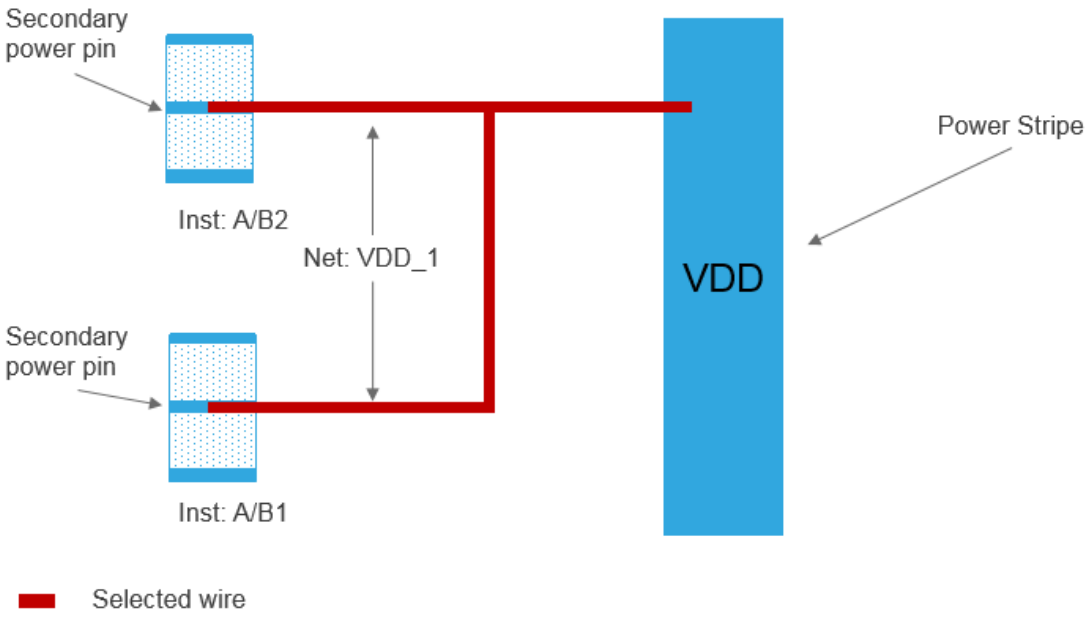
- The following command selects the routing from the P/G pin in instance `A` of net `VDD_1` to the power stripe:
  ```
  select_secondary_pg_net -net VDD_1 -insts {A}
  ```



- The following command selects the routing from the P/G pins in instances `A` and `B` in net `VDD_1` to the power stripe:
```
select_secondary_pg_net -net VDD_1 -insts {A B}
```



- The following command selects the routing from the P/G pins in instances `A/B1` and A/B2 in net `VDD_1` to the power stripe:
```
select_secondary_pg_net -net VDD_1 -insts {A/*}
```



- The following command selects secondary PG net through the `VDDO` pin and checks all its ports:
  ```
  select_secondary_pg_net -insts $instn -pin VDDO
  ```
  If a port of the the `VDDO` pin has an open, the tool prints a message as follows:
  ```
  **WARN: (IMPSPR-405): There is no route for secondary pin "VDDO" to
  inst "PD_CHIPLET2_PADS_PD_CHIPPADS_pads_out_balanced_ls_padring_chiplet2_u_DISP_LSYNC_C_UPF_LS"
  at '3.085500 1.902500'.
  ```

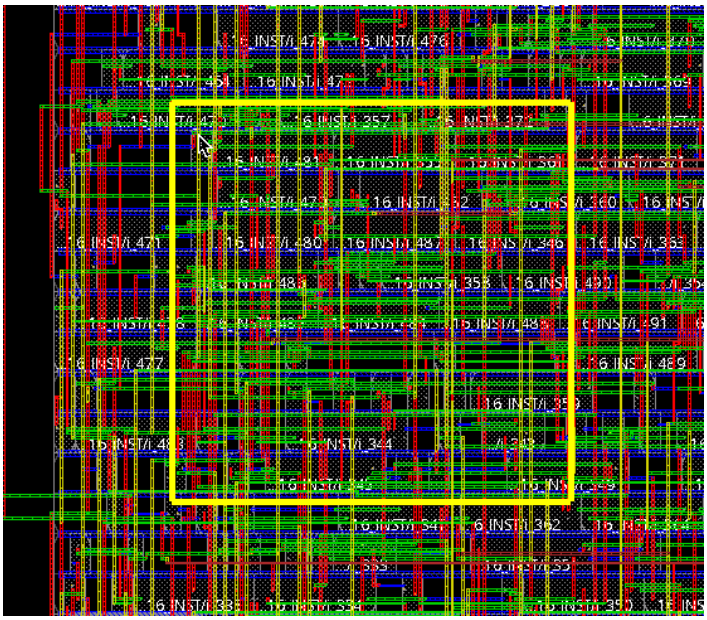
start_parallel_edit

```
start_parallel_edit
[-help]
[-area_restricted]
-region {x1 y1 x2 y2}
```

Initializes parallel editing by drawing a yellow square on the main window to indicate the edit area and saving the physical data, net attributes, via cell names and Non-Default Rules (NDRs) to multiple binary files.



Parameters

`-help`	Prints a brief description that includes type and default information for each `start_parallel_edit` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man start_parallel_edit`
`-area_restricted`	Writes out only the different objects inside or touching the specified edit area. This is a strict interpretation of the region, and ignores the changes made outside of the region. *Data_type*: bool, optional
`-region {x1 y1 x2 y2}`	Specifies the coordinates of the edit area. *Data_type*: rect, required

Example

- The following command marks the specified edit area in yellow and saves the design data to binary files:

```
innovus 8> start_parallel_edit -area_restricted -region {12.524 6.627 0.0 0.0}
Saving net attribute and regular wire/via information
Saving instance information
Saving physical pin information
Saving NDR rule information
Saving routing blockage information
Saving placement blockage information
Saving special wire/via information
```

Common Metric Names

Clock Metrics

The following table provides the list of various clock metrics.

Metric Object Name	Description
`clock.area.buffer` `units: um^2`	Reports the area of clock buffer instances. Data Precision: 2 A smaller number is better when doing HTML comparison.
`clock.area.buffer.<clock>` `units: um^2`	Reports the area of clock buffer instances per clock. Data Precision: 2 A smaller number is better when doing HTML comparison.
`clock.area.clkgate` `units: um^2`	Reports the area of ICG instances. Data Precision: 2 A smaller number is better when doing HTML comparison.
`clock.area.clkgate.<clock>` `units: um^2`	Reports the area of ICG instances per clock. Data Precision: 2 A smaller number is better when doing HTML comparison.
`clock.area.inverter` `units: um^2`	Reports the area of clock inverter instances. Data Precision: 2 A smaller number is better when doing HTML comparison.
`clock.area.inverter.<clock>` `units: um^2`	Reports the area of clock inverter instances per clock. Data Precision: 2 A smaller number is better when doing HTML comparison.

`clock.area.total` `units: um^2`	Reports the total clock area. Data Precision: 2 A smaller number is better when doing HTML comparison.
`clock.area.total.<clock>` `units: um^2`	Reports the total clock area per clock. Data Precision: 2 A smaller number is better when doing HTML comparison.
`clock.capacitance.total`	Reports the total clock (net+pin) capacitance. A smaller number is better when doing HTML comparison.
`clock.capacitance.total.<clock>`	Reports the total clock (net+pin) capacitance per clock. A smaller number is better when doing HTML comparison.
`clock.drv.max_cap`	Reports the total clock max capacitance violations for primary delay corner. A smaller number is better when doing HTML comparison.
`clock.drv.max_cap.total.<clock>.<delay_corner>.<early|late>`	Reports the total clock max capacitance violations per clock. A smaller number is better when doing HTML comparison.
`clock.drv.max_cap.worst`	Reports the worst clock max capacitance violation for primary delay corner. A smaller number is better when doing HTML comparison.
`clock.drv.max_cap.worst.<clock>.<delay_corner>.<early|late>`	Reports the worst clock max capacitance violation per clock. A smaller number is better when doing HTML comparison.
`clock.drv.max_tran.total.<type>.<clock>.<delay_corner>.<early|late>`	Reports the total clock max transition violations per clock per delay corner. A smaller number is better when doing HTML comparison.
`clock.drv.max_tran.worst`	Reports the worst clock max transition violation for primary delay corner. A smaller number is better when doing HTML comparison.
`clock.drv.max_tran.worst.<clock>.<delay_corner>.<early|late>`	Reports the worst clock max transition violation per clock per delay corner. A smaller number is better when doing HTML comparison.
`clock.flexible_htree:<flexible_htree>.instances`	Reports the number instances of the flexible H-tree (excluding sinks). Data Precision: 0

`clock.flexible_htree:<flexible_htree>.latency.<max>`	Reports the latency in the primary half-corner of the flexible H-tree. Data Precision: 3 A smaller number above target is better when doing HTML comparison.
`clock.flexible_htree:<flexible_htree>.levels`	Reports the levels of the flexible H-tree (excluding H-tree sinks). Data Precision: 0
`clock.flexible_htree:<flexible_htree>.preferred_layer_adherence`	Reports the preferred layer adherence ratio of nets of the flexible H-tree. Data Precision: 3
`clock.flexible_htree:<flexible_htree>.sinks`	Reports the number of sinks of the flexible H-tree. Data Precision: 0
`clock.flexible_htree:<flexible_htree>.skew`	Reports the skew in the primary delay half-corner of the flexible H-tree's skew group. Data Precision: 3 A smaller number above target is better when doing HTML comparison.
`clock.flexible_htree:<flexible_htree>.vias`	Reports the number of vias of nets of the flexible H-tree. Data Precision: 0
`clock.flexible_htree:<flexible_htree>.wire_length`	Reports the total wire length of nets of the flexible H-tree. Data Precision: 0
`clock.instances.buffer`	Reports the number of clock buffer instances. A smaller number is better when doing HTML comparison.
`clock.instances.buffer.<clock>`	Reports the number of clock buffer instances per clock. A smaller number is better when doing HTML comparison.
`clock.instances.buffer_and_inverter`	Reports the total number of total clock buffers and inverters. Data Precision: 0 A smaller number is better when doing HTML comparison. internal 1
`clock.instances.clkgate`	Reports the number of ICG instances. A smaller number is better when doing HTML comparison.
`clock.instances.clkgate.<clock>`	Reports the number of ICG instances per clock. A smaller number is better when doing HTML comparison.

`clock.instances.inverter`	Reports the number of clock inverter instances. A smaller number is better when doing HTML comparison.
`clock.instances.inverter.<clock>`	Reports the number of clock inverter instances per clock. A smaller number is better when doing HTML comparison.
`clock.instances.total`	Reports the total number of clock instances. A smaller number is better when doing HTML comparison.
`clock.instances.total.<clock>`	Reports the total number of clock instances per clock. A smaller number is better when doing HTML comparison.
`clock.nets.length.total units: um`	Reports the total length of clock nets. Data Precision: 0 A smaller number is better when doing HTML comparison.
`clock.skew.max`	Reports the maximum global clock skew. A smaller number is better when doing HTML comparison.
`clock.skew.max.<clock>`	Reports the maximum global clock skew per clock.
`clock.skew_groups`	Reports the list of skew groups.
`clock.timing.max_latency.<clock>`	Reports the maximum network latency. A smaller number is better when doing HTML comparison.
`clock.timing.min_latency.<clock>`	Reports the minimum network latency. A smaller number is better when doing HTML comparison.
`clock.timing.period.<clock>`	Reports the clock period. A smaller number is better when doing HTML comparison.
`clock.timing.source_latency.<clock>`	Reports the source latency.
`clock.timing.uncertainty.<clock>`	Reports the clock uncertainty.

Design Metrics

The following table provides the list of various design metrics.

Metric Object Name	Description

`design.area`
`units: um^2`
`type area`
	Total design area
	Data Precision: 0
	A smaller number is better when doing HTML comparisons.

design.area.always_on units: um^2 type area	Total area of always on instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.area_io units: um^2 type area	Total area of area_io instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.blackbox units: um^2 type area	Total area of block instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.block units: um^2 type area	Total area of block instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.block.<block> units: um^2 type area	Design area per block Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.buffer units: um^2 type area	Total area of buffer instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.combinatorial units: um^2 type area	Total area of combinational standard cell logic Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.filler units: um^2 type area	Total design area of filler intances Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.hinst:<block> units: um^2 type area	Design area per block Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.icg units: um^2 type area	Total area of icg instances Data Precision: 0 A smaller number is better when doing HTML comparisons.

design.area.inverter units: um^2 type area	Total area of inverter Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.io units: um^2 type area	Total area of io instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.iso_ls units: um^2 type area	Total area of iso and level shifter instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.latch units: um^2 type area	Total area of latch instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.logical units: um^2 type area	Total area of logical Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.macro units: um^2 type area	Total area of block instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.physical units: um^2 type area	Total area of physical only instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.power_switch units: um^2 type area	Total area of power switches instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.register units: um^2 type area	Total area of register instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
design.area.sequential units: um^2 type area	Total area of sequential instances Data Precision: 0 A smaller number is better when doing HTML comparisons.

`design.area.std_cell`
`units: um^2`
`type area`
	Total area of standard cell instances
	Data Precision: 0
	A smaller number is better when doing HTML comparisons.

`design.bin.density.peak` `units: %`	Peak bin density based on PSP report Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.bin.density.top.010` `units: %`	The average bin density of top 10 bins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.bin.density.top.0100` `units: %`	The average bin density of top 100 bins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.bin.density.top.1` `units: %`	The average bin density of top 1 percent bins among all bins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.bin.density.top.10` `units: %`	The average bin density of top 10 percent bins among all bins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.bin.density.top.2` `units: %`	The average bin density of top 2 percent bins among all bins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.bin.density.top.20` `units: %`	The average bin density of top 20 percent bins among all bins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.bin.density.top.5` `units: %`	The average bin density of top 5 percent bins among all bins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.bin.density.viol.bin`	The number of bins that violate the bin density constraints based on PSP report Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.bin.density.viol.localrow`	The number of local rows that violate the bin density constraints based on PSP report Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1

`design.bin.density.viol.sbin`	The number of sbins that violate the bin density constraints based on PSP report Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.bin.density.viol.subrow`	The number of subrows that violate the bin density constraints based on PSP report Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.bin.viol.100`	The number of bins that have densities more than 100 percent Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.bin.viol.60`	The number of bins that have densities more than 60 percent Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.bin.viol.70`	The number of bins that have densities more than 70 percent Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.bin.viol.80`	The number of bins that have densities more than 80 percent Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.bin.viol.90`	The number of bins that have densities more than 90 percent Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.blockages.place.area`	Placement blockage area Data Precision: 0
`design.blockages.route.area`	Routing blockage area Data Precision: 0
`design.blockages.route.area.layer:<layer>`	Routing blockage area per layer Data Precision: 0
`design.cell.viol.boundary`	The number of cells that are outside of design boundary Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.cell.viol.macro`	The number of cells that are completely blocked by macros Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1

`design.congestion.hotspot.max`	Maximum congestion hotspot size Data Precision: 2 A smaller number is better when doing HTML comparisons.
`design.congestion.hotspot.total`	Total size of all congestion hotspots Data Precision: 2 A smaller number is better when doing HTML comparisons.

`design.density`
`units: %`
`type density`
	Density w/o filler cells
	Data Precision: 1 A smaller number is better when doing HTML comparisons.

`design.density.peak`
`units: %`
`type density`
	Peak design density w/o filler cells
	Data Precision: 1 A smaller number is better when doing HTML comparisons.

`design.floorplan.image` `type imageplot`	Design floorplan image Data Precision: 0
`design.instance.always_on tcl`	Total number of always on instances auto_calculated in um::set_additional_metrics A smaller number is better when doing HTML comparisons.
`design.instance.power_switch`	Total number of power switches A smaller number is better when doing HTML comparisons.
`design.instances`	Total number of instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.always_on`	Total number of always on instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.area_io`	Total number of Area IO instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.blackbox`	Total number of blackbox instances Data Precision: 0 A smaller number is better when doing HTML comparisons.

`design.instances.block`	Total number of block instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.block.<block>`	Number of instances per block Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.buffer`	Total number of buffer instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.combinatorial`	Total number of combinational standard cell instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.filler`	Total number of filler instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.hinst:<block>`	Number of instances per block Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.icg`	Total number of clock gating instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.inverter`	Total number of inverter instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.io`	Total number of IO instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.iso_ls`	Total area of iso and level shifter instances Data Precision: 0 A smaller number is better when doing HTML comparisons.

`design.instances.latch`	Total number of latch instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.logical`	Total number of logical instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.macro`	Total number of block instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.physical`	Total number of physical instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.power_switch`	Total number of power switches Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.register`	Total number of sequential instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.sequential`	Total number of sequential instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.instances.std_cell`	Total number of standard cell instances Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.movement.avg` `units: site`	Average cell movement Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.movement.cell`	Total number of moved cells Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1

`design.movement.clkbuf.avg` `units: site`	Average movement Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.movement.clkbuf.max` `units: site`	Max movement Data Precision: 0 A smaller number is better when doing HTML comparisons. internal 1
`design.movement.clkbuf.moved`	Total number of moved clock buffers and inverters Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.movement.clkgate.avg` `units: site`	Average movement Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.movement.clkgate.max` `units: site`	Max movement Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.movement.clkgate.moved`	Total number of moved ICG instances Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.movement.max` `units: site`	Max cell movement Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.movement.movable`	Number of movable cells Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.movement.moved`	Total number of moved cells Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.movement.sequential.avg` `units: site`	Average movement Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1

`design.movement.sequential.max` `units: site`	Max movement Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.movement.sequential.moved`	Total number of moved sequential instances Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.movement.top.0.05` `units: site`	Top 0.05 percent movement among all cell movements Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.movement.top.0.1` `units: site`	Top 0.1 percent movement among all cell movements Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.movement.top.0.2` `units: site`	Top 0.2 percent movement among all cell movements Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.movement.top.0.5` `units: site`	Top 0.5 percent movement among all cell movements Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.movement.top.1` `units: site`	Top 1 percent movement among all cell movements Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.movement.viol`	The number of cells that violates the max movement constraint Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.multibit.avg_width`	Total bits / total flops Data Precision: 0 A larger number is better when doing HTML comparisons.
`design.multibit.count`	Total number of multi-bit instances Data Precision: 0 A larger number is better when doing HTML comparisons.

`design.multibit.coverage` `units: %`	Total multi-bits / total bits Data Precision: 1 A larger number is better when doing HTML comparisons.
`design.name` `type area`	Design name Data Precision: 0
`design.nets.avg_pin`	Average terms per net Data Precision: 1 A smaller number is better when doing HTML comparisons.
`design.nets.global`	Number of global nets Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.nets.missing_iso`	Number of nets crossing domains w/o ISO Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.nets.signal`	Number of signal nets Data Precision: 0 A smaller number is better when doing HTML comparisons.
`design.overlapping.area.all`	The number of sites that have more than two cells placed on it based on PSP report Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.overlapping.area.nopad`	The number of sites that have more than two non-padded cell area placed on it Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.overlapping.cost`	The cost of sites that have overlapping cells based on PSP report Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.pairpin.ratio.top.1` `units: %`	The average pairpin ratio inside a bin of top 1 percent bins among all bins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.pairpin.ratio.top.10` `units: %`	The average pairpin ratio inside a bin of top 10 percent bins among all bins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1

design.pairpin.ratio.top.2 units: %	The average pairpin ratio inside a bin of top 2 percent bins among all bins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
design.pairpin.ratio.top.20 units: %	The average pairpin ratio inside a bin of top 20 percent bins among all bins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
design.pairpin.ratio.top.5 units: %	The average pairpin ratio inside a bin of top 5 percent bins among all bins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
design.pairspacing.percentage.0 units: %	The percentage of cell pairs with spacing 0 Data Precision: 1 internal 1
design.pairspacing.percentage.1 units: %	The percentage of cell pairs with spacing 1 Data Precision: 1 internal 1
design.pairspacing.percentage.2 units: %	The percentage of cell pairs with spacing 2 Data Precision: 1 internal 1
design.pairspacing.percentage.3 units: %	The percentage of cell pairs with spacing 3 Data Precision: 1 internal 1
design.pairspacing.percentage.4 units: %	The percentage of cell pairs with spacing 4 Data Precision: 1 internal 1
design.pairspacing.percentage.5 units: %	The percentage of cell pairs with spacing 5 Data Precision: 1 internal 1
design.pairspacing.percentage.6 units: %	The percentage of cell pairs with spacing 6 Data Precision: 1 internal 1
design.pairspacing.percentage.7 units: %	The percentage of cell pairs with spacing 7 Data Precision: 1 internal 1
design.pin.density.peak units: %	Peak pin density inside a bin based on PSP report Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
design.pin.density.top.1 units: %	The average pin density inside a bin of top 1 percent bins among all bins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1

`design.pin.density.top.10` `units: %`	The average pin density inside a bin of top 10 percent bins among all bins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.pin.density.top.2` `units: %`	The average pin density inside a bin of top 2 percent bins among all bins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.pin.density.top.20` `units: %`	The average pin density inside a bin of top 20 percent bins among all bins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.pin.density.top.5` `units: %`	The average pin density inside a bin of top 5 percent bins among all bins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.place.drc.image` `type imageplot`	Design place DRC image. Data Precision: 0
`design.power_domains`	List of power domains Data Precision: 0
`design.psp.hpwl`	HPWL wirelength based on PSP report Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.psp.hpwl.crit`	HPWL wirelength for critical nets based on PSP report Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.psp.hpwl.crit.w`	Weighted HPWL wirelength for critical nets based on PSP report Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.psp.hpwl.w`	Weighted HPWL wirelength based on PSP report Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.psp.mst`	MST wirelength based on PSP report Data Precision: 0 A smaller number is better when doing HTML comparisons. internal 1

`design.psp.mst.crit`	MST wirelength for critical nets based on PSP report Data Precision: 0 A smaller number is better when doing HTML comparisons. internal 1
`design.psp.mst.crit.w`	Weighted MST wirelength for critical nets based on PSP report Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.psp.mst.w`	Weighted MST wirelength based on PSP report Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.route.drc.image` `type imageplot`	Design route image. Data Precision: 0
`design.sbin.density.peak` `units: %`	Peak sbin density based on PSP report Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.sbin.density.top.010` `units: %`	The average sbin density of top 10 sbins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.sbin.density.top.0100` `units: %`	The average sbin density of top 100 sbins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.sbin.density.top.1` `units: %`	The average sbin density of top 1 percent sbins among all sbins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.sbin.density.top.10` `units: %`	The average sbin density of top 10 percent sbins among all sbins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.sbin.density.top.2` `units: %`	The average sbin density of top 2 percent sbins among all sbins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.sbin.density.top.20` `units: %`	The average sbin density of top 20 percent sbins among all sbins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1

`design.sbin.density.top.5` `units: %`	The average sbin density of top 5 percent sbins among all sbins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.sbin.viol.100`	The number of sbins that have densities more than 100 percent Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.sbin.viol.60`	The number of sbins that have densities more than 60 percent Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.sbin.viol.70`	The number of sbins that have densities more than 70 percent Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.sbin.viol.80`	The number of sbins that have densities more than 80 percent Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.sbin.viol.90`	The number of sbins that have densities more than 90 percent Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.sitearea.actual`	Actual site area Data Precision: 0 internal 1
`design.sitearea.padding`	Padded site area Data Precision: 0 internal 1
`design.sp.hpwl`	HPWL wirelength based on sp placement WL report Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.sp.steiner`	Formula based Steiner wirelength based on sp placement WL report Data Precision: 0 A smaller number is better when doing HTML comparisons.internal 1
`design.spin.density.peak` `units: %`	Peak pin density inside a sbin based on PSP report Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1

`design.spin.density.top.1` `units: %`	The average pin density inside a sbin of top 1 percent sbins among all sbins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.spin.density.top.10` `units: %`	The average pin density inside a sbin of top 10 percent sbins among all sbins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.spin.density.top.2` `units: %`	The average pin density inside a sbin of top 2 percent sbins among all sbins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.spin.density.top.20` `units: %`	The average pin density inside a sbin of top 20 percent sbins among all sbins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1
`design.spin.density.top.5` `units: %`	The average pin density inside a sbin of top 5 percent sbins among all sbins Data Precision: 1 A smaller number is better when doing HTML comparisons.internal 1

Flow Metrics

The following table provides the list of various flow metrics.

Metric Object Name	Description

`flow.cputime`
`units: s`
`type time`
	Returns the CPU time since the last snapshot
	Data Precision: 0
	A smaller number is better when doing HTML comparisons.

`flow.cputime.not_child`
`units: s`
`type time`
	Returns the CPU time taken since the last snapshot excluding child snapshots
	Data Precision: 0
	A smaller number is better when doing HTML comparisons.

`flow.cputime.total`
`units: s`
`type time`
	Returns the total CPU time
	Data Precision: 0
	A smaller number is better when doing HTML comparisons.

`flow.cputime.user`
`units: s`
`type time`
	Returns the user CPU time since the last snapshot Data Precision: 0 A smaller number is better when doing HTML comparisons.

`flow.cputime.user.not_child`
`units: s`
`type time`
	Returns the user CPU time since the last snapshot excluding child snapshots Data Precision: 0 A smaller number is better when doing HTML comparisons.

`flow.cputime.user.total`
`units: s`
`type time`
	Returns the total user CPU time
	Data Precision: 0
	A smaller number is better when doing HTML comparisons.

`flow.exclude_time_metric` `type bool`	Returns the CPU and Wall time are excluded from parent snapshot Data Precision: 0 inheritance_enabled 0
`flow.machine tcl`	Returns the info hostname description Hostname Data Precision: 0
`flow.machine.load`	Returns the host load average. Data Precision: 2 A smaller number is better when doing HTML comparisons.

`flow.memory`
`units: MB`
`type memory`
	Returns the current memory footprint
	Data Precision: 0
	A smaller number is better when doing HTML comparisons.

`flow.memory.instant`
`units: MB`
`type memory`
	Returns the current memory footprint
	Data Precision: 0
	A smaller number is better when doing HTML comparisons. inheritance_enabled 0

`flow.memory.resident`
`units: MB`
`type memory`
	Returns the current resident memory footprint
	Data Precision: 0
	A smaller number is better when doing HTML comparisons. inheritance_tcl

`flow.memory.resident.instant`
`units: MB`
`type memory`
	Returns the current resident memory footprint
	Data Precision: 0
	A smaller number is better when doing HTML comparisons. inheritance_enabled 0

`flow.memory.resident.peak`
`units: MB`
`type memory`
	Returns the maximum resident memory footprint
	Data Precision: 0
	A smaller number is better when doing HTML comparisons. inheritance_tcl

`flow.memory.resident.peak.instant`
`units: MB`
`type memory`
	Returns the maximum resident memory footprint
	Data Precision: 0
	A smaller number is better when doing HTML comparisons. inheritance_enabled 0

`flow.realtime`
`units: s`
`type time`
	Returns the real time since the last snapshot.
	Data Precision: 0
	A smaller number is better when doing HTML comparisons.

`flow.realtime.not_child`
`units: s`
`type time`
	Returns the real time since the last snapshot excluding child snapshots
	Data Precision: 0
	A smaller number is better when doing HTML comparisons.

`flow.realtime.total`
`units: s`
`type time`
	Returns the total real time
	Data Precision: 0
	A smaller number is better when doing HTML comparisons.

`flow.root_config` `type dict`	Returns the non-default root config option values Data Precision: 0
`flow.run_directory tcl`	Returns the password type directory from the current working directory. Data Precision: 0

Frequency Metrics

The following table provides the list of various frequency metrics.

Metric Object Name	Description
`frequency.violations`	Total number of violation reported Data Precision: 0 A smaller number is better when doing HTML comparison.
`frequency.violations.analysis_view:<view>`	Total number of violation reported per view Data Precision: 0 A smaller number is better when doing HTML comparison.

`frequency.violations.clock`	Total number of violation reported on clock net Data Precision: 0 A smaller number is better when doing HTML comparison.
`frequency.violations.clock.analysis_view:<view>`	Total number of violation reported on clock net per view Data Precision: 0 A smaller number is better when doing HTML comparison.

Power Metrics

The following table provides the list of various power metrics.

Metric Object Name	Description
`power` `units: mW`	Total power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.block.<block>` `units: mW`	Total per block power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.clock` `units: mW`	Total clock power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.clock.total` `units: mW`	Total clock power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.dynamic` `units: mW`	Total dynamic power Data Precision: 2 A smaller number is better when doing HTML comparison.

`power.dynamic.block` `units: mW`	Macro dynamic power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.dynamic.block.<block>` `units: mW`	Total per block dynamic power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.dynamic.clock` `units: mw`	Clock dynamic power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.dynamic.combinatorial` `units: mW`	Combinatorial dynamic power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.dynamic.hinst:<block>` `units: mW`	Total per block dynamic power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.dynamic.io u` `nits mW`	IO dynamic power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.dynamic.macro` `units: mW`	Macro dynamic power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.dynamic.sequential` `units: mW`	Sequential dynamic power Data Precision: 2 A smaller number is better when doing HTML comparison.

`power.dynamic.total` `units: mW`	Total dynamic power Data Precision: 2 A smaller number is better when doing HTML comparison.

`power.dynamic.`
`type: <combinatorial|clock_combinatorial|io|clock_sequential|sequential>`
`units: mW`
	Per type dynamic power
	Data Precision: 2
	A smaller number is better when doing HTML comparison.

`power.hinst:<block>` `units: mW`	Total per block power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.internal` `units: mW`	Total internal power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.internal.block` `units: mW`	Internal Macro power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.internal.block.<block>` `units: mW`	Total per block internal power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.internal.clock` `units: mw`	Internal clock power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.internal.clock_combinatorial` `units: mW`	Internal combinatorial clock power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.internal.clock_sequential` `units: mW`	Internal sequential clock power Data Precision: 2 A smaller number is better when doing HTML comparison.

`power.internal.combinatorial` `units: mW`	Internal combinatorial power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.internal.hinst:<block>` `units: mW`	Total per block internal power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.internal.io` `units: mW`	Internal IO power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.internal.macro` `units: mW`	Internal Macro power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.internal.sequential` `units: mW`	Internal sequential power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.internal.total` `units: mW`	Total internal power Data Precision: 2 A smaller number is better when doing HTML comparison.

`power.internal.type:`
`<combinatorial|clock_combinatorial|io|clock_sequential|sequential>`
`units: mW`
	Per type internal power
	Data Precision: 2
	A smaller number is better when doing HTML comparison.

`power.leakage` `units: mW`	Total leakage power Data Precision: 2 A smaller number is better when doing HTML comparison.

`power.leakage.block` `units: mW`	Macro leakage power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.leakage.block.<block>` `units: mW`	Total per block leakage power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.leakage.clock` `units: mw`	Clock leakage power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.leakage.clock_combinatorial` `units: mW`	Combinatorial clock leakage power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.leakage.clock_sequential` `units: mW`	Sequential clock leakage power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.leakage.combinatorial` `units: mW`	Combinatorial leakage power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.leakage.hinst:<block>` `units: mW`	Total per block leakage power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.leakage.io` `units: mW`	IO leakage power Data Precision: 2 A smaller number is better when doing HTML comparison.

`power.leakage.macro` `units: mW`	Macro leakage power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.leakage.sequential` `units: mW`	Sequential leakage power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.leakage.total units: mW`	Total leakage power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.leakage.type: <combinatorial|clock_combinatorial|io|clock_sequential|sequential>` `units: mW`	Per type leakage power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.switching` `units: mW`	Total switching power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.switching.block` `units: mW`	Macro switching power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.switching.block.<block>` `units: mW`	Total per block switching power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.switching.clock` `units: mw`	Clock switching power Data Precision: 2 A smaller number is better when doing HTML comparison.

`power.switching.clock_combinatorial` `units: mW`	Combinatorial clock switching power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.switching.clock_sequential` `units: mW`	Sequential clock switching power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.switching.combinatorial` `units: mW`	Combinatorial switching power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.switching.hinst:<block>` `units: mW`	Total per block switching power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.switching.io units: mW`	IO switching power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.switching.macro` `units: mW`	Macro switching power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.switching.sequential` `units: mW`	Sequential switching power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.switching.total` `units: mW`	Total switching power Data Precision: 2 A smaller number is better when doing HTML comparison.

`power.switching.type: <combinatorial|clock_combinatorial|io|clock_sequential|sequential>` `units: mW`	Per type switching power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.total` `units: mW`	Total power Data Precision: 2 A smaller number is better when doing HTML comparison.
`power.view`	Power analysis view Data Precision: 0

Rail Metrics

The following table provides the list of various rail metrics.

Metric Object Name	
`rail.averagedemandcurrent.net:<net>` `units: mA`	Average of TC_SUM waveform for net Data Precision: 3
`rail.averagesupplycurrent.net:<net>` `units: mA`	Average of VC_SUM waveform for net Data Precision: 3
`rail.gridcap.net:<net>` `units: pF`	Grid cap for net Data Precision: 3
`rail.intrinsiccap.net:<net>` `units: pF`	Intrinsic cap for net Data Precision: 3
`rail.ir.dynamic.avg.net:<net>` `units: V`	Avg dynamic IR value Data Precision: 3 A smaller number is better when doing HTML comparison.
`rail.ir.dynamic.max.net:<net>` `units: V`	Max dynamic IR value Data Precision: 3 A smaller number is better when doing HTML comparison.
`rail.ir.dynamic.min.net:<net>` `units: V`	Min dynamic IR value Data Precision: 3 A smaller number is better when doing HTML comparison.

`rail.ir.dynamic.view`	Dynamic view name Data Precision: 0
`rail.ir.dynamic.violations.net:<net>`	Number of resistor violating dynamic IR limit value Data Precision: 0 A smaller number is better when doing HTML comparison.
`rail.ir.static.avg.net:<net>` `units: V`	Avg static IR value Data Precision: 3 A smaller number is better when doing HTML comparison.
`rail.ir.static.max.net:<net>` `units: V`	Max static IR value Data Precision: 3 A smaller number is better when doing HTML comparison.
`rail.ir.static.min.net:<net>` `units: V`	Min static IR value Data Precision: 3 A smaller number is better when doing HTML comparison.
`rail.ir.static.view`	Static view name Data Precision: 0
`rail.ir.static.violations.net:<net>`	Number of resistor violating static IR limit value Data Precision: 0 A smaller number is better when doing HTML comparison.
`rail.loadingcap.net:<net>` `units: pF`	Loading cap for net Data Precision: 3
`rail.peakdemandcurrent.net:<net>` `units: mA`	Peak of TC_SUM waveform for net Data Precision: 3
`rail.peaksupplycurrent.net:<net>` `units: mA`	Peak of VC_SUM waveform for net Data Precision: 3
`rail.poweremreport.net:<net>`	Path to the powerem report for the net Data Precision: 0
`rail.referencevoltage.net:<net>` `units: V`	Reference design voltage Data Precision: 3
`rail.rj.avg.net:<net>`	Avg RJ Data Precision: 3 A smaller number is better when doing HTML comparison.

`rail.rj.max.net:<net>`	Max RJ Data Precision: 3 A smaller number is better when doing HTML comparison.
`rail.rj.min.net:<net>`	Min RJ Data Precision: 3 A smaller number is better when doing HTML comparison.
`rail.rj.violations.net:<net>`	Total RJ violation (above EM limit) Data Precision: 0 A smaller number is better when doing HTML comparison.
`rail.rushcurrent.net:<net>` `units: mA`	Rush current for net Data Precision: 3
`rail.thresholdvoltage.net:<net>` `units: V`	Threshold used for rail analysis Data Precision: 3
`rail.totalcap.net:<net>` `units: pF`	Total caps for net Data Precision: 3
`rail.totalinstanceconnected.net:<net>`	Total number of instance connected to the net Data Precision: 0
`rail.totalpowerswitchesturnedon.net:<net>`	Total power switches turned on Data Precision: 0
`rail.wakeuptime.net:<net>` `units: ns`	Wake up time for net Data Precision: 3
`rail.worstircycle.net:<net>` `units: ns`	Worst case time <interval number*resolution> Data Precision: 3
`rail.worstivreport.net:<net>`	Path to net specific iv file Data Precision: 0
`rail.worstivreport.power_domain:<domain>`	Path to domain specific iv file Data Precision: 0

Route Metrics

The following table provides the list of various route metrics.

Metric Object Name	Description
`route.drc`	Total DRC count Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.drc.<layer>`	DRC count per layer Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.drc.<type>`	DRC count per type Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.drc.layer:<layer>`	DRC count per layer Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.drc.total`	Total DRC count Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.drc.type:<type>`	DRC count per type Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.layers`	Number of routing layers Data Precision: 0
`route.map.<layer>`	Congesion map per layer Data Precision: 0 internal 1
`route.map.all`	Congestion map for all layers Data Precision: 0 internal 1
`route.map.hor`	Congestion map for hor layers Data Precision: 0 internal 1

`route.map.layer:<layer>`	Congesion map per layer Data Precision: 0 internal 1
`route.map.ver`	Congestion map for ver layers Data Precision: 0 internal 1
`route.overcon`	Total GR overcon Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.overcon.<layer>`	GR overcon per layer Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.overcon.layer:<layer>`	GR overcon per layer Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.overcon.total`	Total GR overcon Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.overflow.horizontal`	Trial-route horizontal overflow Data Precision: 3 A smaller number is better when doing HTML comparison.
`route.overflow.vertical`	Trial-route vertical overflow Data Precision: 3 A smaller number is better when doing HTML comparison.
`route.pitch.<layer>` `units: um`	Routing pitch per layer Data Precision: 3
`route.pitch.layer:<layer>` `units: um`	Routing pitch per layer Data Precision: 3
`route.shielding.nets`	Number of shielded nets Data Precision: 0
`route.shielding.percentage`	Shielding percentage Data Precision: 0

`route.via`	Total number of vias Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.via.layer:<layer>`	Total number of vias per layer Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.via.multicut`	Total number of MC vias Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.via.multicut.<layer>`	Number of MC vias per layer Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.via.multicut.layer:<layer>`	Number of MC vias per layer Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.via.multicut.percentage`	Percentage of MC vias Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.via.multicut.total`	Total number of MC vias Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.via.singlecut`	Total number of SC vias Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.via.singlecut.<layer>`	Number of SC vias per layer Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.via.singlecut.layer:<layer>`	Number of SC vias per layer Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.via.singlecut.percentage`	Percentage of SC vias Data Precision: 0

`route.via.singlecut.total`	Total number of SC vias Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.via.total`	Total number of vias Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.via.total.<layer>`	Total number of vias per layer Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.width.<layer>` `units: um`	Routing width per layer Data Precision: 3
`route.width.layer:<layer>` `units: um`	Routing width per layer Data Precision: 3
`route.wirelength` `units: um`	Total wirelength Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.wirelength.<layer>` `units: um`	Wirelength per layer Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.wirelength.layer:<layer>` `units: um`	Wirelength per layer Data Precision: 0 A smaller number is better when doing HTML comparison.
`route.wirelength.total` `units: um`	Total wirelength Data Precision: 0 A smaller number is better when doing HTML comparison.

Timing Metrics

The following table provides the list of various timing metrics.

Metric Object Name	Description
`timing.analysis_views.all`	All views of setup/hold timing Data Precision: 0

`timing.analysis_views.all.number`	The number of all views of setup/hold timing Data Precision: 0
`timing.drv.max_cap`	Total max capacitance violation Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.drv.max_cap.total`	Total max capacitance violation Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.drv.max_cap.worst`	Worst max capacitance violation Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.drv.max_fanout`	Total max fanout violations Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.drv.max_fanout.total`	Total max fanout violations Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.drv.max_fanout.worst`	Worst max fanout violation Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.drv.max_length`	Total max length violations Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.drv.max_length.total`	Total max length violations Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.drv.max_length.worst` `units: um`	Worst max length violation Data Precision: 3 A smaller number is better when doing HTML comparison.
`timing.drv.max_tran`	Total max transition violations Data Precision: 0 A smaller number is better when doing HTML comparison.

`timing.drv.max_tran.total`	Total max transition violations Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.drv.max_tran.worst` `units: ns`	Worst max transition violation Data Precision: 3 A smaller number is better when doing HTML comparison.
`timing.drv.report_file`	Location of the timing DRV report file Data Precision: 0
`timing.hold.analysis_views.active`	All active views of hold timing Data Precision: 0
`timing.hold.analysis_views.active.number`	The number of all active views of hold timing Data Precision: 0
`timing.hold.analysis_views.enabled`	All enabled views of hold timing Data Precision: 0
`timing.hold.analysis_views.enabled.number`	The number of all enabled views of hold timing Data Precision: 0
`timing.hold.feps`	Total number of hold failing end points Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.hold.feps.<pathgroup>`	Total number of hold failing end points for a specific path group Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.hold.feps.<view>`	Total number of hold failing end points for a specific view Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.hold.feps.analysis_view:<view>`	Total number of hold failing end points for a specific view Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.hold.feps.analysis_view:` `<view>.path_group:<group>`	Total number of hold failing end points for a specific view and path group Data Precision: 0 A smaller number is better when doing HTML comparison.

`timing.hold.feps.path_group:<group>`	Total number of hold failing end points for a specific path group Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.hold.histogram` `Type: histogram`	Hold TNS histogram Data Precision: 0
`timing.hold.histogram.views` `Type: histogram`	Hold TNS histogram (per view) Data Precision: 0
`timing.hold.paths` `Type: timing_data`	Hold timing path details Data Precision: 0
`timing.hold.paths.path_group:reg2reg` `Type: timing_data`	Hold timing path reg2reg details Data Precision: 0
`timing.hold.pba.histogram` `Type: histogram`	Hold TNS histogram Data Precision: 0
`timing.hold.pba.histogram.views` `Type: histogram`	Hold TNS histogram (per view) Data Precision: 0

`timing.hold.tns`
`units: ns`
`Type: slack`
	Total negative hold slack (all path groups)
	Data Precision: 0

`timing.hold.tns.<pathgroup>`
`units: ns`
`Type: slack`

`units: ns`
`Type: slack`
	Worst negative hold slack for a specific path group
	Data Precision: 3

`timing.hold.worst_path.capture_clock`	Capture clock of the worst hold path Data Precision: 0
`timing.hold.worst_path.freq` `units: GHz`	Frequency: 1/(capture period-slack) of the worst hold path A larger number is better when doing HTML comparison.
`timing.hold.worst_path.frequency` `units: GHz`	Frequency: 1/(capture period-slack) of the worst hold path Data Precision: 0 A larger number is better when doing HTML comparison.
`timing.hold.worst_path.launch_clock`	Launch clock of the worst hold path Data Precision: 0

`timing.hold.worst_path.view`	Analysis view of the worst hold path Data Precision: 0
`timing.setup.analysis_views.active`	All active views of setup timing Data Precision: 0
`timing.setup.analysis_views.active.number`	The number of all active views of setup timing Data Precision: 0
`timing.setup.analysis_views.enabled`	All enabled views of setup timing Data Precision: 0
`timing.setup.analysis_views.enabled.number`	The number of all enabled views of setup timing Data Precision: 0
`timing.setup.feps`	Total number of setup failing end points Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.setup.feps.<pathgroup>`	Total number of setup failing end points for a specific path group Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.setup.feps.<view>`	Total number of setup failing end points for a specific view Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.setup.feps.analysis_view:<view>`	Total number of setup failing end points for a specific view Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.setup.feps.analysis_view:<view>.path_group:<group>`	Total number of setup failing end points for a specific view and path group Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.setup.feps.path_group:<group>`	Total number of setup failing end points for a specific path group Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.setup.histogram` `Type: histogram`	Setup TNS histogram Data Precision: 0

`timing.setup.histogram.views` `Type: histogram`	Setup TNS histogram (per view) Data Precision: 0
`timing.setup.paths` `Type: timing_data`	Setup timing path details Data Precision: 0
`timing.setup.paths.path_group:reg2reg` `Type: timing_data`	Setup timing path reg2reg details Data Precision: 0
`timing.setup.pba.histogram t` `ype histogram`	Setup TNS histogram Data Precision: 0
`timing.setup.pba.histogram.views` `Type: histogram`	Setup TNS histogram (per view) Data Precision: 0
`timing.setup.place.feps`	Total number of setup failing end points according to timing inside placement engine Data Precision: 0 A smaller number is better when doing HTML comparison. internal 1
`timing.setup.place.tns` `units: ns`	Total negative setup slack according to timing inside placement engine Data Precision: 0 A larger number is better when doing HTML comparison. internal 1
`timing.setup.place.wns` `units: ns`	Worst negative setup slack according to timing inside placement engine Data Precision: 3 c mp moreBetterIgnorePositive internal 1

`timing.setup.tns`
`units: ns`
`Type: slack`
	Total negative setup slack (all path groups)
	Data Precision: 0
	A larger number is better when doing HTML comparison.

`timing.setup.tns.<pathgroup>`
`units: ns`
`Type: slack`
	Total negative setup slack for a specific path group
	Data Precision: 0
	A larger number is better when doing HTML comparison.

`timing.setup.tns.<view>`
`units: ns`
`Type: slack`
	Total negative setup slack for a specific view
	Data Precision: 0
	A larger number is better when doing HTML comparison.

`timing.setup.tns.analysis_view:<view>`
`units: ns`
`Type: slack`
	Total negative setup slack for a specific view
	Data Precision: 0
	A larger number is better when doing HTML comparison.

`timing.setup.tns.analysis_view:<view>.path_group:<group>`
`units: ns`
`Type: slack`
	Total negative setup slack for a specific view and path group
	Data Precision: 0
	A larger number is better when doing HTML comparison.

`timing.setup.tns.path_group:<group>`
`units: ns`
`Type: slack`
	Total negative setup slack for a specific path group
	Data Precision: 0
	A larger number is better when doing HTML comparison.

`timing.setup.wns`
`units: ns`
`Type: slack`
	Worst negative setup slack (all path groups)
	Data Precision: 3
	A number below the Target: is better when doing HTML comparison.
	Target: 0

`timing.setup.wns.<pathgroup>`
`units: ns`
`Type: slack`
	Worst negative setup slack for a specific path group
	Data Precision: 3
	A number below the Target: is better when doing HTML comparison.
	Target: 0

`timing.setup.wns.<view>`
`units: ns`
`Type: slack`
	Worst negative setup slack for a specific view
	Data Precision: 3
	A number below the Target: is better when doing HTML comparison.
	Target: 0

`timing.setup.wns.analysis_view:<view>`
`units: ns`
`Type: slack`
	Worst negative setup slack for a specific view
	Data Precision: 3
	A number below the Target: is better when doing HTML comparison.
	Target: 0

`timing.setup.wns.analysis_view:<view>.path_group:<group>`
`units: ns`
`Type: slack`
	Worst negative setup slack for a specific view and path group
	Data Precision: 3
	A number below the Target: is better when doing HTML comparison.
	Target: 0

`timing.setup.wns.path_group:<group>`
`units: ns`
`Type: slack`
	Worst negative setup slack for a specific path group
	Data Precision: 3
	A number below the Target: is better when doing HTML comparison.
	Target: 0

`timing.setup.worst_path.capture_clock`	Capture clock of the worst setup path Data Precision: 0
`timing.setup.worst_path.freq` `units: GHz`	Frequency: 1/(capture period-slack) of the worst setup path A larger number is better when doing HTML comparison.
`timing.setup.worst_path.frequency` `units: GHz`	Frequency: 1/(capture period-slack) of the worst setup path Data Precision: 0 A larger number is better when doing HTML comparison.
`timing.setup.worst_path.launch_clock`	Launch clock of the worst setup path Data Precision: 0
`timing.setup.worst_path.view`	Analysis view of the worst setup path Data Precision: 0
`timing.si.glitches`	Number of SI glitches Data Precision: 0 A smaller number is better when doing HTML comparison.
`timing.si.noise` `units: ns`	Amount of noise delay remaining Data Precision: 3 A smaller number is better when doing HTML comparison.

create_metric_page

```
create_metric_page
[-help]
[-after page_name]
[-before page_name]
[-format {html excel text}]
-name page_name
```

Creates a new metric page.

Creation of a metric page is the first step in creating a metric table for HTML display. After creating a metric page, you need to specify the heading for the metric table using the `create_metric_table_heading` command. After specifying the metric table heading, you create the metric table using the `create_metric_table` command.

Parameters

`-after page_name`	Specifies to insert after the page with this name. *Date_type*: string, optional
`-before page_name`	Specifies to insert before the page with this name. *Date_type*: string, optional
`-format {html excel text}`	Specifies configuration for the `report_metric` format. *Date_type*: enum, optional
`-help`	Prints out the command usage. For a detailed description of the command, use the man command: `man create_metric_page`
`-name page_name`	Specifies the name of the new page. The page name must be unique. *Date_type*: string, required

Examples

- The following command creates the metric page, `User`.

  ```
  create_metric_page -name User
  ```

  The following command creates the `Test` metric page after the `Summary` page.

  ```
  create_metric_page -after Summary -name Test
  ```

create_metric_table

```
create_metric_table
[-help]
[-auto_hide]
[-collapsible_key]
[-format {html excel text}]
-heading table_heading
[-hide_footers]
[-hide_graph_footers]
[-hierarchy_separator separator]
[-id table_id]
[-key regexp_key]
[-per_snapshot]
[-show_label_every frequency]
-type {horizontal vertical cpu dict time_statement histogram imageplot}
```

Creates a metric table.

To create a metric table, you first need to create a metric page using the `create_metric_page` command. After creating a metric page, you need to specify the heading for the metric table using the `create_metric_table_heading` command. After specifying the metric table heading, you create the metric table using the `create_metric_table` command.

Parameters

`-auto_hide`	Specifies whether to auto hide the table. *Date_type*: bool, optional
`-collapsible_key`	Specifies to include collapse key columns in the table with the option to expand them. *Date_type*: bool, optional
`-format {html excel text}`	Specifies configuration for the `report_metric` format. *Date_type*: enum, optional

`-heading` *`heading_id`*	Specifies the id of the heading to append. You need to specify the table heading already created using the `create_metric_table_heading` command.
	Date_type: string, required
	For example, the following command gives an error as the metric table heading `statistics` has not been defined before specifying the heading while creating the table.
	`@[DEV]innovus 5> create_metric_table -id table_id -heading statistics -type horizontal`
	`heading id {statistics} not found`
	`@[DEV]innovus 6> create_metric_table -heading statistics -type horizontal`
	`heading id {statistics} not found`
	`@[DEV]innovus 7>`

`-hide_footers`	Hides the minimum, average, and maximum rows from the bottom of the table. Graph buttons are still shown. *Date_type*: bool, optional
`-hide_graph_footers`	Hides the graph buttons from the bottom of the table. *Date_type*: bool, optional
`-hierarchy_separator` *`separator`*	Shows the metric names with hierarchy using the provided separator. *Date_type*: string, optional
`-id` *`table_id`*	Specifies the id for the new table. *Date_type*: string, optional
`-key` *`regexp_key`*	Specifies the key for any regexp. *Date_type*: string, optional
`-per_snapshot`	Specifies to expand the table per snapshot. *Date_type*: bool, optional
`-show_label_every` *`frequency`*	Specifies the frequency of X-axis labels in the histogram. *Date_type*: int, optional
`-type {horizontal vertical cpu dict time_statement histogram imageplot}`	Specifies the type (horizontal vertical cpu dict time_statement histogram imageplot) of table. *Date_type*: enum, required

Example

The following commands create the `table_s` metric table:

```
innovus1> create_metric_page -name User
```

```
innovus2> create_metric_table_heading -id statistics -page User \
  -title "Average Timing Values Per Snapshot"
innovus3> create_metric_table  -id table_s -heading statistics \
  -per_snapshot -type  horizontal
```

Related Information

- The Unified Metrics chapter in the Innovus Stylus Common UI User Guide

- `report_metric`

create_metric_table_heading

```
create_metric_table_heading
[-help]
[-format {html excel text}]
[-id heading_id]
-page page_name
-title heading_title
[-type {fixed collapse}]
```

Create a new metric heading.

You create the heading for the metric page you created using the `create_metric_page`. After specifying the metric table heading, you create the metric table using the `create_metric_table` command.

Parameters

-help	Prints out the command usage. For a detailed description of the command, use the man command: `man create_metric_table_heading`
`-format {html excel text}`	Specifies configuration for the `report_metric` format. *Date_type*: enum, optional
`-id heading_id`	Specifies the id for the new heading. *Date_type*: string, optional
`-page page_name`	Specifies the page name where the heading will be added. *Date_type*: string, required
`-title heading_title`	Specifies the title of the heading. *Date_type*: string, required
`-type {fixed collapse}`	Specifies the type of heading element, fixed or collapse. *Date_type*: enum, optional

Example

The following commands create the `table_s` metric table with the heading `Average Timing Values Per Snapshot`:

```
innovus2> create_metric_table_heading -id statistics -page User \
  -title "Average Timing Values Per Snapshot"
innovus3> create_metric_table  -id table_s -heading statistics \
  -per_snapshot -type  horizontal
```

Related Information

- The Unified Metrics chapter in the Innovus Stylus Common UI User Guide

- `create_metric_table`

create_snapshot

```
create_snapshot
[pattern]
[-auto {min default}]
-categories [* flow design setup power check clock hold route]
[-exclude_time_metric]
[-name snapshot_name]
```

Creates snapshots of the current metric list at various points in the flow.

All super commands that save metrics call `create_snapshot` to save all metrics in a consistent manner. When `create_snapshot` is called, it creates an internal record designated by a label. The label for super commands are the command names.

Metrics that do not require extraction and/or timing/power analysis are calculated when the metric snapshot is saved. Timing/clock/power metrics are reported only if they are up-to-date (i.e. if `time_design`/`report_ccopt*`/`report_power` have been run). Metrics are saved as part of db and can be accessed using `get_db`. Reporting commands calculate metrics and push them into the metric stream. However, these metrics remain pending until you run `create_snapshot`. This allows the snapshot to contain metrics from more than one reporting command.

Note: Metric values should be saved such that the unit is easily known/accessible.

Parameters

`-auto {min default}`	Specifies the set of auto metrics to `run`. *Date_type*: enum, optional
`-categories [* flow design setup power check clock hold route]`	Specifies the metric categories to compute. *Date_type*: string, optional
`-exclude_time_metric`	Excludes the CPU and wall time from the parent snapshot calculations. *Date_type*: bool, optional
`-name snapshot_name`	Specifies the name of the snapshot. *Date_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `create_snapshot` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_snapshot`
pattern	Specifies specific metrics to save. *Date_type*: string, optional

Example

In the following example, the metrics calculated by the reporting commands. `report_power` and `report_timing_summary`, are pushed into the metric stream by the `create_snapshot` command:

```
innovus1> report_power

innovus2> report_timing_summary

innovus3> create_snapshot -name "setup_and_power"
```

Related Information

define_metric

```
define_metric
[-help]
[-compare {more_better less_better more_better_below_target less_better_above_target
more_better_ignore_positive}]
[-description metricDescription]
[{-id databaseID}]
[-inheritance_tcl TclName]
-name metric_name
[-no_inheritance]
[-precision number_of_decimal_places]
[-target metric_name]
[{-tcl TCL_command_list}[-tools listOfTools] ]
[-threshold reporting_unit]
[-type metricType]
[-units reporting_unit]
[-warning threshold]
```

Defines new metrics that are required by the user.

You can use this command to create new metrics that you need to track. To create new metrics, you need to provide the TCL code required to generate the metric. The TCL can be a sequence of commands that return a value or a procedure that returns a value.

The following command provides the TCL commands `.base_cell.name == HDR*` to define the design.switch_cells metric.

```
define_metric -name design.switch_cells -tcl { return [get_db insts -if {.base_cell.name == HDR*}] }
```

Similarly, a proc can be used to define a metric. The following command provides the `my_get_switch_cells{}` proc to define the `design.switch_cells` metric.

```
define_metric -name design.switch_cells -tcl { return [my_get_switch_cells{}] }
```

The metric is calculated and stored with the other metrics when `create_snapshot` is executed. All `define_metric` commands are saved and restored in the design database.

Parameters

`-compare {more_better less_better more_better_below_target less_better_above_target more_better_ignore_positive}`	Specifies the compare function, `{more_better less_better more_better_below_target less_better_above_target more_better_ignore_positive}`. The comparison options show the good or bad color when the value is below or above the target value as appropriate. *Data_type*: enum, optional
`-description metricDescription`	Specifies the description of the metric. *Data_type*: string, optional

`-id` *databaseID*	Specifies the database ID. *Data_type*: string, optional
`-inheritance_tcl` *TclName*	Specifies Tcl for combining children values. The metric is not executed in the global namespace. The equivalent proc args is {children}. *Data_type*: string, optional
`-name` *metric_name*	Specifies the name of the metric. *Data_type*: string, required
`-no_inheritance`	Disables the inheritance of the metric. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes type and default information for each `define_metric` parameter. For a detailed description of the command and all of its parameters, use the man command: `man define_metric`
`-precision` *number_of_decimal_places*	Specifies the number of decimal places. *Default*: `0` *Data_type*: int, optional
`-target` *metric_name*	Specifies the target or the name of metric containing the target value. *Data_type*: string, optional
`-tcl { TCL_command_list }`	Specifies the list of TCL commands or proc to generate (return) the metric which is of the format `{<value> <unit>}`. When the `-tcl` option is specified, the TCL associated with the metric will be executed whenever `create_snapshot` is called, and the metric will be captured as part of the snapshot. *Data_type*: string, optional
`-threshold` *reporting_unit*	Specifies the threshold for comparing numbers in HTML. If the delta between the two numbers being compared is less than the threshold then the metric will be colored “yellow”. If it is outside the threshold, then it is colored red or green depending on the compare function i.e. whether more is better or less is better. *Data_type*: string, optional
`-tools` *listOfTools*	Specifies the list of tools which the tcl code will run. *Data_type*: string, optional
`-type` *metricType*	Specifies the type of metric.

Data_type: string, optional

The various metrics types are:

- imageplot: A metric type that the renders to an image in the HTML report.
  - Format:

```
<name1> { \
 fill_color "<color>" \
  stroke_color "<color>"\
  data <list of data sets>
} \
<name2> { \
<sub-name1> { \
    fill_color <color> \
    data <list of data sets> \
  } \
  <sub-name2> {...} \
}
```

  Where a data set can be one or more of the following:

  The data on each layer is a string of coordinates (separated by sequences of whitespace and comma) with types. These types are:

  - R - rectangle (x, y, width, height)
  - B - bounding box (x_min, y_min, x_max, y_max)
  - G - closed polygon (x, y, x, y, ...)
  - L - open polyline (x, y, x, y, ...)
  - C - circle (x, y, r)
  - P - point (x, y)

  For rectangles, boxes, circles and points, multiple shapes can be defined without having to repeat the type letter. e.g. R1,2,3,4,5,6,7,8 is two rectangles.

  A value can be defined for shapes by adding a V suffix to the type; this value can then be used to color the shapes according to the value for heat maps. The value is always the first number after the type. This means that two points with values 20 and 40 may look like: PV20,1,2 40,6,5 or: PV20,1,2PV40,6,5.

  Example imageplot TCL dict data:

```
macros { \
fill_color "#FF0000" \
  stroke_color "#0000FF88" \
  data "R5,8,1,2 6,9,2,1 G1,2,3,4,5,6,7,8" \
} \
drcs { \
placement { \
    fill_color "#FF0000" \
    data "P3,4" \
  } \
  routing {...} \
}
```

Layers in the image are named (macros, congestion, normal, other in the above example) and support hierarchy. Layers should not be nested beyond one level deep. The hierarchy is used in the renderer (see below) to toggle the visibility of the layers. It is an error for any layer to be called data (reserved to keep hierarchy clear).

Colors can be defined either as hex or RGB values with optional opacity. Hex values are prefixed with #. RGB values are separated with whitespace.

- #FF0000: Red
- #00FF0040: Green (25% opaque)
- 0 0 255: Blue
- 255 0 255 192: Magenta (75% opaque)

- histogram: The data will be structured as a set of series with shared X-axis labels that are rendered as a stacked histogram.

  Format (TCL dict):

```
labels <list of labels> \
axis_x <name> \
axis_y <name> \
series { \
<series1> { \
   values <list of buckets \
   color "#FF0000" \
} \
```

```
<series2> { \
   values {2 1 0 0} \
   color "#0000FF" \
} \
}
```

Example:

```
get_metric timing.setup.histogram
timing.setup.histogram {labels {-0.320 -0.240 -0.160
-0.080} \
                        series { \
                          reg2reg {color #FF0000
values {43 3 2 3 0}} \
                          reg2cgate {color #0000FF
values {22 4 5 0 0}} \
                        } \
                        axis_x WNS(ns) \
                        axis_y {Failing End Points} \
                        }
```

The labels (a list of strings, shown in the order provided) define the X-axis labels for the histogram, the values in each series define the Y-axis values.

Colors can be defined either as hex or RGB values with optional opacity. Hex values are prefixed with #. RGB values are separated with whitespace.

```
#FF0000       - Red
0 0 255       - Blue
```

- html: Supports the inclusion of raw HTML in a metric. You can place simple html into tables allowing simple links to reports. For example, the following command defines `test_html` as an html type of metric:

  ```
  define_metric -name test_html -type html
  ```

  You can set the html metric, test_html, using the `set_metric` command:

  ```
  set_metric -name test_html -value {<a
  href="url">test</a>}
  ```

- radar: Helps to identify the characteristics of each run by a single graph. It is useful in cases where histogram cannot be used for comparing several runs.
  If a series type is radar, then they must all be radar - i.e. there

	is no mixing of other graph types with radar. Different number of labels/values will result in different points in the graph but the number of labels must match the number of values and all series must have the same number of values.
	
	`{ labels {RCI Fmax Area Power DFM} \`
	`series { \`
	`scenarioA { \`
	`color #0000FF \`
	`values {32 32 28 12 15} \`
	`type radar\`
	`} \`
	`senarioB { \`
	`color #FFA500 \`
	`values {12 12 12 21 28}`
	`type radar\`
	`} \`
	`} \`
	`}`

`-units` *reporting_unit*	Specifies the unit for reporting. *Data_type*: string, optional
`-warning` *threshold*	Specifies the warning threshold or name of metric containing the threshold value. *Data_type*: string, optional

Examples

- The following command defines the the `X20s` metric:

  ```
  define_metric -name X20s
  set_metric -name X20s \
  -value [get_db insts -expr {[regexp X20 $obj(.base_cell)]}]
  ```

  Alternatively, you can define the X20s metrics as follows:

  ```
  define_metric -name X20s -tcl {\
  return [get_db insts -expr {[regexp X20 $obj(.base_cell)]]} \
  }
  ```

  With the `-tcl` option, the TCL associated with the X20s metric will be executed whenever create_snapshot is called.

Related Information

- The Unified Metrics chapter in the Innovus Stylus Common UI User Guide
- `create_snapshot`

delete_metric

```
delete_metric
-help
[{-id databaseID}]
[-name metric_name]
```

Deletes a previously defined (user) metric from all labels.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `delete_metric` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_metric`
`-id databaseID`	Specifies the database ID. *Data_type*: string, optional
`-name metric_name`	Name of the metric to delete. *Data_type*: string, optional

Examples

- The following command deletes the `design.vtmix` metric:

```
delete_metric -name design.vtmix
```

Related Information

- `define_metric`
- `update_metric`
- The Unified Metrics chapter in the Innovus Stylus Common UI User Guide

delete_metric_page

```
delete_metric_page
[-help]
[-format {html excel text}]
-name page_name
```

Deletes a metric page.

Parameters

`-help`	Prints out the command usage. For a detailed description of the command, use the man command: `man delete_metric_page`
`-format {html excel text}`	Specifies configuration for the `report_metric` format. *Data_type*: enum, optional
`-name` *page_name*	Specifies the name of the metric page to be deleted. *Data_type*: string, required

Example

- The following command creates the metric page, `User`.

  ```
  delete_metric_page -name User
  ```

Related Information

- `create_metric_page`
- The Unified Metrics chapter in the Innovus Stylus Common UI User Guide

delete_metric_run

```
delete_metric_run
-help
[-name metric_name]
```

Deletes the specified metric run.

It deletes a set of metrics loaded using `read_metric`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `delete_metric_run` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_metric_run`
`-name` *`metric_name`*	Name of the metric run to be deleted. It defaults to the "current" run. This parameter corresponds to the `-id` parameter of the `read_metric` command. *Data_type*: string, optional

Example

- The following command deletes `run1`, which is read by `read_metric`.

```
read_metric -id run1 metrics.json
delete_metric_run -name run1
```

Related Information

- `read_metric`
- The Unified Metrics chapter in the Innovus Stylus Common UI User Guide

delete_metric_table

```
delete_metric_table
[-help]
[-format {html excel text}]
[-id table_id]
```

Deletes a metric table.

Parameters

`-help`	Prints out the command usage. For a detailed description of the command, use the man command: `man delete_metric_table`
`-format {html excel text}`	Specifies configuration for the `report_metric` format. *Data_type*: enum, optional
`-id table_id`	Specifies the id for the table to be deleted. *Data_type*: string, optional

Related Information

- `report_metric`
- The Unified Metrics chapter in the *Innovus Stylus Common UI User Guide*

delete_metric_table_heading

```
delete_metric_table_heading
[-help]
[-format {html excel text}]
[-id heading_id]
```

Deletes a metric heading.

Parameters

-help	Prints out the command usage. For a detailed description of the command, use the man command: `man delete_metric_table_heading`
`-format {html excel text}`	Specifies configuration for the specified `report_metric` format. *Data_type*: enum, optional
`-id` *heading_id*	Specifies the id of the heading to be deleted. *Data_type*: string, optional

Related Information

- `report_metric`
- The Unified Metrics chapter in the *Innovus Stylus Common UI User Guide*

get_metric

```
get_metric
-help
pattern_name
[-branch list_of_patterns]
[-exclude_inherited]
[-id id_name]
[-names label_name]
[-pending]
[-raw]
```

Gets the current state of metric(s).

You can use this command to query the current state of any metric or metrics from the current specified list of metrics as well as a previous state.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `get_metric` parameter. For a detailed description of the command and all of its parameters, use the man command: `man get_metric`
`-branch list_of_patterns`	Specifies list of patterns to match snapshot branches. This will limit all output to metrics stored in snapshots whose branch matches the specified branch. This requires any inheritance to be re-run to exclude inherited values from non-matching snapshots. *Data_type*: string, optional
`-exclude_inherited`	Specifies not to return any inherited value. *Data_type*: bool, optional
`-id id_name`	Specifies the database ID to output. Default is current database. *Data_type*: string, optional
`-names label_name`	List of patterns to match snapshot names. *Data_type*: string, optional
`pattern_name`	List of patterns to match metrics. This option supports wildcards. *Data_type*: string, optional
`-pending`	Returns metrics from the pending (not yet created) snapshot. *Data_type*: bool, optional
`-raw`	Returns metrics as a raw value i.e without normalization to the defined units. *Data_type*: bool, optional

Examples

- The following command gets the worst negative setup slack for all path groups for the preCTS snapshot from the gold database.

```
innovus1> get_metric -id gold -names prects timing.setup.wns

prects {timing.setup.wns -0.042}
```

- The following command gets the total number of instances for the sync_opt and prects snapshots from the gold database.

```
innovus2 > get_metric -id gold -names "syn_opt prects" design.instances

syn_opt {design.instances 658410} prects {design.instances 708621}
```

Related Information

- The Unified Metrics chapter in the Innovus Stylus Common UI User Guide

get_metric_alias

```
get_metric_alias
[-help]
```

Returns a tcl dictionary of aliases as dictionaries along with the from, to, and order properties.

Parameters

None

Example

The following command renames `path_group:reg2reg` to `reg2reg` with priority order `1`.

```
> set_metric_alias -from path_group:reg2reg -to reg2reg -order 1
```

The following command renames `path_group:reg2cgate` to `reg2cgate` with priority order `2`.

```
> set_metric_alias -from path_group:reg2cgate -to reg2cgate -order 2
```

The following command queries the set of aliases:

```
> get_metric_alias
```

Output

```
>path_group:reg2reg {to reg2reg order 1} path_group:reg2cgate {to reg2cgate order 2}
```

Related Information

- The Unified Metrics chapter in the *Innovus Stylus Common UI User Guide*

get_metric_config

```
get_metric_config
-help
-format {html excel text}
```

Gets the current metric configuration setting.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `get_metric_config` parameter. For a detailed description of the command and all of its parameters, use the man command: `man get_metric_config`
`-format {html excel text}`	Specifies configuration for the specified `report_metric` format. *Data_type*: enum, optional

Example

The following prints the current defined pages, heading and tables:

```
foreach page_name [dict keys [get_metric_config ]] {
  puts "\nPage : $page_name"
  puts "-----------------------------------------"
  foreach page [dict get [get_metric_config] $page_name] {
    foreach key [dict keys $page] {
      if {($key == "id")} {
        set id [dict get $page $key]
      }
      if {($key == "component")} {
         puts "$key : $id ([dict get $page $key])"
      }
    }
  }
}
```

Related Information

- `report_metric`
- The Unified Metrics chapter in the *Innovus Stylus Common UI User Guide*

get_metric_definition

```
get_metric_definition
-help
[-id metric_id]
-name metric_name
```

Returns the metric definition of the specified metric.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `get_metric_definition` parameter. For a detailed description of the command and all of its parameters, use the man command: `man get_metric_definition`
`-id metric_id`	Specifies the database ID to output. *Data_type*: string, optional
`-name label_name`	Specifies the metric name. *Data_type*: string, required

Examples

- The following command queries the attributes of the `timing.setup.wns` metric:

```
innovus 1> get_metric_definition -name timing.setup.wns

metric timing.setup.wns

units ns

type slack

description {Worst negative setup slack (all path groups)}

dp 3

cmp moreBetterBelowTarget

target 0
```

- The following command queries all defined metrics:

```
innovus 1> foreach m [get_metric_definition -name *] {puts $m }
```

Related Information

- The Unified Metrics chapter in the *Innovus Stylus Common UI User Guide*

get_metric_header

```
get_metric_header
-help
[-id db_id]
-name header_name
```

Returns the metric header information set by the `set_metric_header` command.

Parameters

`-id` *db_id*	Specifies the database ID. *Data_type*: string, optional
`-name` *header_name*	Specifies the name of the header. *Data_type*: string, required
`-help`	Outputs a brief description that includes type and default information for each `get_metric_header` parameter. For a detailed description of the command and all of its parameters, use the man command: `man get_metric_header`

Example

The following command sets the value `bar` of the metric header `foo`:

```
> set_metric_header -name timing -value high
```

The following command returns the header value of the metric header `foo`

```
> get_metric_header -name timing

high
```

Related Information

- `set_metric_header`

metric Category Attributes

The root attributes in the metric category are:

- metric_advanced_url_endpoint
- metric_capture_depth
- metric_capture_design_image
- metric_capture_design_image_blockages
- metric_capture_design_image_power_intent
- metric_capture_design_image_route_drc
- metric_capture_max_drc_markers
- metric_capture_min_count
- metric_capture_overwrite
- metric_capture_pba_tns_histogram
- metric_capture_timing_analysis_mode
- metric_capture_per_view
- metric_capture_reg2reg_metrics
- metric_capture_timing_paths
- metric_capture_timing_path_groups
- metric_capture_tns_histogram
- metric_capture_tns_histogram_buckets
- metric_capture_tns_histogram_paths
- metric_capture_tns_histogram_max_slack
- metric_capture_vth_per_power_domain
- metric_category_default
- metric_current_run_id
- metric_enable
- metric_summary_metrics

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `metric` category, use the following command:

```
get_db -category metric
```

metric_advanced_url_endpoint

```
metric_advanced_url_endpoint base_url
```

Default: `""`

Data_type: string, read/write

Specifies the base URL for the advanced metric server.

metric_capture_depth

```
metric_capture_depth depth
```

Default: `1`

Data_type: int, read/write

Specifies the depth for capturing hinst design and power metrics.

metric_capture_design_image

```
metric_capture_design_image {true | false}
```

Default: `true`

Data_type: bool, read/write

Captures design image.

metric_capture_design_image_blockages

```
metric_capture_design_image_blockages {true | false}
```

Default: `true`

Data_type: string, read/write

Captures blockages in the design image.

metric_capture_design_image_power_intent

```
metric_capture_design_image_power_intent {true | false}
```

Default: `true`

Data_type: string, read/write

Captures power intent objects in the design image.

metric_capture_design_image_route_drc

```
metric_capture_design_image_route_drc {true | false}
```

Default: `true`

Data_type: string, read/write

Captures route DRC markers in the design image.

metric_capture_max_drc_markers

`metric_capture_max_drc_markers` *max_number*

Default: `1000`

Data_type: int, read/write

Specifies the maximum number of DRC markers to include in metric image.

metric_capture_min_count

`metric_capture_min_count` *instanceCount*

Default: `1000`

Data_type: int, read/write

Specifies the minimum instance count for capturing hinst design and power metrics.

metric_capture_overwrite

`metric_capture_overwrite {true | false}`

Default: `false`

Data_type: bool, read/write

Overwrites the pending metrics during the `create_snapshot` category capture.

metric_capture_pba_tns_histogram

`metric_capture_pba_tns_histogram {true | false}`

Default: `false`

Data_type: bool, read/write

Captures the PBA histogram data for TNS.

metric_capture_timing_analysis_mode

`metric_capture_timing_analysis_mode {gba | ipba}`

Default: `gba`

Data_type: enum, read only

Controls the timing analysis mode for metric capture during create_snapshot categories setup and hold; gba, ipba.

- `gba`: graph based analysis
- `ipba`: path based analysis, retime_method == path_slew_propagation, retime_mode == exhaustive, timing_path_based_exhaustive_pba_bounded_mode == true

metric_capture_per_view

`metric_capture_per_view {true | false}`

Default: `true`

Data_type: bool, read/write

Captures the timing metrics per analysis_view.

metric_capture_reg2reg_metrics

`metric_capture_reg2reg_metrics [true | false}`

Default: `false`

Data_type: bool, read/write

Forces the capture of reg2reg metrics regardless of path groups.

metric_capture_timing_paths

`metric_capture_timing_paths` *`numberOfPaths`*

Default: `10`

Data_type: int, read/write

Specifies the number of paths to capture for detailed display.

metric_capture_timing_path_groups

`metric_capture_timing_path_groups` *`path_group`*

Default: `10`

Data_type: string, read/write

Controls the path groups for which detailed timing path information (full timing path report and display) is to be captured . By default, it is empty and the tool captures all and reg2reg. If the attribute is set to a list of groups, the tool will use the listed groups. The related metric name is `timing.setup.paths.path_group:<group>`.

metric_capture_tns_histogram

`metric_capture_tns_histogram {true | false}`

Default: `true`

Data_type: bool, read/write

Captures the histogram data for TNS.

metric_capture_tns_histogram_buckets

`metric_capture_tns_histogram_buckets` *`numberOfBuckets`*

Default: `50`

Data_type: int, read/write

Specifies the number of buckets for the TNS histogram.

metric_capture_tns_histogram_paths

`metric_capture_tns_histogram_paths` *`numberOfPaths`*

Default: `10000`

Data_type: int, read/write

Specifies the number of paths to capture for the TNS histogram.

metric_capture_tns_histogram_max_slack

`metric_capture_tns_histogram_max_slack` *`maximum_slack_value`*

Default: `0`

Data_type: int, read/write

Specifies the maximum slack value for the TNS histogram. You can change its value if you need to shift the y axis.

metric_capture_vth_per_power_domain

`metric_capture_vth_per_power_domain {true | false}`

Default: `false`

Data_type: bool, read/write

Captures vth metrics per power domain.

metric_category_default

`metric_category_default` *`category`*

Default: `design`

Data_type: string, read/write

Specifies to capture the default metric categories if none are provided.

metric_current_run_id

```
metric_current_run_id
```

Default: `""`

Data_type: string, read/write

Specifies the current unique run ID returned by the advanced metric server.

metric_enable

```
metric_enable {true | false}
```

Default: `false`

Data_type: bool, read/write

Enables metric snapshot capture with `create_snapshot`.

metric_summary_metrics

```
metric_summary_metrics {flow.cputime flow.realtime timing.setup.tns timing.setup.wns}
```

Default: flow.cputime flow.realtime timing.setup.tns timing.setup.wns

Data_type: string, read/write

Specifies summary metrics to be inherited when viewing snapshots and runs.

pop_snapshot_stack

```
pop_snapshot_stack
```

Pops the metrics saved since the last push.

The `pop_snapshot_stack` command works in conjunction with `push_snapshot_stack` to create metric hierarchies. Any metrics captured inside a push/pop must be saved via `create_snapshot` (implicit or explicit) or they will be lost.

Parameters

None

Example

The following code shows the usage of `pop_snapshot_stack`:

```
read_design ...
push_snapshot_stack
```

```
place_design
pop_snapshot_stack
create_snapshot -label place
push_snapshot_stack
opt_design -pre_cts
pop_snapshot_stack
create_snapshot -label prects
push_snapshot_stack
ccopt_design
time_design -post_cts
time_design -post_cts -hold
pop_snapshot_stack
create_snapshot -label cts
# ------------------------------------------------------------------
```

This will result in the following snapshot hierarchy:

```
place {
place_design {
<metrics>
}
}
prects {
opt_design -pre_cts {
<metrics>
}
}
cts {
ccopt_design {
<metrics>
}
time_design -post_cts {
<metrics>
}
time_design -post_cts -hold {
<metrics>
}
}
```

Related Information

- create_snapshot
- push_snapshot_stack
- The Unified Metrics chapter in the *Innovus Stylus Common UI User Guide*

push_snapshot_stack

`push_snapshot_stack`

Creates a hierarchy for metric capture. All metrics captured inside the hierarchy is saved at this level during snapshot creation (implicit or explicit). Snapshot hierarchies can be nested so any number of hierarchies are supported.

Note: Each `push_snapshot_stack` must have a corresponding `pop_snapshot_stack`.

Parameters

None

Example

The following code shows the usage of `push_snapshot_stack`:

```
read_design ...
push_snapshot_stack
place_design
pop_snapshot_stack
create_snapshot -label place
push_snapshot_stack
opt_design -pre_cts
pop_snapshot_stack
create_snapshot -label prects
push_snapshot_stack
ccopt_design
time_design -post_cts
time_design -post_cts -hold
pop_snapshot_stack
create_snapshot -label cts
# ------------------------------------------------------------------------
```

This will result in the following snapshot hierarchy:

```
place {
place_design {
<metrics>
}
}
prects {
opt_design -pre_cts {
<metrics>
}
}
cts {
ccopt_design {
<metrics>
}
time_design -post_cts {
```

```
<metrics>
}
time_design -post_cts -hold {
<metrics>
}
}
```

Related Information

- pop_snapshot_stack
- The Unified Metrics chapter in the *Innovus Stylus Common UI User Guide*

read_metric

```
read_metric
[-help]
[-id snapshotName]
metricsFile
[-merge]
[-previous UniqueID]
```

Loads a previously saved metric file for querying, reporting, and comparing.

The `read_metric` command allows you to manually load previous saved metrics files into an Innovus session. You can load any number of these files. However, these files should have a unique id.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `read_metric` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man read_metric`
`-id snapshotName`	Specifies the name of snapshot to create or overwrite. *Data_type*: string, optional
metricsFile	Specifies the name of the metrics file. *Data_type*: string, required
`-merge`	Merges the metrics into the named snapshot, instead of replacing. *Data_type*: bool, optional
`-previous UniqueID`	Specifies the uuid of previous snapshots for the new pending snapshot. *Data_type*: string, optional

Example

The following code shows the usage of the `read_metric` command along with the `write_metric` command:

```
# ------------------------------------------------------------------

# Generate a XML file for all timing, power, and flow metrics from

# from prects to postcts for a previous run (id v101)

# ------------------------------------------------------------------

read_metric -id v101 run101/dbs/postcts.enc.dat/design.metrics
```

```
write_metric -id v101 -format xml -labels prects-postcts v101.xml
```

Related Information

- write_metric
- The Unified Metrics chapter in the *Innovus Stylus Common UI User Guide*

read_metric_config

```
read_metric_config
[-help]
fileName
[-format {html excel text vivid}]
```

Reads the YAML file written by the `write_metric_config` command.

Parameters

fileName	Specifies the name to read metric configuration from. *Data_type*: string, required
`-format {html excel text vivid}`	Specifies the configuration for specified `report_metric` format. *Data_type*: enum, optional
`-help`	Outputs a brief description that includes type and default information for each `read_metric_config` parameter. For a detailed description of the command and all of its parameters, use the man command: `man read_metric_config`

Example

The following example writes the YAML structure in the `text` format in `small.text`, reads the YAML file, and generates the report in the text format.

```
> write_metric -format text small.text ;

> read_metric_config -format text small.yaml

> report_metric  -format text
```

Related Information

- report_metric
- `write_metric_config`
- The Unified Metrics chapter in the *Innovus Stylus Common UI User Guide*

read_metric_html_package

```
read_metric_html_package
[-help]
filename
```

Overwrites the HTML for `report_metric -format vivid` and the vivid page configuration (accessible via `read_metric_config`/`write_metric_config`) with the contents from the specified *`filename`*.

Parameters

`filename`	Specifies the name of the file from where the tool will read the metric package. If the specified *`filename`* is not a supported format, the tool will give an error message that the file format is invalid. *Data_type*: string, required
`-help`	Outputs a brief description that includes the type and default information for each `read_metric_html_package` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man read_metric_html_package`

Related Information

report_metric

```
report_metric
[-help]
pattern
-format {html json excel text vivid}
[-id metricID]
[-names listOfNames]
[-out_file fileName]
```

Allows the user to generate reports in various file formats.

Parameters

`-format {html json excel text vivid}`	Specifies the output type. *Data_type*: enum, optional
`-help`	Outputs a brief description that includes type and default information for each `report_metric` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_metric`
`-id metricID`	Specifies the ID of metrics to report. Supports multiple metric IDs for excel and html formats. The first ID specified will be considered the "gold" value for comparison with other IDs. *Data_type*: string, optional
`-names listOfNames`	Specifies the list of names. *Data_type*: string, optional **Note**: Wildcards are supported.
pattern	Specifies the pattern to match. *Data_type*: string, optional
`-out_file fileName`	Specifies the name of the target file. *Data_type*: string, optional

Example

The following example writes the YAML structure in the `text` format in `small.text`, reads the YAML file, and generates the report in the text format.

```
> write_metric_config -format text small.text ;

> read_metric_config -format text small.yaml

> report_metric  -format text
```

Related Information

- read_metric_config

report_qor

```
report_qor
[-help]
[pattern]
[-format {html json}]
[-id metricID]
[-names listOfNames]
[-out_file fileName]
```

Allows the user to generate reports in various file formats.

Parameters

`-help`	Prints a brief description that includes the type and default information for each system root attribute.
pattern	Specifies the pattern to be matched. *Data_type*: string, optional
`-out_file` *fileName*	Specifies the name of the target file. *Data_type*: string, optional
-format {html json}	Specifies the output format. *Data_type*: enum, optional
`-id` *metricIDs*	Specifies the IDs of metrics to report. Multiple IDs will produce a comparison, first is gold. *Data_type*: string, optional
`-names` *listOfNames*	Specifies the list of names. You can use wildcards. *Data_type*: string, optional

Related Information

- The Unified Metrics chapter in the *Innovus Stylus Common UI User Guide*

reset_metric_config

```
reset_metric_config
```

Removes all metric configuration.

Parameters

None

Related Information

- The Unified Metrics chapter in the Innovus Stylus Common UI User Guide

reset_metric_run_id

`reset_metric_run_id`

Clears the run ID and the related data from the current state so that `flowtool -ref_run` or similar command does not add snapshots to the original reference run in AUM.

Parameters

None

Related Information

- `flowtool`
- The Unified Metrics chapter in the *Innovus Stylus Common UI User Guide*

run_metric_category

```
run_metric_category
[-help]
-category category_name
```

Runs the specified category.

Parameters

`-help`	Describes the command usage.
`-category category_name`	Specifies the name of the category, such as design, setup, hold, clock, power, route, check, flow, to be run. Each category updates the metric associated with that category. *Data_types*: string, optional

Related Information

- The Unified Metrics chapter in the *Innovus Stylus Common UI User Guide*

set_metric

```
set_metric
-name metric_name
-help
-value metric_value
```

Sets any defined metric to a value.

Parameters

`-name` *`metric_name`*	Specifies the name of the metric. *Data_type*: string, required
`-help`	Outputs a brief description that includes type and default information for each `set_metric` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_metric`
`-value` *`metric_value`*	Specifies the value of the metric. *Data_type*: string, required

Examples

The following command sets the value `.base_cell.name == HDR*` to the metric `design.switch_cells`.

```
innovus 1> set_metric -name design.switch_cells [get_db insts -if {.base_cell.name == HDR*}]
```

Related Information

- The Unified Metrics chapter in the Innovus Stylus Common UI User Guide

set_metric_alias

```
set_metric_alias
[-help]
-from old_name
[-no_overwrite]
[-order order_of_priority]
-to new_name
```

Renames a metric name, prefixed with the name of a layer, analysis view, path group etc, to another name. For example, you can rename `path_group:reg2reg` to `reg2reg` using the `set_metric_alias` command.

Parameters

`-from` *`old_name`*	Specifies the metric object name to be changed. *Data_type*: string, required
`-help`	Outputs a brief description that includes type and default information for each `set_metric_alias` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man set_metric_alias`.
`-no_overwrite`	Specifies to not overwrite an already set alias. *Data_type*: bool, optional
`-order` *`order_of_priority`*	Specifies the order of priority of metric object in tables. *Data_type*: int, optional
`-to` *`new_name`*	Specifies the new name for the metric object. *Data_type*: string, required

Example

- The following command renames `path_group:reg2reg` to `reg2reg` with priority order `1`.

  ```
  > set_metric_alias -from path_group:reg2reg -to reg2reg -order 1
  ```

- The following command renames `path_group:reg2cgate` to `reg2cgate` with priority order `2`.

  ```
  > set_metric_alias -from path_group:reg2cgate -to reg2cgate -order 2
  ```

- The following command queries the set of aliases:

  ```
  > get_metric_alias
  ```

  Output

  ```
  >path_group:reg2reg {to reg2reg order 1} path_group:reg2cgate {to reg2cgate order 2}
  ```

Related Information

- The Unified Metrics chapter in the *Innovus Stylus Common UI User Guide*

set_metric_header

```
set_metric_header
[-id db_id]
-name header_name
-help
-value header_value
```

Sets the name of a metric header.

Parameters

`-id db_id`	Specifies the database ID. *Data_type*: string, optional
`-name header_name`	Specifies the name of the header. *Data_type*: string, required
`-help`	Outputs a brief description that includes type and default information for each `set_metric_header` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_metric_header`
`-value header_value`	Specifies the value of the header. *Data_type*: string, required

Related Information

- The Unified Metrics chapter in the *Innovus Stylus Common UI User Guide*
- `delete_metric_header`

update_metric

```
update_metric
[-help]
[-format {html excel text}]
[-graph_type {treemap line none}]
[-group group_title]
[-header header_name]
[-link_file_metric metric_name]
[-link_table table]
[-metric metric_name]
[-no_shared_max]
[-renderer html_format]
[-show_graph]
-table table_id
[-title html_table_title]
```

Updates a metric.

Parameters

`-format {html excel text}`	Specifies configuration for the specified `report_metric` format. *Data_type*: enum, optional
`-graph_type {treemap line none}`	Specifies the type of graph to use in the table (treemap |line |none). *Default*: `line` *Data_type*: enum, optional
`-group group_title`	Specifies the group title to be used in the html table. *Data_type*: string, optional
`-header header_name`	Specifies the header name to be added. *Data_type*: string, optional
`-help`	Prints out the command usage. For a detailed description of the command, use the `man` command: `man update_metric`
`-metric metric_name`	Specifies the metric name to be added. *Data_type*: string, optional
`-no_shared_max`	When specified for a `-renderer` histogram metric, the Y axis of all the histograms in a single column stop sharing the same max Y value. *Data_type*: bool, optional

`-link_file_metric` *metric_name*	Specifies the name of the metric containing filename to open when the metric value is clicked. *Data_type*: string, optional
`-link_table` *table*	Specifies the table to scroll to when the metric value is clicked. *Data_type*: string, optional
`-renderer` *html_format*	Forces a specific html format renderer for the histogram metric. *Data_type*: string, optional
`-show_graph`	Specifies whether to show this metric in a comparison graph. *Data_type*: bool, optional
`-table` *table_id*	Specifies the id of table to which the metric will be added. *Data_type*: string, required
`-title` *html_table_title*	Specifies the title to be used in the html table. *Data_type*: string, optional

Example

The following sequence of commands create the `table_s` metric table and update the table using the `update_metric` command.

```
innovus 1> create_metric_page -name User

innovus 2> create_metric_table_heading -id statistics -page User  -title "Average Timing Values Per Snapshot"

innovus 3> create_metric_table -id table_s -heading statistics -per_snapshot -type  horizontal

innovus 4> update_metric -table table_s -metric user.avg_slack -group "Timing Statistics" -title avg_slack

innovus 5> update_metric -table table_s -metric user.arith_mean -group "Timing Statistics" -title arith_mean

innovus 6> update_metric -table table_s -metric user.geom_mean -group "Timing Statistics" -title geom_mean

innovus 7> update_metric -table table_s -metric user.rms -group "Timing Statistics" -title rms
```

Related Information

- The Unified Metrics chapter in the *Innovus Stylus Common UI User Guide*

update_metric_definition

```
update_metric_definition
[-help]
[-compare compareFunction]
[-description metricDescription]
[-inheritance_tcl TclName]
-name metric_name
[-no_inheritance]
[-precision number_of_decimal_places]
[-target metric_name]
[-tcl {TCL_command_list}[-tools listOfTools]]
[{-id databaseID}
[-threshold reporting_unit]
[-type metricType]
[-units reporting_unit]
[-warning threshold]
```

Updates the specified properties of an already-existing metric definition with the same name.

Note: If a metric does not exist with the name, the command returns an error.

Parameters

`-compare compareFunction`	Specifies the compare function, `[moreBetter|lessBetter|moreBetterBelowTarget|lessBetterAboveTarget]`. The comparison options show the good or bad color when the value is below or above the target value as appropriate. *Data_type*: string, optional
`-description metricDescription`	Specifies the description of the metric. *Data_type*: string, optional
`-id databaseID`	Specifies the database ID. *Data_type*: string, optional
`-inheritance_tcl TclName`	Specifies Tcl for combining children values. The metric is not executed in the global namespace. The equivalent proc args is {children}. *Data_type*: string, optional
`-name metric_name`	Specifies the name of the metric. *Data_type*: string, required
`-no_inheritance`	Disables the inheritance of the metric. *Data_type*: bool, optional

`-help`	Outputs a brief description that includes type and default information for each `update_metric_definition` parameter. For a detailed description of the command and all of its parameters, use the man command: `man update_metric_definition`
`-precision` *`number_of_decimal_places`*	Specifies the number of decimal places. *Data_type*: int, optional *Default*: 0
`-target` *`metric_name`*	Specifies the target or the name of metric containing the target value. *Data_type*: string, optional
`-tcl { ` *`TCL_command_list`* ` }`	Specifies the list of TCL commands or proc to generate (return) the metric which is of the format `{<value> <unit>}`. *Data_type*: string, optional
`-threshold` *`reporting_unit`*	Specifies the threshold for comparing numbers in HTML. If the delta between the two numbers being compared is less than the threshold then the metric will be colored “yellow”. If it is outside the threshold, then it is colored red or green depending on the compare function i.e. whether more is better or less is better. *Data_type*: string, optional
`-tools` *`listOfTools`*	Specifies the list of tools in which the tcl code will run. *Data_type*: string, optional

`-type` *`metricType`*	Specifies the type of metric.
	Data_type: string, optional
	The various metrics types are:
	• imageplot: A metric type that the renders to an image in the HTML report.
	• Format:
	`<name1> { \`
	` fill_color "<color>" \`
	`  stroke_color "<color>"\`
	`  data <list of data sets>`
	`} \`
	`<name2> { \`
	`<sub-name1> { \`
	`  fill_color <color> \`
	`  data <list of data sets> \`

```
  } \
  <sub-name2> {...} \
}
```

Where a data set can be one or more of the following:

The data on each layer is a string of coordinates (separated by sequences of whitespace and comma) with types. These types are:

- R - rectangle (x, y, width, height)
- B - bounding box (x_min, y_min, x_max, y_max)
- G - closed polygon (x, y, x, y, ...)
- L - open polyline (x, y, x, y, ...)
- C - circle (x, y, r)
- P - point (x, y)

For rectangles, boxes, circles and points, multiple shapes can be defined without having to repeat the type letter. e.g. R1,2,3,4,5,6,7,8 is two rectangles.

A value can be defined for shapes by adding a V suffix to the type; this value can then be used to color the shapes according to the value for heat maps. The value is always the first number after the type. This means that two points with values 20 and 40 may look like: PV20,1,2 40,6,5 or: PV20,1,2PV40,6,5.

Example imageplot TCL dict data:

```
macros { \
fill_color "#FF0000" \
  stroke_color "#0000FF88" \
  data "R5,8,1,2 6,9,2,1 G1,2,3,4,5,6,7,8" \
} \
drcs { \
placement { \
    fill_color "#FF0000" \
    data "P3,4" \
  } \
  routing {...} \
}
```

Layers in the image are named (macros, congestion, normal, other in the above example) and support hierarchy. Layers should not be nested beyond one level deep. The hierarchy is used in the renderer (see below) to toggle the visibility of the layers. It is an error for any layer to be called data (reserved to keep hierarchy clear).

Colors can be defined either as hex or RGB values with optional opacity. Hex values are prefixed with #. RGB values are separated with whitespace.

- #FF0000: Red
- #00FF0040: Green (25% opaque)
- 0 0 255: Blue
- 255 0 255 192: Magenta (75% opaque)

- histogram: The data will be structured as a set of series with shared X-axis labels that are rendered as a stacked histogram.

  Format (TCL dict):

```
labels <list of labels> \
axis_x <name> \
axis_y <name> \
series { \
<series1> { \
   values <list of buckets \
   color "#FF0000" \
} \
<series2> { \
   values {2 1 0 0} \
   color "#0000FF" \
} \
}
```

  Example:

```
get_metric timing.setup.histogram
timing.setup.histogram {labels {-0.320 -0.240 -0.160 -0.080} \
                        series { \
                          reg2reg {color #FF0000 values {43 3 2
3 0}} \
                          reg2cgate {color #0000FF values {22 4
5 0 0}} \
                        } \
                        axis_x WNS(ns) \
                        axis_y {Failing End Points} \
                        }
```

  The labels (a list of strings, shown in the order provided) define the X-

	axis labels for the histogram, the values in each series define the Y-axis values.
	Colors can be defined either as hex or RGB values with optional opacity. Hex values are prefixed with #. RGB values are separated with whitespace.
	`#FF0000 - Red`
	`0 0 255 - Blue`
	• html: Supports the inclusion of raw HTML in a metric. You can place simple html into tables allowing simple links to reports. For example, the following command defines `test_html` as an html type of metric:
	`define_metric -name test_html -type html`
	You can the html metric, test_html, using the `set_metric` command:
	`set_metric -name test_html -value {<a href="url">test</a>}`

`-units` *reporting_unit*	Specifies the unit for reporting. *Data_type*: string, optional
`-warning` *threshold*	Specifies the warning threshold or name of metric containing the threshold value. *Data_type*: string, optional

Example

- The following command updates the `-precision` attribute of the `timing.setup.wns` metric:

```
innovus 1> update_metric_definition -name timing.setup.wns -precision 2
innovus 2> get_metric_definition -name timing.setup.wns
metric timing.setup.wns units ns
type slack description {Worst negative
setup slack (all path groups)}
dp 2
cmp moreBetterBelowTarget
target 0
```

Related Information

write_metric

```
write_metric
[pattern]
[-format output_format]
[-id metric_id]
[-merge]
[-names list_of_patterns]
[-out_file fileName]
```

Writes the current set of metrics to a file or stdout.

The write_metric command is used by `write_db` to write the metrics in the JSON format in the database directory. Super commands use `write_metric` to write metrics into the log file (stdout). This can also be used to write metrics in various formats by the user.

Parameters

`-format output_format`	Specifies the output format, json, xml, csv, tcl. *Default*: JSON *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `write_metric` parameter. For a detailed description of the command and all of its parameters, use the man command: `man write_metric`
`-id metric_id`	Specifies a list of labels from read_metrics. *Default*: Current metric *Data_type*: string, optional
`-merge`	Merges the results into an existing file. *Data_type*: bool, optional
`-names list_of_patterns`	Specifies the list of patterns to match snapshot names. *Data_type*: string, optional
`pattern`	List of regular expressions to chose metrics to write. Default is all metrics (*). *Data_type*: string, optional
`-out_file fileName`	Specifies the name of the file in which metrics is written. *Data_type*: string, optional

Example

The following code shows the usage of the `write_metric` command:

```
# ------------------------------------------------------------------
# Generate a XML file for all timing, power, and flow metrics from
# from prects to postcts for a previous run (id v101)
# ------------------------------------------------------------------
read_metric -id v101 run101/dbs/postcts.enc.dat/design.metrics
write_metric -id v101 -format xml
```

Related Information

- `read_metric`
- `write_db`
- The Unified Metrics chapter in the *Innovus Stylus Common UI User Guide*.

write_metric_config

```
write_metric_config
[-help]
fileName
[-format {html excel text vivid}]
```

Writes the YAML structure for the requested format (text, html, or excel) to a file. As the configuration is written in YAML format, you can customize the page layout and table content you need in the report such as adding pages and tables, or adding new metrics to existing tables, removing metrics from existing tables, and rearranging the metric ordering.

Parameters

fileName	Specifies the name of the file in which metric config is written. *Data_type*: string, required
-format {html excel text vivid}	Specifies the config for specified report_metric format. *Data_type*: enum, optional
-help	Outputs a brief description that includes type and default information for each write_metric_config parameter. For a detailed description of the command and all of its parameters, use the man command: man write_metric_config

Example

generates the report in the text format.

> write_metric_config -format text small.text ; *# Edit the summary table*

> read_metric_config -format text small.yaml

> report_metric -format text

- report_metric

rename_snapshot

```
rename_snapshot
[-help]
[-branch newBranch]
[-id metricID]
[-name newName]
-uuid snapshotuuid
```

Allows you to rename existing snapshots.

`rename_snapshot` does not support canonical paths and cannot change the location of a snapshot within the hierarchy.

Parameters

`-branch` *`newBranch`*	Specifies the new branch for the snapshot. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `rename_snapshot` parameter. For a detailed description of the command and all of its parameters, use the man command: `man rename_snapshot`
`-id` *`metricID`*	Specifies the metric database ID to change. If you do not specify any id, the tool will take current database as default. *Data_type*: string, optional **Note**: You can find the uuid of a snapshot by using `get_metric` for the uuid metric.
`-name` *`newName`*	Specifies the new name for the snapshot. The tool will error out if you set the name to empty string. *Data_type*: string, optional
`-uuid` *`snapshotuuid`*	Specifies the snapshot UUID. The tool will error out if there is no snapshot with the provided uuid. *Data_type*: string, required

Related Information

- `get_metric`

delete_metric_header

```
delete_metric_header
[-help]
[-id database_id]
-name header_name
```

Deletes the metric header.

Parameters

`-help`	Prints out the command usage. For a detailed description of the command, use the man command: `man delete_metric_header`
`-id` *`database_id`*	Specifies the database ID *Data_type*: string, optional
`-name` *`header_name`*	Specifies the header name to be deleted. *Data_type*: string, required

Example

- The following command deletes the metric header, `User`.

  ```
  delete_metric_header -name User
  ```

Related Information

- `set_metric_header`
