Deletes the specified flightline net bundle. If a net is part of multiple net bundles and you delete one of the net bundles, other net bundles containing the net are not affected.

You can create flightline net bundles using the `gui_create_user_bundle_net` command and display them using the `gui_show_user_bundle_nets` command.

Note: `gui_delete_user_bundle_net` removes the specified net bundle. If you want to retain the net bundle but just want to clear its flightlines from the display area, use the `-remove` option of `gui_show_user_bundle_nets` instead.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_delete_user_bundle_net` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_delete_user_bundle_net`
name	Specifies the name of the flightline net bundle to be removed. *Data_type*: string, required

Examples

- The following command deletes the flightline net bundle `bundle_1`:

  ```
  gui_delete_user_bundle_net bundle_1
  ```

Related Information

- `gui_create_user_bundle_net`
- `gui_show_user_bundle_nets`

gui_deselect

```
gui_deselect
[-help]
{-all  |
-rect {x1 y1 x2 y2} |
-point {x y} |
-line {x1 y1 x2 y2}}
```

Deselects objects as per the parameters you specify. If `-all` is specified, deselects all selected objects.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_deselect` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_deselect`
`-all`	Deselects all objects. *Data_type*: bool, optional
`-line {x1 y1 x2 y2}`	Deselects objects through which the specified line passes. *Data_type*: rect, optional
`-point {x y}`	Deselects objects at the specified point. *Data_type*: point, optional
`-rect {x1 y1 x2 y2}`	Deselects objects within the specified box coordinates. *Data_type*: rect, optional

Related Information

- `deselect_obj`
- `gui_select`

- The Main Window chapter in *Menu Reference*
    - *Tool Box Widgets*

gui_dim_foreground

```
gui_dim_foreground
[-help]
-light_level {default medium dark}
```

Dims the display area to the specified level. Use this command to view selected and highlighted objects clearly against the dimmed foreground. This command is especially useful when you are debugging.

The equivalent bindkey is F12.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_dim_foreground` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_dim_foreground`.
`-light_level {default medium dark}`	
	Specifies the brightness level of the foreground in the display area. *Data_type*: enum, required

Related Information

- `gui_highlight`
- `gui_select`
- View Menu chapter in *Menu Reference*
  - *Dim Background*

gui_find_ui

```
gui_find_ui
[-help]
[name]
[-before name]
[-checked true | false]
[-command string]
[-disabled true | false]
[-enable_variable string]
[-foreground string]
[-icon filename]
[-in parent_name]
[-label string]
[-movable true | false]
[-newline true | false]
[-shortcut string]
[-tooltip string]
[-type {menu toolbar submenu command check radio separator toolbutton}]
[-underline index]
[-value string]
[-variable string]
[-visible_variable string]
```

Enables you to retrieve an element's name by specifying a property-value combination.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_find_ui` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_find_ui`
`name`	Specifies the name of the parent element to define the search scope. If multiple elements are found with the same *`name`*, the first matched element is searched. If *`name`* is not specified, a global search is performed. *Data_type*: string, optional

`-before` *name*	Returns the element that is positioned just before the element identified by *name*. *Data_type*: string, optional
`-checked {true | false}`	Returns the names of check boxes and radio buttons with the specified checked state. *Data_type*: bool, optional
`-command` *string*	Returns the name of the interface element that executes the specified command string. **Note:** You can use the `-command` parameter only for elements of type `command, check, radio` or `toolbutton`. *Data_type*: string, optional
`-disabled {true | false}`	Returns the name of the interface elements with the specified state. **Note:** You can use the `-disabled` parameter only for elements of type `menu, submenu, command, check, radio` or `toolbutton`. *Data_type*: bool, optional
`-enable_variable` *string*	Returns the name of the interface elements with the specified Enable status. *Data_type*: string, optional
`-foreground` *string*	Returns the name of the tool button with the specified foreground color of the icon. **Note:** You can use the `-foreground` parameter only for elements of type `toolbutton`. *Data_type*: string, optional

`-icon` *`filename`*	Returns the name of the tool button with the specified image file in its icon. *`filename`* can be the full path of the icon file or an icon name supported by Innovus. The icon names used in Innovus can be queried using the `gui_get_ui` command. **Note:** The `-icon` parameter is applicable only for elements of type `toolbutton`. *Data_type*: string, optional
`-in` *`parent_name`*	Returns the name of the interface elements with the specified parent name. *Data_type*: string, optional
`-label` *`string`*	Returns the name of the interface element with the specified label. **Note:** This parameter is NOT applicable for elements of type `separator`. *Data_type*: string, optional
`-movable true | false`	Returns whether the object is movable or not. This parameter is applicable only for elements of type `toolbar`. *Data_type*: bool, optional
`-newline {true | false}`	Returns the name of the toolbars with the specified newline status. **Note:** The `-newline` parameter is applicable only for elements of type `toolbar`. *Data_type*: bool, optional
`-shortcut` *`string`*	Returns the name of the interface elements with the specified shortcut key. **Note:** You can use the `-shortcut` parameter only for elements of type `command`, `check`, `radio`, or `toolbutton`. *Data_type*: string, optional

`-tooltip` *`string`*	Returns the name of the toolbar or toolbutton with the specified tooltip text. **Note:** The `-tooltip` parameter is applicable only for elements of type `toolbar` and `toolbutton`. *Data_type*: string, optional
`-type {menu | toolbar | submenu | command | check | radio | separator | toolbutton}`	
	Returns the name of the interface elements of the specified type. *Data_type*: enum, optional
`-underline` *`index`*	Returns the name of the interface elements that has character with the specified integer index underlined in the element label. The index begins with `0`, so for example, to find elements that have the third character in their label underlined, specify an index value of 2. *Data_type*: int, optional
`-value` *`stringValue`*	Returns the name of the radio button with the specified value. **Note:** The `-value` parameter is applicable only for elements of type `radio`. *Data_type*: string, optional
`-variable` *`string`*	Returns the name of the check boxes or radio buttons with the specified the Tcl global variable. *Data_type*: string, optional
`-visible_variable` *`string`*	Returns the name of the interface elements with the specified Visible status. *Data_type*: string, optional

Examples

- The following command returns the names of all the menus in the main window:

  ```
  gui_find_ui main -type menu
  ```

  The software returns the following:

  ```
  file view edit partition fplan power place eco clock route timing verify pvs tools
  windows flow help
  ```

- The following command returns the name of the element before the Help menu in the main window:

  ```
  gui_find_ui -before help
  ```

  The software returns the following:

  ```
  flow
  ```

- The following command returns the name of the element with a label "*CCOpt Clock Tree Debugger...*" on the menu in the main window:

  ```
  gui_find_ui -label "CCOpt Clock Tree Debugger..."
  ```

  The software returns the following:

  ```
  _CCOpt_Clock_Tree_Debugger...
  ```

  You can then get any property of the element by using `gui_get_ui`. For example:

  ```
  gui_get_ui _CCOpt_Clock_Tree_Debugger... -command
  ```

  The software returns the following:

  ```
  ctdMainWin::createSetting
  ```

  Here, `ctdMainWin::createSetting` is the command that is invoked when the menu item labeled *CCOpt Clock Tree Debugger...* is clicked.

- The following command returns the name of the element that invokes the command `ctdMainWin::createSetting`:

  ```
  gui_find_ui main -command ctdMainWin::createSetting
  ```

  The software returns the following:

  ```
  _CCOpt_Clock_Tree_Debugger...
  ```

- The following command returns the name of the element with shortcut key F:

  ```
  gui_find_ui -shortcut F
  ```

  The software returns the following:

  ```
  tbView.ac.view.fit
  ```

- The following set of commands can be used to get the names of the items in the Edit -> Bus

Guide submenu:

1. Find the name of the submenu with the label "Bus Guide:
   ```
   gui_find_ui -label "Bus Guide"
   ```
   The software returns the following:
   ```
   edit.busguide
   ```
2. You can then use the following command to find the elements in the "Bus Guide" submenu:
   ```
   gui_find_ui -in edit.busguide
   ```
   The software returns the following:
   ```
   _Edit... _Color _Clear_Color
   ```

- The following command returns all movable toolbars in the main window:
  ```
  gui_find_ui -movable true
  ```
  The software returns the following:
  ```
  tbFile tbEdit tbView tbTools tbReport tbToolBox we main.layout.selectbar
  ```

gui_fit

```
gui_fit [-help]
```

Fits the entire design in the viewable window. You can use this command at any stage of the design flow to view the design in entirety.

Parameters

`-help`	Prints a brief description of the `gui_fit` command. For a detailed description of the command, use the `man` command: `man gui_fit`.

Related Information

- `gui_zoom`
- View Menu chapter of the *Menu Reference*
  - *Fit*

gui_get_box

`gui_get_box`

Returns the coordinates of the box you draw on the user interface.

When you enter this command, the software displays a hint on the status bar prompting you to click on the Main Window to indicate the first point of the box. You are then prompted to click at the second point, which represents the diagonally opposite corner of the box. After you click the mouse twice, the software returns the coordinates of the box defined by the two corners you specified. The coordinates are returned in mircon units in the format *`x1 y1 x2 y2`*.

Parameters

`-help`	Prints a brief description of the `gui_get_box` command. For a detailed description of the command, use the `man` command: `man gui_get_box`.

Related Information

- `gui_get_coord`
- `gui_get_coords`
- `gui_view_box`

gui_get_coord

```
gui_get_coord [-help]
```

Returns the coordinates of the point you click on the user interface.

When you enter this command, the software displays a hint on the status bar prompting you to click at a point on the Main Window. After you click the mouse, the software returns the `x` and `y` coordinates of the point you specified. The coordinates are returned in mircon units, such as 675.423 461.9775.

Parameters

`-help`	Prints a brief description of the `gui_get_coord` command. For a detailed description of the command, use the `man` command: `man gui_get_coord`.

Related Information

- `gui_get_box`
- `gui_get_coords`

gui_get_coords

```
gui_get_coords [-help]
```

Returns the coordinates of the points you click on the user interface.

When you enter this command, the software displays a hint on the status bar prompting you to click at the first point on the Main Window. You are then prompted to click at subsequent points or press `Esc` to stop. After you press the `Esc` key, the software returns the coordinates of all the points you clicked in micron units in the format *`x1 y1 x2 y2 x3 y3...`*

Parameters

`-help`	Prints a brief description of the `gui_get_coords` command. For a detailed description of the command, use the `man` command: `man gui_get_coords`.

Example

The following command returns coordinates of the three points you click in the UI:

```
> gui_get_coords
```

On the status bar, the following message is displayed:

```
Enter Lines: Point 1. Press ESC to stop
```

On clicking the first point, the status bar message changes to:

```
Enter Lines: Point 2. Press ESC to stop
```

On clicking the second point, the status bar message changes to:

```
Enter Lines: Point 3. Press ESC to stop
```

After clicking all the required points, press ESC to stop. The coordinates of the three points you clicked are returned at the command prompt:

```
0.007 0.05 0.038 0.05 0.038 0.02
```

Related Information

- gui_get_box
- gui_get_coord

gui_get_ui

```
gui_get_ui
[-help]
[name]
[-quiet]
[ -before
 | -checked
 | -children
 | -command
 | -disabled
 | -dock_widget
 | -enable_variable
 | -foreground
 | -geometry
 | -icon
 | -in
 | -label
 | -menu
 | -message
 | -movable
 | -newline
 | -shortcut
 | -statusbar
 | -title
 | -toolbar
 | -tooltip
 | -type
 | -underline
 | -value
 | -variable
 | -visible
 | -visible_variable ]
```

Retrieves the current value of the specified property of the element that is being queried. Using the `gui_get_ui` command, you can query all the properties in the `gui_add_ui` command for each type. In addition, depending on the `type`, some special properties are supported too as described below:

- For elements of type `menu/submenu/toolbar`:
    - `gui_get_ui` *name* `-children`
      Returns a list of all the child elements of the specified interface element.

- For `main` (main window):
    - `gui_get_ui main -menu`
      Returns a list of all the menus in the main window.
    - `gui_get_ui main -toolbar`
      Returns the list of all the toolbars in the main window.
    - `gui_get_ui main -statusbar`
      Returns the status bar in the main window.
    - `gui_get_ui main -geometry`
      Returns the geometry of the main window in the format *`width`*x*`height`*+*`x`*+*`y`*.
    - `gui_get_ui main -title`
      Returns the title of the main window.
    - `gui_get_ui main -closecmd`
      Returns the close confirmation command of the main window.
    - `gui_get_ui main -visible`
      Returns the visibility status of the main window.
- For `statusbar`:
    - `gui_get_ui name -message`
      Returns the current message of the status bar.
    - `gui_get_ui name -visible`
      Returns the visibility status of the status bar.
    - `gui_get_ui name -in`
      Returns the parent element of the status bar.

`statusbar` also supports the `-enable_variable` and `-visible_variable` parameters.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_get_ui` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_get_ui`
`name`	Specifies as a string the name of the interface element you want to query. If multiple widgets are found with the same *`name`*, the first matched widget is queried. Returns an error if there is no element with the specified name. *Data_type*: string, optional
`-before`	When specified, returns the element that occurs before the element identified by *`name`*. *Data_type*: string, optional
`-checked`	Returns the on/off state of the specified check box or radio button. If the check box or radio button is selected, returns `true`. If it is deselected, returns `false`. *Data_type*: bool, optional
`-children`	Returns child elements of specified interface element. **Note:** You can use this parameter with elements of type `menu`, `submenu`, and `toolbar`. *Data_type*: string, optional
`-command`	Returns the Tcl command to be executed when the specified element you are adding is invoked. **Note:** You can use the `-command` parameter only with elements of type `command, check, radio` or `toolbutton`. *Data_type*: string, optional

`-disabled`	When specified, returns whether the specified interface element is enabled (`false`) or disabled (`true`). **Note:** You can use the `-disabled` parameter only with elements of type `menu, submenu, command, check, radio` or `toolbutton`. The parameter is NOT applicable for elements of type `toolbar` and `separator`. *Data_type*: bool, optional
`-dock_widget`	Returns the dock widget in the window. *Data_type*: string, optional
`-enable_variable`	Represents the Tcl global variable for Enable status. *Data_type*: string, optional
`-foreground`	Returns the foreground color of the icon for the specified toolbutton. **Note:** You can use the `-foreground` parameter only with elements of type `toolbutton`. *Data_type*: string, optional
`-geometry`	Returns the width, height, and coordinates of the main window. **Note:** The `-geometry` parameter is applicable only for the main window, which is type `main`. *Data_type*: string, optional
`-icon`	Returns the file name of the specified toolbutton. **Note:** The `-icon` parameter is applicable only for elements of type `toolbutton`. *Data_type*: string, optional
`-in`	Returns the name of the parent element. *Data_type*: string, optional
`-label`	Returns the label of the specified element. **Note:** This parameter is NOT applicable for elements of type `separator`. *Data_type*: string, optional

`-menu`	Returns the names of the menus in the main window. **Note:** This parameter is applicable only for the main window, which is type `main`. *Data_type*: string, optional
`-message`	Returns the message on the status bar. **Note:** This parameter is applicable only for the status bar. *Data_type*: string, optional
`-movable`	Returns whether object is movable or not. *Data_type*: bool, optional
`-newline`	Returns whether or not the specified toolbar starts in a new row. **Note:** The `-newline` parameter is applicable only for elements of type `toolbar`. *Data_type*: bool, optional
`-quiet`	Displays the current settings for the specified parameters in the Tcl list format. *Data_type*: bool, optional
`-shortcut`	Returns the shortcut key for a command, check box, radio button, or toolbutton. **Note:** You can use the `-shortuct` parameter only with elements of type `command`, `check`, `radio`, or `toolbutton`. *Data_type*: string, optional
`-statusbar`	Returns the name of the main window's status bar. **Note:** This parameter is applicable only for the main window (`main`). *Data_type*: string, optional
`-title`	Returns the text on the main window's title bar. **Note:** This parameter is applicable only for the main window (`main`). *Data_type*: string, optional

`-toolbar`	Returns the toolbars in the window. *Data_type*: string, optional
`-tooltip`	Returns the tooltip text for the specified toolbar or toolbutton. **Note:** The `-tooltip` parameter is applicable only for elements of type `toolbar` and `toolbutton`. *Data_type*: string, optional
`-type`	Returns the type of the specified element. *Data_type*: enum, optional
`-underline`	Returns the integer index of the underlined character in the element label. **Note:** The `-underline` parameter is NOT applicable for elements of type `toolbar, separator,` and `toolbutton`. *Data_type*: int, optional
`-value`	Returns the value stored in the associated variable of the specified radio button. **Note:** The `-value` parameter is applicable only for elements of type `radio`. *Data_type*: string, optional
`-variable`	Returns the Tcl global variable for the specified check box or radio button. *Data_type*: string, optional
`-visible`	Returns the visibility status of the element. *Data_type*: string, optional
`-visible_variable`	Represents the Tcl global variable for Visible status. *Data_type*: string, optional

Examples

- The following command returns the names of all the menus in the main window:

  ```
  gui_get_ui main -menu
  ```

  The software returns the following:

  ```
  file view edit partition fplan power place eco clock route timing verify pvs tools
  windows flow help
  ```

- The following command returns the label on element named `verify`:

  ```
  gui_get_ui verify -label
  ```

  The software returns the following:

  ```
  Check
  ```

- The following command returns whether the Select bar in the main layout is movable:

  ```
  gui_get_ui main.layout.selectbar -movable
  ```

gui_get_visible_bumps

```
gui_get_visible_bumps
[-help]
```

Returns the names of all visible bump cells in the design if some bumps have been hidden in the design.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_get_visible_bumps` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_get_visible_bumps`

Examples

- The following command returns the name of all visible bumps in the designs:
  ```
  innovus 17> gui_get_visible_bumps
  ```

Related Information

- `gui_set_visible_bumps`

gui_get_visible_net_groups

```
gui_get_visible_net_groups
[-help]
```

Returns the names of the visible net groups if some net groups have been hidden in the design. If all net groups are visible, this command has no effect.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_get_visible_net_groups` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_get_visible_net_groups`

Examples

- The following command returns the name of all visible net groups in the designs:

  ```
  innovus 17> gui_get_visible_net_groups
  test_ng
  ```

Related Information

- `gui_set_visible_net_groups`

gui_get_visible_nets

```
gui_get_visible_nets
[-help]
```

Returns the names of the visible nets if some nets have been hidden in the design. If all nets are visible, this command has no effect.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_get_visible_nets` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_get_visible_nets`

Examples

- The following command returns the name of all visible nets in the designs:

  ```
  > gui_get_visible_nets
  ram1/subram02_lower/TESTACT_INST_PERIWDSRAM001PAA512W27C3/tpo_a_9_
  ```

Related Information

- `gui_set_visible_nets`

gui_group_hinst

```
gui_group_hinst
[-help]
[-type {flex_model} | hinst]
```

Moves one level up the hierarchy for the specified module guide and displays the next module. The `gui_group_hinst` command is equivalent to the *Group* widget on the toolbar.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_group_hinst` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_group_hinst`
hinst	Specifies the name of the hierarchical instance to be grouped. *Data_type*: string, optional
`-type {`*flex_model*`}`	Specifies the type of objects to be grouped. At present, only the `flex_model` type is supported. *Data_type*: enum, optional

Examples

- The following command goes one level up the specified module:
  `gui_group_hinst DTMF_INST/TDSP_CORE_INST`
- The following command groups all flexModels, including flex_module and flex_instgroup, up to the partition or instance group level:
  `gui_group_hinst -type flex_model`

Related Information

- `gui_ungroup_hinst`
- The Main Window chapter in *Menu Reference*
    - *Toolbar Widgets*

gui_hide

```
gui_hide
[-help]
```

Hides the Innovus main window.

You can run the `gui_show` command to re-display the Innovus main window.

Parameters

`-help`	Prints out the command usage. For a detailed description of the command, use the `man` command: `man gui_hide`

Related Information

- `gui_show`
- The Main Window chapter of the *Menu Reference*
  - *Closing or Hiding the GUI*

gui_highlight

```
gui_highlight
[-help]
[object+]
[-color colorValue | -auto_color  | -original]
[-index indexValue]
[-pattern patternValue | -original]
```

Highlights selected or specified objects with the Highlight Set available through the *View - Highlight Selected* menu. The value for the index corresponds to the Highlight Set that will be applied. For example, a value of 4 for the index specifies that all selected objects will be highlighted with the same color and pattern as available for the *Highlight Set #4* in the *View - Highlight Selected* menu. You can use this command at any stage in the design flow.

You can also provide a specific color and/or pattern to be used. All selected objects will be highlighted with the color and/or pattern that you specify.

If you specify a color and or pattern, the Highlight Set corresponding to the index value will be updated to use the color and pattern specified. For example, if you specify an index value of 5, color `green`, and pattern `backslash`, the *Highlight Set #5* will get updated to have the color `green` and the pattern `backslash`.

You can remove highlight from the highlighted objects through the `gui_clear_highlight` command or through the *View - Clear Highlight* menu.

Note: If an object is selectable, you can highlight it using the `gui_highlight` command.

Use the `gui_highlight_pin` command to highlight shapes for specified SIGNAL/POWER pins.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_highlight` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_highlight`
object+	Specifies object pointer list for highlighting. *Data_type*: (any_object)+, optional

`-auto_color`	Specifies the object color automatically. When this parameter is specified, the selected object is highlighted with a different color each time you call the `gui_highlight` command. **Note**: This parameter cannot be used with `-index` or `-color`. *Data_type*: bool, optional
`-color` *`colorValue`*	Specifies the color value for the specified object. The color value is the same as that available through the Edit Highlight Color form (*View - Edit Highlight Color*). You can also use the Red Green Blue (RGB) value in the following format: #*`V1V2V3`* where V1, V2, and V3 are the hexadecimal values for the red, green, and blue color components respectively. For example, you can specify the value `#CC66FF`. *Default:* The color defined for the Highlight Set corresponding to the index value is used. *Data_type*: string, optional
`-index` *`indexValue`*	Specifies the index value for highlighting the specified objects. All objects that are selected will be highlighted with the same color and pattern as defined in corresponding Highlight Set in the *View - Highlight Selected* menu. As an example, if you specify a value of 3 for index, all objects that are selected will be highlighted with the same color and pattern as available for the *Highlight Set #3* in the *View - Highlight Selected* menu. Note that the maximum value is related to the *Number of Highlight Color* setting in the Edit Highlight Color form. If this value is 64, the maximum acceptable value for the `-index` option is 64. If set to 256, the maximum acceptable value for `-index` is 256. *Data_type*: int, optional, min=1, max=256

`-original`	Highlights the object in original color. This option is useful if you want to check a specific object more closely with the background dimmed. An object highlighted in original color will stand out in the dimmed background:  **Note**: This parameter cannot be used with `-index`, `-color`, or `-pattern`. *Data_type*: bool, optional
`-pattern` *patternValue*	
	Specifies the pattern value for the specified object. The pattern value is the same as the Stipple Value available through the Edit Highlight Color form. *Default:* The pattern (Stipple Value) for the Highlight Set corresponding to the index value is used. *Data_type*: string, optional

Examples

- The following command highlights all selected objects with the same color and pattern as defined for the *Highlight Set #4* in the *View - Highlighted Selected* menu.

  ```
  gui_highlight -index 4
  ```

- The following command highlights all selected objects with the color `green` and the pattern `dot4`. The index values is set to 5 and, therefore, the command will also change the definition of the *Highlight Set #5* (*View - Highlight Selected* menu) to have color `green` and pattern `dot4`.

  ```
  gui_highlight -index 5 -color green -pattern dot4
  ```

- The following command highlights all selected objects with the color corresponding to the RGB hexadecimal value `#33FF66` and the pattern `horizontal`. The index values is set to 3 and, therefore, the command will also change the definition of the *Highlight Set #5* (*View - Highlight Selected* menu) to have color `#33FF66` and pattern `horizontal`.

  ```
  gui_highlight -index 3 -color #33FF66 -pattern horizontal
  ```

gui_highlight_pin

```
gui_highlight_pin
[-help]
-inst string
-pin string
[-original | -index indexValue]
[-original | -color colorValue]
[-original | -pattern patternValue]
```

Highlights the shapes of all specified SIGNAL/POWER instance pins with the Highlight Set available through the *View - Highlight Selected* menu. The value for the index corresponds to the Highlight Set that will be applied. For example, a value of 4 for the index specifies that all selected objects will be highlighted with the same color and pattern as available for the *Highlight Set #4* in the *View - Highlight Selected* menu.

You can also provide a specific color and/or pattern to be used. All specified pins will be highlighted with the color and/or pattern that you specify.

Note: If you specify a color and or pattern, the Highlight Set corresponding to the index value will be updated to use the color and pattern specified. For example, if you specify an index value of `5`, color `green`, and pattern `backslash`, the *Highlight Set #5* will get updated to have the color `green` and the pattern `backslash`.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `gui_highlight_pin` parameter. For a detailed description of the command and all of its parameters, use the man command: `man gui_highlight_pin`

`-color` *colorValue*	Specifies the color value for the specified object. The color value is the same as that available through the Edit Highlight Color form, which can be accessed by selecting *View - Edit Highlight Color*. You can also use the Red Green Blue (RGB) value in the following format: `#`*V1V2V3* where *V1*, *V2*, and *V3* are the hexadecimal values for the Red, Green, and Blue color components, respectively. For example, you can specify the value `#CC66FF`. *Default:* The color defined for the Highlight Set corresponding to the specified index value is used. *Data_type*: string, optional
`-index` *indexValue*	Specifies the index value for the specified object. By default, all specified pins are highlighted with the same color and pattern as defined in the *Highlight Set* corresponding to the specified index value in the *View - Highlight Selected* submenu. For example, if you specify a value of 3 for index, all specified pins are highlighted with the same color and pattern as available for *Highlight Set #3* in the *View - Highlight Selected* submenu. *Data_type*: int, required
`-inst` *string*	Specifies the name of instance. *Data_type*: string, required
`-original`	Highlights the instance pin in original color. This option is useful if you want to check a specific instance pin more closely with the background dimmed. An object highlighted in original color will stand out in the dimmed background. **Note**: This parameter cannot be used with `-index`, `-color`, or `-pattern`. *Data_type*: bool, optional
`-pattern` *patternValue*	Specifies the pattern value for the specified object. The pattern value is the same as the *Stipple* value available through the Edit Highlight Color form. *Default:* The pattern (*Stipple* value) defined for the Highlight Set corresponding to the specified index value is used. *Data_type*: string, optional

`-pin string`	Specifies the name of SIGNAL/POWER pin to be highlighted. You can specify more than one pin name. *Data_type*: string, required

Examples

- The following command highlights the SIGNAL pins `E` and `D` of instance `U1` using the color yellow and the solid pattern:
  ```
  gui_highlight_pin -inst U1 -pin {E D} -color yellow -pattern solid -index 1
  ```
- The following command highlights the SIGNAL pin `E` and the POWER pin `gnd` of instance `U1` using the color yellow and the solid pattern:
  ```
  gui_highlight_pin -inst U1 -pin {E gnd} -color yellow -pattern solid -index 1
  ```

Related Information

gui_highlight_pin_connection

```
gui_highlight_pin_connection
[-help]
-from_pin pin
[-mode {wire_segment | whole_net | flight_line}]
-to_pin pin
[-with_arrow | -select_only]
[-net_color_index index_value | -select_only]
[-inst_color_index index_value | -select_only]
```

Highlights the full timing path or its segment in the text format while generating the sign-off timing report. Use this command to quickly debug the timing path (timing point information) used in the tool.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `gui_highlight_pin_connection` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man gui_highlight_pin_connection`
`-from_pin pin`	Specifies the name of the starting pin to be highlighted. *Data_type*: (pin), required
`-inst_color_index index_value`	
	Specifies the instance color index value (an integer value from 1 to 64) for the specified timing path. *Data_type*: int, optional, min=1, max=64
`-mode {wire_segment | whole_net | flight_line}`	

	Specifies the draw mode between the starting and ending pins. *Data_type*: enum, optional
`-net_color_index` *index_value*	
	Specifies the net color index value (an integer value from 1 to 64) for the specified timing path. *Data_type*: int, optional, min=1, max=64
`-select_only`	Selects only the specified path for highlighting. *Data_type*: bool, optional
`-to_pin` *pin*	Specifies the name of the ending pin to be highlighted. *Data_type*: (pin), required
`-with_arrow`	Specifies whether or not the connection is defined with an arrow. *Data_type*: bool, optional

Example

The following command highlights a line drawn from the specified input pin to output pin while generating the sign-off timing report:

```
gui_highlight_pin_connection -from_pin ffa/Q -U7/A -mode flight_line
```

The timing report generated is shown below:

```
:::::::Timing Report::::::::::

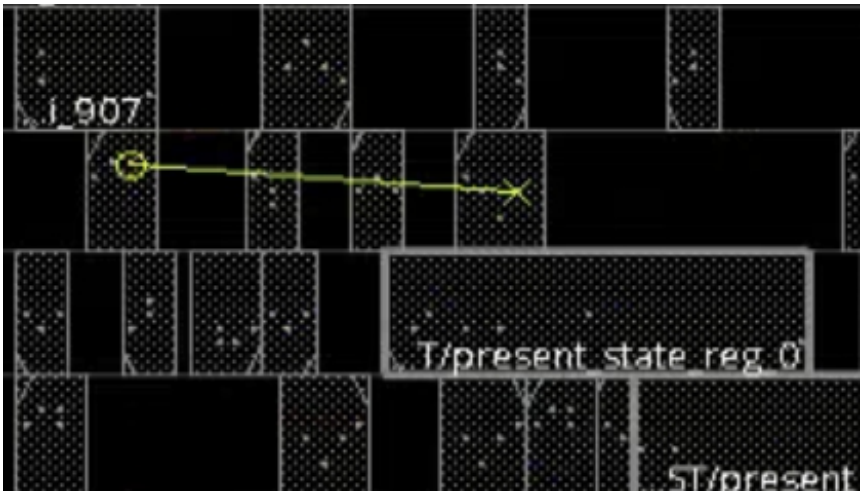
:::::::END:::::::::::
```

The drawn layout along with the highlighted line is shown in the below picture:



gui_list_marker

```
gui_list_marker [-help]
```

Gives a list of GUI markers in the design layout.

Parameters

`-help`	Prints a brief description of the `gui_list_marker` command. For a detailed description of the command, use the `man` command: `man gui_list_marker`.

Example

- The following command shows a list of GUI markers:
  ```
  gui_list_marker
  ```
  The following is displayed:
  ```
  {name:aa  coordinate:(100.000 100.000)}
  ```

Related Information

- `gui_add_marker`
- `gui_remove_marker`

gui_open_cell_view

```
gui_open_cell_view [-help]
```

Opens the Cell Viewer. The Cell Viewer provides a convenient way to view the content of a cell, cell view, or partition without having to zoom into the design. It provides an artwork window for viewing the following objects:

- any LEF library cell
- any via cell
- any OpenAccess database cell view
- abstract view of any partition in the design
- power grid view

You can use the `gui_open_cell_view` command at any stage of the design flow.

Parameters

`-help`	Prints a brief description of the `gui_open_cell_view` command. For a detailed description of the command, use the `man` command: `man gui_open_cell_view`.

Related Information

- `gui_close_cell_view`
- Tools Menu chapter of the *Menu Reference*
  - *Cell Viewer*

gui_open_schematic

```
gui_open_schematic
[-help]
[-name string]
[-type {module cone}]
[-objs <inst | net | pin | port | hinst>+ | -selected]
```

Opens the schematic view of the specified or selected objects.

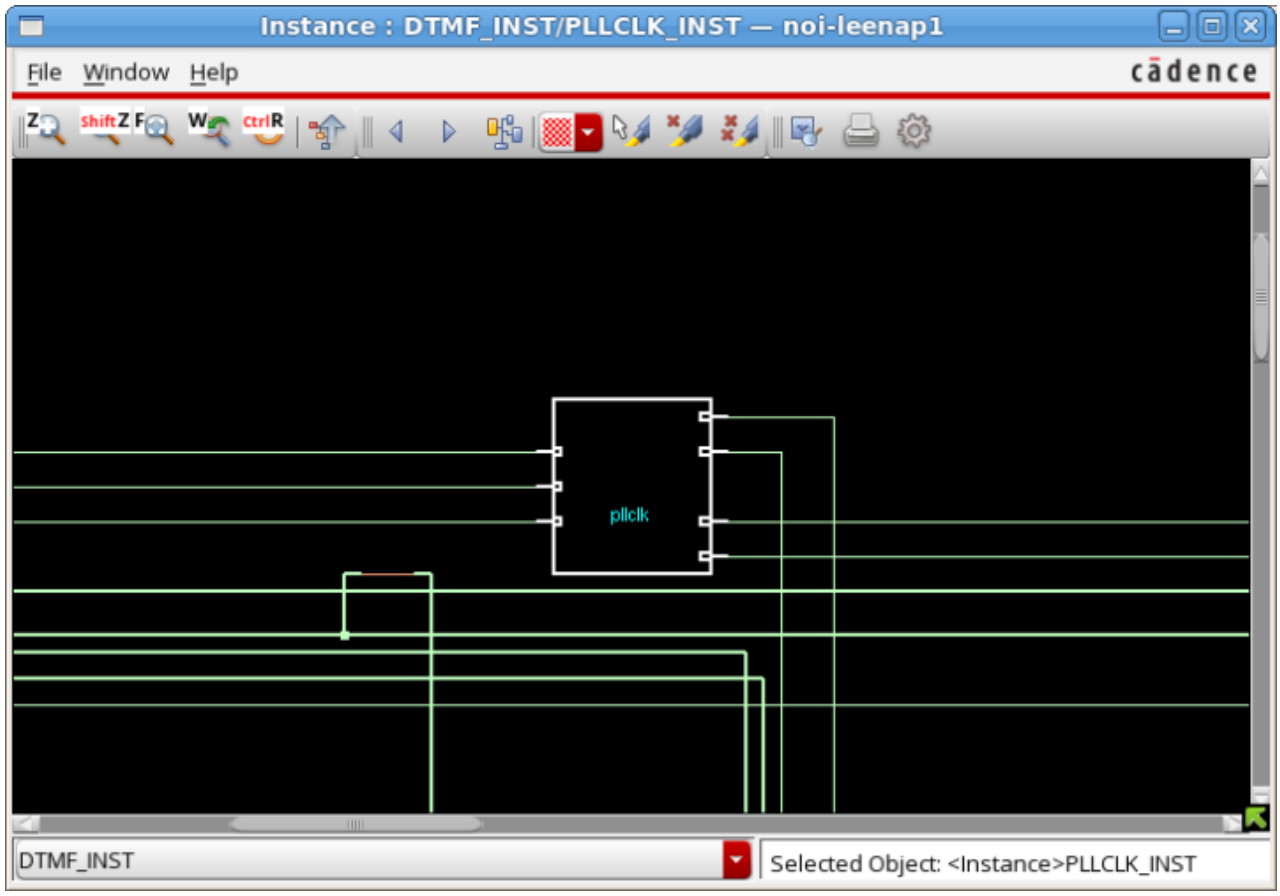
Parameters

`-help`	Prints out the command usage. For a detailed description of the command, use the `man` command: `man gui_open_schematic`
`-name` *`string`*	Specifies a unique window name for the schematic view to be opened. *Data_type*: string, optional
`-objs <inst | net | pin | port | hinst>+`	
	Specifies the object(s) to be added in the schematic view. If multiple objects are specified, the Schematic Viewer can be opened only in the flattened mode (`-type cone`). As the default schematic mode is hierarchical, this means you must always specify `-type cone` when specifying multiple objects. **Note**: This option cannot be used with `-objs` or `-type module`. *Data_type*: (*inst*|*net*|*pin*|*port*|*hinst*)+, optional
`-selected`	Specifies that the selected object(s) are to be added in the schematic view. If multiple objects are selected, the Schematic Viewer can be opened only in the flattened mode (`-type cone`). As the default schematic mode is hierarchical, this means you must always specify `-type cone` when selecting multiple objects. **Note**: This option cannot be used with `-objs` or `-type module`. *Data_type*: bool, optional
`-type {module cone}`	Specifies the type of schematic to be opened. If you specify `cone`, the tool opens the Schematic Viewer to display schematic in the flattened mode. If you specify `module`, the tool opens the Schematic Viewer to display schematic in the hierarchical mode. *Default*: `module` *Data_type*: enum, optional

Examples

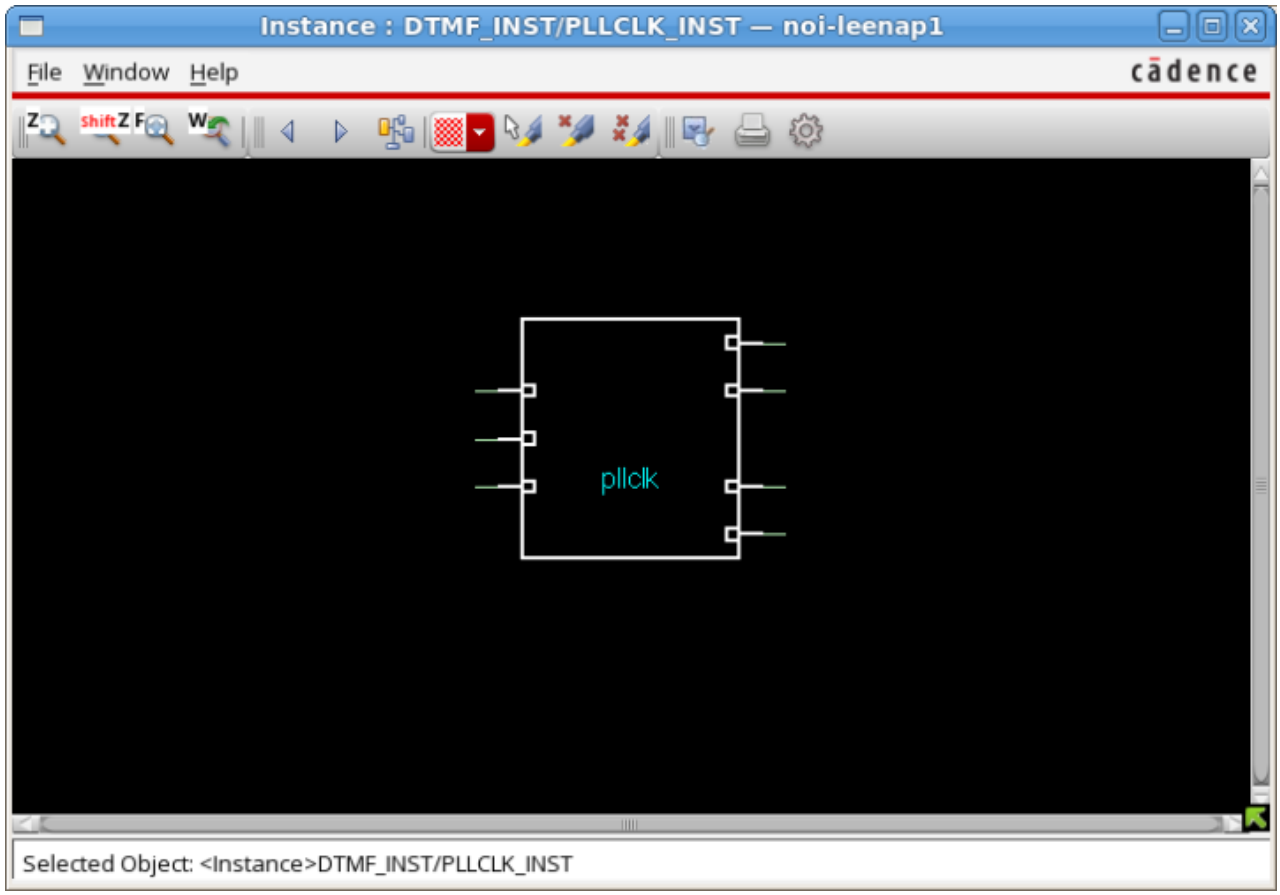
- The following command opens the schematic for the specified instance in the hierarchical mode:

```
gui_open_schematic -objs DTMF_INST/PLLCLK_INST
```



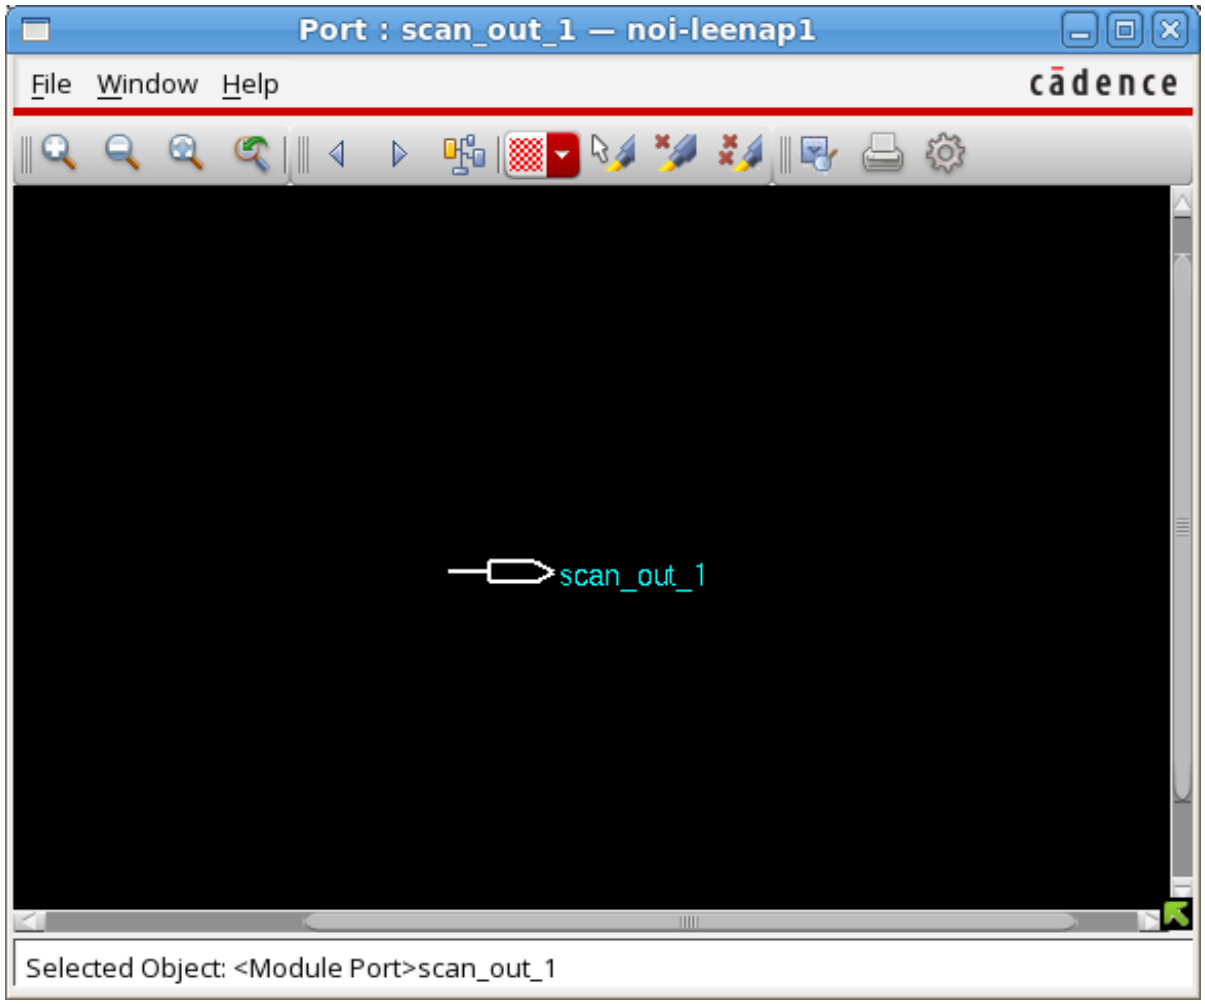
- The following command opens the schematic for the specified instance in the flattened mode:

```
gui_open_schematic -objs DTMF_INST/PLLCLK_INST -type cone
```



- The following command opens the schematic for the selected object in the flattened mode:

```
gui_open_schematic -selected -type cone
```



- The following command opens the schematic for multiple selected objects in the flattened mode:

```
gui_open_schematic -selected -type cone
```

gui_pan

```
gui_pan
[-help]
dx
dy
```

Specifies that the new center of the viewing window should shift from the current center of the viewing window by (*x*, *y*) microns. Use this command at any stage in the design flow to pan or move the design view in a specific direction.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_pan` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_pan`.
dx	Specifies that the design center should shift *dx* microns on the x-axis from the center of the viewing window. You can specify positive or negative values for *dx*. A positive value specifies shifting to the right on the x axis. *Data_type*: float, required
dy	Specifies that the design center should shift `dy` microns on the y axis values from the center of the viewing window. You can specify positive or negative values for *dy*. A positive value specifies shifting up on the y axis. *Data_type*: float, required

Example

The following example shifts the design center to the right by 200 microns and down by 300 microns from the center of the viewing window.

```
gui_pan 200 -300
```

Related Information

- View Menu chapter in the *Menu Reference*
  - *Pan*
- The Main Window chapter in the *Menu Reference*
  - *Mouse Operations*

gui_pan_center

```
gui_pan_center [-help] x y
```

Pans in the viewable window to the center point defined by the specified coordinates. Use this command at any stage of the design flow to view the design area around a specific point.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_pan_center` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_pan_center`.
x	Specifies the x coordinate of the center point. *Data_type*: float, required
y	Specifies the y coordinate of the center point. *Data_type*: float, required

Example

The following command pans the viewable window to the center point (x=100, y=200)

```
gui_pan_center 100 200
```

Related Information

  - *Mouse Operations*

gui_pan_page

`gui_pan_page [-help] x y`

Pans the viewable window in pages defined by the offsets. The size of each page is equal to the size of the current viewable window. Use this command at any stage of the design flow.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_pan_page` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_pan_page`.
x	Specifies the `x` offset to indicate number of pages to pan. A positive value of *x* specifies a pan of *x* pages to the right. *Data_type*: float, required
y	Specifies the `y` offset to indicate number of pages to pan. A positive number of *y* specifies a pan of *y* pages toward the top. *Data_type*: float, required

Examples

- The following command pans the display to the right by one page
  ```
  gui_pan_page 1 0
  ```
- The following command pans the display to the left by one page
  ```
  gui_pan_page -1 0
  ```

gui_redo

```
gui_redo [-help]
```

Returns the design to the state it was in immediately prior to issuing the `gui_undo` command. It can only be used to reinstate power planning, bump placement, and selected floorplanning and wire editing functions that were removed with the `gui_undo` command.

You can use this command after you use the `gui_undo` command for any of the following text commands:

- Selected bump placement commands:
  - `create_bump`
  - `delete_bumps`
- Selected floorplanning commands:
  - `align_selected`
  - `flip_or_rotate_obj`
  - `move_obj`
  - `snap_floorplan`
  - `snap_floorplan_io`
  - `space_selected`
- Selected power planning commands:
  - `add_rings`
  - `add_stripes`
  - `update_power_vias`
  - `route_special`
- All wire editor commands:
  - `create_fillet`
  - `convert_special_routes_for_eco`
  - `delete_fillet`
  - `delete_routes`

- deselect_routes
- edit_add_polygon_point
- edit_add_route_point
- edit_add_trim_metal
- edit_create_via
- edit_cut_route
- edit_duplicate_routes
- edit_end_polygon_point
- edit_end_route_point
- edit_merge_routes
- edit_move_routes
- edit_resize_routes
- edit_rotate
- edit_split_routes
- edit_split_wide_routes
- edit_trim_routes
- edit_update_route_layer
- edit_update_route_net
- edit_update_route_rule
- edit_update_route_status
- edit_update_via
- select_routes

Parameters

`-help`	Prints a brief description of the `gui_redo` command. For a detailed description of the command, use the `man` command: `man gui_redo`

Related Information

- `gui_undo`
- Edit Menu chapter in the *Menu Reference*
  - *Undo*
  - *Redo*

gui_redraw

```
gui_redraw [-help]
```

Refreshes the display in the viewable window. This command performs the same function as the *Redraw* icon (CTRL+R keyboard shortcut). You can use this command at any stage in the design flow.

Parameters

`-help`	Prints a brief description of the `gui_redraw` command. For a detailed description of the command, use the `man` command: `man gui_redraw`.

gui_register_edit_callback

```
gui_register_edit_callback
[-help]
-command string
-edit_type {selection pre-move post-move}
```

Adds the callback function to the specified move action. In GUI, the move action involves the following three steps:

1. Click an object.
2. Move the object to the new location.
3. Click to place the object at the new location and complete the move.

The callback function is implemented based on the move action specified with the `-edit_type` parameter.

Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man gui_register_edit_callback`
`-command string`	Specifies the name of the callback function. *Data_type*: string, required
`-edit_type {selection pre-move post-move}`	Specifies the GUI edit function: • `selection` - Implements the callback function when an object is selected (after Step 1). • `pre-move` - Implements the callback function just before the object is placed at the new location (after Step 2, just before you change the coordinates in Step 3). • `post-move` - Implements the callback function after an object is moved (after Step 3, when the tool updates the DB records). *Data_type*: enum, required

Example

Consider the following proc definition:

```
proc move_event_callback {args} {
     set objList $args
     foreach obj $objList {
           set type [dbGet $obj.objType]
           if {$type == "sdp"} {
                custom_snap_sdp $obj
           } elseif {$type == "inst"} {
                set cellName [dbGet $obj.cell.name]
                if {[regexp grf $cellName]} {
                     custom_snap_grf $obj
                }
           }
}
}
```

The following command adds the `move_event_callback` function to the selected object just before the move is completed:

```
gui_register_edit_callback -edit_type pre_move -command {move_event_callback [dbGet selected]}
```

Related Information

- `report_gui_edit_callback`
- `gui_unregister_edit_callback`

gui_remove_marker

```
gui_remove_marker
[-help]
{-name <string> | -all }
```

Removes a marker from the design layout.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`-all`	Removes all markers from the design layout. *Data_type*: bool, required
`-name <string>`	Specifies the name of the marker to be removed from the design layout. *Data_type*: string, required

Related Information

- `gui_add_marker`
- `gui_list_marker`

gui_report_trace_flightline

```
gui_report_trace_flightline
[-help]
-file report_name
```

Saves information about the all flightlines traced through the `gui_trace_flightline` command to the specified file.

Parameters

`-help`	Prints a brief description of the `gui_report_trace_flightline` command. For a detailed description of the command, use the `man` command: `man gui_report_trace_flightline`.
`-file report_name`	Specifies the name of the report file. *Data_type*: string, required

Example

The following set of commands reports all traced flightlines:

```
innovus 3> gui_trace_flightline -inst  DTMF_INST/DMA_INST/present_state_reg_3 -sink -
sink_level 2 -sink_color pink
innovus 4> gui_trace_flightline -inst DTMF_INST/RESULTS_CONV_INST/r852_reg_5 -sink -
sink_level 2 -sink_color green
innovus 5> gui_report_trace_flightline -file file1
```

```
The tool saves the report as follows:
```

```

gui_schematic_load_view

```
gui_schematic_load_view
[-help]
-file file_name
[-name name]
```

Loads the specified schematic file.

⚠ This commands work only in the cone view (flattened mode).

Parameters

`-help`	Prints a brief description of the `gui_schematic_load_view` command. For a detailed description of the command, use the `man` command: `man gui_schematic_load_view`.
`-file` *file_name*	Specifies the name of the schematic file to be loaded.
`-name` *name*	Specifies a unique window name for the opened schematic view.

Related Information

- `gui_open_schematic`
- `gui_schematic_save_view`

gui_schematic_save_view

```
gui_schematic_save_view
[-help]
-file file_name
```

Saves the current schematic view into the specified file.

⚠ This commands work only in the cone view (flattened mode).

Parameters

`-help`	Prints a brief description of the `gui_schematic_save_view` command. For a detailed description of the command, use the `man` command: `man gui_schematic_save_view`.
`-file` *`file_name`*	Specifies the name of the file in which to save the schematic view.

Related Information

- `gui_open_schematic`
- `gui_schematic_load_view`

gui_select

```
gui_select
[-help]
{-point {x y} |
-line {x1 y1 x2 y2} |
-rect {x1 y1 x2 y2}}
[-toggle  | -append  | -next]
[-point {x y} [-next ]]
```

Selects objects as per the parameters you specify. Use `-point` to select the object at the specified coordinate, `-line` to select the objects through which the specified line passes, or `-rect` to select the objects falling within the specified box coordinates.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_select` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_select`
`-append`	Appends the selection. This is equivalent to pressing the `Shift` key while selecting an object using the GUI. *Data_type*: bool, optional
`-line {x1 y1 x2 y2}`	Selects by line. Use this parameter to select the objects through which the specified line passes. *Data_type*: (point)+, optional
`-next`	Steps to next object under point. This is same as using space bar while selecting an object using the GUI. *Data_type*: bool, optional
`-point {x y}`	Selects the object at the specified point. *Data_type*: point, optional
`-rect {x1 y1 x2 y2}`	Selects by box. Use this parameter to select the objects falling within the specified rectangular area. *Data_type*: rect, optional
`-toggle`	Toggles the selection. This is equivalent to pressing the `Ctrl` key while selecting an object using the GUI. *Data_type*: bool, optional

Examples

- The following command selects the objects that are totally enclosed within the box defined by the coordinates (`x = 10, y = 200`) and (`x = 100, y = 50`):
  ```
  gui_select -rect {10 200 100 50}
  ```
- The following command selects all the objects falling across the specified line coordinates:
  ```
  gui_select -line {168.654 994.049 688.129 436.224}
  ```
- The following command selects the objects crossed by the specified line and appends them to the current selection:
  ```
  gui_select -line {169.622 996.049 698.290 446.240} -append
  ```
- The following command toggles the selection on the objects in the specified bounding box. If the objects are previously selected, the command deselects them and vice versa:
  ```
  gui_select -rect {10 200 100 50} -toggle
  ```

gui_select_highlighted

```
gui_select_highlighted
[-help]
[-type {inst wire via}]
```

Selects highlighted objects. If `-type` is specified, selects highlighted objects of the specified type.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_select_highlighted` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_select_highlighted`
`-type {inst wire via}`	Specifies the type of the highlighted objects to be selected. Options are: • `inst` - Selects highlighted instances • `wire` - Selects highlighted wires • `via` - Selects highlighted vias *Data_type*: enum, optional

Examples

- The following command selects all highlighted instances.
  ```
  gui_select_highlighted -type instance
  ```

Related Information

- `gui_highlight`
- `gui_select`

gui_set_obj_color

```
gui_set_obj_color
[-help]
{[-obj_name InstOrHInstName | -obj_type typeList]
[-multicolor | -color_id colorID]
[-include_children {off | color | multicolor}]
[-reset]}
```

Sets the color for objects of the specified name or type. You can choose to include children when specifying object color for a hierarchical instance (HInst).

The `gui_set_obj_color` command is typically used during floorplanning to color objects that are currently displayed in the design display area. You can use this command to distinguish between objects of different type or between objects belonging to different instances, hierarchical instances, instance groups, or power domains.

Before using the `gui_set_obj_color` command, you should have:

- Loaded the floorplan
- Ungrouped objects so that only required objects are displayed in the design display area in the Floorplan or Physical view.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `gui_set_obj_color` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_set_obj_color`.
`-color_id` *`colorID`*	Specifies the color ID from 0 to 29. The color value for the color ID is the same as specified in the Module Color Preference form (accessed by clicking *Floorplan - Edit Floorplan - Color Module*). *Default*: Color ID `0` *Data_type*: int, optional, min=0, max=29

`-include_children {off | color | multicolor}`	Specifies whether the children of the hierarchical instance will be colored simultaneously when you specify a color for an HInst. You can set one of the following options: • `off`: The child instances will not be colored. • `color`: The child instances are colored the same color as their parent instance. • `multicolor`: The child instances are colored in multiple colors. *Data_type*: enum, optional
`-multicolor`	Uses multiple colors to color objects of the specified type, instance, or hierarchical instance. *Data_type*: bool, optional
`-obj_name` *InstOrHInstName*	Specifies the name of the instance, hierarchical instance, power domain, or instance group whose objects are to be colored. You can specify an object list, such as `objectName {A,B}`. *Data_type*: string, optional
`-obj_type` *typeList*	Specifies the list of type of objects that are to be colored, such as `BusGuide`, `Module`, `PowerDomain`, and `InstGroup`. *Data_type*: string, optional
`-reset`	Resets the object color. *Data_type*: bool, optional

Example

- The following command colors the `DTMF_INST/TDSP_CORE_INST` instance with color `3`, as specified in the Module Color Preference form:
  ```
  gui_set_obj_color -obj_name DTMF_INST/TDSP_CORE_INST -color_id 3
  ```
- The following command colors the `DTMF_INST/TDSP_CORE_INST` instance and its children with color `3`, as specified in the Module Color Preference form:
  ```
  gui_set_obj_color -obj_name DTMF_INST/TDSP_CORE_INST -color_id 3 -include_children color
  ```

- The following command colors the children of the `DTMF_INST/TDSP_CORE_INST` instance in multiple colors:

  ```
  gui_set_obj_color -obj_name DTMF_INST/TDSP_CORE_INST -include_children multicolor
  ```

gui_set_power_rail_display

```
gui_set_power_rail_display
[-help]
[-enable_result_browser {true | false}]
[-enable_rlrp {true | false}]
[-enable_voltage_sources {true | false}]
[-filter_max max_value]
[-filter_min min_value]
[-legend {off ne nw se sw}]
[-plot plot_type]
[-range_max max_value]
[-range_min min_value]
[-reset_color_scale {true | false}]
[-filter_color {on | off | color_name}]
[-enable_percentage_range {true | false}]
[-thermal_layer_name thermal_layer]
[-tile_count_x value]
[-tile_count_y value]
[-tile_size_x value]
[-tile_size_y value]
[-customized_range {value1 value2 ... value9}]
[-grid {on | off}]
[-enable_auto_apply {true | false}]
```

Controls the display of the main window widgets, such as legend, result browser, voltage source, filter range, and RLRP path.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `gui_set_power_rail_display` parameter. For a detailed description of the command and all of its parameters, use the man command: `man gui_set_power_rail_display`.
`-customized_range {value1 value2 ... value9}`	

	Specifies the color scale range values for the 8 filters between the minimum and maximum values of the color gradient based (*Basic*) filter. The value list must contain 9 values. The filter ranges for the 8 buckets are evenly divided by default. This parameter can be used to customize the filter ranges. You can either modify the color range using the GUI (Basic button) or the `-customized_range` parameter. **Example**: `gui_set_power_rail_display -plot ir -customized_range { 1 10 12 13 14 15 16 17 49 }` *Data_type*: string, optional
`-enable_auto_apply {true | false}`	
	Specifies to automatically redraw the layout after modifying the color scale range values. This parameter allows you to enable/disable the *Auto Apply for Color Scale* checkbox of the Power Rail Plots form using the Tcl script instead of the GUI option. The default value of this parameter is `false`. *Data_type*: bool, optional
`-enable_percentage_range {true | false}`	
	Specifies to display the color gradients for the following plots by percentage in the GUI: • IR Drop • IVDD • IVDN The percentage value is based on the nominal voltage value of each rail/instance. It displays high percentage voltages in red and low percentage voltages in blue. *Default* : `false` *Data_type*: bool, optional
`-enable_result_browser {true | false}`	
	When set to `true` it enables the result browser. *Default* : `false` *Data_type*: bool, optional

`-enable_rlrp {true | false}`	
	When set to `true` it enables the display of the RLRP path. The rail analysis must include RLRP analysis (`set_rail_analysis_config -enable_rlrp_analysis true`) in order to have the required data for this functionality. *Default* : `false` *Data_type*: bool, optional
`-enable_voltage_sources {true | false}`	
	Displays voltage sources (power pads) using white pixels in the layout canvas. *Default* : `false` *Data_type*: bool, optional
`-filter_color {on | off | color_name}`	
	Allows to set the color of the filtered out resistors specified using the scissor filter range. By default, the filtered resistors are not displayed. If you want to view these resistors, you can use this parameter to enable the visibility of resistors and set desired colors for them. The valid values of this parameter are: • `on` – enables the visibility of the filtered out resistors. • `off` - disables the visibility of the filtered out resistors. • *`color_name`* - enables the visibility of filtered out resistors and set the color of resistors per the specified color name. *Data_type*: string, optional
`-filter_max max_value`	

	Specifies the maximum value of the scissor filter range that will be plotted. You can use the scissor filter range to filter out the resistors and nodes that you do not want to view, and obtain statistics only for the instances in the specified filter range. Optional, but if specified, the `-plot` option is required, and requires both `-filter_min` and `-filter_max` to be specified. *Data_type*: float, optional
`-filter_min` *max_value*	
	Specifies the minimum value of the scissor filter range that will be plotted. Optional, but if specified, the `-plot` option is required, and requires both `-filter_min` and `-filter_max` to be specified. *Data_type*: float, optional
`-grid {on | off}`	
	Allows you to control the grid display when viewing the Voltage Source Current (VC) and Voltage across Package Model (VU) plots. The default value of this parameter is `on`. You can set this parameter to `off` to hide the grid view for better display and easier analysis of the plot data. *Data_type*: string, optional
`-legend {off ne nw se sw}`	
	Displays the filter color and range details. When you set `gui_set_power_rail_display -legend` to one of the location (`ne nw se sw`) , this opens the legend at the specified location on the design layout. Use `gui_set_power_rail_display -legend off` to close the legend. *Default*: `off` *Data_type*: enum, optional
`-plot` *plot_type*	
	Plots the specified plot type. See Plot Types for a description of each of the plot types. *Data_type*: enum, optional
`-range_max` *max_value*	

	Specifies the maximum value of the color scale. Optional, but if specified, the `-plot` option is required, and requires both `-range_min` and `-range_max` to be specified. *Data_type*: float, optional
`-range_min` *min_value*	
	Specifies the minimum value of the color scale. Optional, but if specified, the `-plot` option is required, and requires both `-range_min` and `-range_max` to be specified. *Data_type*: float, optional
`-reset_color_scale {true | false}`	
	Specifies to reset the maximum (`-range_max`) and minimum (`-range_min`) values of the color scale to the default plot data values. For example, when you specify `-plot ir`, the default value for `-range_min` is `0` and `-range_max` is `100`. You can modify the color scale, such as set `-range_min` to `0` and `-range_max` to `20`. To reset the color scale of the IR drop plot to default, you can specify the `-reset_color_scale` parameter. *Data_type*: bool, optional
`-thermal_layer_name` *thermal_layer*	
	Displays the specified layer of the temperature map. **Example:** `set_power_rail_display -thermal_layer_name VIA_7` *Data_type*: string, optional
`-tile_count_x` *value*	

	Specifies the number of tiles in the x direction. This parameter is used to resize the tile power density plot. You can either specify the tiles by count (`tile_count_x` and `tile_count_y`) or specify the tiles by size (`tile_size_x` and `tile_size_y`). When you resize the tile power density (`tpd`) plot in the batch or GUI mode, the software automatically invokes the `report_power` command and resizes the plot. This feature allows you to resize the `tpd` plot without having to restore the power database (`power.db`) again. *Data_type*: int, optional
`-tile_count_y` *value*	
	Specifies the number of tiles in the y direction. This parameter must be specified with the `tile_count_x` parameter. *Data_type*: int, optional
`-tile_size_x` *value*	
	Specifies the horizontal dimension of each tile polygon in *µm*. This parameter is used to resize the tile power density plot. You can either specify the tiles by count (`tile_count_x` and `tile_count_y`) or specify the tiles by size (`tile_size_x` and `tile_size_y`). When you resize the tile power density (`tpd`) plot in the batch or GUI mode, the software automatically invokes the `report_power` command and resizes the plot. This feature allows you to resize the `tpd` plot without having to restore the power database (`power.db`) again. The following is an example of specifying tiles by size: `gui_set_power_rail_display -plot tpd -tile_size_x 100 -tile_size_y 100` *Data_type*: float, optional
`-tile_size_y` *value*	
	Specifies the vertical dimension of each tile polygon in *µm*. This parameter must be specified with the `tile_size_x` parameter. *Data_type*: float, optional

Plot Types

Plot Type	Description
`ac`	Available/feasible capacitance (Farad) Displays the feasible decoupling capacitance that can be added in the area. The feasible capacitance in the area is calculated based on the filler cells placement. The program matches the placed filler cells with the decap cells available in the power-grid library and computes the feasible capacitance. The capacitance of the decap cell is stored in the power-grid library.
`cap`	Ggrid capacitance (Farad) Plots the capacitance of the extracted power-grid network.
`cvi1`	Customized File 1 Plots the user-specified instance voltage file.
`dd`	Decoupling capacitance (decap) density (Farad/um ^{2}) Plots decap density of the design. The decap density is the cell internal decoupling capacitance in the unit area (µm ^{2}).
`dr`	Decoupling capacitance required Reports the decoupling capacitance required to fix dynamic IR-drop violations. This option suggests how much decap needs to be added in a given area to fix the IR-drop violations. The voltage threshold used to determine the IR-drop violations for this analysis is the value specified by the `-threshold` option of the `set_pg_nets` command.
`effr`	Effective resistance (ohm) - instance based Display the effective resistance results for all instances.
`node_reff`	Effective resistance (ohm) - node based Display the effective resistance results for all nodes.
`ipc`	Instance Peak Current Display the peak current of each instance.

`ivdn`	Instance Voltage Drop (Volts) – net-based Plots the net-based instance voltage drop.
`ivdd`	Instance Voltage Drop (Volts) – domain-based Plots the domain-based instance voltage drop. For domain based, at least one power and one ground net must be selected.
`fd`	Filler cell density (1/µm ^{2}) Displays the filler cell density per unit area (µm ^{2}). The plot can be used to analyze the feasibility of adding decap cells by replacing the filler cells and not changing the placement of the logic cells.
`freq`	Frequency domain (Hz) Displays the associated clock frequency of all instances in the design. The instances associated with multiple clock domains are displayed using the fastest clock frequency. This plot can be used to analyze and debug the power distribution in the design.
`ip`	Instance total power (mW) The total power consumed by each instance is displayed. The total power is the sum of the internal, switching and leakage power of the instance. The power data is read from the power database and can be specified using the `-power_db` option or it is queried directly from memory, if power calculation is run during the session.
`ip_i`	Instance internal power (mW) The power consumed by charging and discharging of the internal interconnect and device capacitances of the instance.
`ip_l`	Instance leakage power (mW) The power consumed by devices when not switching.
`ip_s`	Instance switching power (mW) The power consumed by charging and discharging of the interconnect or output load.
`ipd_i`	Specifies internal power density in mW/um ^{2} .

`ipd_l`	Specifies leakage power density in mW/um ^{2} .
`ipd_s`	Specifies switching power density in mW/um ^{2} .
`ipd_t`	Specifies total power density in in mW/um ^{2} .
`ir`	IRdrop or voltage drop (Volts) Displays the IRdrop across each extracted power-grid segment in the design.
`jrms`	Specifies current density as j/jmax based on the Irms current. This plot is only supported for dynamic analysis. A jrms gif file will be saved in the state directory that shows where the Irms based EM violation occurred. This plot type allows you to verify the analysis results of "jrms" using the GUI.
`load`	Loading capacitance (Farad) Displays the output loading capacitance driven by the instance. This plot can be used to analyze and debug the regions with high switching power.
`pi`	Power-switch (gate) current violation: I/Idsat Displays the ratio of current through the power-switch and the saturation current (Idsat) of the power-switch. This plot can be used to analyze and debug whether the current through power-switches exceeds the saturation current characterized for the power-switch devices. The saturation current and on-resistance of the power-switches are characterized and stored inside the power-grid library of the power-switch cell. A ratio of greater than 1 means that the current requirement of the power-gated block can not be met with placed power-switch instance. Either the power-switch needs to be made larger or power-switch instances need to be added.
`ptpd`	Profiling Tile Power Density Displays the tile-based power density plot for the vector profiling flow. You can enable this plot using the `read_power_rail_results -profiling_power_file` *`file`* command. You can also view the power density for the different tile co-ordinates in the *Details* tab of the Result Browser.

`pv`	Voltage drop across power-switch (Volt) Displays the IRdrop across power-switch instances. This plot can be used to analyze and debug the IRdrop inside the power-gated block, e.g. if the IRdrop across power-switches is already high, the IRdrop inside the power-gated block will be much higher. In this case, the power-switch placement will have to be refined in order to resolve the IRdrop problem.
`rc`	Resistor current (Amp) Displays the current across power-grid resistor segments. This plot can be used to analyze and debug how the current flows from the voltage sources into the rest of the design, e.g. high current should flow from pads to the top-level routing level layers and then to the lower level metal layers. This plot can also be used to debug current density violations (`rj`).
`rlrp`	The total resistance of the instance along the least resistive path. Displays the total resistance of the instance along the least resistive path, meaning the resistance of the instance along the path from where it gets the most amount of current. This plot can be used to analyze and debug the power-grid integrity early in the design stage. An instance with high resistance is likely to have high static or dynamic IRdrop depending on the vector that is simulated later in the design cycle. This plot can be also used during decap optimization, since regions with high dynamic IRdrop and high resistance may not be improved upon by adding decaps, because the effectiveness of decoupling capacitance depends on the resistance of the power-grid network. The plot displays the RLRP paths for power (purple color) and ground (white color) nets in different colors for the identification of paths and ease of analysis. You can also highlight the least resistive path of the instance using the GUI and selecting the instance with left mouse button. The *RLRP Path* checkbox should be enabled.

`res`	Grid resistance (ohm) Displays the total resistance of the least resistive path from each node to voltage source. This plot can be used to view high resistance regions of the power-grid. It is useful during IRdrop and decap analysis to identify weak power-grid connectivity. The GUI also allows you to view the resistor-based RLRP path. To view the resistor-based RLRP path: 1. Select the *res* Rail plot, and the *RLRP Path* checkbox. 2. Select a resistor. The GUI highlights the least effective resistance path to the nearest voltage source, and opens the *Resistance Path* form.
`rj`	Resistor current density, J/Jmax. Displays the current density (current per unit area) violation on each power-grid segment using the ratio of calculated current density and maximum allowed current density. A ratio of greater than 1 means that the current density limit of the segment is violated. The current density limits are supplied by the foundry and can be read during analysis using the `set_rail_analysis_mode -em_models` command.
rs	Specifies the plot type for resistor sensitivity.
`sem_avg`	Average Current Density Displays average current limit violations in the design. This plot is enabled when you specify `check_ac_limits -method avg`.
`sem_peak`	Peak Current Density Displays peak current limit violations in the design. This plot is enabled when you specify `check_ac_limits -method peak`.
`sem_rms`	RMS Current Density Displays RMS current limit violations in the design. This plot is enabled when you specify `check_ac_limits -method rms`.
`slack`	Instance slack (Seconds) Displays worst instance slack. The slack data is queried from either the timing database or if the power database is specified using `-power_db` option, then the worst slack data is read from the power database. When using an external TWF, the slack data is read from the TWF.

`tc`	Tap current (Amp) Displays the current consumed by the instance devices or current taps. During rail analysis, it is based on the power consumption of the instance and is distributed inside the cell. The current distribution inside the cell is based on the extracted device netlist stored inside the power-grid library of the cell. The current distribution is generally based on the device width, length, and spice models. This plot can be used to analyze and debug IRdrop inside the macro.
`td`	Transition density (Hz) Displays the worst transition density (activity * frequency) of the instance. This plot can be used to analyze and debug activity distribution and high power density regions.
`thermal`	Instance thermal Displays the instance temperature distribution for the chip. The plot shows tile-based temperature for instances. When you click on an instance, the *Attribute Viewer* window opens and displays the instance temperature in the *Thermal* field.
`unc`	Unconnected segments Displays power-grid segments that are disconnected from the voltage source (power pads). This plot can be used to debug unusually high IRdrop in the region.
`vc`	Voltage source current (Amp) Displays current through the voltage sources (power pads). This plot can be used to analyze the current carrying capacity of the power-pad.
`vu`	Voltage drop across package (Volt) Displays voltage drop across package. If analysis is run with package model attached to the power pads, this plot displays the IRdrop due to package RLCK elements.

Examples

- The following command specifies that `div` data will be plotted without loading design DEF:

```
gui_set_power_rail_display\
-plot div
```

- The following command enables the visibility of the filtered out resistors without changing the color:

```
gui_set_power_rail_display -filter_color on
```

- The following command enables the visibility of the filtered out resistors and also changes the color to red:

```
gui_set_power_rail_display -filter_color red
```

Related Information

- `gui_set_power_rail_layers_nets`

[-instance_voltage_method {Worst | Best | Avg | WorstAvg}]
[-instance_voltage_window {1| 0}]
[-via_size {1 | 2 | 3 | 4 | 5 | 6}]
```

Controls the visibility of the layers, the opacity of the rail analysis or design database, and the visibility of power/ground nets.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `gui_set_power_rail_layers_nets` parameter. For a detailed description of the command and all of its parameters, use the man command: `man gui_set_power_rail_layers_nets`.
`-design_opacity value`	

	Specifies the design opacity value for the design database. The opacity range is from 0-100%, the default value is `60`. *Data_type*: float, optional
`-disable_nets {`*names*`}`	
	Hides the specified nets. This parameter is mutually exclusive to the `-enable_nets` and `-nets` parameters. *Data_type*: string, optional
`-disable_report_layers {all|`*layer_names*`}`	
	Hides the report (user-defined layers to be used for processing) layers. You can use `all` to hide all layers, or list the specific layers that are not to be displayed. This parameter is mutually exclusive to the `-enable_report_layers` and `-layers` parameters. *Data_type*: string, optional
`-disable_switch_nets {all|`*net_names*`}`	
	Hides the specified switch nets. You can use `all` to hide all the switch nets, or list the specific switch nets that are not to be displayed. This parameter is mutually exclusive to the `-enable_switch_nets` parameter. *Data_type*: string, optional
`-disable_visible_layers {all|`*layer_names*`}`	
	Specifies which layers should not be made visible when plotting. You can use `all` to hide all layers, or list the specific layers that are not to be displayed. This parameter is mutually exclusive to the `-enable_visible_layers` and `-layers` parameters. *Data_type*: string, optional
`-disable_visible_signal_em_layers {all|`*layer_names*`}`	

	Specifies which signal EM layers should not be made visible when plotting. You can use `all` to hide all layers, or list the specific layers that are not to be displayed. This parameter is mutually exclusive to the `-enable_visible_signal_em_layers` parameter. *Data_type*: string, optional
`-enable_nets {`*names*`}`	
	Displays only the specified nets. This parameter is mutually exclusive to the `-disable_nets` and `-nets` parameters. *Data_type*: string, optional
`-enable_report_layers {all|`*layer_names*`}`	
	Specifies to select the user-defined layers to be used for processing. You can use `all` to select all layers, or list the specific layers that are to be selected. This parameter is mutually exclusive to the `-disable_report_layers` and `-layers` parameters. *Data_type*: string, optional
`-enable_switch_nets {all|`*net_names*`}`	
	Displays the specified switch nets. You can use `all` to display all the switch nets, or list the specific switch nets that are to be displayed. This parameter is mutually exclusive to the `-disable_switch_nets` parameter. *Data_type*: string, optional
`-enable_visible_layers {all|`*layer_names*`}`	
	Specifies which layers should be made visible when plotting. You can use `all` to display all layers, or list the specific layers that are to be made visible. This parameter is mutually exclusive to the `-disable_visible_layers` and `-layers` parameters. *Data_type*: string, optional
`-enable_visible_signal_em_layers {all|`*layer_names*`}`	

	Specifies which signal EM layers should be made visible when plotting. You can use `all` to select all layers, or list the specific layers that are to be selected. This parameter is mutually exclusive to the `-disable_visible_sem_layers` parameter. *Data_type*: string, optional
`-instance_voltage_method {Worst | Best | Avg | WorstAvg}`	
	Allows different methods of computing effective instance voltage during rail analysis. Using this option, you can write out the Best, Worst, or Average effective instance voltage between power and ground nets. The WorstAvg method computes the average instance voltage during each evaluation window defined by the IV Window field, and reports the worst average instance voltage out of all the windows. If IV Method is WorstAvg and IV Window is whole, then this method will report average voltage across all time steps in simulation. Default : `Worst` *Data_type*: enum, optional
`-instance_voltage_window {1| 0}`	
	Controls the EIV plot. EIV is obtained by processing the voltage waveforms and finding the worse-case effective voltage between the power and ground pins during a specific window. There are two options to view EIV plots: • `1` – both switching and timing windows (window EIV) • `0` – worst of the entire rail simulation (worst EIV) *Data_type*: bool, optional
`-layers {{name report0/1 visible0/1}{...}}`	

	Controls the visibility of layers. You can enable or disable the reporting and visibility of specific layer. For example, `-layer {{M1 1 1} {M2 0 0}` means enable reporting and visibility of layer M1, and disable reporting and visibility of layer M2 This parameter is mutually exclusive to the `-disable_report_layers, -disable_visible_layers, -enable_visible_layers,` and `-enable_report_layers` parameters. *Data_type*: string, optional
`-nets {{all_power 0/1}{all_ground 0/1}}`	
	Controls the display of all the power and ground nets. When `all_power` is set to `0`, hides all power nets, and when set to `1`, displays all power nets. When `all_ground` is set to `0`, hides all ground nets, and when set to `1`, displays all ground nets. This parameter is mutually exclusive to the `-enable_nets` and `-disable_nets` parameters. *Data_type*: string, optional
`-rail_analysis_opacity` *value*	
	Specifies the opacity value for the rail analysis output. The opacity range is from 0-100%, the default value is `100`. *Data_type*: float, optional
`-show_layer_net_setting_list {true | false}`	

	Displays the current status (OFF/ON) of all layers and nets in the console. The following is an example of the output:
	`#-------------------------------#`
	`# Layers  Report  Visible #`
	`# RD  ON  ON #`
	`# M0  ON  ON #`
	`.....`
	`#-------------------------------#`
	`# PowerNets  Status #`
	`# VDD  ON #`
	`# VDDm  ON #`
	`#-------------------------------#`
	`# GroundNets Status #`
	`# VSS  ON #`
	`#-------------------------------#`
	Data_type: bool, optional

`-via_size {1 | 2 | 3 | 4 | 5 | 6}`	
	Specifies to modify and control the size of vias in the GUI. The default via size is `1`. The possible via size values are `1`, `2`, `3`, `4`, `5`, and `6`.

Examples

- The following command specifies the layers that will be visible:

```
gui_set_power_rail_layers_nets \
 -enable_visible_layers{RD M1 V12 M2 V23 M3 V34 M4 V45 M5 V56 M6} \
 -enable_nets {vdd vdd_1}
```

- The following commands describe the use model for enabling and disabling switch nets. Here, consider a net `VDD` with three switch nets `VDD_sw0`, `VDD_sw1`, and `VDD_sw2`:
  - The following command hides the switch net `VDD_sw0`:

    ```
    set_power_rail_layers_net -disable_switch_nets {VDD {VDD_sw0}}
    ```

    Displays `VDD_sw1` and `VDD_sw2`.
  - The following command hides all the switch nets:

    ```
    set_power_rail_layers_net -disable_switch_nets {VDD {all}}
    ```
  - The following command displays the switch net `VDD_sw0`:

    ```
    set_power_rail_layers_net -enable_switch_nets {VDD {VDD_sw0}}
    ```
  - The following command displays all the switch nets:

    ```
    set_power_rail_layers_net -enable_switch_nets {VDD {all}}
    ```

gui_set_select_hinst_color

```
gui_set_select_hinst_color
[-help]
[-color_id colorID]
```

Specifies the color Id for the selected hierarchical instances.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_set_select_hinst_color` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_set_select_hinst_color`
`-color_id colorID`	Specifies the color Id to apply to all selected hierarchical instances. The color value for the color id is the same as specified in the Module Color Preference form (accessed by clicking *Floorplan - Edit Floorplan - Color Module*) *Default*: If no Id is specified, the color Id `0` is applied to all the selected hierarchical instances. *Data_type*: int, optional

Example

The following command applies color Id 5 to all the selected hierarchical instances:

```
gui_set_select_hinst_color -color_id 5
```

Related Information

- `gui_clear_hinst_colors`
- `gui_set_obj_color`

gui_set_tool

```
gui_set_tool
[-help]
mode
```

Selects specified tool widget in the main window and enters interactive mode.

For more information on tool widgets, see the "Tool Widgets" section in the The Main Window chapter of the *Innovus Menu Reference*.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_set_tool` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_set_tool`
mode {select | move | ruler | util | cut | obstruct | layerBlk | ptnFeed | ptnPinBlk | ptnPinGuide | addWire | addVia | cutWire | stretchWire | addPoly | addBusGuide | p2pRoute}	
	Specifies the interactive mode to enter. The following modes are supported: • `select` - Chooses the Select tool widget in the main window. • `move` - Selects the Move/Resize/Reshape tool widget in the main window. • `ruler` - Selects the Create Ruler tool widget in the main window. • `util` - Selects the Query Area Density tool widget in the main window. • `cut` - Selects the Cut Rectilinear tool widget in the main window. • `obstruct` - Selects the Create Placement Blockage widget in the main window. • `layerBlk` - Selects the Create Routing Blockage tool widget in the main window.

	• `ptnFeed` - Selects the Create Physical Feedthrough tool widget in the main window. • `ptnPinBlk` - Selects the Create Pin Blockage tool widget in the main window. • `ptnPinGuide` - Selects the Create Pin Guide tool widget in the main window. • `addWire` - Selects the Edit Wire tool widget in the main window. • `addVia` - Selects the Add Via tool widget in the main window. • `cutWire` - Selects the Cut Wire tool widget in the main window. • `stretchWire` - Selects the Move/Resize Wire tool widget in the main window. • `addPoly` - Selects the Add Polygon tool widget in the main window. • `addBusGuide` - Selects the Edit Bus Guide tool widget in the main window. • `p2pRoute` - Selects the Point to Point Route tool widget in the main window. *Data_type*: string, required

Example

The following command is used to enter the Create Ruler mode in the design window.

```
gui_set_tool ruler
```

[-foreground string]
[-geometry string | -full_screen {true | false}]
[-icon filename]
[-in name]
[-label string]
[-message string]
[-movable {true | false}]
[-newline {true | false}]
[-shortcut string]
[-statusbar string]
[-title string]
[-tooltip string]
[-underline integer]
[-value string ]
[-variable string]
[-visible {true | false}]
[-visible_variable string]
```

Sets the specified property of an element. Use this command to customize the Innovus graphical interface by configuring various interface elements, such as submenus and commands. The properties that can be set for a specific element depends on the `type` of that element. To see the list of properties that can be set for each type, see the "Accepted Properties for Each Type" section below.

For elements of type `menu`, `submenu`, `command`, `check`, `radio`, `separator`, `toolbar`, and `toolbutton`, the `gui_set_ui` command works like the tk command *`widget`*`configure`. For the main window (`main`), it works like the tk command `wm`.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_set_ui` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_set_ui`
`name`	Specifies the name of the element whose property is to be set. An error is returned if specified *`name`* does not exist. *Data_type*: string, required
`-before` *`name`*	Sets the specified element before the element identified by *`name`*. *Data_type*: string, optional
`-checked {true | false}`	Checks or unchecks the specified element. **Note:** You can use the `-checked` parameter only for elements of type `check` or `radio`. *Data_type*: bool, optional
`-command` *`string`*	Specifies the Tcl command to be executed when the specified element is invoked. **Note:** You can use the `-command` parameter only if you are adding elements of type `command, check, radio` or `toolbutton`. *Data_type*: string, optional
`-disabled {true | false}`	Disables or enables the specified interface element. **Note:** You can use the `-disabled` parameter only for elements of type `menu, submenu, command, check, radio` or `toolbutton`. The parameter is NOT applicable for elements of type `toolbar` and `separator`. *Data_type*: bool, optional
`-enable_variable` *`string`*	Sets the Tcl global variable for Enable status. *Data_type*: string, optional

`-foreground` *`string`*	Specifies the foreground color of the icon of the specified interface element. **Note:** You can use the `-foreground` parameter only if you are adding an element of type `toolbutton`. *Data_type*: string, optional
`-full_screen {true | false}`	
	Maximizes the main window. This property can be set only for the element `main`. **Note:** This option cannot be used with `-geometry`. *Data_type*: bool, optional
`-geometry` *`string`*	Modifies the geometry of the specified window element. *Data_type*: string, optional
`-icon` *`filename`*	Specifies the file name of the toolbutton icon. *`filename`* can be the full path of the icon file or an icon name supported by Innovus. The icon names used in Innovus can be queried using the `gui_get_ui` command. For list of supported image formats for the icon file, see the "Supported Image Formats" section of the Customizing the User Interface chapter in the *User Guide*. **Note:** The `-icon` parameter is applicable only for elements of type `toolbutton`. *Data_type*: string, optional
`-in` *`name`*	Specifies the name of the parent element. *Data_type*: string, optional
`-label` *`string`*	Specifies the label to be displayed on the element being modified. **Note:** This parameter is NOT applicable for elements of type `separator`. *Data_type*: string, optional

`-message` *string*	Specifies the message to be displayed on the element being modified. **Note:** This parameter is applicable for elements of type `statusbar`. *Data_type*: string, optional
`-movable {true | false}`	Specifies whether or not the element being modified should be movable. **Note:** The `-movable` parameter is applicable only for elements of type `toolbar`. *Data_type*: bool, optional
`-newline {true | false}`	Specifies whether or not the element being modified should be on a new row. **Note:** The `-newline` parameter is applicable only for elements of type `toolbar`. *Data_type*: bool, optional
`-shortcut` *string*	Specifies the shortcut key for a command, check box, radio button, or toolbutton. **Note:** You can use the `-shortcut` parameter only if you are modifying elements of type `command`, `check`, `radio`, or `toolbutton`. *Data_type*: string, optional
`-statusbar` *string*	Sets the statusbar of the specified window element. *Data_type*: string, optional
`-title` *string*	Specifies the window title. *Data_type*: string, optional
`-tooltip` *string*	Specifies the tooltip text for the toolbar or toolbutton you are adding. **Note:** The `-tooltip` parameter is applicable only for elements of type `toolbar` and `toolbutton`. *Data_type*: string, optional

`-underline` *integer*	Specifies the integer index of the character to be underlined in the element label. The index begins with `0` and should have a value less than or equal to the length of the element label. For instance, if you want the second letter of the element label to appear underlined, specify *integer* as `1`. **Note:** The `-underline` parameter is NOT applicable for elements of type `toolbar, separator,` and `toolbutton`. *Data_type*: int, optional
`-value` *stringValue*	Specifies the value to be stored in the associated variable when the specified radio button is selected. **Note:** The `-value` parameter is applicable only for elements of type `radio`. *Data_type*: string, optional
`-variable` *string*	When modifying a check box or radio button, specifies the Tcl global variable for the item. *Data_type*: string, optional
`-visible {true | false}`	Specifies the visibility status of the element being modified. *Data_type*: bool, optional
`-visible_variable` *string*	Sets the Tcl global variable for Visible status. *Data_type*: string, optional

Accepted Properties for Each Type

The accepted properties for each type are listed below.

- For the main window (`main`), the following properties can be set:

  `-geometry {`*widthxheight* `|` *widthxheight+x+y*`}`

  `-title` *title*

  `-close_command` *string*

  `-visible true | false`

- For a status bar (`statusbar`), the following property can be set:

  `-enable_variable` *string*

  `-in` *parentname*

```
-message msg
-visible true | false
-visible_variable string
```

- For elements of type `menu` or `submenu`, the following properties can be set:

```
-enable_variable string
-before nextSiblingName]
-disabled true | false
-in parentName
-label label
-underline index
-visible true | false
-visible_variable string
```

- For elements of type `command`, `radio`, and `check`, the following properties can be set:

```
-disabled true | false
-label label
-underline index
-command commandName
-in parentName
-before nextSiblingName
-enable_variable string
-visible true | false
-visible_variable string
-shortcut string
```

  For `radio` and `check`, the `-checked` and `-variable` properties can also be set.

- For elements of type `toolbutton`, the following properties can be set:

```
-state normal | disabled
-label label
-tooltip toolTipText
-underline index
-foreground colorName
-icon iconName
-command commandName
```

```
-in parentName
-before nextSiblingName
-enable_variable string
-visible true | false
-visible_variable string
-shortcut string
```

Examples

- The following command changes the label of the *Verify* menu in the main window to *NewCheck*:
  ```
  gui_set_ui verify -label NewCheck
  ```
- The following command maximizes the Innovus main window:
  ```
  gui_set_ui main -full_screen
  ```

gui_set_visible_bumps

```
gui_set_visible_bumps
[-help]
{-bump_cells bump_cell_name| -all}
```

Displays only the bumps with the specified bump cell names and hides all other bumps.

To redisplay all bumps, specify the `-all` parameter.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_set_visible_bumps` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_set_visible_bumps`
`-all`	Displays all bumps. ⚠ By default, all bumps are displayed. When you specify `gui_set_visible_bumps bump_cell_name`, the tool displays only the bumps with the specified bump cell names and hides all other bumps. You can then use `gui_set_visible_bumps -all` to redisplay all bumps.
`-bump_cells names`	Displays only the bumps with the specified bump cell names and hides all other bumps. You can specify multiple bump cell names.

Examples

- The following command displays only the bumps with bump cell as BUMPCELL:
  ```
  gui_set_visible_bumps -bump_cells BUMPCELL
  ```
- The following command displays all bumps:
  ```
  gui_set_visible_bumps -all
  ```

Related Information

- gui_get_visible_bumps

gui_set_visible_net_groups

```
gui_set_visible_net_groups
[-help]
{net_group_names | -all}
```

Displays only the specified net groups and hides all other net groups.

To display all net groups, specify the `-all` parameter.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_set_visible_net_groups` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_set_visible_net_groups`
`-all`	Displays all the net groups.
net_group_names	Displays only the specified net groups and hides all other net groups. You can specify multiple net group names.

Examples

- The following command hides all net groups except the specified one:
  ```
  gui_set_visible_net_groups test_ng
  ```

Related Information

- `gui_get_visible_net_groups`

gui_set_visible_nets

```
gui_set_visible_nets
[-help]
{nets | -all}
```

Displays only the specified nets and hides all other nets.

To display all nets, specify the `-all` parameter.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_set_visible_nets` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_set_visible_nets`
`-all`	Displays all nets. *Data_type*: bool, optional
nets	Displays only the specified nets and hides all other nets. You can specify multiple net names. *Data_type*: (net)*, optional

Examples

- The following command hides all nets except the specified net:
  ```
  gui_set_visible_nets inst1/lower/net_1
  ```

Related Information

- `gui_get_visible_nets`

gui_show

```
gui_show
[-help]
```

Opens the Innovus main window.

If you run the `gui_show` command when the Innovus main window is already displayed, the tool retains the current zoom level and displays the main window without refreshing it. For example:

```
innovus 23> zoom_box 94 -640 95 -645
innovus 24> gui_show
```

This displays the main window with the design zoomed to the coordinates " `94 -640 95 -645` ".

If you started the Innovus software with the `innovus -no_gui` command, you can use `gui_show` to pop up the main window.

You can run the `gui_hide` command to hide the Innovus main window.

Parameters

`-help`	Prints out the command usage. For a detailed description of the command, use the `man` command: `man gui_show`

Related Information

- `gui_hide`
- The Main Window chapter of the *Menu Reference*
    - *Closing or Hiding the GUI*

gui_show_edge_number

```
gui_show_edge_number [-help]
[-objects string]
[-reset]
```

Displays edge numbers on the sides of the selected or specified objects in the GUI. Currently, you can display edge numbers on partitions and blocks. This feature is useful if you need to indicate the partition or block edge number in your script.

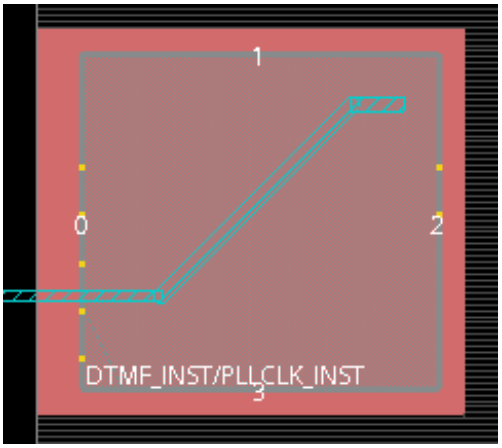
Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_show_edge_number` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_show_edge_number`
`-objects` *`string`*	Specifies the name of the object for which the edge numbers should be displayed. If you want to specify multiple object names, enclose them in braces or double quotation marks. Currently, you can display the edge numbers for partitions and blocks. *Data_type*: string, optional
`-reset`	Clears the edge numbers from the specified or selected objects on the GUI. If you want to clear the edge numbers for all objects, use the `-reset` parameter with `-objects *`. *Data_type*: bool, optional

Examples

- The following command displays the edge numbers on the `DTMF_INST/PLLCLK_INST` block in the GUI:

  ```
  gui_show_edge_number -objects DTMF_INST/PLLCLK_INST
  ```

- The following command clears the edge numbers from all blocks:

  ```
  gui_show_edge_number -objects * -reset
  ```

Related Information

- `gui_select`

gui_show_floorplan_snapshot

```
gui_show_floorplan_snapshot
[-help]
-dir string
[-name string]
[-view string]
```

Opens a window *SnapShot Result* for viewing saved snapshots. Snapshots are selected based on the options: `-dir` and `-name`. The window displays design views controlled by the `-view` option and also shows QoR parameters (WNS,TNS, Placement Overlap, and congestion) saved at the time of creating the snapshot.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `gui_show_floorplan_snapshot` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_show_floorplan_snapshot`.
`-dir` *string*	Specifies the directory of the saved snapshot, when opted alone it will show all snapshots saved in the directory. *Data_type*: string, required
`-name` *string*	Specifies the name of snapshot to be viewed in the *SnapShot Result* window. *Data_type*: string, optional
`-view` *string*	Specifies the view of the design you want to see in *SnapShot Result* window. You can see multiple views by listing them under this option. *Default:* The fplan view is shown in the *SnapShot Result* window. *Data_type*: string, optional

Note: This command will not work in the `-nowin` mode.

Examples

- The following command will show all the snapshots present in the directory `/work/user1`, along with all QoR parameters (WNS, TNS, Placement Overlap, and Congestion). By default only the fplan view will be displayed.

  ```
  gui_show_floorplan_snapshot -dir {/work/user1}
  ```

- The following command will show snapshots with the name `cts` along with all QoR parameters (WNS, TNS, Placement Overlap, and Congestion). By default only the fplan view will be displayed.

  ```
  gui_show_floorplan_snapshot -dir {/work/user1} -name cts
  ```

- The following command will show snapshots with the name `cts` along with all QoR parameters (WNS, TNS, Placement Overlap, and Congestion). Only design views `cts`will be shown as opted under the -view option.

  ```
  gui_show_floorplan_snapshot -dir {/work/user1} -name cts -view cts
  ```

- The following command will show all the snapshots present in the directory `/work/user1`along with all QoR parameters (WNS, TNS, Placement Overlap, and Congestion). All the views will be shown side by side.

  ```
  gui_show_floorplan_snapshot -dir {/work/user1} -view {fplan amoeba place}
  ```

Related Information

- `gui_create_floorplan_snapshot`
- Tools Menu chapter of *Menu Reference*
  - *Create Snapshot*
  - *View Snapshot*

gui_show_user_bundle_nets

```
gui_show_user_bundle_nets
[-help]
[-keep_existing]
-net_bundle bundleName
[-remove]
```

Displays flightlines for the specified net bundle. Bundled nets help you with data flow analysis before and after layout. Net bundles can be created and viewed in floorplan and amoeba views. When you run the `gui_show_user_bundle_nets` command, Innovus switches automatically to the net bundle mode and clears flightlines based on selection.

You can create flight line net bundles using the `gui_create_user_bundle_net` command and delete them using the `gui_delete_user_bundle_net` command.

Note: When selecting objects, you can choose to display flightlines for only bundled nets by using the *Only Show Net Bundle Flight Line* option in the Preferences form. If this option is not selected, the net bundle flightlines are displayed along with other flightlines.

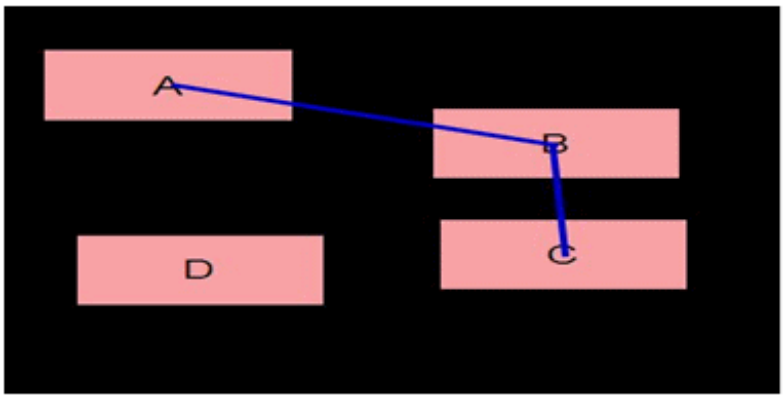
Parameters

`-help`	Prints a brief description that includes type and default information for each gui_show_user_bundle_nets parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_show_user_bundle_nets`
`-keep_existing`	Retains existing net bundle flightlines while displaying the flightline of specified net bundles. If this option is not specified, the command clears existing flightlines before displaying specified net bundle flightlines. *Data_type*: bool, optional
`-net_bundle` *bundleName*	Specifies the name of the net bundle whose flightlines you want to display. You can specify more than one net bundle. *Data_type*: string, required
`-remove`	Clears flightlines of specified net bundle from the display area. If no net bundle name is specified, all flightlines based on net bundles are removed. **Note:** This option only clears the flightlines of the net bundle from the display area. If you want to remove the net bundle itself, use the `gui_delete_user_bundle_net` command. *Data_type*: bool, optional

Examples

- The following command displays flightlines of the net bundle `bundle_1`. Here, `bundle_1` contains `net_1`, which is just between A and B, and `net_2`, which is just between B and C:

  ```
  gui_show_user_bundle_nets -net_bundle bundle_1
  ```

- The following command displays flightlines of the net bundle `bundle_2` while retaining flightlines of `bundle_1`. Here, `bundle_2` contains `net_3`, which is among B, C, and D:

  ```
  gui_show_user_bundle_nets -net_bundle bundle_2 -keep_existing
  ```

  
  Note: The same flightlines could also be displayed in a single step by using the following command:

  ```
  gui_show_user_bundle_nets -net_bundle {bundle_1 bundle_2}
  ```

Related Information

- `gui_create_user_bundle_net`
- `gui_delete_user_bundle_net`
- View Menu chapter of the *Menu Reference*
    - *Preferences - Flightline*

gui_trace_flightline

```
gui_trace_flightline
[-help]
-inst instance_name
[-max_inout_number value]
{[-sink  -sink_level value -sink_color string] | [-source  -source_level value -
source_color string]}
```

Traces flightlines for the specified instance from either the output pins (with `-sink`) or the input pins (with `-source`). The flightlines drawn with `gui_trace_flightline` are not dependent on instance selection. These flightlines are cleared only when you use `gui_clear_trace_flightline`.

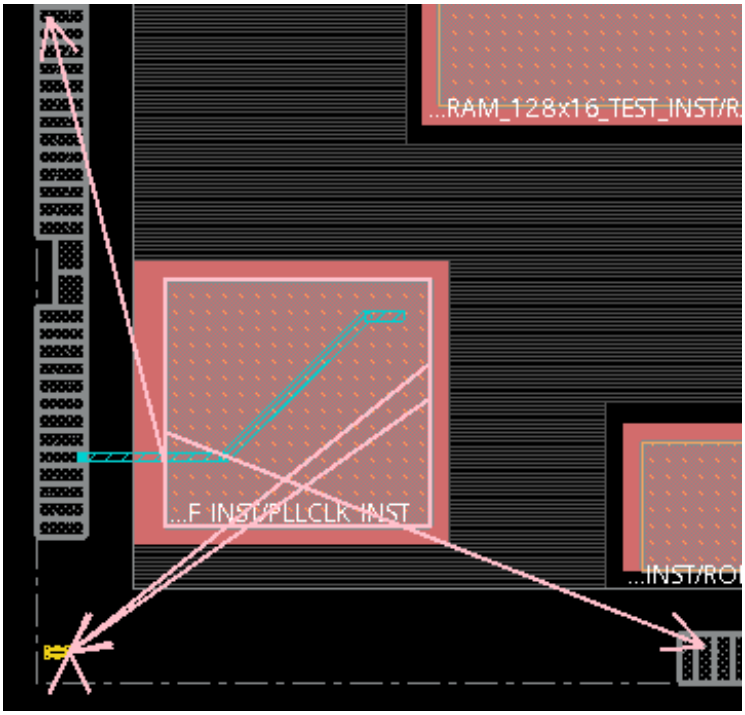
Parameters

`-help`	Prints a brief description of the `gui_trace_flightline` command. For a detailed description of the command, use the `man` command: `man gui_trace_flightline`.
`-inst` *`instance_name`*	Specifies the name of the instance from which the flightline starts. *Data_type*: string, required
`-max_inout_number` *`value`*	Specifies the maximum number of net terms. If the net has more terms than the specified number, the tool skips this net while tracing the flightline. *Default*: 50 *Data_type*: int, optional
`-sink`	Traces flightlines from the output pins of the specified instance. You must also specify `-sink_color` and `-sink_level` with this option. You cannot use this option with any of the `-source*` options. *Data_type*: bool, optional
`-sink_color` *`string`*	Specifies the color of the sink trace. *Data_type*: string, optional
`-sink_level` *`value`*	Specifies the sink trace level. *Data_type*: string, optional
`-source`	Traces flightlines from the input pins of the specified instance. You must also specify `-source_color` and `-source_level` with this option. You cannot use this option with any of the `-sink*` options. *Data_type*: bool, optional
`-source_color` *`string`*	Specifies the color of the source trace. *Data_type*: string, optional
`-source_level` *`value`*	Specifies the source trace level. *Data_type*: string, optional

Examples

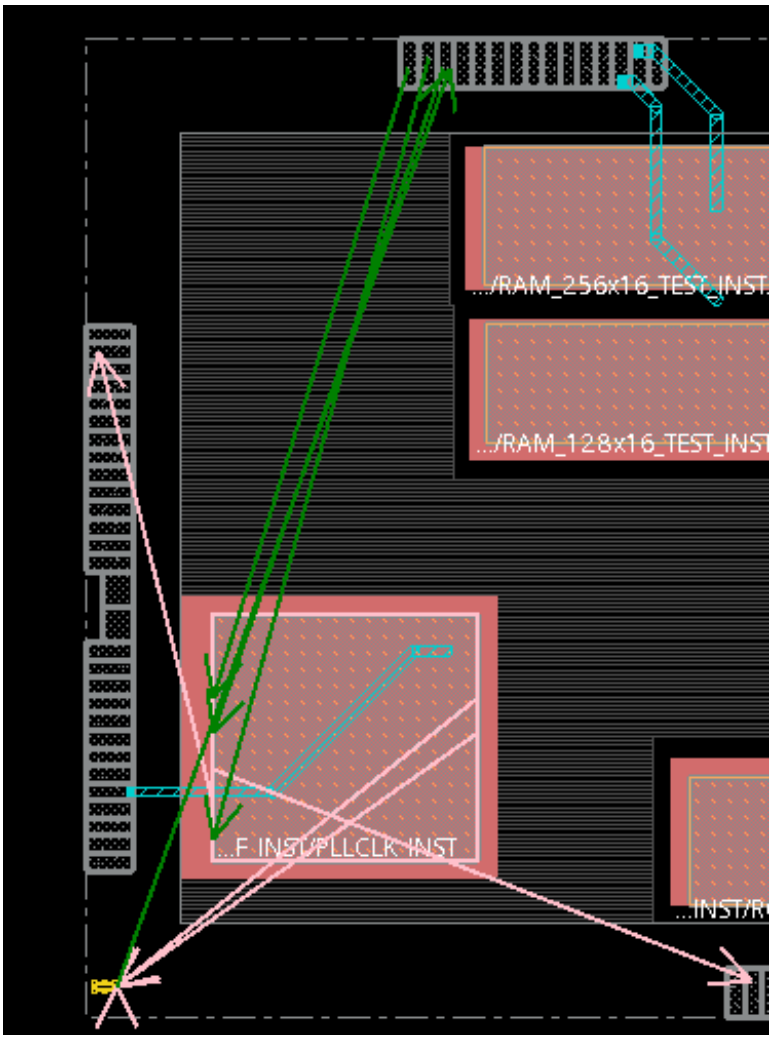
- The following command traces flightlines for the `DTMF_INST/PLLCLK_INST` instance from the output pins for `2` logic levels in the color `pink`:

  ```
  gui_trace_flightline -inst DTMF_INST/PLLCLK_INST -sink -sink_level 2 -sink_color pink
  ```



- The following command traces flightlines for the `DTMF_INST/PLLCLK_INST` instance from the input pins for `2` logic levels in the color `green`:

  ```
  gui_trace_flightline -inst DTMF_INST/PLLCLK_INST -source -source_level 2 -source_color green
  ```



Related Information

gui_undo

```
gui_undo [-help]
```

Undoes the previous edit made with any bump placement, floorplanning, power planning, or wire edit commands listed below.

- Selected bump placement commands:
  - create_bump
  - delete_bumps
- Selected floorplanning commands:
  - align_selected
  - flip_or_rotate_obj
  - move_obj
  - snap_floorplan
  - snap_floorplan_io
  - space_selected
- Selected power planning commands:
  - add_rings
  - add_stripes
  - update_power_vias
  - route_special
- All wire editor commands:
  - create_fillet
  - convert_special_routes_for_eco
  - delete_fillet
  - delete_routes
  - deselect_routes
  - edit_add_polygon_point

- edit_add_route_point
- edit_add_trim_metal
- edit_create_via
- edit_cut_route
- edit_duplicate_routes
- edit_end_polygon_point
- edit_end_route_point
- edit_merge_routes
- edit_move_routes
- edit_resize_routes
- edit_rotate
- edit_split_routes
- edit_split_wide_routes
- edit_trim_routes
- edit_update_route_layer
- edit_update_route_net
- edit_update_route_rule
- edit_update_route_status
- edit_update_via
- select_routes

You can use the gui_redo command to redo an edit that was reversed with gui_undo.

Parameters

`-help`	Prints a brief description of the `gui_undo` command. For a detailed description of the command, use the `man` command: `man gui_undo`

Related Information

- `gui_redo`
- Edit Menu chapter in the *Menu Reference*
  - *Undo*
  - *Redo*

gui_ungroup_hinst

```
gui_ungroup_hinst
[-help]
[-type {flex_model} | hinst]
[-type {flex_model} [-display_all_constraints ]]
```

Displays the submodules for the specified module guide. The `gui_ungroup_hinst` command is equivalent to the *Ungroup* widget on the toolbar.

If you try to ungroup a module that contains only standard cells and marcos but does not contain any submodules, the tool ignores the ungroup request and issues the following warning:

**WARN: (IMPSYT-3162): Cannot ungroup Module 'DTMF_INST/RAM_128x16_TEST_INST' because it has no child.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_ungroup_hinst` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_ungroup_hinst`
`-display_all_constraints`	Displays all constraints, such as fences, guides, regions, and soft guides, regardless of the current hierarchy. When this option is specified, you can view the child constraints. *Data_type*: bool, optional
hinst	Specifies the name of the hierarchical instance (hinst) to be ungrouped. *Data_type*: string, optional
`-type {flex_model}`	Specifies the object type to be ungrouped. At present, only the `flex_model` type is supported. If you specify `-type {flex_model}`, the command ungroups all hierarchical instances or parent hinst down to the flex_module and/or flex_instgroup level. *Data_type*: enum, optional

Examples

- The following command ungroups the specified module and displays its submodules:
  ```
  gui_ungroup_hinst DTMF_INST/TDSP_CORE_INST
  ```
- The following command ungroups all hierarchical instances or parent hinst down to the flex_module and/or flex_instgroup level:
  ```
  gui_ungroup_hinst -type {flex_model}
  ```

Related Information

- `gui_group_hinst`
- The Main Window chapter in *Menu Reference*
  - *Toolbar Widgets*

gui_unregister_edit_callback

```
gui_unregister_edit_callback
[-help]
[-command string]
-edit_type {selection pre-move post-move}
```

Removes the callback function from the specified move action. In GUI, the move action involves the following three steps:

1. Click an object.
2. Move the object to the new location.
3. Click to place the object at the new location and complete the move.

The callback function is implemented based on the move action specified with the `-edit_type` parameter.

Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man gui_unregister_edit_callback`
`-command` *string*	Specifies the name of the callback function. *Data_type*: string, optional
`-edit_type {selection pre-move post-move}`	Specifies the GUI edit function: • `selection` - Implements the callback function when an object is selected (after Step 1). • `pre-move` - Implements the callback function just before the object is placed at the new location (after Step 2, just before you change the coordinates in Step 3). • `post-move` - Implements the callback function after an object is moved (after Step 3, when the tool updates the DB records). *Data_type*: enum, required

Example

Consider the following proc definition:

```
proc move_event_callback {

     set objList [dbGet selected]

     foreach obj $objList {

           set type [dbGet $obj.objType]

           if {$type == "sdp"} {

                custom_snap_sdp $obj

           } elseif {$type == "inst"} {

                set cellName [dbGet $obj.cell.name]

                if {[regexp grf $cellName]} {

                     custom_snap_grf $obj

                }

           }

}

}
```

The following command triggers the `move_event_callback` function on the selected object just before the move is completed:

```
register_gui_edit_callback -edit_type pre_move -command move_event_callback
```

The following command removes the callback to the `move_event_callback` function:

```
gui_unregister_edit_callback -edit_type pre_move -command move_event_callback
```

Related Information

- `gui_register_edit_callback`
- `report_gui_edit_callback`

gui_view_box

```
gui_view_box [-help]
```

Reports the coordinates of the current area being viewed in the GUI.

Parameters

`-help`	Prints out the command usage. For a detailed description of the command, use the `man` command: `man gui_view_box`

Example

The following command reports the coordinates of the current area being viewed in the GUI:

```
innovus 9> gui_view_box

93.367 -646.465 103.294 -638.724
```

Related Information

- `gui_zoom`

gui_write_flightline

```
gui_write_flightline
[-help]
-file file_name
[-net_window]
```

Saves the flightline information of the selected instance to the specified file.

Parameters

`-help`	Prints a brief description of the `gui_write_flightline` command. For a detailed description of the command, use the `man` command: `man gui_write_flightline`.
`-file file_name`	Specifies the name of the file in which the flightline information will be saved. *Data_type*: string, required
`-net_window`	Saves the contents of the Flightline Net Window. *Data_type*: bool, optional

Example

The following command saves the flightline information to a file named `flight1`:

```
gui_write_flightline -file flight1
```

Here's a sample report:

```

gui_write_flow_gifs

```
gui_write_flow_gifs
[-help]
-dir string
[-full_window]
-prefix string
```

Dumps images at various stages of the Innovus Stylus Common UI flow, when executed in the batch mode. The stages include congestion map, cell density map, floorplan view, and colored hierarchy map.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_write_flow_gifs` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_write_flow_gifs`
`-dir string`	Specifies the output directory. *Data_type*: string, required
`-full_window`	Maximizes the window. *Data_type*: bool, optional
`-prefix string`	Specifies the file prefix. *Data_type*: string, required

Example

The following command dumps full screen images at the various stages of the Innovus flow to the `TEST` directory:

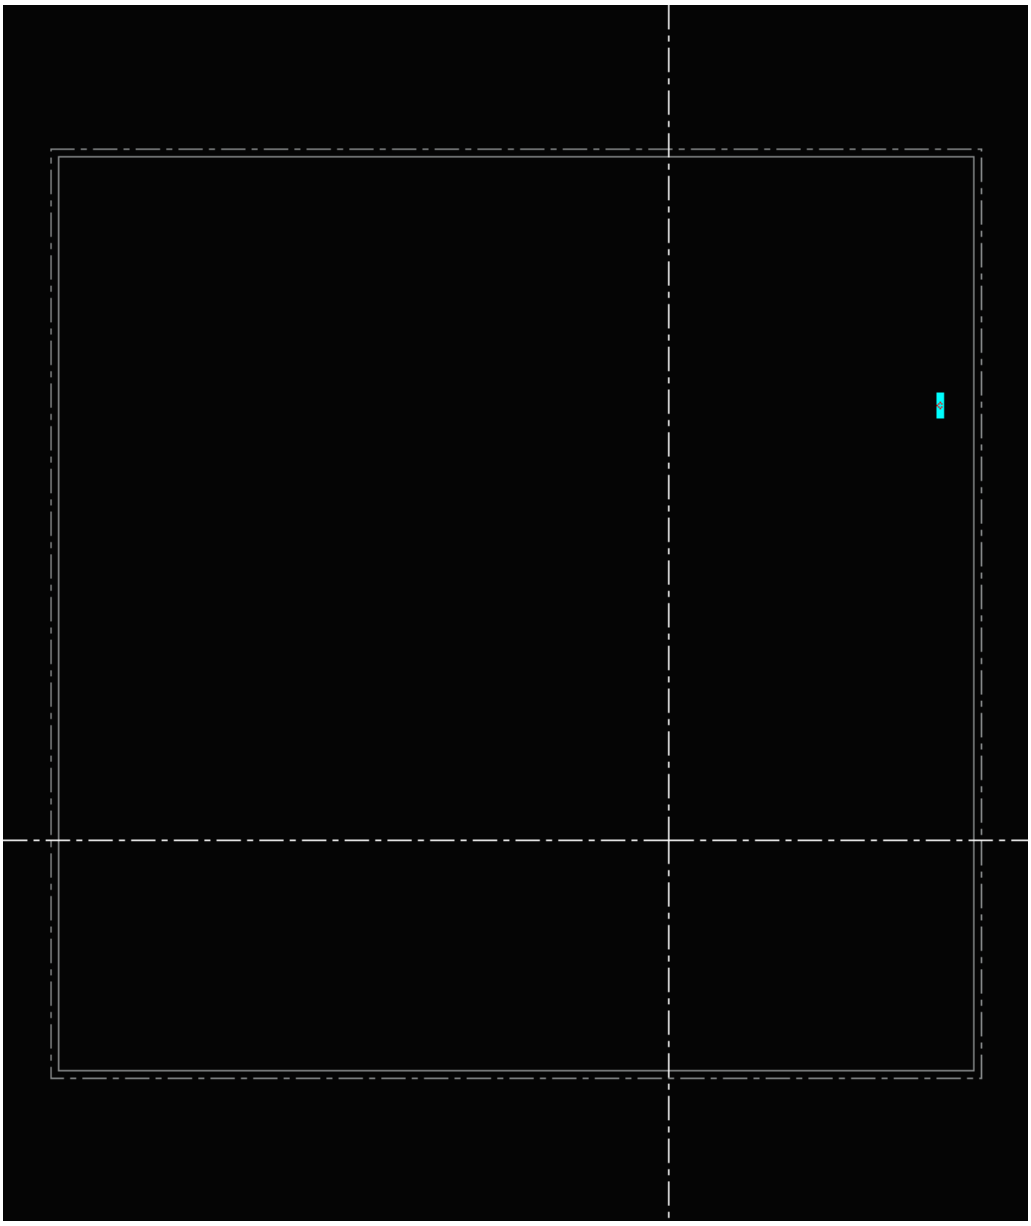
```
gui_write_flow_gifs -dir TEST -prefix [dbGet top.name] -full_window
```

The following images are dumped in the `TEST` directory:

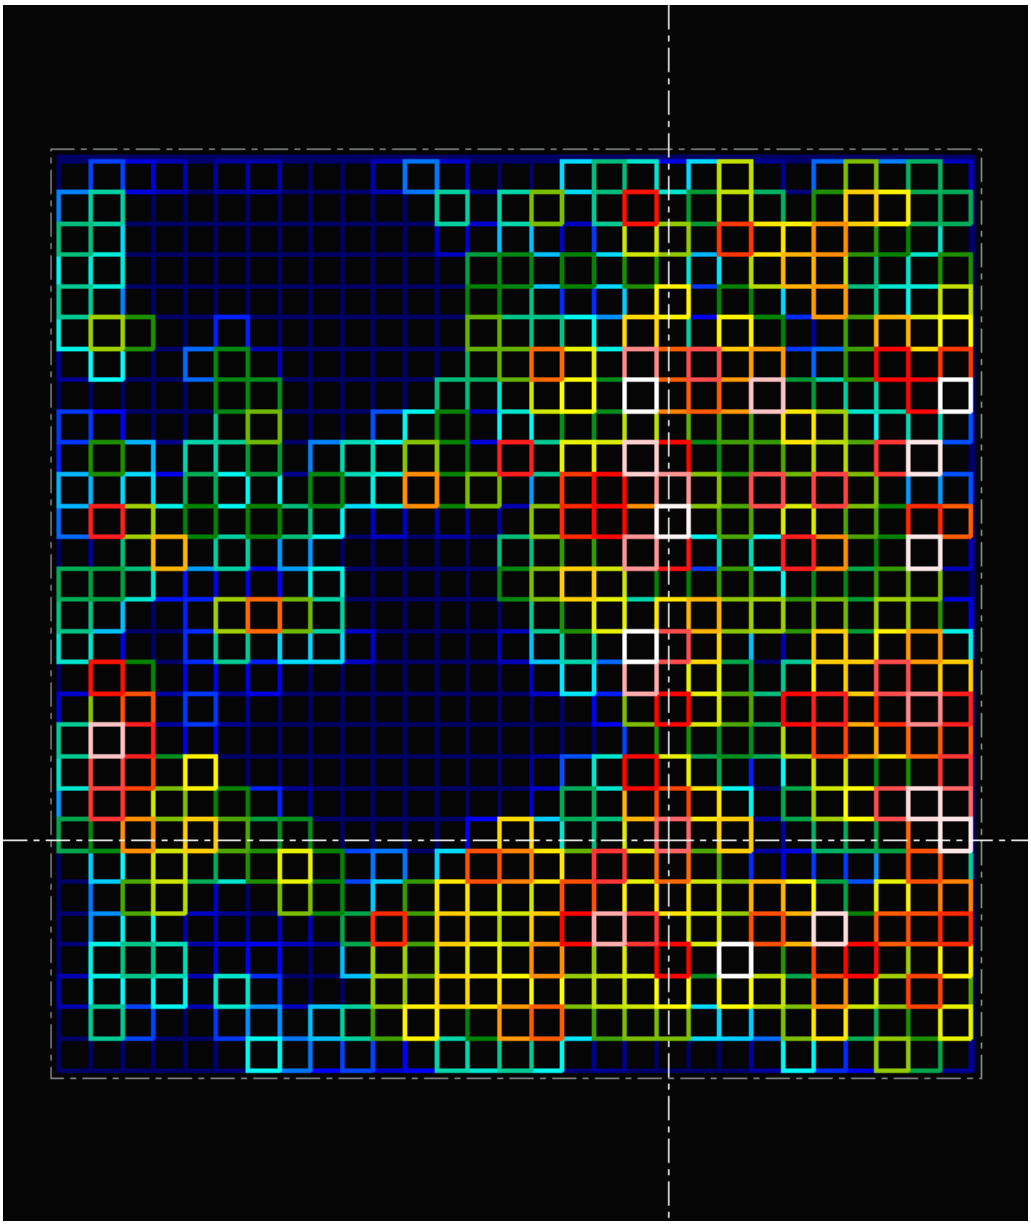
1. `congestion`

2. `density`
3. `floor`
4. `placement`
5. `route_all`
6. `route_C4`
7. `route_C5`
8. `route_C6`
9. `route_M1`
10. `route_M2`
11. `route_M3`
12. `specialroute`
13. `violations`

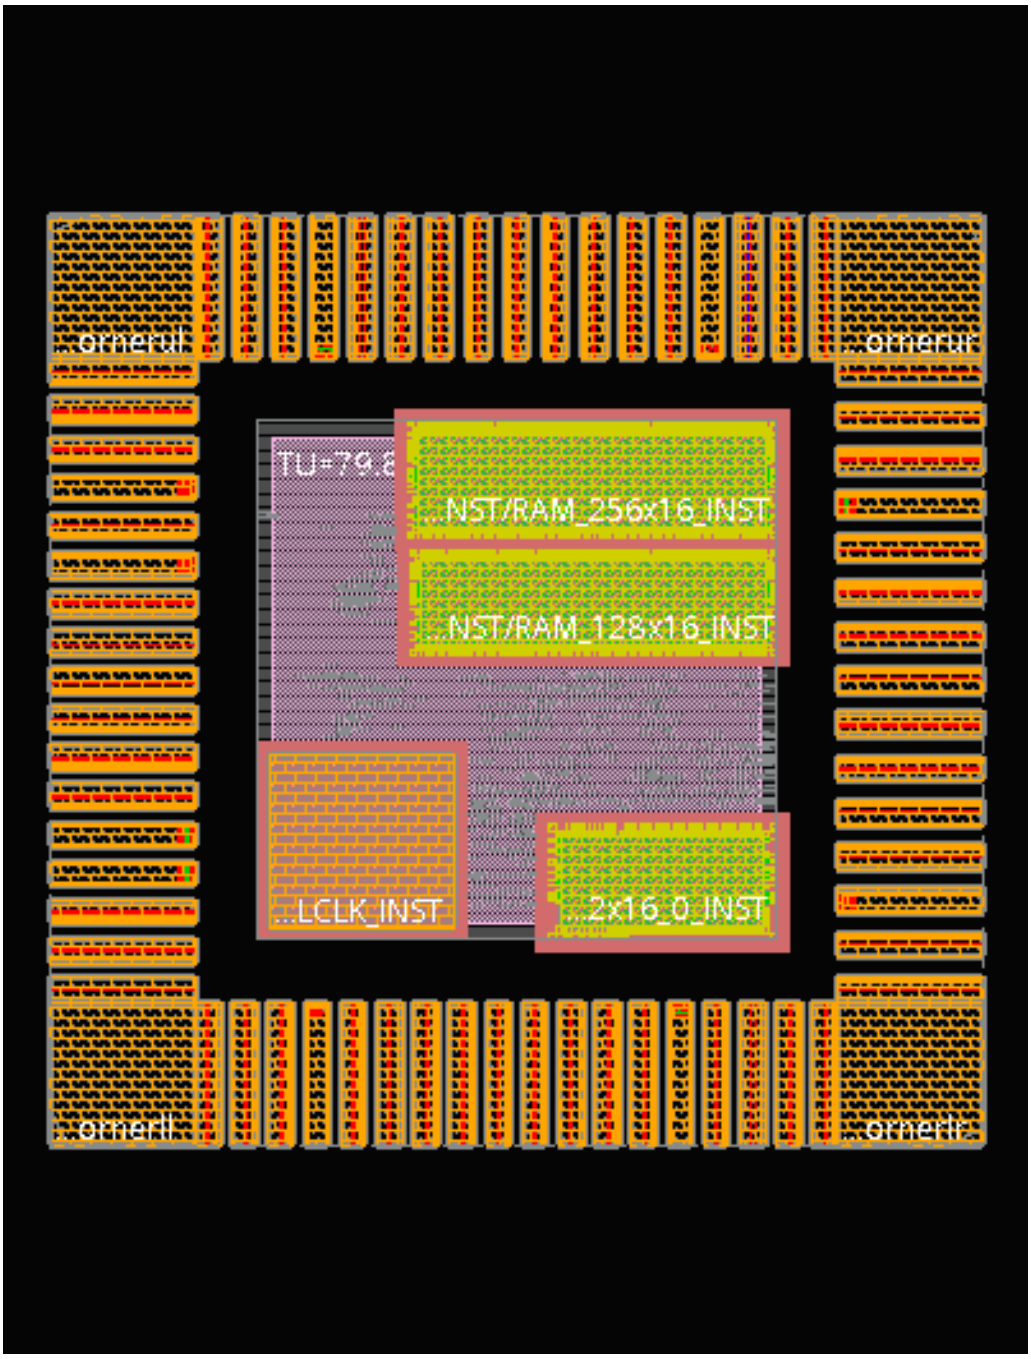
Following is the `congestion` image:



Following is the `density` image:



Following is the floor image:



ornerUL
ornerUR

- write_to_gif

gui_write_picture

```
gui_write_picture
[-help]
filename
[-format {bmp gif jpg jpeg png pbm pgm ppm xbm xpm}]
[-width integer_value -height integer_value]
[-window string]
```

Saves a snapshot of the layout or specified window with the specified name in the current directory. You can specify the size as well as the format in which you want to save the snapshot. The command also prints out overlay maps with legends.

You can use this command at any stage of the design flow.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_write_picture` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_write_picture`

filename	Specifies the name of the picture file as a string. You can specify the file extension as well.
	
	Note: The file extension you specify does not control the format of the picture. The picture file is dumped in the PNG format by default or the format you explicitly specify with `-format`. For example, the following command saves the `testShot` picture file in the PNG format:
	`innovus 34> gui_write_picture testShot.gif`
	
	current_directory`@file testShot.gif`
	`testShot.gif: PNG image data, 540 x 688, 8-bit/color RGB, non-interlaced`
	
	Data_type: string, required

`-format {bmp gif jpg jpeg png pbm pgm ppm xbm xpm}`	

	Specifies the format of the picture file. *Default*: `png` *Data_type*: enum, optional
`-height` *integer_value*	
	Specifies the height of the picture as an integral value. **Note**: The `-width` parameter is required when `-height` is specified. *Min*: 100 *Max*: 20000 *Data_type*: int, optional
`-width` *integer_value*	
	Specifies the width of the picture as an integral value. **Note**: The `-height` parameter is required when `-width` is specified. *Min*: 100 *Max*: 20000 *Data_type*: int, optional
`-window` *string*	Specifies the ID of the window that you want to dump. You can use the following IDs: • For Layout Viewer: `designview.win` • For Cell Viewer: `.uiCellView.win` If `-window` is not specified, the main layout window is dumped out by default. *Data_type*: string, optional

Examples

- The following command captures the layout window and saves it in the default PNG format with the name *test2* and the dimensions 1000 x 1000 in the current directory:

  ```
  gui_write_picture test2 -width 1000 height 1000
  ```

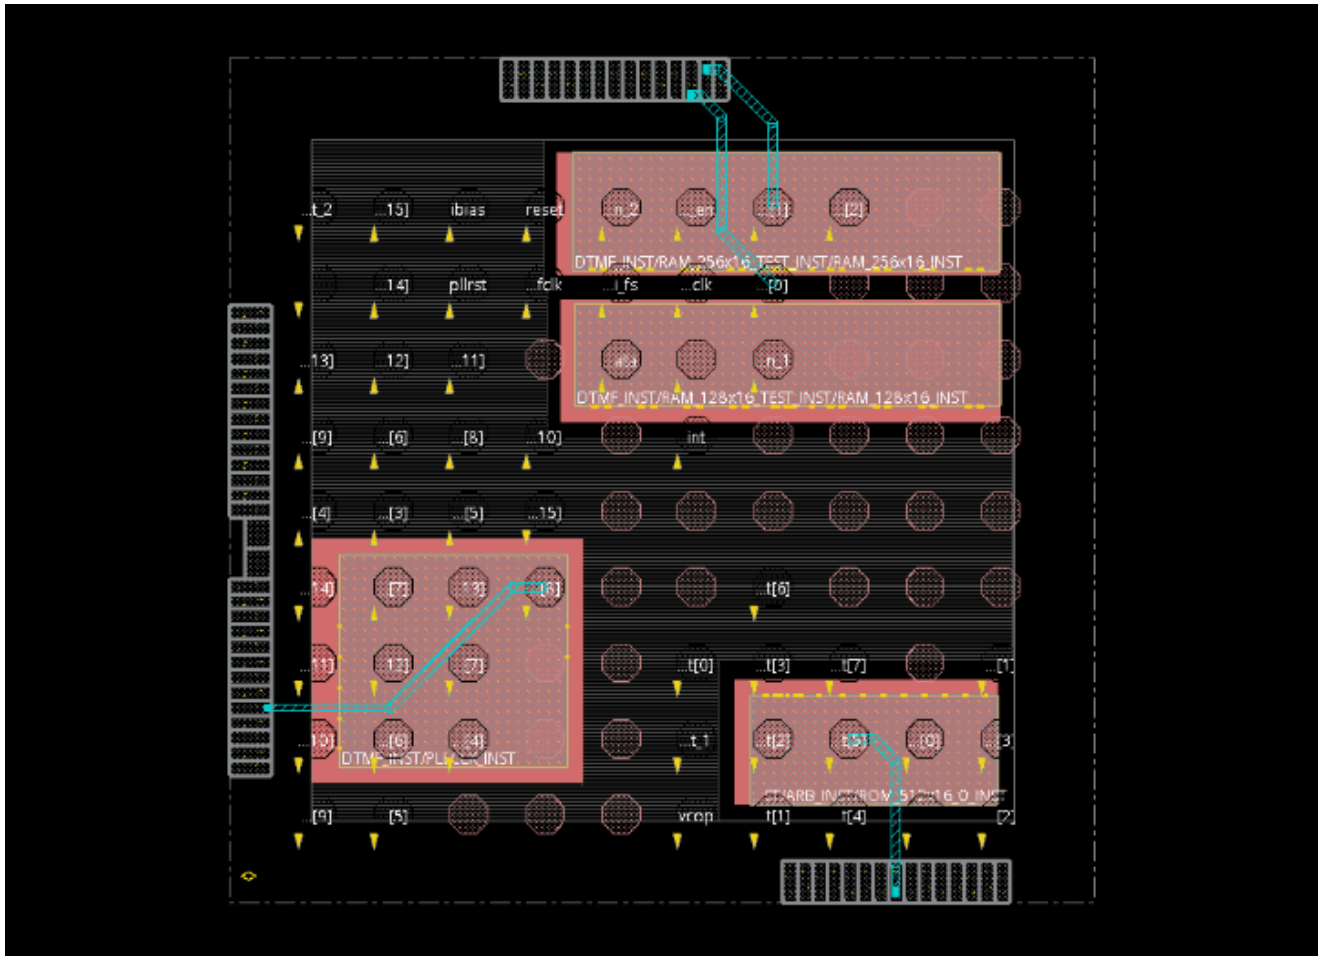
- The following command captures the layout window and saves it in the GIF format with the name *test1.gif* in the current directory:

  ```
  gui_write_picture -format gif test1.gif
  ```

- The following command captures the layout viewer window and saves it in PNG format with the name testShot.png in the current directory:

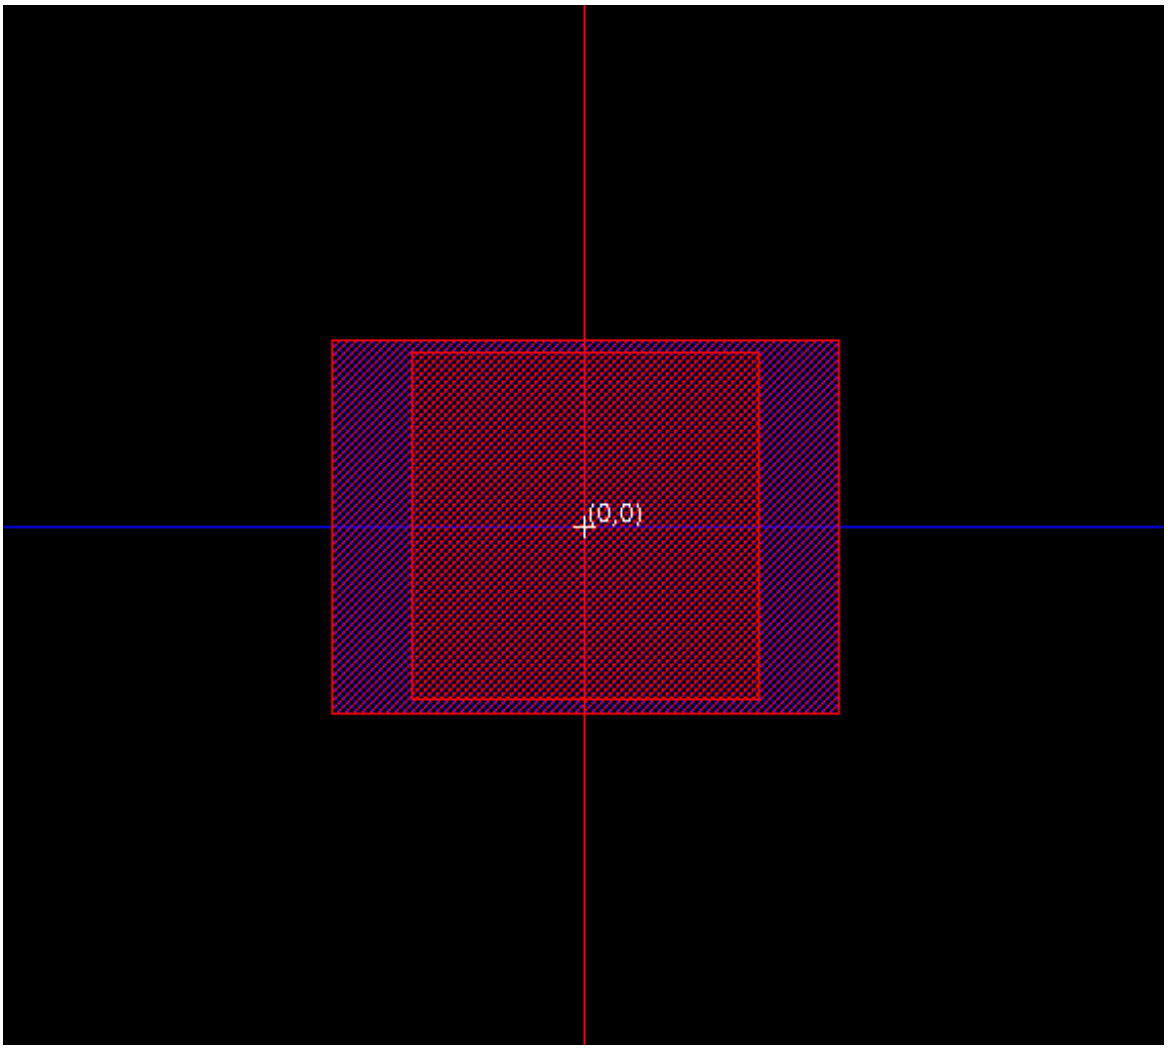
  ```
  gui_write_picture testShot.png -window designview.win
  ```

  Note: You must have the layout viewer open.



- The following command captures the view in the cell viewer window and saves it in PNG format with the name testCell.png in the current directory:

  ```
  gui_write_picture testCell.png -window .uiCellView.win
  ```



Related Information

gui_zoom

```
gui_zoom
[-help]
[-to {x y}[-to_radius value]]
[-selected [-margin integer_value]]
{-in  | -out  | -selected  | -to {x y} | -rect {x1 y1 x2 y2}}
```

Zooms into or out of the viewable window as per the specified parameters.

Parameters

`-help`	Prints a brief description that includes type and default information for each `gui_zoom` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_zoom`.
`-in`	Zooms into the viewable window by two times. *Data_type*: bool, optional

`-margin integer_value`	Specifies the zoom margin ratio for the viewable window. The zoom margin is the minimum spacing between the bounding box of the selected object(s) and the layout view.  The minimum value is `0` and the maximum value is `99`. The `gui_zoom -selected` parameter must be specified if you are specifying `-margin`. *Default*: 50 *Data_type*: int, optional
`-out`	Zooms out from the viewable window by two times. *Data_type*: bool, optional
`-rect {x1 y1 x2 y2}`	Zooms in the viewable window to show all of the rectangular area that is defined by the specified coordinates. *Data_type*: rect, optional
`-selected`	Zooms in the viewable window to the area that encloses the selected objects. *Data_type*: bool, optional
`-to {x y}`	Zooms in the viewable window to the point defined by the coordinates, `x` and `y`. *Data_type*: point, optional

`-to_radius value`	Zooms in the viewable window to a radius of the specified value in microns, with center at the point specified by `-to {x y}`. *value* is of type float. *Default*: 150 microns **Note**: The `-to {x y}` parameter must be specified with this parameter. *Data_type*: float, optional

Examples

- The following command zooms in the viewable window to the area enclosed by the lower-left coordinates (`450 531`) and the upper-right coordinates (`550 631`):

  ```
  gui_zoom -rect {450 531 550 631}
  ```

- When the following command is run, the display zooms in to point with x=100 and y=200. The display area is centered at this point and has the default radius of 150 microns:

  ```
  gui_zoom -to {100 200}
  ```

- When the following command is run, the display zooms in to point with x=100 and y=200. The display area is centered at this point and has a radius of 50 microns:

  ```
  gui_zoom -to {100 200} -to_radius 50
  ```

[-physical_db dir_name]
[-profiling_power_file file]
[-top_cell_name topcell_name]
[-tile_thermal_config_file filename]
```

Loading power/rail analysis results into GUI.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `read_power_rail_results` parameter. For a detailed description of the command and all of its parameters, use the man command: `man read_power_rail_results`.
`-cell_library { library1.cl}`	
	Specifies the single cell library that is required to load the state directory. The specified cell library must contain the technology layer information that is required to load the state directory. Therefore, you do not need to load all cell libraries used during analysis. *Data_type*: string, optional
`-custom_value_inst_file_1 file`	
	Specifies the name of the custom value instance file (CVIF). This file can be used to display a user-specified instance voltage file in GUI. The format of the CVIF file is: *value1 instancename1* *value2 instancename2* .... where, *value1* and *value2* are voltage values mapping to the specified instance. You can use the `cvil` argument of the `gui_set_power_rail_display -plot` command parameter to view the EIV map in GUI. *Data_type*: string, optional
`-data_type {rail | all}`	
	Controls the type of data to be loaded in the GUI. The possible arguments of this parameter are: • `rail` - Loads only the rail analysis results. • `all` - Loads both the power and rail analysis results. This is the default value. *Data_type*: enum, optional
`-detail_delta_temperature_file file`	

	Specifies the name of the detailed wire-based delta temperature file from self-heating analysis. *Data_type*: string, optional
`-die_instance_name` *dieinstname*	
	Specifies the name of the die whose results you need to view. This parameter is only applicable to the multi-die analysis flow (`set_rail_analysis_mode -die_mode multi-die`). The `-die_instance_name` parameter must be specified with the `-rail_directory` parameter (multi-die rail directory). *Data_type*: string, optional
`-effective_resistance_file` *file*	
	Specifies the result file from effective resistance analysis (only instance-based result is supported). When the rail analysis plot type `effr` is selected and a result file is specified, the layout shows effective resistance analysis result for each instance. **Note**: Currently, this feature only supports loading one net at a time. *Data_type*: string, optional
`-enable_plots` *plot_names*	
	Specifies the list of power or rail plots names that are to be loaded. *Data_type*: string, optional
`-esd_directory` *dir*	
	Specifies the ESD analysis directory. *Data_type*: string, optional
`-esd_em` *dir*	

	Specifies the name of the directory where the current density/EM results generated by a previous ESD analysis run reside. This parameter allows you to selectively load the required EM result directory if there are multiple ESD EM result directories under the `ESD` directory. You must either load the rail directory (`-rail_directory`) before running this command, or specify the rail directory with the `-esd_em` parameter. *Data_type*: string, optional
`-instances` *instancenames*	
	Specifies a list of instances to load in the GUI. This parameter loads only those partitions that include the specified instances. The `-instances` parameter allows you to analyze parts of the designs, thereby reducing the loading time and memory footprint. The `-instances` parameter is applicable to the Voltus-XP flow only.
`-instance_delta_temperature_file` *file*	
	Specifies the name of the instance-based delta temperature file from self-heating analysis. This is the device instance temperature. *Data_type*: string, optional
`-instance_voltage_method { best | worst | avg | worstavg }`	
	Loads the instance voltage data for the specified EIV computing method. If this parameter is not specified (default), the instance voltage results for all the four methods are loaded. *Data_type*: string, optional
`-instance_voltage_window { timing | whole }`	
	Loads the instance voltage data for the selected EIV window. If this parameter is not specified (default), the instance voltage results for both the timing and switching windows, and the entire rail simulation are loaded. *Data_type*: string, optional
`-nets` *net_names*	

	Loads only the specified nets in the domain-based state directory to the GUI. If this parameter is not specified with the `-rail_directory` parameter, all the nets will be loaded. *Data_type*: string, optional
`-power_db` *file*	
	Specifies the power database file. This file was created by using the `power_write_db` attribute. *Data_type*: string, optional
`-physical_db` *dir_name*	
	Specifies the name of the hierarchical design directory to be loaded to the GUI along with the rail analysis results. *Data_type*: string, optional
`-profiling_power_file` *file*	
	Specifies to display the tile-based power density results generated from the vector profiling flow. *Data_type*: string, optional
`-reset`	
	Frees the loaded analysis state directory or power database from the memory. *Data_type*: bool, optional
`-rail_directory` *dir*	
	Specifies the rail analysis directory. You can load all the domain results by selecting the automatically generated analysis directory under the output directory (`<domain>_<temp>_<dynamic/avg>_#`), or load individual nets by going one level further and selecting the net directory. *Data_type*: string, optional
`-short_file` *file*	

	Specifies the path to the short violations report (`voltus_short.report`) . This file is generated using the `set_rail_analysis_config -report_shorts true` command parameter, and is located in the work directory. *Data_type*: string, optional
`-signal_em_db` *file*	
	Specifies to read the signal electromigration data from the specified database file generated by the `check_ac_limits -report_db` command parameter. *Data_type*: string, optional
`-thermal_file` *filename*`.txt`	
	Specifies to load the tile-based temperature map file generated by Sigrity Celsius to be used for both power calculation and IR drop analysis. The following is an example of reading the thermal map file: `read_power_rail_results -rail_directory output/static_rail/core_25C_avg_1/ -thermal_file output/power_map_by_layer.txt gui_set_power_rail_display -plot thermal` *Data_type*: string, optional
`-tile_delta_temperature_file` *file*	
	Specifies the name of the tile-based delta temperature file of self-heating analysis. This is the worst instance temperature among all wire segments in a tile. This is also layer-based. The FEOL or cell layer is used to show the device instance temperature. *Data_type*: string, optional
`-tile_thermal_config_file` *filename*	

	Specifies to load the configuration file that contains the mapping between the hierarchical levels with corresponding layer-based temperature map files generated by Celsius (system-level thermal analysis tool). When specified, you can view tile-based temperature distribution for each layer of the chip.
	
	The following is the format and example of the configuration file:
	<hierarchy> <block name> <X_tile_no,Y_tile_no> <LEF/DEF Flip/Rotation> <temperature map>
	`TOP DIE 0,0 N /thermal_data/DIE_TemperatureMap`
	`TOP/IP1 IP1 25,50 N /thermal_data/IP1_TemperatureMap`
	`TOP/IP1/B1 B1 50,125 N /thermal_data/B1_TemperatureMap`
	`TOP/IP1/B2 B2 200,125 S /thermal_data/B2_TemperatureMap`
	
	This is a mandatory parameter for the `tile_thermal` plot when loading hierarchical temperature maps.
	
	Data_type: string, optional

`-top_cell_name` *topcell_name*	
	Specifies the name of the top module or top cell name to be loaded. This parameter must be specified with the `-physical_db` parameter. *Data_type*: string, optional

Examples

- The following command specifies the appropriate files needed for viewing the instance voltage and power data:

```
read_power_rail_results\
    -rail_directory analysis/domain_25C_avg_1 \
    -power_db powermeter.db \
```

- The following command specifies to load the VDD and VSS nets for the worst and best EIV methods during the entire simulation:

```
read_power_rail_results -rail_directory dynamic_rail/core_25C_dynamic_1 \
    -nets { VDD VSS } -instance_voltage_window { whole } -instance_voltage_method
{ worst best }
```

- The following command specifies to load only the rail directory:

```
read_power_rail_results -rail_directory dynamic_rail/core_25C_dynamic_1 -data_type
rail
```

- The following command specifies to load the hierarchical database and the rail analysis results to the GUI:

```
read_power_rail_results -rail_directory ./dynamic_rail/latest/ -physical_db
/dma/Dynamic/saveDB -top_cell_name dma_mac
```

- The following command specifies to display the tile-based power density results in the GUI:

```
read_power_rail_results -profiling_power_file
./vectorProfileResults/profile.rpt.density
```

Related Information

- report_power_rail_results
- "Static Power, IRdrop and EM Analysis" in the *Voltus Stylus Common UI User Guide*

read_workspace

```
read_workspace
[-help]
[-dir directory]
-name workspaceName
```

Loads the named workspace from the specified directory. A workspace contains customized main window settings including:

- Size and placement of window
- Specific orientation of toolbars
- Docking status
- Visibility settings

You can use the `read_workspace` command at any stage in the design flow to load a previously saved workspace. However, if you want Innovus to load a specific workspace automatically on starting, you need to first set that workspace as default using the `set_default_workspace` command.

Parameters

`-help`	Prints a brief description that includes type and default information for each `read_workspace` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man read_workspace`
`-dir` *`directory`*	Specifies the directory from which the workspace is to be loaded. The default search order to access directories for loading workspaces is as below: • Current working directory • User home directory The `-dir` parameter is useful if you have workspaces with the same name in both the current working directory and your home directory. If you do not specify `-dir`, the software loads the *`workspaceName`* workspace from the current working directory. *Data_type*: string, optional
`-name` *`workspaceName`*	Specifies the name of the workspace to be loaded. *Data_type*: string, required

Example

The following example loads the `MyWorkspace` workspace from the current working directory.

```
read_workspace -name MyWorkspace
```

report_gui_edit_callback

```
report_gui_edit_callback
[-help]
[-edit_type {selection pre-move post-move}]
[-file string]
```

Reports the callback functions added to the specified move action. In GUI, the move action involves the following three steps:

1. Click an object.
2. Move the object to the new location.
3. Click to place the object at the new location and complete the move.

The callback function is implemented based on the move action specified with the `-edit_type` parameter.

Note that the `report_gui_edit_callback` command does not report the default callback functions.

Parameters

`-help`	Prints the usage of the command. For a detailed description of the command, use the `man` command: `man report_gui_edit_callback`
`-edit_type {selection pre-move post-move}`	Specifies the GUI edit function: • `selection` - Implements the callback function when an object is selected (after Step 1). • `pre-move` - Implements the callback function just before the object is placed at the new location (after Step 2, just before you change the coordinates in Step 3). • `post-move` - Implements the callback function after an object is moved (after Step 3, when the tool updates the DB records). *Data_type*: enum, optional
`-file` *string*	Specifies the name of the file. *Data_type*: string, optional

Examples

Consider the following proc definitions:

```
proc move_callback_1 {
     ...
}
proc move_callback_2 {
     ...
}
proc select_callback_1 {
     ...
}
```

- The following commands add the specified callback functions to the selected object based on the selection and on the post-move operations, as specified below:

```
gui_register_edit_callback -edit_type post-move -command move_callback_1

gui_register_edit_callback -edit_type post-move -command move_callback_2

gui_register_edit_callback -edit_type selection -command select_callback_1
```

- The following command reports all the callback functions on the console:

```
> report_gui_edit_callback

################################
# GUI Callback Function Report
################################
Post Move:
move_callback_1
move_callback_2

Selection:
select_callback_1
```

- The following command prints the callback functions on the post-move operation to the file `cb_move`:

  ```
  report_gui_edit_callback -edit_type post-move -file cb_move
  ```

  The contents of the file is as follows:

  ```
  ##########################################################################

  #  Generated by:      Cadence Innovus 18.10-d133_1

  #  OS:                Linux x86_64(Host ID sjfib212)

  #  Generated on:      Sun Oct  8 19:51:35 2017

  #  Design:            DTMF_CHIP

  #  Command:           report_gui_edit_callback -edit_type post-move -file cb_move

  ##########################################################################

  Post Move:

  move_callback_1

  move_callback_2
  ```

Related Information

- gui_register_edit_callback
- gui_unregister_edit_callback

report_power_rail_results

```
report_power_rail_results
[-help]
[-append]
[-enable_filter_summary]
[-file_name file ]
[-filter_max max_value]
[-filter_min min_value]
[-ignore_limit_bound]
[-layers {All, layer_names } ]
[-limit N ]
[-nets {all | all_pwr | all_gnd | net_names}]
[-plot plot_type]
[-range_max max_value]
[-range_min min_value]
[-region x1 y1 x2 y2]
[-rlrp_inst {instance_name}]
```

Generates RLRP, region-based, and rail/power/capacitance reports.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `report_power_rail_results` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_power_rail_results`.
`-append`	Appends instance reports to the current report file.
`-enable_filter_summary`	
	Displays a summary of the filtered data in the histogram given in the *Summary* tab of the Result Browser form.

`-file_name` *file*	
	Specifies the name of the text based violation report file to be created. The default file name is: • for region-based report: `region_x1_y1_x2_y2.rpt` • for RLRP report: `rlrp_instname.rpt` • for plot-based report: `power_rail_`*plot*`.rpt` *Data_type*: string, optional
`-filter_max` *max_value*	
	Specifies the maximum value to include in the report. Use this option to further filter out the data within the range specified. This is used to obtain statistic of filter range. Optional, but if specified, the `-plot` option is required, and requires both `-filter_min` and `-filter_max` to be specified. *Data_type*: float, optional
`-filter_min` *max_value*	
	Specifies the minimum value to include in the report. Use this option to further filter out the data within the range specified. This is used to obtain statistic of filter range. Optional, but if specified, the `-plot` option is required, and requires both `-filter_min` and `-filter_max` to be specified. *Data_type*: float, optional
`-ignore_limit_bound`	
	Specifies to ignore the maximum upper limit of `10000`, and instead use the higher value given with the `-limit` parameter for specifying the number of data points to be printed in the power/rail report. *Data_type*: bool, optional
`-layers {all,` *layer_names* `}`	

	Specifies the layers to be reported. You can use `all` for reporting all layers, or list the specific layers that are to be reported. If this parameter is specified, you must specify the `-plot` parameter. *Data_type*: string, optional
`-limit` *N*	
	Specifies the number of data points printed in the report. If this parameter is specified, you must specify the `-plot` parameter. *Default* : first `1000` data points *Data_type*: float, optional
`-nets {all | all_pwr | all_gnd |` *net_names*`}`	
	Specifies the nets to be used for analysis reporting. You can use `all` for reporting all nets, `all_pwr` for reporting all power nets, `all_gnd` for reporting all ground nets, or list the specific nets that are to be reported. If this parameter is specified, you must specify the `-plot` parameter. This parameter also allows you to specify the switched and always-on nets to be used for analysis reporting. The following is the use model to generate a report for the specified switched net: `report_power_rail_results -plot ir -nets {`*switchedNetName*`}` The following is the use model to generate a report for the specified always-on net, including its switched nets: `report_power_rail_results -plot ir -nets {`*alwaysOnNetName*`}` **`-all`** You must specify `-all` to include all switched nets associated with the specified always-on net. *Data_type*: string, optional
`-plot` *plot_type*	
	Plots the specified plot type. See Plot Types for a description of each of the plot types. *Data_type*: enum, optional
`-range_max` *max_value*	

	Specifies the maximum value to report. Optional, but if specified, the `-plot` option is required, and requires both `-range_min` and `-range_max` to be specified. *Data_type*: float, optional
`-range_min` *min_value*	
	Specifies the minimum value to report. Optional, but if specified, the `-plot` option is required, and requires both `-range_min` and `-range_max` to be specified. *Data_type*: float, optional
`-region` *x1 y1 x2 y2*	
	Measures tap current and capacitance information in the specified region defined by x1, y1, and x2 y2 coordinates, and prints results in the log file. *Data_type*: rect, optional
`-rlrp_inst` *instance_name*	
	Reports the RLRP path for the specified instance. The default file name of the RLRP path report is `<`*rlrp_instname*`.rpt>`. You can modify the file name using the `-file_name` parameter. *Data_type*: string, optional

Plot Types

Plot Type	Description

`ac`	Available/feasible capacitance (Farad) Displays the feasible decoupling capacitance that can be added in the area. The feasible capacitance in the area is calculated based on the filler cells placement. The program matches the placed filler cells with the decap cells available in the power-grid library and computes the feasible capacitance. The capacitance of the decap cell is stored in the power-grid library.
`activity`	Displays the worst activity for the output and inout pins of every instance.
`cap`	Grid capacitance (Farad) Plots the capacitance of the extracted power-grid network.
`dd`	Decoupling capacitance (decap) density (Farad/um ^{2}) Plots decap density of the design. The decap density is the cell internal decoupling capacitance in the unit area (µm ^{2}).
`dr`	Decoupling capacitance required Reports the decoupling capacitance required to fix dynamic IR-drop violations. This option suggests how much decap needs to be added in a given area to fix the IR-drop violations. The voltage threshold used to determine the IR-drop violations for this analysis is the value specified by the `-threshold` option of the `set_pg_nets` command.
`ivdn`	Instance Voltage Drop (Volts) – net-based Plots the net-based instance voltage drop.
`ivdd`	Instance Voltage Drop (Volts) – domain-based Plots the domain-based instance voltage drop. For domain based, at least one power and one ground net must be selected.
`fd`	Filler cell density (1/µm ^{2}) Displays the filler cell density per unit area (µm ^{2}). The plot can be used to analyze the feasibility of adding decap cells by replacing the filler cells and not changing the placement of the logic cells.

`freq`	Frequency domain (Hz) Displays the associated clock frequency of all instances in the design. The instances associated with multiple clock domains are displayed using the fastest clock frequency. This plot can be used to analyze and debug the power distribution in the design.
`ip`	Instance total power (mW) The total power consumed by each instance is displayed. The total power is the sum of the internal, switching and leakage power of the instance. The power data is read from the power database and can be specified using the `-power_db` option or it is queried directly from memory, if power calculation is run during the session.
`ip_i`	Instance internal power (mW) The power consumed by charging and discharging of the internal interconnect and device capacitances of the instance.
`ip_l`	Instance leakage power (mW) The power consumed by devices when not switching.
`ip_s`	Instance switching power (mW) The power consumed by charging and discharging of the interconnect or output load.
`ipd_i`	Specifies internal power density in mW/um ^{2} .
`ipd_l`	Specifies leakage power density in mW/um ^{2} .
`ipd_s`	Specifies switching power density in mW/um ^{2} .
`ipd_t`	Specifies total power density in in mW/um ^{2} .
`ip_tr`	Displays toggle rates for all instances. The toggle rate for an instance is calculated as the average of toggle rates of all outputs of the instance. This plot allows you to determine the design area that toggles more than the others.

`ir`	IRdrop or voltage drop (Volts) Displays the IRdrop across each extracted power-grid segment in the design.
`jrms`	Specifies current density as j/jmax based on the Irms current. This plot is only supported for dynamic analysis. A jrms gif file will be saved in the state directory that shows where the Irms based EM violation occurred. This plot type allows you to verify the analysis results of "jrms" using the GUI.
`load`	Loading capacitance (Farad) Displays the output loading capacitance driven by the instance. This plot can be used to analyze and debug the regions with high switching power.
`pi`	Power-switch (gate) current violation: I/Idsat Displays the ratio of current through the power-switch and the saturation current (Idsat) of the power-switch. This plot can be used to analyze and debug whether the current through power-switches exceeds the saturation current characterized for the power-switch devices. The saturation current and on-resistance of the power-switches are characterized and stored inside the power-grid library of the power-switch cell. A ratio of greater than 1 means that the current requirement of the power-gated block can not be met with placed power-switch instance. Either the power-switch needs to be made larger or power-switch instances need to be added.
`pv`	Voltage drop across power-switch (Volt) Displays the IRdrop across power-switch instances. This plot can be used to analyze and debug the IRdrop inside the power-gated block, e.g. if the IRdrop across power-switches is already high, the IRdrop inside the power-gated block will be much higher. In this case, the power-switch placement will have to be refined in order to resolve the IRdrop problem.

`rc`	Resistor current (Amp) Displays the current across power-grid resistor segments. This plot can be used to analyze and debug how the current flows from the voltage sources into the rest of the design, e.g. high current should flow from pads to the top-level routing level layers and then to the lower level metal layers. This plot can also be used to debug current density violations (`rj`).
`rlrp`	The total resistance of the instance along the least resistive path. Displays the total resistance of the instance along the least resistive path, meaning the resistance of the instance along the path from where it gets the most amount of current. This plot can be used to analyze and debug the power-grid integrity early in the design stage. An instance with high resistance is likely to have high static or dynamic IRdrop depending on the vector that is simulated later in the design cycle. This plot can be also used during decap optimization, since regions with high dynamic IRdrop and high resistance may not be improved upon by adding decaps, because the effectiveness of decoupling capacitance depends on the resistance of the power-grid network. You can also highlight the least resistive path of the instance using the GUI and selecting the instance with left mouse button. The *RLRP Path* checkbox should be enabled.
`res`	Displays the total resistance of the least resistive path from each node to voltage source. This plot can be used to view high resistance regions of the power-grid. It is useful during IRdrop and decap analysis to identify weak power-grid connectivity.
`rj`	Resistor current density, J/Jmax. Displays the current density (current per unit area) violation on each power-grid segment using the ratio of calculated current density and maximum allowed current density. A ratio of greater than 1 means that the current density limit of the segment is violated. The current density limits are supplied by the foundry and can be read during analysis using the `set_rail_analysis_mode -em_models` command.
rs	Specifies the plot type for resistor sensitivity.

`slack`	Instance slack (Seconds) Displays worst instance slack. The slack data is queried from either the timing database or if the power database is specified using `-power_db` option, then the worst slack data is read from the power database. When using an external TWF, the slack data is read from the TWF.
`tc`	Tap current (Amp) Displays the current consumed by the instance devices or current taps. During rail analysis, it is based on the power consumption of the instance and is distributed inside the cell. The current distribution inside the cell is based on the extracted device netlist stored inside the power-grid library of the cell. The current distribution is generally based on the device width, length, and spice models. This plot can be used to analyze and debug IRdrop inside the macro.
`td`	Transition density (Hz) Displays the worst transition density (activity * frequency) of the instance. This plot can be used to analyze and debug activity distribution and high power density regions.
`tpd`	Displays power density map with user-specified grid size.
`unc`	Unconnected segments Displays power-grid segments that are disconnected from the voltage source (power pads). This plot can be used to debug unusually high IRdrop in the region.
`vc`	Voltage source current (Amp) Displays current through the voltage sources (power pads). This plot can be used to analyze the current carrying capacity of the power-pad.
`vu`	Voltage drop across package (Volt) Displays voltage drop across package. If analysis is run with package model attached to the power pads, this plot displays the IRdrop due to package RLCK elements.

Examples

- The following command will report the worst 100 IR segments on Metal 1 of the VDD net:
  ```
  report_power_rail_results -plot ir -layers M1 -limit 100 -nets VDD
  ```
- The following command will report the IR drop of the VDD_ring switched net:
  ```
  report_power_rail_results -plot ir -net {VDD_ring}
  ```
- The following command will report the IR drop of the VDD_AO always-on net, including its switched nets:
  ```
  report_power_rail_results -plot ir -net {VDD_AO} -all
  ```
- The following command filters the data such that it does not display the data points below 200 in the Result Browser histogram:
  ```
  report_power_rail_results -plot ivdd -filter_min 200 -enable_filter_summary
  ```

- "Static Power, IRdrop and EM Analysis" in the *Voltus Stylus Common UI User Guide*

set_default_workspace

```
set_default_workspace
[-help]
[-dir directory]
-name workspaceName
```

Sets specified workspace as the default. The default workspace is loaded automatically when the software starts. So if you want Innovus to load a workspace automatically at startup, you need to first save it as default.

Parameters

`-help`	Prints a brief description that includes type and default information for each `set_default_workspace` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man set_default_workspace`
`-dir` *`directory`*	Specifies the location of the workspace to be set as default. *Data_type*: string, optional
`-name` *`workspaceName`*	Specifies the name of the workspace to be set as default. *Data_type*: string, required

Example

The following example sets the `TestWorkspace` workspace in the current working directory as default.

```
set_default_workspace -name TestWorkspace
```

Related Information

- `delete_workspace`
- `read_workspace`
- `write_workspace`
- Windows Menu chapter of the *Menu Reference*
    - *Workspaces*

view_last

```
view_last [-help]
```

Displays the last view window or the previous view. This command provides the same function as the Zoom Previous icon (bindkey *w*).

Parameters

`-help`	Prints a brief description of the `view_last` command. For a detailed description of the command, use the `man` command: `man view_last`.

Related Information

- `gui_zoom`
- `view_next`
- The Main Window chapter in the Menu Reference

view_next

`view_next [-help]`

Displays the next view window. This command provides the same function as the *Next* toolbar widget. You can use the `view_next` command or the *Next* toolbar widget to switch from the current display to the next location in the *Go To Saved Area* list or the next zoom level in the zoom sequence saved in the design memory. The equivalent bindkey is `Y`. When you press the `Y` bindkey or execute the `view_next` command repeatedly, the tool cycles through all saved views (saved areas and zoom levels).

Parameters

`-help`	Prints a brief description of the `view_next` command. For a detailed description of the command, use the `man` command: `man view_next`.

Related Information

- `gui_zoom`
- `view_last`
- The Main Window chapter in the Menu Reference

write_color_preference

```
write_color_preference
[-help]
[-dir <string>]
-file_name <string>
[-include_custom]
```

Writes color preferences for the Innovus main display as specified in the Color Preferences form.

Parameters

`-help`	Prints a brief description that includes type and default information for each `write_color_preference` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_color_preference`
`-dir` *string*	Specifies the directory path. By default, the color preference file is saved in the current directory. *Data_type*: string, optional
`-file_name` *string*	Specifies the name of the color preference file. *Data_type*: string, required
`-include_custom`	Includes the settings in the Customize Tab form within the Color Preferences form. *Data_type*: bool, optional

Related Information

- `set_preference`
- The Main Window chapter of the Menu Reference
  - *Color Preferences*
- View Menu chapter of the Menu Reference
  - *All Colors*

write_hinst_colors

`write_hinst_colors [-help] out_file`

Saves the current color setting for a hierarchical instance from the Module Color Preference form to a file. The Module Color Preference form is accessed by clicking *Floorplan - Edit Floorplan - Color Module*.

Parameters

`-help`	Prints a brief description that includes type and default information for each `write_hinst_colors` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_hinst_colors`.
`out_file`	Specifies the name of the file that stores 30 color settings starting with the `set_layer_preference` command. This is the same behavior as the *Save* button on the Module Color Preference form. *Data_type*: string, required

Example

The following command saves the current color setting for a hierarchical instance from the Module Color Preference form to a file named `hinstColorFile`:

```
write_hinst_colors hinstColorFile
```

Related Information

- `gui_clear_hinst_colors`

- `gui_set_select_hinst_color`
- `write_color_preference`
- Floorplan Menu chapter in the *Menu Reference*
    - *Color Module*

write_to_gif

`write_to_gif [-help] out_file`

Saves a snapshot of the current screen to a GIF file with the specified name in the current directory. You can use this command at any stage of the design flow.

Parameters

`-help`	Prints a brief description that includes type and default information for each `write_to_gif` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_to_gif`.
`out_file`	Specifies the name of the output file as a string. *Data_type*: string, required

Example

The following example captures the current screen and saves it to *`test1.gif`* in the current directory.

```
write_to_gif test1.gif
```

Related Information

- `gui_create_floorplan_snapshot`
- `gui_write_picture`
- `gui_write_flow_gifs`
- Tools Menu chapter of *Menu Reference*
  - *Write To GIF File*

write_workspace

```
write_workspace
[-help]
[-dir directory]
-name workspaceName
```

Saves the named workspace to the specified directory. You can then load the workspace whenever you want from the specified directory by using the `read_workspace` command. A workspace contains customized main window settings including:

- Size and placement of window
- Specific orientation of toolbars
- Docking status
- Visibility settings

Parameters

`-help`	Prints a brief description that includes type and default information for each `write_workspace` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_workspace`
`-dir directory`	Specifies the directory in which the workspace is to be saved. *Default*: Current working directory *Data_type*: string, optional
`-name workspaceName`	Specifies the name of the workspace to be saved. *Data_type*: string, required

Example

The following example saves the current window settings to the `TestWorkspace` in the current working directory.

```
write_workspace -name TestWorkspace
```

commit_module_model

```
commit_module_model
[-help]
[-copy_mmmc_latencies]
[-merged_mmmc_map_file mapFiles]
[-merged_mmmc_sdc_files mergedSdcFiles]
[-mmmc_file fullChipSdc]
[-mmmc_module_model_tag modelTag]
[-propagate_clocks]
[-cpf_file filename | -1801 filename]
```

Commits module models.

Parameters

`-1801 filename`	Specifies IEEE 1801 file. *Data_type*: string, optional

`-copy_mmmc_latencies`	Copies clock latencies of all analysis views at the top-level design and applies them after assembling the design:
	When this option is specified, the command will do following after assembling the design:
	`foreach view [all_analysis_views] {`
	`update_analysis_view -name $view -latency_file $latency_map($view)`
	`}`
	Where `latency_map` has clock latency files for all views.

`-cpf_file filename`	Specifies the name of the full chip CPF file to be used. *Data_type*: string, optional

`-help`	Outputs a brief description that includes the type and default information for each `commit_module_model` parameter. For a detailed description of the command and all of its parameters, use the man command: `man commit_module_model`
`-merged_mmmc_map_file` *mapFiles*	Specifies merge hierarchical mmmc map files. *Data_type*: string, optional
`-merged_mmmc_sdc_files` *mergedSdcFiles*	Specifies SDC files for different dies. *Data_type*: string, optional
`-mmmc_file` *fullChipSdc*	Specifies the name of the full chip MMMC view file. *Data_type*: string, optional
`-mmmc_module_model_tag` *modelTag*	Specifies MMMC module model tag. *Data_type*: string, optional

`-propagate_clocks`	Changes clock ideal to propagated clock. When this option is specified, you can run the following commands:
	`set_interactive_constraint_modes [all_constraint_modes -active]`
	`set_propagated_clock [all_clocks]`

Related Information

- `set_interactive_constraint_modes`
- `set_propagated_clock`

create_ilm_from_files

```
create_ilm_from_files
[-help]
[-cell block_name]
[-incremental]
-model_type {timing | cts | si}
[-overwrite]
[-si_timing_window_file xtwf_file.spef]
{-out_dir directory_name | -oa_cellview lib cell view}
[-verilog_file cell_name.v [-cell_prefix cell_prefix -uniquify_netlist]]
[-sdc_file file_name -timing_view view_name]
[-spef_file spef_file.spef -rc_corner RC_corner_name]
[-opt_stage stage]
```

Creates an ILM directory from existing data. It can only create non-merged models. This command is useful in situations where an ILM is to be created through external inputs or using data from third party models into a format that could be recognized by Innovus.

If the data files already exist in the specified directory, the tool stops and generates an error message. You can overwrite existing files by specifying `-overwrite`. You can add files to the directory by specifying `-incremental`.

The command also creates a tcl script (cell_name_ILM.tcl) that you can source in your command file. The script contains the following command:

```
read_ilm -cell cell_name -out_dir dir_name
```

Parameters

`-cell` *block_name*	Specifies the name of the block. *Data_type*: string, required
`-cell_prefix` *cell_prefix*	Specifies the cell prefix. *Data_type*: string, optional
`-oa_cellview` *lib cell view*	Specifies the library name, cell name, and view name in the OpenAccess database format. *Data_type*: string, optional

`-opt_stage` *stage*	Specifies the optimization stage, preCTS or postCTS. *Data_type*: string, optional
`-out_dir` *dir_name*	Stores the ILM data in the specified directory: the absolute directory path or the path relative to the current directory. *Data_type*: string, optional
`-incremental`	Lets you add files in addition to the existing files to the directory. *Data_type*: bool, optional
`-model_type {timing | cts | si}`	Specifies the type of ILM model, i.e timing, cts or si,. *Data_type*: enum, required
`-help`	Outputs a brief description that includes the type and default information for each `create_ilm_from_files` parameter. For a detailed description of the command and all of its parameters, use the man command: man `create_ilm_from_files`.
`-overwrite`	Overwrites existing files in the directory. *Data_type*: bool, optional
`-rc_corner` *RC_corner_name*	Specifies the RC corner name for MMMC analysis. It identifies the specified corner to be used with -spef_file. *Data_type*: string, optional
`-sdc_file` *file_name*	Specifies an existing .sdc file that you want to include in the directory. It identifies the sdc file to be used with the specified view. *Data_type*: string, optional

`-spef_file` *`spef_name`*`.spef`	Specifies an existing .spef file that you want to include in the directory. It identifies the spef file to be used with the specified corner. *Data_type*: string, optional
`-timing_view` *`view_name`*	Specifies the view name for the ILM module. It identifies the specified view to be used with `-sdc`. *Data_type*: string, optional
`-uniquify_netlist`	Uniquifies the input Verilog netlist. This ensures that there are no errors when ILMs are being loaded. Using this parameter, each sub-module for an ILM has a unique name, which is composed of the time stamp and its original name. For example, in top_sm WedJun31138212009$data_path, top_sm specifies the top-level design, WedJun31138212009 specifies the time stamp, and $data_path specifies the original module name. *Default*: `Off` *Data_type*: bool, optional
`-verilog_file` *`netlist_name`*`.v`	Specifies the verilog file you want to include in the ILM data directory. *Data_type*: string, optional
`-si_timing_window_file` *`xtwf_file.spef`*	Specifies the .xtwf file that you want to include in the directory. *Data_type*: string, optional

Examples

- The following commands create two module directories:

  ```
  create_ilm_from_files -cell blk1 -out_dir A -model_type timing -verilog_file V1.v
  -spef_file 1.spef -rc_corner corner1 -sdc_file sdcfile1 -timing_view view1

  create_ilm_from_files -cell blk2 -out_dir A -model_type si -verilog_file V2.v -
  spef_file 2.spef -rc_corner corner2 -sdc_file sdcfile2 -timing_view view2
  ```

- The command creates two tcl files in the current directory. The `blk1_ILM.tcl` file contains the following command:

  ```
  read_ilm -out_dir A -cell blk1
  ```

  The `blk2_ILM.tcl` file contains the following command:

  ```
  read_ilm -out_dir A -cell blk2
  ```

Related Information

- `read_ilm`

flatten_ilm

```
flatten_ilm
[-help]
```

Flattens the interface logic models (ILMs) at the top level so that the entire design can be analyzed at the top. When you use this command, the software switches from blackbox view to ILM view.

If you do not run `flatten_ilm`, the ILM netlist will not be visible to the Innovus software. You can switch between the ILM view and the blackbox view using the `flatten_ilm` and `unflatten_ilm` commands.

All super commands such as `time_design`, `place_design`, and `opt_design` flatten the ILMs internally and hence no explicit `flatten_ilm` is required. However, you should use this command for other timing related commands. For example, for the `report_timing` command, you need to run `flatten_ilm` before reporting timing. It would not work in the unflattened mode.

Example:

```
flatten_ilm

report_timing
```

Parameters

`-help`	Outputs a brief description that includes the usage of the `flatten_ilm` command.

Related Information

- `opt_design`
- `place_design`
- `report_timing`
- `time_design`
- `unflatten_ilm`
- Top-level Timing Closure Methodologies chapter of the *Innovus Stylus Common UI User Guide*.

get_ilm_type

```
get_ilm_type
[-help]
[-model]
```

Displays the model type set using `set_ilm_type`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `get_ilm_type` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man get_ilm_type`
`-model`	Outputs the model type. *Data_type*: bool, optional

Examples

- The following example displays the current setting for the `-model` parameter:

  ```
  get_ilm_type -model
  ```

  The software displays the following information:

  ```
  timing
  ```

Related Information

- `set_ilm_type`

ilm Category Attributes

The root attributes in the ilm category are:

- ilm_filter_internal_path
- ilm_keep_async
- ilm_keep_flatten
- ilm_keep_high_fanout_ports
- ilm_keep_inst_in_sdc
- ilm_keep_loopback
- ilm_max_num_insts
- ilm_max_num_registers
- ilm_slack_driven

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `ilm` category, use the following command:

```
get_db -category ilm
```

ilm_filter_internal_path

```
ilm_filter_internal_path {true|false}
```

Default: `false`

Data_type: bool, read/write

When set to true, group paths are created for internal paths with slack adjustment of 9999. Therefore, all internal paths are filtered out from the timing report.

Related Command

- `write_ilm`

ilm_keep_async

```
ilm_keep_async {true|false}
```

Default: `false`

Data_type: bool, read/write

Keeps paths from asynchronous input ports when ILMs are created by `write_ilm`. For example, paths from an input port to the reset pin of interface sequential instances, but not to the internal sequential instances.

Related Command

- `write_ilm`

ilm_keep_flatten

```
ilm_keep_flatten {true|false}
```

Default: `true`

Data_type: bool, read/write

Makes flow work under the flattenIlm mode

ilm_keep_high_fanout_ports

```
ilm_keep_high_fanout_ports {true|false}
```

Default: `true`

Data_type: bool, read/write

Keeps high-fanout input port paths when ILMs are created by `write_ilm`.

Related Commands

- `write_ilm`

ilm_keep_inst_in_sdc

`ilm_keep_inst_in_sdc {true|false}`

Default: `false`

Data_type: bool, read/write

Keeps instances which have constraints on it.

Related Command

- `write_ilm`

ilm_keep_loopback

`ilm_keep_loopback {true|false}`

Default: `false`

Data_type: bool, read/write

Keeps loop back paths when ILMs are created by `write_ilm`.

When set to `true`, then any path touching a net used for the ILM model is also included. This is done for better model accuracy, so that the actual capacitance on an output port could affect the delay on a net which feeds an internal path that is normally not included in the ILM model. This also degrades the reduction ratio (`#ILM_insts/#all_inst`) for the block.

Related Commands

- `write_ilm`

ilm_max_num_insts

`ilm_max_num_insts` *`maxInstances`*

Default: `1000`

Data_type: int, read/write

Specifies the maximum number of instances.

ilm_max_num_registers

```
ilm_max_num_registers maxRegisters
```

Default: `40`

Data_type: int, read/write

Specifies the maximum number of registers.

ilm_slack_driven

```
ilm_slack_driven {true|false}
```

Default: `false`

Data_type: bool, read/write

Specifies slack driven ILM generation.

opt_cloud_design

```
opt_cloud_design
[-help]
{-pre_cts -post_cts}
[-block_type {all flexIlm}]
[-cloud_dir directory]
[-cloud_type {sdc lib reverseIlm}]
[-out_dir directory]
[-prefix prefix]
[-partition_list list_of_partitions | -area {x1 y1 x2 y2} | -top_only  | -block_only ]
```

Provides the ability to optimize chip-level design. It supports three different optimization methods:

- **ReverseILM**: It is a model that represents the design of a particular partition block plus the pushed-down top-level clock network and I/O logics path that made up the “cloud”. With reverseILM technology, tool can make the logic changes inside the partition block but logics that are outside the block design are read-only. The behavior is reverse or opposite to ILM.
- **Color SDC**: It generates SDC for each master/clones, then define a new mode (named with color) to include all the SDCs for master/clones.
- **Rainbow cloud**: It generates new lib and new modes for each master/clones to include more accurate information for optimization

⚠ This command is a limited-access feature in this release. It is enabled by a variable specified using the `set_limited_access_feature` command. To use this feature, contact your Cadence representative to explain your usage requirements, and make sure this feature meets your needs before deploying it widely.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `opt_cloud_design` parameter. For a detailed description of the command and all of its parameters, use the man command: `man opt_cloud_design`

`{-pre_cts -post_cts}`	Specifies the opt_design stage. *Data_type*: enum, required
`-area {x1 y1 x2 y2}`	Specifies area coordinates for area optimization. *Data_type*: string, optional
`-block_only`	Optimizes at the block-level only. *Data_type*: bool, optional
`-block_type {all flexIlm}`	Specifies the block model type. By default, full block-level netlist will be used for the top-level optimization. Otherwise, the flexILM model will be used. *Default*: `all` *Data_type*: enum, optional
`-cloud_dir` *directory*	Specifies the directory to save the cloud opt data. *Data_type*: string, optional
`-cloud_type {sdc lib reverseIlm}`	Specifies the cloud model type. Use sdc, lib, or reverseIlm for color SDC, rainbow cloud, or reverseIlm optimization techniques, respectively. *Default*: `lib` *Data_type*: enum, optional
`-out_dir` *directory*	Specifies the directory to save the report file. *Data_type*:
`-prefix` *prefix*	Specifies the prefix for the report file. *Data_type*: string, optional
`-partition_list` *list_of_partitions*	Specifies the list of partition names that will be optimized at their block-level designs before optimizing the top-level design. *Data_type*: string, optional
`-top_only`	Optimizes at the top-level only. *Data_type*: bool, optional

Related Information

- place_cloud_design

place_cloud_design

```
place_cloud_design
[-help]
[-dir working_directory]
[-no_pre_place_opt]
```

Runs Hierarchical Timing Closure Flow with the reverseILM placement.

The Hierarchical Timing Closure Flow:

- Honors predefined partition fence and module definition
- Uses reverseILM technology to enable pin-less and budget-less flow for the block placement
- Supports distributed placement for quick TAT

⚠ This command is a limited-access feature in this release. It is enabled by a variable specified using the `set_limited_access_feature` command. To use this feature, contact your Cadence representative to explain your usage requirements, and make sure this feature meets your needs before deploying it widely.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `place_cloud_design` parameter. For a detailed description of the command and all of its parameters, use the man command: `man place_cloud_design`
`-dir working_directory`	Specifies the working directory. *Data_type*: string, optional
`-no_pre_place_opt`	Disables the pre-place optimization. *Data_type*: bool, optional

Related Information

- opt_cloud_design

read_ilm

```
read_ilm
[-help]
{[-cell cellName [-directory dirName]] | -oa_cellview lib cell view}
```

Specifies ILM data directory for the specified block. You can run `read_ilm` multiple times in the same session. Each time you specify `read_ilm`, the software overwrites the previous setting for the block. If master/clones exist in the design, the cell name will have the name of the master partition.

Note: You can use this command only if the ILMs are unflattened (`unflatten_ilm`) or the design is in black box view. You cannot change ILM settings in flattened or ILM view.

The syntax is order-dependent. You must specify `-cell` before you specify `-directory`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `read_ilm` parameter. For a detailed description of the command and all of its parameters, use the man command: `man read_ilm`
`-cell` *`cellName`*	Specifies the block name. *Data_type*: string, optional
`-oa_cellview` *`lib cell view`*	Specifies the library name, cell name, and view name in the OpenAccess database format. *Data_type*: string, optional
`-directory` *`dirName`*	Specifies the directory for the files you want to read. *Data_type*: string, optional ⚠ For OA flow, the `-directory` option is not required and `read_ilm` is used as follows: `read_ilm -cell pll_fbdiv` The flow automatically finds the OA path when the `-directory` for `read_ilm` is not set.

Examples

- The following commands create ilms and specify ilms for an OA design:

```
#create ilms for each block
write_ilm -oa_cellview {OA_PTN_LIB tdsp_core abstract}
write_ilm -oa_cellview {OA_PTN_LIB results_conv abstract}
#specify ilms in top level
read_ilm -cell tdsp_core
read_ilm -cell results_conv
```

- The following commands specifies directory `dir_dsp_core` for block `tdsp_core`, and directory `dir_onemore` for block `onemore`:

```
read_ilm -cell tdsp_core -directory dir_dsp_core
read_ilm -cell onemore -directory dir_onemore
```

- The following commands show how to reset the ILM directory from `dir_tdsp_core` to `dir2_tdsp_core`:

```
read_ilm -cell tdsp_core -directory dir_tdsp_core
read_ilm -cell tdsp_core -directory dir2_tdsp_core
```

  These commands are equivalent to the following commands, which include `reset_ilm`:

```
read_ilm -cell tdsp_core -directory dir_tdsp_core
reset_ilm -cell tdsp_core
read_ilm -cell tdsp_core -directory dir2_tdsp_core
```

Related Information

- `reset_ilm`
- `unflatten_ilm`
- `write_ilm`

report_ilm_status

```
report_ilm_status
[-help]
```

Reports ILM status information including ILM block names, ILM data locations, and if the design is in the flattened or unflattened state.

You can use this command at any time in the flow, but it only reports ILM information if you have already specified ILMs in the design.

Parameters

`-help`	Outputs a brief description of the `report_ilm_status` command. For a detailed description of the command, use the man command: `man report_ilm_status`

Example

The following command generates the ILM status report for `dtmf_recvr_core`:

```
@[DEV]ilmView 2> report_ilm_status

================================================================================
Current design: dtmf_recvr_core
Current view is ILM (after flatten_ilm)
Current ILM data is for si mode.
================================================================================

Cell                      Model-Type       Use-Type       Stage       Instance Name
--------------------------------------------------------------------------------
results_conv                 All             ILM           -          RESULTS_CONV_INST
tdsp_core                    All             ILM           -           TDSP_CORE_INST

ILM/flexILM Data Location :
--------------------------------------------------------------------------------
results_conv : .../libs/ilm/results_conv.ilm
tdsp_core : .../libs/ilm/tdsp_core.ilm
================================================================================
```

Related Information

- reset_ilm
- unflatten_ilm
- write_ilm

reset_ilm

```
reset_ilm
[-help]
-cell cellName
```

Unspecifies the ILM cell.

This is used to unspecify a previously specified ILM. This would be useful in situations where ILMs are to be removed from the design, to put them in non-ILM or black box mode.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `reset_ilm` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reset_ilm`
`-cell` *`cellName`*	The name of the block to unspecify. *Data_type*: string, required

Related Information

- `reset_ilm`
- `unflatten_ilm`
- `write_ilm`

set_ilm_type

```
set_ilm_type
[-help]
[-model {timing si}]
```

Controls the behavior of commands in the presence of ILMs.

ILM models can be an SI model or a non-SI model. In the flow, sometimes an explicit `flatten_ilm` needs to be performed to perform the underlying operation. Based on the nature of operation, an appropriate model could be invoked/switched with the above command.

Use the `get_ilm_type` command to display the current settings for the `set_ilm_type` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_ilm_type` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_ilm_type`.
`-model {timing si}`	Specifies the ILM model that is to be used by the `flatten_ilm` command. All the timing-related commands require data to be in the flattened state (physical command require unflattened state). Design commands such as `opt_design` and `time_design` automatically set this parameter before flattening ILMs. However, the CTE commands and some clock commands, which can be run in the flattened mode require manual settings. • Use the `si` model for flattening the SI ILM model. • Use the `timing` model for flattening the non-SI related timing commands. *Default*: `timing` *Data_type*: enum, optional

Examples

- The following command can be used to get timing reports containing the SI push-out delays on nets using the `-set_ilm_type -model` command:

```
set_ilm_type -model si

# Flattens to SI model

flatten_ilm

# Turns on SI aware delay calculation

set_db delaycal_enable_si true

# Adds increemental delay column (for SI push-out delays)
#  in timing output:

set_global_report_timing_format {instance arc cell fanout load slew delay
incr_delay arrival}

# Minimizes the width of the report such that it easily
# fits into the screen without wrapping

set_table_style -name report_timing -no_frame -indent 0

report_timing
```

Note: You can also invoke the Global Timing Debugger (*Timing - Debug Timing - Generate*)

Related Information

- flatten_ilm
- get_ilm_type
- opt_design
- time_design

unflatten_ilm

```
unflatten_ilm
[-help]
```

Reverts the ILM back to its original hard macro view.

You can use this command after the `flatten_ilm` command.

Note: `unflatten_ilm` will take no effect if the design is already in the unflattened mode.

Many physical commands would not work in the flattened mode. They would need to be unflattened before performing the operation.

For example:

```
flatten_ilm

report_timing

unflatten_ilm
```

Parameters

`-help`	Outputs a brief description that includes the usage of the `unflatten_ilm` command.

Example

The following command flattens all partitions and their ILM designs to the top-level. After reporting timing, the design is reverted back to the unflattened state with the `unflatten_ilm` command.

```
flatten_ilm

report_timing

unflatten_ilm
```

Related Information

- `flatten_ilm`
- Top-level Timing Closure Methodologies chapter of the *Innovus Stylus Common UI User Guide*.

update_partition

```
update_partition
[-pin_location]
[-post_eco_suffix postECOSuffix]
{-flex_ilm_eco}
{-golden_block_dir directory}
-flex_ilm_dir directory
[-eco_dir directory]
[-full_netlist_with_eco_dir directory -flex_ilm_eco_dir directory]
```

Creates a new partitioned output that contains the optimized blocks and top. It also performs ECO on the original block. The ECO output is saved as new Innovus database in the partitioned block. The ECO would happen only on `flexILM` partitions and not the regular blocks.

Parameters

`-eco_dir` *directory*	Specifies the scratch directory for partitioning and running distributed ECO job after optimization. *Data_type*: string, optional
`-flex_ilm_dir` *directory*	Specifies the new partitioned output directory containing optimized blocks/top and ECO results. *Data_type*: string, optional
`-flex_ilm_eco`	Performs ECO on FlexILM modules. **Note:** This is default. *Data_type*: bool, optional
`-flex_ilm_eco_dir` *directory*	Specifies the postOpt FlexILM data directory. *Data_type*: string, optional
`-full_netlist_with_eco_dir` *directory*	Specifies the directory to store full netllist ECO result. *Data_type*: string, optional
`-golden_block_dir` *directory*	Specifies the golden database directory for individual blocks. *Data_type*: string, optional
`-pin_location`	Updates new partition pin locations into the golden block DB. This option does not allow new added logic ports. *Data_type*: bool, optional
`-post_eco_suffix` *postECOSuffix*	Specifies the suffix name that will be part of generated postECO DB name. *Data_type*: string, optional

write_ilm

```
write_ilm
[-help]
[-allow_ilm_eco]
[-ignore_ports ListOfPorts]
[-keep_all]
[-keep_selected]
[-model_type {timing si all}]
[-no_inter_clock_path]
[-overwrite]
[-remove_power_ground]
[-to_dir dirName  | -oa_cellview {lib | cell | view}]
[ [-opt_stage {prects postcts}] ]
```

Creates the specified directory containing ILM files with the appropriate level of extraction for specific model type such as timing, si, or for all models. For MMMC, ILM models will be generated based on constraint modes.

The `write_ilm` command creates a reduced set of instances representing only the interface paths, that is, paths from the I/O ports of the design to the first level of sequential instances (latches are considered sequential elements).

The command automatically modifies the module name with the following rule:

```
topModuleName+timestampl+$+moduleName
```

Parameters

`-help`	Outputs a brief description that includes type and default information for each `write_ilm` parameter. For a detailed description of the command and all of its parameters, use the man command: `man write_ilm`
`-allow_ilm_eco`	Allows ECO changes within the ILM block.
`-ignore_ports` *ListOfPorts*	Specifies list of ports where these ports and the associated interface path(s) which are starting or ending at these ports will not be included in the ILM model. *Data_type*: string, optional

`-keep_all`	Preserves the complete logic of block and hence does not do any logic pruning based on constraints or path groups. **Note:** Since the complete logic is preserved, so all the ILM views, that is, timing, CTS, and SI share the same model data. *Data_type*: bool, optional
`-keep_selected`	Preserves all selected instances and nets (in addition to those normally kept) when you create ILMs. Selected instances are those instances that drive the selected nets. You can select instances or nets using the `select_obj` command, then use `write_ilm -keep_selected`. By default, no additional instances and nets are preserved. *Data_type*: bool, optional
`-model_type {timing | si | all}`	Specifies the type of ILM model to be created. Default: `all` • `all`: Ensures that all models are written. • `timing`: Ensures that only the timing model is written for non-SI based timing, optimization, or clock tree commands. • `si`: Ensures that only the SI model is written that can be used for the SI based timing and optimization commands. *Data_type*: enum, optional
`-no_inter_clock_path`	Minimizes the clock latency at the upper-level CTS when the non-boundary flop in ILM has the maximum clock latency.
`-oa_cellview {lib | cell | view}`	Specifies OA cell view information for generated ILMs. The `-oa_cellview` option cannot be used in non-OA flow. For non-OA flow, you use the `-to_dir` option instead. *Data_type*: string, optional
`-overwrite`	Overwrites existing files. *Data_type*: bool, optional

`-opt_stage {preCTS | postCTS}`	Specifies the optimization stage, preCTS or postCTS. This option should be specified both for ILM and flexILM creation. *Data_type*: enum, optional
`-remove_power_ground`	Removes PG ports, PG nets, PG pin connections, and replaces PG net connections on signal pins with 1'b1 or 1'b0 .
`-to_dir` *dirName*	Specifies the output directory name where ILMs file will be saved. If the design is not an OA design, this option must be specified. *Data_type*: string, optional

Examples

- The following command generates both timing model and SI model in directory BlockA:
  `write_ilm -dir BlockA`
- The following command only generates timing model and saves it in directory BlockA:
  `write_ilm -dir BlockA -model_type timing`

Note: In the current ILM flow, SDC constraints originally specified against the complete flat netlist for the design get filtered when being applied against the ILM view of the design.

Note: The ilm Category Attributes also affect the instances that `write_ilm` command will preserve to model the block.

Sample Summary Report

The following is a sample summary report generated at the end of the `write_ilm` command:

```
-------------------------------------------------------------

Model                Reduced Instances         Reduced Registers

ilm_data             7153/7621 (93%)              174/285 (61%)
si_ilm_data          6793/7621 (89%)              160/285 (56%)
-------------------------------------------------------------
```

In this report, the reduction ratio in the `ilm_data` model is 93 percent which means that 7153 out the total 7621 instances for this block have been eliminated. Only 468 instances are written to the Verilog netlist for the `ilm_data` model out of which 111 instances are registers.

This summary report applies to a block using MMMC. Therefore, views with worst reduction ratio are displayed for each model.

Note: You can run the following commands for improving the reduction ratio:

```
set_db ilm_keep_high_fanout_ports false
```

Related Information

- `ilm Category Attributes`
- `read_ilm`
- "Creating ILMs for Shared Modules" in the Top-level Timing Closure Methodologies chapter of the *Innovus Stylus Common UI User Guide*.

read_ilm_eco_db

```
read_ilm_eco_db
[-help]
{-dir directoryName | -module_model_tag tagName}
```

Reads an ECO file after restoring a block-level design for non-iHDB flow.

- For iHDB flow, you should use `read_module_model -add_ons {eco}` command to read the ECO file. Internally, `reread_module_model -add_ons {eco}` will source `<cellName>_eco.tcl` script that internally calls the `read_ilm_eco_db -module_module_tag` command.
- For non-iHDB flow, if you use `write_ilm_eco_db -module_model_tag`, you should use `read_ilm_eco_db -module_model_tag` to read an ECO file at block-level design.

Parameters

`-help`	Outputs a brief description of the `read_ilm_eco_db` command. For a detailed description of the command, use the man command: `man read_ilm_eco_db`
`-dir` *directoryName*	Specifies the directory name to write the ILM eco database. At the block-level design, if you use this command to read in the ECO changes, the command will automatically find out about the design name and only load/read the ECO file for this specific design.
`-module_model_tag` *tagName*	Specifies the tag name to use for iHDB. Use this option if `write_ilm_eco_db -module_model_tag` is used to save ECO file(s).

Related Topics

- read_module_model
- write_ilm_eco_db

write_ilm_eco_db

```
write_ilm_eco_db
[-help]
-cell tcl_obj]
{-dir directoryName  | -module_model_tag tagName}
```

Saves netlist and placement information changes::

- Generates a binary ECO file that can be read/loaded back to a block-level design
- Generates the ECO TCL script with `read_ilm_eco_db -module_model_tag` for iHDB
- Output as corresponding ECO report file for viewing purpose

Parameters

`-help`	Outputs a brief description of the `write_ilm_eco_db` command. For a detailed description of the command, use the man command: `man write_ilm_eco_db`
`-cell` *`tcl_obj`*	Specifies a cell name for ECO information to be written out. If the specified cell name does not have any ECO change, both ECO and report files will be empty. If this option is not specified, the command will write ECO information for all ILMs specified in the design EVEN an ILM cell is not allowed for ECO. This to make sure accumulated ECO information will be preserved/saved as an ILM can be opened and then closed later during the flow. If there is no ECO change done to a particular cell, its ECO and report files will be empty.
`-dir` *`directoryName`*	Specifies a directory name where ECO files will be saved. All the ECO and/or report files should be saved under the convention *`dirName/cellName/cellName.eco`* and *`dirName/cellName/cellName.rpt`*, respectively.
`-module_model_tag` *`tagName`*	Specifies the model tag name where ECO file, ECO TCL, and its report will be saved. This option should be used for Stylus hierarchical DB.

add_route_via_defs

```
add_route_via_defs
-help
[ -ndr_only ]
```

This command is used to auto-generate vias required by nanoroute for the default and non-default rules (NDRs). The vias are based on the wire-widths of the routing-rule and are created to meet all the DRC via enclosure rules with variations for good pin-access, variations of double-cut vias for good double-cut via utilization, and min-area vias required for stacked-vias that have no route connected to meet the min-area metal rule.

The command only creates vias in the current Innovus session; they are not saved and restored for usage in a later Innovus session. So this command is normally only used for experimentation, or possibly if you just want temporary extra DFM vias to be used for this one session. If you want to save the vias for usage by nanoroute in later Innovus sessions, use `add_route_vias_auto true`. The command is not set to "on" by default as add_route_vias Category attributes are set to `false` by default.

The command requires correct DRC rules (e.g. enclosure, spacing, minimum-cut, min-area rules, etc), and at least one LEF VIARULE GENERATE statement (or OpenAccess standardViaDef) for every via layer used for routing (as required by OpenAccess). The cut enclosure values in the VIARULE GENERATE statement are not used except for old LEF technology files (LEF version 5.5 and older) that have no enclosure rules (this is not recommended usage, but is kept for backward compatability). The VIARULE cut-spacing values are ignored–only the DRC cut-spacing values are used.

No predefined vias are required (e.g LEF VIA DEFAULT, or NONDEFAULTRULE USEVIA or an OpenAccess validVias list for any routing ConstraintGroup are not needed).

Any predefined vias that do exist, are kept unless `add_route_vias_ [delete_via_before_generation` is used (see below). Generated vias are compared to predefined vias and if they are geometrically identical, that specific generated via is not kept so no duplicate vias are created.

Note: NDRs that have the same widths as the default rule will inherit the same vias, including any pre-defined vias.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `add_route_via_defs` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man add_route_via_defs`.
`-ndr_only`	Specifies vias generation for non-default rules only. When specified, it generates signal routing vias for all NDR (non-default rules) and skips generating via for default rule. It is always used for designs having full set of default rule vias, but not sufficient non-default rule vias. *Data_type*: bool, optional

Example

- `add_route_via_defs`
  Will add auto-generated vias to any existing vias for all routing rules.
- The following command generates vias for all NDRs, including the NDRs created by create_route_rule command.
  ```
  add_route_via_defs -ndr_only
  ```
  You must use `add_route_vias_auto true` and `add_route_vias_ndr_only true` in the Innovus flow.

Related Information

- `write_via_defs`
- `generate_special_via Category Attributes`

add_route_vias Category Attributes

The root attributes in the `add_route_vias` category are:

- add_route_vias_auto
- add_route_vias_ndr_only

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `add_route_vias` category, use the following command:

```
get_db -category add_route_vias
```

add_route_vias_auto

```
add_route_vias_auto {true | false}
```

Default: `false`

Data_type: bool, read/write

Enables auto via generation when design is loaded. The option is of type bool.

add_route_vias_ndr_only

```
add_route_vias_ndr_only {true | false}
```

Default: `false`

Data_type: bool, read/write

Generates vias for non default rules only.

check_design

```
check_design
[-help]
[-out_file fileName]
{[-type {library netlist power_intent timing hierarchical pin_assign budget assign_statements place
opt cts route signoff all}]
[-no_check ]}
```

Checks that all prerequisites to run all or part of the hierarchical or block implementation flow are met.

The `check_design` command checks the preconditions for major flow steps before they are run. If there are errors identified by `check_design`, the current script will stop. A complete list of errors is dumped to `-out_file`.

Some examples of problems that will cause design checks to fail include:

- Cells used in the design that cannot be legally placed
- Tracks misaligned with some or all cell pins
- In advanced processes, power nets that cannot be colored in the expected pattern once cells are placed
- Cell rows that are unblocked for placement but where pin layers are obstructed
- Cell rows that are unusable due to orientation and power rail misalignment
- Cells instantiated in the netlist that have no timing model defined
- Tracks blocked by power grid spacing constraints
- Instances not covered by a true timing path in any view
- ILM model with no clock tree defined
- No hold fixing cells are specified and delay cells are not usable
- No clock inverters, buffers, clock gates or logic cells are specified and the library cells are not usable for clock trees
- CTS cannot balance all skew groups without increasing insertion delay
- Preserved nets and cells in the clock tree that will violate other constraints because they cannot be resized or buffered.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `check_design` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man check_design`.
`-type`	

-type

Specifies the category of the flow to be checked.

The intent is to run `check_design` before each of the operation in the list, such as run `check_place -place` before placement to make sure there are no issues that would cause issues during placement. Each of the categories run several checks related to that operation.

- `library`: Checks the library integrity and corrects binding of all design instances to library cells or RTL modules (hinst → module, inst → base_cell/lib_cell).
  - For physical_only library, check_design will flag libcells that have only LEF but no .lib representation.
  - For logical_only library, check_design will flag libcells that have only .lib but no LEF representation.
  - For unresolved library, check_design will check if design instance is missing binding (hinst → module, inst → base_cell/lib_cell)
- `netlist`: Checks the netlist integrity at any point in the flow.
  - For undriven netlist, check_design will check the list of input/inout hpins/pins with no driver on the net connected to it (driver can be input port or output hpin/pin).
  - For multiple_driver netlist, check_design will check the list of input/inout pins or output/inout ports with more than one driver on their net)
  - For unloaded netlist, check_design will check the input/inout ports or output hpins/pins with no load (input/inout pins) in their fanout or hinsts/insts that have nothing connected to any output pin)
  - For constant netlist, check_design will check the output ports or input pins/hpins that are driven by a logical constant 0/1.
  - For feedthrough netlist, check_design will check the hinsts, where every output pin is directly driven by an input pin, w/o any logic in between).
- `power_intent`: Checks related to MSV setup including power domain/fence checks. .
- `timing`: Performs checks related to timing setup integrity. This check is run prior to running any operation that requires timing information. **Note**: The `check_timing` command should still be used for more exhaustive timing checks.
- `hierarchical`: Performs checks related to the hierarchical flow. This type checks if a partition has a fence. If not, it will give an error. It also checks if the partition fence is outside the core boundary. If it is outside, the check will give an error. This check is run before running hierarchical design operations.
- pin_assign: Checks related to pin assignment for partitioning flows. This check is run before pin assignment.
- `budget`: Checks related to time budgeting for partitioning flows. This check is run before timing budgeting.
- `assign_statements`: Performs checks for the netlist for assign statements. This check is run

	before exporting a netlist for signoff. • `place`: Checks related to placement such as PG rail alignment, pin access issues, missing followpin in the rails of standard cells, misaligned well tap cell, and missing termination cell. This check is run before placement. • `opt`: Checks related to optimization such as checks for available cells. This check is run before optimization. • `cts`: Checks related to clock tree definition such as constraint targets and route types. This is run before cts but after creating the clock tree spec. This check cannot run with pre-cts Innovus DB (just after place_opt_design). You need to set CCOpt option (target skew, target trans, etc) and also need to load the CCOpt spec file. • `route`: Checks related to routing such as congestion, placement, and pin access issues. The `-type` route cannot be run with pre-placed DB. This check is run before routing. It is useful to run check_drc ahead of time so the design markers are up to date. • `signoff`: Checks related to the signoff activities including extraction and ECOs. This check is run before TSO. To use this types, you need to set the Tempus path, else the tool will give an error. • `all`: Checks related to all categories. **Note**: `-type` or `-no_check` is required (except when using `-help` argument) *Data_type*: (enum)+, required
`-no_check`	Just echo out all the messages that would be checked, don't do any checks Do not run the checks but echo the checks that would run per the categories provided by the user. *Data_type*: bool, required
`-out_file` *fileName*	Specifies the output report file. Contents dumped to this file are in the Tcl format. Sourcing this file will create a TCL dictionary of the violations found by `check_design`. *Data_type*: string, optional

Examples

- The following example shows the usage of the `-out_file` option:

```
> check_design -type "place cts route" -out_file checks.tcl
```

- check_place
- check_timing

check_unique

```
check_unique
[-help]
[-verbose]
```

Checks the uniqueness of the netlist. Certain features, such as clock tree synthesis and IPO, require a module (a non-leaf cell) to be instantiated only once. If the netlist is unique, the result is `1`; otherwise, the result is `0`.

You can use the `check_unique` command after importing a design.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `check_unique` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man check_unique`.
`-verbose`	Displays the names of modules instantiated more than once. *Data_type*: bool, optional

Example

The following command checks the uniqueness of the netlist and displays the names of any modules instantiate more than once:

```
innovus 4> check_unique -verbose
```

The sample output is as shown below:

```
Non-leaf cell A instantiated 2 times.
0
```

Related Information

- `check_netlist`

compare_def

```
compare_def
[-help]
in_file
[-ignore_cell_place lef_macro_classes_list [-check_cell_prefix prefix_list]]
[-ignore_layer_from layer]
[-ignore_layer_to layer]
[-ignore_logic_change]
[-place_blockage]
[-report_file in_file]
[-row]
[-special_net_pin]
[-unit units_value]
[-bump]
[-def_as_golden]
[-metal_shape_only]
```

Compares a DEF file with the physical design data in the Innovus database and reports any differences. For example, after you perform an Engineering Change Order (ECO) and make changes to a DEF file, you can use the `compare_def` command to compare the new file to the information stored in the Innovus database.

You can use the `compare_def` command after importing a design.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `compare_def` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man compare_def`.

`-bump`	Checks only bump-related objects, such as bump and areaio instance in the COMPONENTS section, bump assignment, and special routing in the SPECIALNETS section.The information reported includes: • Added, moved, and deleted bumps • Added, changed, and deleted routing • Added, changed, and deleted net assignments **Note:** When this option is specified, `compare_def` suppresses checks on default objects, such as standard cells and blocks, and only checks bump-related objects. *Data_type*: bool, optional
`-check_cell_prefix` *prefix_list*	Checks instances whose instance name begins with the specified prefix. You can use this parameter only if you also specify the `-ignore_cell_place` parameter. If you specify more than one prefix, you must enclose the list in braces, for example, `{CORE PAD}`. Default: All LEF `MACRO` classes specified by the `-ignore_cell_place` parameter are ignored. *Data_type*: string, optional
`-def_as_golden`	Treats the DEF file as the golden file when comparing the DEF file to the data in the database. By default, the software compares the DEF to the data in the database and reports the differences relative to the database. For example, `ADDINST` in the report file means the instance is not in the database, but in the DEF file. When you specify `-def_as_golden`, the software reports the differences relative to the DEF file. Therefore, if the instance is not in the database, but is in the DEF file, `DELINST` is written in the report file. *Data_type*: bool, optional

in_file	Specifies the name of the DEF file you want to compare with the physical design data in the database. *Data_type*: string, required
-ignore_cell_place *lef_macro_classes_list*	Ignores the specified cell classes, for example {CORE PAD}. *Data_type*: string, optional
-ignore_layer_from *layer*	Ignores the specified metal or cut layer, and all metal and cut layers above. You can specify this parameter with the -ignore_layer_to parameter to select a layer range. You must specify metal layers as M1, M2, M3, and so on, and cut layers as V1, V2, V3, and so on. *Default:* All layers are compared. *Data_type*: (layer), optional
-ignore_layer_to *layer*	Ignores the specified metal or cut layer, and all metal and cut layers below. You can specify this parameter with the -ignore_layer_from parameter to select a layer range. You must specify metal layers as M1, M2, M3, and so on, and cut layers as V1, V2, V3, and so on. *Default:* All layers are compared. *Data_type*: (layer), optional
-ignore_logic_change	Ignores logic changes when comparing a DEF file with the physical design data in the Innovus database. *Data_type*: bool, optional
-metal_shape_only	Without the option, the command will report the same routing segment or via with one pair of line as difference - one with "ADDWIRE/ADDVIA" and one with "DELWIRE/DELVIA" - in the report file if it is on a different net or if its routing type has changed from special to regular or vice versa between db and def file. With the option, the command will not report such difference in report file. *Data_type*: bool, optional

`-place_blockage`	Compares placement blockage and block halo equivalence. *Data_type*: bool, optional
`-report_file` *in_file*	Specifies the name of the report containing the results of the comparison. *Default:* `defPhyDiff.rpt` *Data_type*: string, optional
`-row`	Compares row and site equivalence, name, location, and orientation. *Data_type*: bool, optional
`-special_net_pin`	Compares snet pins. *Data_type*: bool, optional
`-unit` *units_value*	Uses the specified `UNITS` value (typically, the `UNITS` value in the DEF file) to scale all distance values in the report file. *Default:* Uses the current database unit (DBU) value in the database, derived from the LEF information, to scale distance values. *Data_type*: string, optional

Example

- The following command compares data in the `myDEF` file with that in the database, and writes the results to `myResultsFile.rpt`:

  ```
  compare_def myDEF -report_file myResultsFile.rpt
  ```

- The following command checks rows, placement blockages, and block halos in `myDEF`. This example checks all instances except class `CORE` and `PAD`; however, it checks `CORE` and `PAD` cells whose instance name prefix is `PRE`. This example also checks all wires and vias except for those on and between layers `M2` and `M6`, and writes the comparison results to `myResultsFile.def`.

  ```
  compare_def -row -place_blockage -ignore_cell_place {CORE PAD} -check_cell_prefix PRE -
  ignore_layer_from M2 -ignore_layer_to M6 -report_file myResultsFile.def myDEF
  ```

create_pin_text

```
create_pin_text
[-help]
[-format {assura dracula pvs}]
pin_text_file_name
{[-nets { nets… } ]
[-cells { cells … } ]}
[-layer_map fileName ]
[-format {assura dracula pvs}]
[-layer_map fileName]
[-offset {x y}]
{{[-nets nets…] [-cells cells …]} pin_text_file_name}
```

Generates a file containing pin text information for nets and cells. You can read this file into Layout Versus Schematic (LVS) tools such as Dracula® and Assura™ for debugging problem areas.

You can use the `create_pin_text` command after you have finished placing, routing, and verifying your design in Innovus.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `create_pin_text` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_pin_text`.
`-cells` *cells …*	Specifies the list of leaf-level cells or top cell for which the pin text information is to be generated. The list of cells can be specified within braces or quotes. Additionally, pin text information can be output for all the cells using `"*"`. The `x y` values generated for the pin text are coordinates in user units local to the cell. You should not specify this parameter with the `-nets` parameter if you want to use this file with Dracula; however, you can specify both parameters if you use Assura or a third-party LVS tool. *Data_type*: string, optional
`-format {assura dracula pvs}`	Specifies the output format. *Data_type*: enum, optional

`-layer_map` *fileName*	Specifies the name of the file that contains the mapping between LEF layers and layers defined in the LVS tool. The layer map file has the following format: `LEF_LAYER_NAME VERIF_LAYER_NAME` If you do not specify this parameter, Innovus assumes that the LEF layer names and LVS layer names are identical. *Data_type*: string, optional
`-nets` *nets…*	Lists the name of the nets for which you want to generate pin text. You cannot use a wildcard (`*`) to specify all nets. You must use braces to enclose the list of nets. You should not specify this parameter with the `-cells` parameter if you want to use this file with Dracula; however, you can specify both parameters if you use Assura or a third-party LVS tool. *Data_type*: string, optional
`-offset {x y}`	Changes the design origin by -offset x y. *Data_type*: point, optional
pin_text_file_name	Specifies the pin text output file name. For information about the output file format see the Examples section below. *Data_type*: list, required

Examples

- The `create_pin_text` command creates a file containing one line of data for each cell or net you specify. The line has the following format:

  `name X= x Y= y ATTACH= verif_layer_name cell_name`

  The elements are:

name	Specifies the net name (from the `-nets` parameter) or pin name (from the `-cell` parameter).
`X=` *x* `Y=` *y*	Specifies the x and y coordinates for the pin text.
`ATTACH=` *verif_layer_name*	Specifies the layer name used in the LVS tool.

cell_name	Specifies the cell name. The default is the top cell name.

- The following command creates a file, `pins.txt`, containing pin text information for `clk1` and `VDD`:

  ```
  create_pin_text -nets {clk1 VDD} pins.txt
  ```

  The output file would resemble the following:

  ```
  clk1 X=0.0 Y=10.0 ATTACH=metal1 top_cell

  VDD X=-10.0 Y=-10.0 ATTACH=metal2 top_cell

  VDD X=20.0 Y=20.0 ATTACH=metal3 top_cell
  ```

- The following command creates a file, `hedtext.txt`, for cells `block1` and `block2`:

  ```
  create_pin_text -cells {block1 block2} hedtext.txt
  ```

  The output file would resemble the following:

  ```
  pin1b1 X=0.0 Y=0.0 ATTACH=metal1 block1
  pin2b1 X=1.0 Y=1.0 ATTACH=metal2 block1
  ```

  and so on, until all pins for `block1` are listed. Coordinates are local to `block1`.

  ```
  pin1b2 X=0.0 Y=0.0 ATTACH=metal2 block2
  pin2b2 X=1.0 Y=1.0 ATTACH=metal2 block2
  ```

  and so on, for all pins for `block2`.

- The following command creates a file, `pins.txt`, containing pin text information for `clk1`, `clk2`, and `rst` pins of the top cell `myTopCell`:

  ```
  create_pin_text -nets {clk1 clk2 rst} -cells {myTopCell} pins.txt
  ```

  The output file would resemble the following:

  ```
  clk1 X=204.27 Y=157.64 ATTACH=METAL2 myTopCell
  clk2 X=152.13 Y=0.28 ATTACH=METAL2 myTopCell
  rst X=0.33 Y=167.72 ATTACH=METAL2 myTopCell
  ```

create_tracks

```
create_tracks
[-help]
-direction direction
-layer layerNameList
-num numOfTrack
-start coordinate
-step step
```

Creates non-uniformed, customized tracks in selected design area. Typically, the routing grid is generated when the floorplan is initialized. The first track is located at an offset from the placement grid set by the OFFSET value for the layer in the LEF file. The track spacing is the PITCH value for the layer defined in LEF.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `create_tracks` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man create_tracks`.
`-direction` *direction*	Specifies track direction as a string. *Data_type*: string, required
`-start` *coordinate*	Specifies the starting coordinate to create the track. The unit for the coordinates is user unit (micron). *Data_type*: float, required
`-num` *numOfTrack*	Specifies the number of tracks to create for the grid. You cannot specify `0 numtracks`. *Data_type*: int, required
`-step` *step*	Specifies the spacing between the tracks. *Data_type*: float, required
`-layer` *layerNameList*	Specifies the routing layer used for the tracks. You can specify more than one layer. *Data_type*: string, required

Related Information

- add_tracks
- check_tracks
- delete_tracks

delete_tracks

```
delete_tracks
[-help]
[-direction {X|Y}]
[-layer layerNameList]
```

Deletes a set of tracks in the database. Without arguments, it deletes all the tracks in the database.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `delete_tracks` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_tracks`.
`-direction {X|Y}`	Specifies the direction of the track to be deleted. X indicates vertical lines; Y indicates horizontal lines. *Data_type*: string, optional
`-layer layerNameList`	Specifies the routing layer on which the tracks to be deleted. You can specify more than one layer. *Data_type*: string, optional

Example

- The following command deletes all the tracks in the database:
  ```
  delete_tracks
  ```

design Category Attributes

The root attributes in the design category are:

- design_backside_bottom_routing_layer
- design_backside_top_routing_layer
- design_bottom_routing_layer
- design_compressed_pg_db
- design_cong_effort
- design_dual_rail_via_pitch
- design_early_clock_flow
- design_express_route
- design_high_freq_interposer_flow
- design_ignore_followpin_vias
- design_merge_trim_shapes
- design_power_effort
- design_flow_effort
- design_process_node
- design_pessimistic_mode
- design_slack_weighting_method
- design_tech_node
- design_top_routing_layer
- design_trim_grid_group

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `design` category, use the following command:

```
get_db -category design
```

design_backside_bottom_routing_layer

`design_backside_bottom_routing_layer` *layerName*

Default: ""

Data_type: string, read/write

Specifies the highest backside LEF layer name for global and detail routing.

design_backside_top_routing_layer

```
design_backside_top_routing_layer layerName
```

Default: ""

Data_type: string, read/write

Specifies the lowest backside LEF layer name for global and detail routing.

design_bottom_routing_layer

```
design_bottom_routing_layer layerName
```

Default: ""

Data_type: bool, read/write

Specifies the lowest LEF layer name for global and detail routing.

For a special partial routing on the first routing layer in certain nodes, the routing enablement of that layer must be a global decision in the entire flow of the design. For example, if M0 or M1 routing is enabled, you need to set `set_db -design_bottom_routing_layer M0/1` from the init step. This bottom routing layer setting must not be changed in later stages of the flow.

design_compressed_pg_db

```
design_compressed_pg_db {true | false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether the compressed PG feature is enabled. When it is set to `true`, `read_db` will automatically compress the PG data while loading the design. You can use `get_db current_design .is_pg_compressed` to check if PG in the design is compressed.

design_cong_effort

```
design_cong_effort {low medium high auto}
```

Default: `auto`

Data_type: enum {low medium high auto}, read/write

Specifies the congestion effort level.

design_dual_rail_via_pitch

```
design_dual_rail_via_pitch min_via_pitch min_filler_via_pitch cell_boundary_spacing
```

Default: `""`

Data_type: string, read/write

This attribute is used when two horizontal power-rails on the first and third routing layer are used for standard-cells, and the min-spacing of stacked-vias between the dual-rails is controlled during placement and routing.

- *`min_via_pitch`*: It is the minimum center-to-center pitch of the stacked-vias touching any active standard-cell (not a filler cell).
- *`min_filler_via_pitch`*: It is the minimum center-to-center pitch of the stacked-vias touching only filler cells.
- *`cell_boundary_spacing`*: Specifies how close a PIN or OBS shape must be to the cell boundary to block a stacked-via in the power rail at that point.

The placer makes sure that there is room for a stacked-via as required, the global routers estimate the congestion cost before the stacked-vias are created, and the power-router adds them during the followpin routing as required.

design_early_clock_flow

```
design_early_clock_flow {true | false}
```

Default: `false`

Data_type: bool, read/write

Enables the early clock flow.

design_express_route

```
design_express_route {true | false}
```

Default: `false`

Data_type: bool, read/write

With "-flowEffort express", should routing-stage be forced.

design_high_freq_interposer_flow

```
design_high_freq_interposer_flow {true | false}
```

Default: `false`

Data_type: bool, read/write

Specifies the flow as a high frequency interposer flow. When set to `true`, `set_integration_route_constraint` will auto turn off the options which are not suitable for interposer routing.

design_ignore_followpin_vias

```
design_ignore_followpin_vias {true | false}
```

Default: `false`

Data_type: bool, read/write

Directs the detailed placer, optimization, and signal routing to ignore any special_via with the followpin shape. You can use this attribute if the two bottom routing layers both have a horizontal routing direction, and you use dual power-rails on those two layers on top of each other for the standard-cell power rails.

In this usage, other commands and options will add as many special_via as possible between the power-rails, and remove any special_via that cause spacing violations between the sViaInst cut shapes and any cell or signal routing cut shapes. This gives the placer and router more freedom to get higher density, run faster, but still put as many special_via as possible between the dual power-rails.

When set to true, followpin vias are ignored during detailed placement, optimization, and routing.

design_merge_trim_shapes

```
design_merge_trim_shapes {{layers layer_name_list gap gap_value max_merge_num number_of_max_merge ma
sks {mask_num ...}} ...}
```

Default: `""`

Data_type: string, read/write

Specifies the setting for trim shapes merge.

- `layers`: You use this t specify the trim layer list which needs to merge trim shapes.
- `Gap`: You use this setting when the end to end gap is less the value.
- `max_merge_num`: You use this to specify the max trim shapes number that are merged.
- `masks`: You use this to specify the trim shapes color that needs to be merged.

design_power_effort

```
design_power_effort {none low high}
```

Default: `none`

Data_type: enum {none low high}, read/write

Specifies the effort to reduce the dynamic and leakage power. The tradeoff between dynamic and leakage power can also be controlled.

- `none`: No power optimization is performed and power is not considered during timing optimization.
- `low`: Power is considered during timing optimization and power optimization is performed in all flow stages.
- `high`: Additional algorithms are used to minimize power consumption. Turnaround time with this option will be longer than using `low` or `none`.

design_flow_effort

```
design_flow_effort {express standard extreme}
```

Default: `standard`

Data_type: enum {express standard extreme}, read/write

Guides the effort of every super-command.

- express: Configures the flow to give the best turnaround time with good WNS/area correlation as compared to the standard flow. The flow is appropriate for prototyping.
- `standard`: Configures the flow to give the best overall combination of quality of results and full-flow turnaround time. This flow is appropriate for the majority of designs.
- `extreme`: Configures the flow to give the best quality of results at some cost in turnaround time. This flow is appropriate for designs where timing closure is challenging.

design_process_node

```
design_process_node ProcessTechnologyValue
```

Default: `90`

Data_type: int, read/write

Specifies the process technology value to set for all the applications. Units in nanometers (nm).

design_pessimistic_mode

```
design_pessimistic_mode {true false}
```

Default: `false`

Data_type: bool, read/write

Specifies that the delay calculation compatibility mode should be used for correlating to external signoff analysis tools. This mode adjusts delay calculation settings to ensure the best match to the third party engine while maintaining a degree of pessimism to help limit optimistic outliers in the external signoff analysis tool.

design_slack_weighting_method

```
design_slack_weighting_method {unity_weighting view_based_weighting}
```

Default: `unity_weighting`

Data_type: enum {unity_weighting view_based_weighting}, read/write

Specifies slack weighting to be used in the implementation flow.

design_tech_node

```
design_tech_node{N22|N12|N10|N7|N7Plus|N6|N5|N5PlusPlus|N4|N3|N3E|N2|S11|S10|S8|S7|S5|S4|S3|S2|G7|G5
|ICF|I7|I5|P1277|P1278|P1280|C12|C7|unspecified}
```

Default: `unspecified`

Data_type: enum {N22|N12|N10|N7|N7Plus|N6|N5|N5PlusPlus|N4|N3|N3E|N2|S11|S10|S8|S7|S5|S4|S3|S2|G7|G5|ICF|I7|I5|P1277|P1278|P1280|C12|C7|unspecified}, read/write

Sets the design technology node.

The node value is normally automatically set by `read_physical` while loading the LEF technology and the tool prints a message mentioning the auto-detected node. However, if the auto-detection does not work, you will see a message like this:

```
## Check design process and node:
## Both design process and tech node are not set.
```

In such cases, you will need to set the value directly using `design_process_node` and `design_tech_node`.

design_top_routing_layer

```
design_top_routing_layer layerName
```

Default: `""`

Data_type: string, read/write

Specifies the highest LEF layer name for global and detail routing.

design_trim_grid_group

```
design_trim_grid_group groupName
```

Default: `""`

Data_type: string, read/write

Specifies the group name of the set from which the trim metal grid will be used for placement and routing. If the specified group name does not exist in LEF, the tool will return an ERROR.

See the LEF documentation on the TRIMMETALTRACK keyword for more details.

disconnect_dangling_port

```
disconnect_dangling_port
[-help]
[-keep_input]
[-keep_output]
[-keep_inout]
[-partition_only]
```

Disconnects dangling nets from ports in the whole design, from the top level to the bottom level. Use `report_dangling_ports` to report the dangling ports.

You can use the `disconnect_dangling_port` command after importing a design.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `disconnect_dangling_port` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man disconnect_dangling_port`.
`-keep_input`	Keeps the input dangling port connected. *Data_type*: bool, optional
`-keep_output`	Keeps the output dangling port connected. *Data_type*: bool, optional
`-keep_inout`	Keeps the inout dangling port connected. *Data_type*: bool, optional
`-partition_only`	Disconnects dangling nets in partitions only. *Default:* Disconnects all dangling nets. *Data_type*: bool, optional

Example

- The following command disconnects dangling wires in partitions only:

```
disconnect_dangling_port -partition_only
```

- The following set of commands first reports the dangling ports and then disconnects them:

```
innovus > report_dangling_ports -outfile danglingport.rpt
```

  Sample content of the file `danglingport.rpt`:

```
Port sel of module user_DFT_inst_BandA_0
Port a of module user_DFT_inst_BandA_0
Port b of module user_DFT_inst_BandA_0
Port y of module user_DFT_inst_BandA_0

innovus > disconnect_dangling_port
Port sel of module user_DFT_inst_BandA_0 is disconnected...
Port a of module user_DFT_inst_BandA_0 is disconnected...
Port b of module user_DFT_inst_BandA_0 is disconnected...
Port y of module user_DFT_inst_BandA_0 is disconnected...
4 connected dangling ports are disconnected.
```

Related Information

- report_dangling_ports

Import and Export Without Category Attributes

The root attributes in the design category are:

- ignore_max_via_stack_rule
- read_write_lef_check_uncolored_shapes
- write_def_stream_check_uncolored
- write_lec_files
- write_lec_directory_naming_style
- write_lec_dft_constraints
- write_lef_abstract_customer_header

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

ignore_max_via_stack_rule

```
ignore_max_via_stack_rule {true | false}
```

Default: `false`

Data_type: `boolean`, `read/write`

The tech lef file contains `MAXVIASTACK` syntax by default. You can use `ignore_max_via_stack_rule` to turn off `MAXVIASTACK` syntax checking. When `ignore_max_via_stack_rule` is set to `true`, the `MAXVIASTACK` rule in the tech lef file is ignored.

read_write_lef_check_uncolored_shapes

```
read_write_lef_check_uncolored_shapes {pin_only | on | off}
```

Default: `off`

Default: enum, read/write

Specifies whether to check for uncolored LEF PIN and OBS shapes on multi-mask routing layers when reading or writing LEF files. If the check is on, LEF read or write commands will error out if there are any uncolored routing layer shapes (cut layers are not checked). If set to `pin_only`, only check LEF PIN shapes and ignore LEF OBS shapes.

- During `write_lef_abstract`, if the tool finds any uncolored physical pin and if `read_write_lef_check_uncolored_shapes` is set to `on`, the tool will print an error message, and will not

write out uncolored shapes to the LEF file. However, if `read_write_lef_check_uncolored_shapes` is set to `off`, the tool will not check the uncolored object and dump all physical pins into the macro lef. In this case, the tool does not print any error message.

- When the tool reads the LEF file and finds any uncolored macro pin, and if `read_write_lef_check_uncolored_shapes` is set to `on`, the tool will print an error message and only read colored shapes into the design. However, if `read_write_lef_check_uncolored_shapes` is set to `off`, the tool will not check the uncolored object and will read the definition of all macros into the design. In this case, the tool does not print any error message.

When read_write_lef_check_uncolored_shapes is set to `auto`, the tool automatically turns on the checking feature for N5 or N3 tech node.

The `read_write_lef_check_uncolored_shapes` attribute controls the behavior of following commands or flow:

- `write_lef_abstract`
- `read_db` and init design flow
- `update_lef_macro`

`read_write_lef_check_uncolored_shapes` does not impact `write_lef_library` and read/write oa tech.

write_def_stream_check_uncolored

```
write_def_stream_check_uncolored {true 1 false 0 metal_only}
```

Default: `false`

Data_type: enum, read/write

`true` above N5 nodes and `metal_only` for N5 and below nodes

Specifies how to check and ignore uncolored shapes on DPT layers during DEF out and stream out.

- `true 1`: `write_def` and `write_stream` will go through all wires/vias/physical pins first. If the related layer has the definition for the "MASK" and "SAMEMASK" rules, tool checks the object if a color should be assigned.
- `false 0`: Ignores to check the uncolored object.
- `metal_only`: Only checks the color on the metal (including wires, physical pins, and top/bottom layer of vias).

write_lec_files

```
write_lec_files {true | false}
```

Default: `true`

Data_type: bool, read/write

Specifies whether the `write_do_lec` command should write intermediate files to the verification directory specified

by the `write_lec_directory_naming_style` attribute. If false, no files are written.

write_lec_directory_naming_style

`write_lec_directory_naming_style` *`directory`*

Default: `fv/invs/%s`

Data_type: string, read/write

Specifies the directory name where the `write_do_lec` command will write verification files when the `write_lec_files` attribute is `true`. The directory will be created if it does not already exist, and will be overwritten if the existing directory has the same name. A `%s` in the string is replaced with the design name. For example, it will overwrite the directory for the same design, but not for a different design. A `%d` in the string is replaced with a unique integer to avoid overwriting any existing directory.

write_lec_dft_constraints

`write_lec_dft_constraints` *`TCLDirectory`*

Default: `""`

Data_type: string, read/write

Specifies a TCL directory that holds the LEC DFT pin constraints from the last LEC run. It is passed forward through the `write_design` command. The `write_do_lec` command will automatically include this constraint in the specified file.

write_lef_abstract_customer_header

`write_lef_abstract_customer_header` *`header_information`*

Default: `""`

Data_type: string, read/write

Writes LEF abstract files with the customer-specified header information.

init_design

```
init_design [-help]
```

Initializes the database and ensures that the tool is ready for full execution.

You must use the following commands in the order shown below before calling `init_design`.

1. set_db to set various init root attributes as desired. Normally init_power_nets and init_ground_nets are set here. See init Category Attributes chapter for all the init root attributes. You can see the current values with: get_db init*
2. read_mmmc to read timing data from an MMMC file. This step does error checking and creates MMMC objects (analysis_views, delay_corners, etc.). It reads in any timing libraries required by the set_analysis_view command inside the MMMC file, but it defers reading SDC and other files until they are needed later. This is optional for Innovus but required for Tempus.
3. read_physical to read in physical technology and library data from LEF or OpenAccess. This is required for Innovus, and optional for Tempus.
4. read_netlist to read in the netlist from Verilog or OpenAccess. This is required, and the design and netlist objects are created at this time.
5. read_power_intent to read in CPF or IEEE 1801 files. The files are read in and various error checks are done, but no power_domain objects are created until init_design is called. This step is optional.
6. `init_design` to step through the defined MMMC objects, the netlist objects, and the power intent data to build up the full representation of the design. After initialization is complete, the design is in a consistent state and is ready for timing analysis, floorplanning, placement, etc. Any data required by active views from set_analysis_view inside the MMMC file (e.g. SDC files) is read in at this time.

In Stylus mode, `eval_legacy {init_design}` will fail with an error message because Legacy initialization is not supported in Stylus. Also, `init_design` silently sets `init_mmmc_version to 2` because only MMMC2 is supported in Stylus.

Additionally, the `init_design` command:

- Initializes the default bounding box of square size with 70% utilization
- Creates default rows, the site of row depends on the height of the cell used in the netlist
- Creates track in the box based on the tech LEF

The `init_design` command can be broken into the following sub-steps:

1. Power Domain Creation. The power_domain objects are created and then bound to the design data as defined in the CPF or IEEE1801 files. At the end of this sub-step, every instance in the system is associated with its power domain.
2. Bind Power Domains to Timing Conditions. The power_domains are bound to the correct timing_conditions (library_sets and opconds) based on the `create_delay_corner` commands in the MMMC file. In this sub-step, the active delay_corners are processed with each instance getting assigned to the appropriate

library_set and opcond.

3. Constraint Loading. The SDC files (and any other timing related files) required by the active analysis_views are loaded and error checking is done.
4. Active View Setting. The final step is to set the active views based on the `set_analysis_view` command in the MMMC file, and to perform final checks to ensure any active analysis_view is fully and completely defined. Now the design is ready for execution.

Timing Incremental Updates

After `init_design`, you can enter new MMMC commands (e.g. create_analysis_view, create_delay_corner, etc.) at the command line. These commands populate the mmmc database objects, and perform error checking to report missing data. No data load takes place during command entry. Instead, the loading of new libraries, constraints, and so on, is deferred until a set_analysis_view command that requires the new data is given.

Note: Reading new design data (netlist) and new physical data (LEF/OA) incremental updates is not allowed. After the first `init_design` is completed, these steps are effectively disabled. If you issue a `read_netlist` or `read_physical` command after the first `init_design`, the tool returns an error.

Note: The annotation data, such as SPEF or SDF, cannot be loaded if the design has not been initialized properly with the `init_design` command.

Parameters

`-help`	Prints out the command usage. For a detailed description of the command, use the `man` command: `man init_design`

Example

Here is an example of a typical init script.

```
set_db init_power_nets {VDD VDD2}

set_db init_ground_nets VSS

read_mmmc mmmc.tcl                    #Only .lib files for the active views are read at this time

read_physical -lef {tech.lef stdcell.lef}  #The technology LEF must be first

read_netlist {design.v block.v}

read_power_intent -cpf design.cpf

init_design
```

Related Information

- create_delay_corner
- init Category Attributes
- read_mmmc
- read_netlist
- read_physical
- read_power_intent
- set_db
- set_analysis_view

init Category Attributes

The root attributes in the `init` category are:

- init_check_netlist
- init_check_output_pin_constant
- init_delete_floating_hnets
- init_design_netlist_type
- init_design_uniquify
- init_ground_nets
- init_ignore_pg_pin_polarity_check
- init_keep_empty_modules
- init_lef_files
- init_min_dbu_per_micron
- init_mmmc_files
- init_no_new_assigns
- init_oa_abstract_views
- init_oa_default_rule
- init_oa_design_cell
- init_oa_design_lib
- init_oa_design_view
- init_oa_foundry_rule
- init_oa_layout_views
- init_oa_ref_libs
- init_oa_search_libs
- init_oa_special_rule
- init_oa_tech_lib
- init_power_intent_files
- init_power_nets
- init_read_netlist_allow_port_mismatch
- init_read_netlist_allow_undefined_cells
- init_read_netlist_files

- init_sync_relative_path
- init_timing_enabled

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `init` category, use the following command:

```
get_db -category init
```

init_check_netlist

```
init_check_netlist {true | false}
```

Default: `false`

Data_type: bool, read/write

After reading in the netlist, it performs the same checks as `check_design -type netlist`.

Related Commands

- `init_design`
- `check_design`

init_check_output_pin_constant

```
init_check_output_pin_constant {true | false}
```

Default: `true`

Data_type: bool, read/write

Stops the Verilog reader if any output (or inout) signal pins have any 1'b0 or 1'b1 constants that would cause shorts to power/ground.

The default value of this boolean variable is `TRUE`.

Related Commands

- `init_design`

init_delete_floating_hnets

```
init_delete_floating_hnets {true | false}
```

Default: `false`

Data_type: bool, read/write

If `true`, an hnet (Verilog wire statement) that has nothing connected to it, is deleted from the netlist. The default value is `false` in Innovus to allow for netlist repair.

Related Commands

- `init_design`

init_design_netlist_type

```
init_design_netlist_type  netlist_source
```

Default: `Verilog`

Data_type: string, read/write

Specifies the source of the design netlist. You can specify either `Verilog` or `OA`.

Example

- The following command specifies Verilog as the source of the design netlist.
  ```
  set_db init_design_netlist_type {Verilog}
  ```

Related Commands

- `init_design`

init_design_uniquify

```
init_design_uniquify {true |false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether the top is uniquified. When set to `true`, the design will be uniquified during the read and flatten process. Optimization is not allowed on a non-unique design. For use in a master/clone partitioning flow, the value should be `false`.

Example

- The following command specifies that the design should be uniquified automatically during `init_design`:

  ```
  set_db init_design_uniquify true
  ```

Related Commands

- `init_design`

init_ground_nets

```
init_ground_nets  list_of_nets
```

Default: `{}`

Data_type: string, read/write

Specifies the list of global ground nets used in the design.

Example

- The following command specifies `VSS` as the ground net used in the design.

  ```
  set_db init_ground_nets {VSS}
  ```

Related Commands

- `init_design`

init_ignore_pg_pin_polarity_check

```
init_ignore_pg_pin_polarity_check list
```

Default: `{}`

Data_type: string, read/write

Space separated list of leaf cell pin names to ignore polarity checking during `connect_global_net` and CPF operations. Allows USE POWER pin to be connected to a USE GROUND net (or vice versa).

When specified, GNC/CPF are allowed to silently make connections to PG pins that are not of the same polarity as the PG net that they are being connected to. The list of pin names is only checked for the case where a polarity check failed and then can be ignored and connected in spite of the polarity mismatch.

Example

```
set_db init_ignore_pg_pin_polarity_check "bias"
```

Related Commands

- connect_global_net

init_keep_empty_modules

```
init_keep_empty_modules {true | false}
```

Default: true

Data_type: string, read/write

By default, usage of an empty Verilog module that has no matching library cell name becomes an empty hinst. If this value is false, a dummy library cell is created, and its usage becomes an inst. You should then use other commands to 'fix' the dummy library cell before proceeding in the flow.

Related Commands

- delete_empty_hinsts
- read_db

init_lef_files

```
init_lef_files  list_of_files
```

Default: {}

Data_type: bool, read/write

Specifies the list of LEF files to be imported. This attribute cannot be used with init_oa_ref_libs.

Example

- The following command specifies technology.lef and stdcell.lef as the LEF files to be imported.

  ```
  set_db init_lef_files {technology.lef stdcell.lef}
  ```

Related Commands

- init_design
- write_db

init_min_dbu_per_micron

```
init_min_dbu_per_micron DBUPerMicron
```

Default: 0

Data_type: int, read/write

Sets the minimum database units per micron allowed when LEF files initialize the database units.

You can specify a value for the minimum database units per micron allowed when LEF files initialize the database units. This option is intended for users with LEF files that have database units that are not fine enough for NanoRoute to run properly, that is when NanoRoute requires the LEF database units to be finer than the manufacturing grid. If you do not want to modify your LEF file, you can use this option to override the LEF database units value.

The default value is `0`, which means that the software uses the LEF file units. The software uses the units set in the LEF file, if the LEF units are greater than the minimum database units you specify. Conversely, if the units you specify are greater than the LEF units, the software uses the units you specify. The value you set is saved so the next time you open the design it will have the same database units.

Related Commands

- `read_db`

init_mmmc_files

```
init_mmmc_files  file_name
```

Default: `{}`

Data_type: string, read/write

Specifies a Tcl command script that contains the analysis view configurations for multi-mode multi-corner (MMMC) timing analysis and optimization. If this view definition file is not in the current directory, specify the complete path to the file.

Example

- The following command specifies `mmmc.tcl` as the MMMC view definition file.

  ```
  set_db init_mmmc_files {mmmc.tcl}
  ```

Related Commands

- `init_design`

init_no_new_assigns

```
init_no_new_assigns {true | false}
```

Default: `false`

Data_type: bool, read/write

Turns on an assign-free flow. By default, applications like optimization can add Verilog assigns to remove unnecessary buffers and reduce power. If you have external tools that do not support Verilog assigns, you can set this value to true to prevent applications from adding any new assign statements to the Verilog netlist. If there are existing assigns in the Verilog netlist you can remove them with the `delete_assigns` command..

Related Commands

- `init_design`

init_oa_abstract_views

`init_oa_abstract_views` *`list_of_views`*

Default: `""`

Data_type: string, read/write

Specifies the OpenAccess view names that the tool should examine to find the equivalent LEF MACRO information (for example, PINS, OBS, FOREIGN). If this value is null (`""`), the tool uses `abstract` as the value.

The `read_netlist` command uses `init_oa_abstract_views` list for on-demand loading of missing cells. It is used by the `read_physical` and `read_netlist` commands.

Example

- The following command sets ABS1 as the OpenAccess view to be examined for equivalent LEF MACRO information.

  ```
  set_db init_oa_abstract_views {ABS1}
  ```

Related Commands

- `init_design`
- `read_netlist`
- `read_physical`

init_oa_default_rule

`init_oa_default_rule` *`ruleName`*

Default: `{}`

Data_type: string, read/write

Specifies a constraint group name at the start of the Innovus session. The name provided would be used by Innovus for reading the place-and-route technology rules from the constraint group.

If the user-specified constraint group is not found, Innovus outputs an error during `init_design`. If no value is specified for init_oa_default_rule, Innovus falls back to the default look-up mechanism for `LefDefaultRouteSpec` constraint group used by any place-and-route tool. Follow these guidelines while using this parameter:

- You can set this attribute only at the start of Innovus session or after running reset_design.
- You will need to resolve conflicts in a design arising due to the two incompatible constraint groups used in two design running in two different Innovus sessions.

The specified constraint group must have the following:

- Valid layers
- Valid vias
- Width
- Spacing

Related Commands

- `init_design`

init_oa_design_cell

`init_oa_design_cell` *`cellname`*

Default: `{}`

Data_type: string, read/write

Specifies the OpenAccess design cell name to be used.

Example

- The following command specifies `myOACell` as the OpenAccess database cell.

  ```
  set_db init_oa_design_cell {myOACell}
  ```

Related Commands

- `init_design`

init_oa_design_lib

`init_oa_design_lib` *`libraryname`*

Default: `{}`

Data_type: string, read/write

Specifies OpenAccess design cell name to be used. Set by the `read_netlist -oa_cell_view` command.

Example

- The following command specifies `myOALib` as the OpenAccess database library.

  ```
  set_db init_oa_design_lib {myOALib}
  ```

Related Commands

- `init_design`
- `read_netlist`

init_oa_design_view

`init_oa_design_view` *viewname*

Default: `{}`

Data_type: string, read/write

Specifies the OpenAccess design view name to be used.

Example

- The following command specifies `myOAView` as the OpenAccess database view.

  ```
  set_db init_oa_design_view {myOAView}
  ```

Related Commands

- `init_design`

init_oa_foundry_rule

`init_oa_foundry_rule` *foundry_rule_name*

Default: `{}`

Data_type: string, read/write

Specifies the foundry constraint group to be used in OpenAccess. If your technology library contains multiple `foundry_innovus_XXXX` constraint groups, use the `init_oa_foundry_rule` attribute to specify which one of them has to be read in during design initialization. This attribute is used by the init_design command.

Example

- The following command specifies `foundry_innovus_2` as the foundry constraint group to be used during design initialization:

  ```
  set_db init_oa_foundry_rule {foundry_innovus_2}
  ```

Related Commands

- `init_design`

init_oa_layout_views

`init_oa_layout_views` *`list_of_views`*

Default: `{}`

Data_type: string, read/write

Specifies the list of OpenAccess view names to be processed for cell layout viewing (GDSII equivalent).

It is also used in the case where a Verilog netlist is read and views from the `init_oa_layout_views` list are used in the Quick Abstract Inference flow to derive abstract information from layout views for cells that were not processed from the libraries in the `read_physical -oa_ref_libs` list. The `read_netlist` command uses `init_oa_layout_view` list for on-demand loading of missing cells. Used by the `read_physical` and `read_netlist` commands.

Example

- The following command specifies `LAY3` as the layout view to be imported.

  ```
  set_db init_oa_layout_views {LAY3}
  ```

Related Commands

- `init_design`
- `read_netlist`
- `read_physical`

init_oa_ref_libs

`init_oa_ref_libs` *`list_of_OA_libs`*

Default: `{}`

Data_type: string, read/write

Specifies the list of OpenAccess reference libraries to import. Each reference library is processed using the abstract view name list (`init_oa_abstract_views`). The first library in the list indicates the library that was used for

the technology information unless `read_physical -oa_tech_lib` is specified. All cells from the specified libraries are read. It is important to include the standard cell library in the list to make sure that cells that are not in the current netlist are read and available for optimization. The `init_oa_abstract_views` and `init_oa_layout_views` lists specify which views of the cells are read. Set by the `read_physical -oa_ref_libs` command.

For example, if the reference library is `"lib1 lib2"`, and the abstract view name list is `"abstract abstract2"`, LEF MACRO information is processed for `lib1` with the `abstract` view. Then, for any cells in `lib1` that do not have `abstract` but do have `abstract2`, that view is processed for MACRO information. If a cell has both views, the first one is used. The process then is repeated for `lib2`.

The `init_oa_ref_libs` attribute cannot be used `with init_lef_files`.

Example

- The following command specifies `OAREFLIB1 OAREFLIB2` as the OpenAccess reference libraries.

  ```
  set_db init_oa_ref_libs {OAREFLIB1 OAREFLIB2}
  ```

Related Commands

- `init_design`
- `init_oa_search_libs`
- `read_physical`
- `write_db`

init_oa_search_libs

```
init_oa_search_libs  list_of_OA_ref_libs
```

Default: *

Data_type: string, read/write

Specifies the list of OpenAccess reference libraries to be searched when cells are used in the Verilog netlist that are not included in the list of cells in the libraries specified in `init_oa_ref_libs` list. By default all libraries in the cds.lib are searched. The `init_oa_abstract_views` and `init_oa_layout_views` lists are used to indicate which view names are looked for during the search. Applies only when `read_netlist` command is used to process a Verilog netlist to specify the connectivity to be read. Set by the `read_physical -oa_search_libs` command and used by the `read_netlist` command.

Related Commands

- init_design
- init_oa_ref_libs
- read_netlist
- read_physical

init_oa_special_rule

```
init_oa_special_rule name
```

Default: {}

Data_type: string, read/write

Specifies the default rule to be used in OpenAccess to define the via search order for power routing. Typically used to specify a metal stack LEFSpecialRouteSpec type constraint group to read from the technology library if the library contains multiple metal stacks. If nothing is specified, then the constraint group with the name LEFSpecialRouteSpec is searched in OpenAccess. It is used by the read_physical command.

Related Commands

- init_design
- read_physical

init_oa_tech_lib

```
init_oa_tech_lib lib_name
```

Default: {}

Data_type: string, read/write

Specifies the OpenAccess library to use as a source of technology information. If not specified, the first library in the init_oa_ref_lib list will be used. Applies only when read_netlist is used to process a Verilog netlist. It is set by the read_physical -oa_tech_lib command.

Related Commands

- init_design
- read_netlist
- read_physical

init_power_intent_files

```
init_power_intent_files string
```

Default: ""

Data_type: string*, read-only

Specifies the power intent files read by the previous run of the `read_power_intent` command.

init_power_nets

```
init_power_nets  list_of_power_nets
```

Default: `{}`

Data_type: string, read/write

Specifies the list of global power nets used in the design.

Example

- The following command specifies `VDD` as the power net in the design.

  ```
  set_db init_power_nets {VDD}
  ```

Related Commands

- `init_design`

init_read_netlist_allow_port_mismatch

```
init_read_netlist_allow_port_mismatch  {true | false}
```

Default: `false`

Data_type: bool, read/write

If `false`, a Verilog instance with ports that do not match the Verilog module or library cell definition will cause an error and exit. If `true`, an error message occurs, but the extra ports are added to the module or library cell definition to allow the inconsistent netlist to be read in and debugged further. The default is `true` for Innovus to allow repair of ‘dirty netlists’, but `false` for Tempus that normally does not tolerate ‘dirty netlists’.

Related Commands

- `init_design`

init_read_netlist_allow_undefined_cells

```
init_read_netlist_allow_undefined_cells  {true | false}
```

Default: `true`

Data_type: bool, read/write

If false, a Verilog reference to an undefined cell (for example, a Verilog module name that has no matching library cell and no Verilog module definition) causes an error and an exit after parsing the netlist. If `true`, an empty Verilog module is created with a warning. The default value is `true` in Innovus to allow repair of 'dirty netlists'. An empty module will become an hinst or inst depending on the value of `init_keep_empty_modules`.

Related Commands

- `init_design`

init_read_netlist_files

```
init_read_netlist_files filenames
```

Default: `""`

Data_type: string,

A list of Verilog files read in during initialization. `read_netlist` will set this root attribute to the list of input files given to it. The original input file names are retained through the flow for reference, and used by `write_do_lec` for comparison of the default golden netlist file names.

init_sync_relative_path

```
init_sync_relative_path {true | false}
```

Default: `false` (You must change your working directory to the directory saved in the previous design session before you restore the design.)

Data_type: bool, read/write

Synchronizes all relative paths in the top.globals file to the current working directory. Use this parameter if you want to restore the design without first changing your current working directory to the directory saved in the previous design session.

Example

- The following command synchronizes all relative paths to the current working directory:
  ```
  set_db init_sync_relative_path  true
  ```

Related Commands

- read_db

init_timing_enabled

```
init_timing_enabled {true | false}
```

Default: true

Data_type: bool, read-only

If read_physical is issued before read_mmmc or read_libs in Genus and Tempus, an error will be issued. In Innovus, doing this will result in init_timing_enabled being set to false by the tool. Innovus will be in physical only mode, and any attempt to set timing data will result in an error.

read_db

```
read_db
[-help]
[-dynamic_view analysis_view]
[-hold_views hold_views]
[-leakage_view analysis_view]
[-no_binary_constraint]
[-no_timing]
[-read_globals tcl_file]
[-setup_views setup_views]
{[in_dir [-mmmc_file fileName][-lef_files list_of_files]] | [-oa_lib_cell_view {libname cellname viewname} [-mmmc_file fileName]]}
[ -no_timing_graph ]
```

Reads a saved database created by write_db in a previous session. It auto-detects the database type and loads it. An OpenAccess DB format is read with -oa_lib_cell_view {*libname cellname viewname*} while a native Innovus DB format is read using *in_dir* for the DB directory name.

The write_db command optionally includes various types of data, including timing-graph data and RC extraction data. So, the state of the DB after read_db depends on what was written, and you may need to repeat RC extraction, timing analysis, etc. if that data was not saved.

For OpenAccess usage, simple digital-only designs generally go back and forth with no special handling. But some types of Virtuoso custom data cannot be represented directly in the Innovus DB, and are stored “on the side” by read_db and geometrically equivalent data is visible in Innovus. That data is then restored by write_db when you write back to OA using the correct OA settings.

There are different types of OA methodologies and flows supported that are controlled by root attributes. Use get_db oa* to see the attributes, and look at the *Mixed Signal Interoperability Guide* for more details on their effects on write_db/read_db.

Note:

- Innovus does not support loading another DB while a design is already in memory.
- You should not modify the contents of a saved DB (*.enc.dat or *.db) at any time. If the contents of the saved DB are modified, restoring such modified DB might cause problems later or lead to DB corruption or crashes.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `read_db` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man read_db`
`-dynamic_view` *analysis_view*	Specifies the analysis view for the dynamic power analysis. *Data_type*: string, optional
`-lef_files` *list_of_files*	Specifies the LEF files name for loading. Use this option if you want to override the existing LEF files in the design being restored and load different LEF files instead. • This option is intended to allow upgrading to new versions of LEF files that are compatible with the old versions. The list of all LEF files used by this design must be given. • If any pin locations or cell boundaries or OBS shapes are changed for used cells, new DRC violations may occur. • If pins are added or removed from used cells, or used cells are removed, fatal errors may occur when loading the netlist. • If the removed pins and cells are unused in the design, warnings or errors may still occur if any library-specific data was stored for those cells or pins during the design flow (such as dont_touch data) **Examples** Existing LEFs used by `write_db`: `tech.lef`, `A.lef` You can change `A.lef` to `A_v2.lef` as given below: `read_db place.dat -lef_files {tech.lef A_v2.lef}` *Data_type*: string, optional

`-leakage_view` *`analysis_view`*	Specifies the analysis view for leakage power analysis. *Data_type*: string, optional
`-oa_lib_cell_view` *`string`*	Specifies the library name, cell name, and view name for reading an OpenAccess DB design. *Data_type*: string, optional
`-mmmc_file`	Specifies the path name to a Multi-Mode/Multi-Corner (MMMC) configuration file (for example, the same file format used by `read_mmmc`) to replace the MMMC file saved by `write_db` (and all the corresponding .lib files, .sdc files, *_power_constraints.tcl etc. referenced by the MMMC file). If a new MMMC file is specified using -mmmc_file, the RC data saved by the previous session may mismatch with the new MMMC file and cause issues. If `read_db -mmmc_file` is specified, by default, the tool will not load the RC data. You need to re-extract RC after the design is loaded. **Note**: CTS configuration will not be read with `-mmmc_file`. You need to re-run `create_clock_tree_spec` after `read_db` to create a new CTS configuration against the new MMMC configuration. *Data_type*: bool, optional
`-no_binary_constraint`	Specifies not to load the binary timing constraint .tcz file even it is saved to disk in the previous session. *Data_type*: bool, optional
`-no_timing_graph`	Skips reading the timing graph even if it was saved to the disk by `write_db`. *Data_type*: bool, optional
`-hold_views` *`hold_views`*	Specifies the hold views for loading, rather than the hold views active during `write_db`. *Data_type*: string, optional

`-no_timing`	Skips reading of the MMMC file, timing libraries and timing constraints. *Data_type*: bool, optional **Note:** • Most designs that use LEF rely on the .lib information to define the bus order for MACROs that have bus bit terminals. Therefore, using the `-no_timing` option can result in the connectivity to bus ports of leaf level instances being reversed. When `.lib` information is not available, the default is for bus ports to be treated as descending (for example, [7:0]). When using Verilog modules or OpenAccess abstract views to define the bus order, the connectivity will still be correct even when `-no_timing` is specified. • Timing libraries cannot be loaded in the same session after a design is read using the `-no_timing` option. You must use `read_db` without the `-no_timing` option in a new session to load the design with timing libraries and constraints. • If you save a design after `read_db -no_timing`, it will not save timing information unless you use `write_db -add_ignored_timing`. *Data_type*:
`-read_globals` *`tcl_file`*	Specifies the UDM variables to be honored when restoring the design. You need to provide a Tcl file stating the pre-defined UDM variable names to be honored. *Data_type*: string, optional
`in_dir`	Specifies the directory from which to load the DB files. If the *`in_dir`* name ends with .tar.gz it is treated as a gzipped tar file (see `write_db -gzip` option) that is extracted into the directory first. So `read_db test.tar.gz` will create a directory named test with all the DB files inside it. *Data_type*: string, required
`-setup_views` *`setup_views`*	Specifies the setup views for loading rather than the setup views active during `write_db`. *Data_type*: string, optional

Examples

- The following command loads the saved design files from the test.dat directory:

  ```
  read_db test.dat
  ```

  For physical-only editing, you can do this to speedup read_db/write_db by ignoring the timing during read_db, and adding it back during write_db.

  ```
  read_db test1.dat -no_timing
  <physical-only editing>
  write_db test2.dat -add_ignored_timing
  ```

  Then in a new session

  ```
  read_db test2.dat       #has timing from test1.dat
  ```

  If the logical netlist was modified during editing of test1.dat, then reading test2.dat may have unpredictable timing results.

- The following command reads the `placed.dat` design but replaces the saved MMMC settings in the design with the settings in `new_mmmc.tcl`:

  ```
  read_db placed.dat -mmmc_file new_mmmc.tcl
  ```

  Then create a new CTS configuration:

  ```
  create_clock_tree_spec
  ```

- The following command reads the `"designLib top placed"` OpenAccess cellview but replaces the existing MMMC settings in the design with the settings in `new_mmmc.tcl`:

  ```
  read_db -oa_lib_cell_view "designLib top placed" -mmmc_file new_mmmc.tcl
  ```

read_def

```
read_def
[-help]
file_name
[-add_blockage]
[-all_warning]
[-components]
[-delete_bump]
[-delete_special_route]
[-ignore_drcfill]
[-ignore_pg_connectivity]
[-nets]
[-preserve_shape]
[-remove_half_wire_extension_on_pin]
[-special_nets]
[-special_route_user_class user_class_name]
[-verilog_from_def_netlist_flow]
[-incremental_routing]
```

Loads the specified DEF file. `read_def` can be used at any step after importing a design. The typical usage is:

- Load a DEF file containing the floorplan saved by Innovus or other tool.
- Load a DEF file containing the scan chain information so that placement can do scan chain reorder.
- Load a DEF file containing the cell's placement and routing saved by Innovus or other tool.

ⓘ When you load a DEF file, you must be at the same level in the hierarchy where the DEF file was saved.

The Innovus software loads the DEF file information into the database in several ways, depending on the object:

- Tracks, gcells, rows, die area
  The software deletes all of the existing objects in the database and reads in the new information.

  Note: The `read_def` command can read a rectilinear die area, but converts it to a rectangular die area with blockages at the cut off area.
- Blockages, fills, special nets
  The software compares the physical data (such as shape and layer) to the existing data in the database. If it finds the same data in the database, it ignores the data in the DEF file. If the data does not already exist, the software adds it to the database. For special nets, the software merges wire segments in the DEF file with any existing ones in the database that overlap and have the same attributes, such as layer, width, shape, and direction. The software does not delete any existing data.
- Nondefault rules, vias
  The software adds the objects to the database if they do not already exist there. If a nondefault rules

definition with the same name already exists, the software ignores the one in the DEF file. If a via definition with the same name already exists, and the via is a fixed via, the software ignores the one in the DEF file. If a generated via definition with the same name already exists, the geometries are read, but the name might be changed. The software does not delete any existing objects of these types.

The DEF reader checks the NDR rule only if its name is "DEFAULT" and checks whether all definition of the "DEFAULT" NDR match the LEF default rule. If the NDR rule name is not DEFAULT, the tool will give the following warning message:

```
WARN: The definition of "s%" are different between the NDR Rule "DEFAULT" in DEF file and the implicit default rule in LEF File.
```

Also, DEF reader will not create a "DEFAULT" NDR in DB, and give following warning message:

```
WARN: Innovus does not allow user to specify an NDR rule named as "DEFAULT", ignore it when reading the DEF file and use LEF rule to replace it.
```

- Nets
  For each net in the DEF file, the software removes the existing regular routing (not special routing), then adds the routing from the DEF file for this net.
- Pins
  For each pin in the DEF file, the software removes the existing physical information for the pin, then adds the physical information from the DEF file for this pin. If a pin does not already exist, and it is a power or ground pin, the software adds it to the database. If the pin is not a power or ground pin, the software generates an error message.
- Groups, regions
  If a group name in the DEF file matches an existing hierarchical instance name in the database, the region's boundary constraint is attached to the hierarchical instance, overriding any existing boundary constraint. The software checks whether the group members belong to the hierarchical instance, and generates a warning message if any do not belong. If a group name does not match any hierarchical instance name, the software creates the instance group with an attached region boundary constraint, if one exists. Regions that are not used by groups in the same DEF file are ignored. The software does not remove existing groups.

  Note: You can import DEF files containing wildcards (`*`) in the `GROUPS` statement. The `read_def` command does not support multiple groups per region.
- Components
  You cannot add new logical cells. You can add new physical cells, such as:
  - Cells with `CLASS PAD`
  - Cells with `CLASS COVER` and no signal pin
  - Instance with `+ SOURCE DIST`

You can use the `read_def` command after importing a design.

Note: Do not attempt to use the `read_def -verilog_from_def_netlist_flow` command in any other Tcl scripts.

After loading the DEF netlist using the `read_def -verilog_from_def_netlist_flow` command, you can perform floorplanning, non-timing driven placement and routing, wire editing, and verification. You cannot use the DEF netlist flow for parasitic extraction, delay calculation, and timing-driven placement and routing effectively because the DEF names do not properly match the Verilog names used in timing constraints and timing analysis.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `read_def` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man read_def`
`-add_blockage`	Converts undefined instances (except COVER cells) into blockages. *Data_type*: bool, optional
`-all_warning`	Lists all warning messages issued when you load the DEF file. *Default:* Limits the number of warning messages to the first 1,000. *Data_type*: bool, optional
`-components`	Reads the `COMPONENTS` section of the DEF file and ignores other sections, except when the `-nets` or `-special_nets` parameters are specified. *Data_type*: bool, optional
`-delete_bump`	Deletes all bumps in the database before reading the DEF file. *Data_type*: bool, optional
`-delete_special_route`	Deletes all special routes in the database before reading the DEF file. This includes the RDL routing as well as the power and ground special routes in the design. *Data_type*: bool, optional

`-ignore_drcfill`	Ignores the special routing with the DRCFILL shape attribute. *Data_type*: bool, optional
`-ignore_pg_connectivity`	Ignores the pg connectivity in the SPECIALNETS and NETS sections. *Data_type*: bool, optional
file_name	Specifies the name of the DEF file to load. *Data_type*: bool, optional
`-incremental_routing`	Prevents deletion of the whole routing of the signal net, and just adds the new wires and vias. *Data_type*: bool, optional
`-nets`	Reads the `NETS` section of the DEF file and ignores other sections, except when the `-components` or `-special_nets` parameters are specified. *Data_type*: bool, optional
`-preserve_shape`	Prevents creation of symbolic center-line connected routing data and preserves the routing data as-is. *Data_type*: bool, optional
`-remove_half_wire_extension_on_pin`	Truncates the half-width extension back to zero extension for all wire end points that overlap a pin. This is useful for DEF files created by `write_def -add_half_wire_extension_on_pin`, which forces all `NETS` section routing to use the default half-width wire extension. **Note:** Using this parameter can cause DRC violations. *Data_type*: bool, optional
`-special_route_user_class` *user_class_name*	
	Sets the specified user-class name on all the special routes read in from the DEF file. *Data_type*: string, optional

`-special_nets`	Reads the `SPECIALNETS` and `VIAS` sections of the DEF file and ignores other sections, except when the `-components` or `-nets` parameters are specified. *Data_type*: bool, optional
`-verilog_from_def_netlist_flow`	Reconciles the names in the DEF and Verilog files . This procedure is required if you want to retrieve any information that matches the original DEF file. *Data_type*: bool, optional

Example

- The following command loads the `TOPCHIP` DEF placement file:

  ```
  read_def TOPCHIP.def
  ```

- The following command loads the power grid from a DEF file:

  ```
  read_def -special_nets TOPCHIP.def
  ```

Related Information

  - "Pre-Mask ECO Changes from a New DEF File"

read_def Category Attributes

The root attributes in the write_def category are:

- read_def_check_mask_shifts

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `write_def` category, use the following command:

```
get_db -category read_def
```

read_def_check_mask_shifts

```
read_def_check_mask_shifts {on | off | bypass}
```

Default: `off`

Data_type: enum {off | on | bypass}, read/write

Checks conflicts between DEF COMPONENT MASKSHIFT and MACRO MASKSHIFT values with the LEF FIXEDMASK and LAYERMASKSHIFT values, respectively, in the technology and MACRO sections. You can set the following values:

- `on`: When the variable is set as on, the the tool will check for the conflict. In case of a conflict, the tool will give an error and stop running.
- `off`: When the variable is set as off, the tool will not check for the conflict.
- `bypass`: When the variable is set as bypass, the tool will give and error message and will continue running.

Related Command

- `read_def`

read_mmmc

```
read_mmmc
[-help]
file_name
```

Reads in the Multi-Mode, Multi-Corner (MMMC) file. MMMC refers to the full set of timing libraries, constraints, and the associated modes.

When the `read_mmmc` command is run, the MMMC file is read and processed. The majority of elements in the MMMC control file is saved in the MMMC caching attributes. Except for the library sets defined by the first `set_analysis_view` command, no data is loaded into the database. This command does basic syntax checking on the MMMC commands, rejecting commands that have incorrect options and commands that are not MMMC or tcl commands. However, no consistency checking is performed. For example, if a constraint mode is used in an analysis view, but is not defined, it will not be flagged.

The MMMC file contents are cached in attributes in the database. These attributes allow you to write out a full and complete MMMC file later in the flow. In addition, the names of the MMMC files are cached for querying.

The exceptions to data set load are the libraries pointed to by the first `set_analysis_view` command in the MMMC file. These library sets are loaded into the database. This load uses the standard library parser, and includes standard library syntax checking.

The `read_mmmc` command corresponds to the *Timing* step of the Initialization flow:

In the *Timing* step, the MMMC objects are set up by populating the basic MMMC information attributes. As Synthesis needs library information before the *Design* step, the *Timing* step also loads some library information. The library data to be loaded is pointed to by the first `set_analysis_view` command in the MMMC file.

See **Example** section for more details.

At a minimum, the MMMC file must contain one each of:

```
create_library_set
create_rc_corner
create_timing_condition
create_delay_corner
create_constraint_mode
create_analysis_view
set_analysis_view
```

If the MMMC file does not contain this minimum set, an error will be issued.

Note: The library sets can be specified with absolute paths in the MMMC, or relative to the local directory or to library search path attributes. The tool first attempts to load based on the name in the MMMC. If the library is not found, the tool sweeps through the search directory list in the specified order. Only the first hit is loaded.

Parameters

`-help`	Prints a brief description that includes type and default information for each `read_mmmc` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man read_mmmc`
`file_name`	Specifies the name of the MMMC file. *Data_type*: string, required

Example

When reading an MMMC file with `read_mmmc`, the tool sets the MMMC attributes with the data specified in the file. When the first `set_analysis_view` command is processed, the tool loads in the libraries specified by this analysis view. No other data is loaded.

For example, consider an MMMC file with the following commands:

```
create_library_set -name LS1 -timing [list lib1.lib lib2.lib lib3.lib]
create_library_set -name LS2 -timing [list lib4.lib lib5.lib lib6.lib]
create_library_set -name LS3 -timing [list lib7.lib lib8.lib lib9.lib]
create_rc_corner -name QX -qrc_tech file.qrc
create_timing_condition -name TC1 -library_set LS1
create_timing_condition -name TC2 -library_set LS2
create_timing_condition -name TC3 -library_set LS3
create_delay_corner -name DC1 -timing_condition {TC1 PD2@TC2} -rc_corner QX
create_delay_corner -name DC2 -timing_condition {TC1 PD2@TC3} -rc_corner QX
create_constraint_mode -name CM1 -sdc_files cond1.sdc
create_constraint_mode -name CM2 -sdc_files cond2.sdc
create_analysis_view -name AV1 -constraint_mode CM1 -delay_corner DC1
```

```
create_analysis_view -name AV2 -constraint_mode CM2 -delay_corner DC2
set_analysis_view -setup AV1 -hold AV2
```

When the `set_analysis_view` command is processed, the tool traces backwards from that command to determine the library set. In this case, the analysis view specified by `set_analysis_view` is AV1. The AV1 analysis view points to domain corner DC1, which in turn points to two library sets, LS1 and LS2. As a result, lib1.lib and lib2.lib are loaded into the database.

In this case, lib3.lib is not loaded into the database during `read_mmmc` because it is not in the library sets required by the analysis view.

- `set_analysis_view`
- `write_mmmc`

read_name_mapping

```
read_name_mapping
[-help]
in_file
[-debug]
```

Reads a name mapping file which records the mapping relationship between the original HDL (RTL bit level) names in Genus to the corresponding gate-level netlist names in Genus or Innovus for primary ports or reg/wire variables, and any logical phase inversions generated by Genus.

It can be used for Power Analysis using RTL switching activities and Formal Verification with Conformal LEC to facilitate key point mapping between the RTL names and the Innovus gate-level names. Innovus will not modify the incoming string <RTL_bit_level_name> and will attach this information to the corresponding netlist pin or port objects.

The input syntax of the file is as follows:

```
add mapped point RTL_bit_level_name netlist_inst_q_pin_or_port [-invert]
```

- *RTL_bit_level_name*: It is the hierarchical name of an RTL bit-level object corresponding to primary ports or reg/wire variables using “/” for the hierarchy delimiter
- *netlist_inst_q_pin_or_ports*: It is the hierarchical name of a gate-level instance q-pin or a port
- [-invert]: It indicates a logical phase inversion has been done during optimization for this pin or port

Parameters

-help	Prints a brief description that includes the type and default information for each read_name_mapping parameter. For a detailed description of the command and all of its parameters, use the man command: man read_name_mapping
-debug	Print debug info. *Data_type*: bool, optional
in_file	Name of input name mapping file. *Data_type*: string, required

Example

The following example show how different bits are merged into a multi-bit cell, so using simpler names is better.

```
add  mapped  point  IL_reg[1]      CDN_MBIT_reg/Q1      -invert
```

```
add  mapped  point  TRNS1_reg[0]   CDN_MBIT_reg/Q2
add  mapped  point  Vflag_reg      CDN_MBIT_reg/Q3
add  mapped  point  Zflag_reg      CDN_MBIT_reg/Q4
```

Example of the name mapping format used by Genus in presence of complex typed-names:

```
add mapped point clk clk //in
add mapped point sel sel //in
add mapped point in1[1] in1[1] //in
add mapped point in1[0] in1[0] //in
add mapped point out1[1] out1[1] //out
add mapped point out1[0] out1[0] //out
add mapped point out3/x[1] out3[x][1] //out
add mapped point out3/x[0] out3[x][0] //out
add mapped point isub/out1/x[1] isub_out1_reg[x][1]/Q
add mapped point isub/out1/x[0] isub_out1_reg[x][0]/Q
add mapped point out1[1] out1_reg[1]/Q
add mapped point out1[0] out1_reg[0]/Q
add mapped point out3/x[1] out3_reg[x][1]/Q
add mapped point out3/x[0] out3_reg[x][0]/Q
```

Related Information

- write_name_mapping

read_netlist

```
read_netlist
[-help]
{{in_file | -oa_cell_view {lib cell view}} [-top top_module_name]} | {-def def_file_name}}
```

Reads in a Verilog structural netlist. A structural Verilog file contains only structural Verilog-1995 constructs, such as module and gate instances, concurrent assignment statements, references to nets, bit-selects, part-selects, concatenations, and the unary ~ operator.

`read_netlist` supports reading an encrypted Verilog file. The file can be created by command `encrypt -verilog`. To be loaded, the encrypted Verilog must have suffix ".vp", like mydesign.vp. `read_netlist` also supports OpenAccess through the `-oa_cell_view` option.

The `read_netlist` command corresponds to the *Design* step of the Initialization flow:

During the *Design* step, the design is loaded into the database with `read_netlist`. After issuing this command, the database objects are populated and can be queried and manipulated (ungrouped, renamed, and so on). Full error checking is performed on the design details. This includes, but is not limited to, unresolved references, port mismatches, and empty modules.

Parameters

`-help`	Prints a brief description that includes the type and default information for each read_netlist parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man read_netlist`.
`-def` *`def_file_name`*	Specifies a DEF file to read for the netlist. This option cannot be used with any Verilog files or OA cell views. The DEF netlist is a "flat" netlist with no Verilog logical hierarchy. You can perform floorplanning, non-timing driven placement, routing, wire editing, and DRC checking. You cannot use the DEF netlist for parasitic extraction, delay calculation, and timing analysis because the flat DEF names do not match the hierarchical Verilog names used in timing constraints and timing analysis. *Data_type*: string, required
`in_file`	Specifies the list of netlist files. *Data_type*: string, required
`-oa_cell_view {`*`lib cell view`*`}`	Specifies the name of the design object to be loaded in {lib cell view} format. No other options can be used if this option is specified. *Data_type*: string, optional
`-top` *`top_module_name`*	Specified the top module name. By default, `read_netlist` identifies the highest module and links to that. If there are multiple top modules, the command returns an error. *Data_type*: string, optional

Example

- The following command reads the netlist with `dtmf_recvr_core` as the top module:

```
read_netlist mydesign.v -top_module dtmf_recvr_core
```

Related Information

- encrypt
- init_design
- read_mmmc
- read_physical
- write_netlist
- write_netlist Category Attributes

read_physical

```
read_physical
[-help]
{[-oa_ref_libs lib1 [lib2] ... [-oa_search_libs lib1 [lib2] ...][-oa_tech_lib lib]] |[-
add_oa_ref_libs lib1 [lib2]... [-oa_lib_path libPath]] | -lefs lib1 [lib2] ... |  -add_lefs lib1
[lib2] ...}
```

Reads the physical library information. When this command is run, the physical library information is loaded into the database. Both LEF and OA are supported, but not simultaneously.

The `read_physical` command corresponds to the *Physical* step of the Initialization flow:

During the *Physical* step, the physical libraries (OA or LEF) are loaded into the tool's database using `read_phsyical`. When the command is issued, the database is loaded with the specified objects, and is available for querying of attributes associated with the physical data, such as size, layer details, and so on.

The tool uses the standard OA parser, and performs full error checking on the physical data. When the command is complete, a full timing library set (via `read_mmmc`) and a physical library set would have been loaded into the database.

If `-lef` is used, the technology LEF must be first specified.

This command is optional for Synthesis and STA, but is required for Implementation.

The tool can support a physical only mode when the attribute `init_physical_only` is set to `true`. This attribute must be set prior to `read_physical`, otherwise an error will be issued.

Parameter

`-add_lefs` *lib1 [lib2]*	Specifies a list of LEF files to read and to add to the original list of LEF files that were added before `init_design`. This option can only be used after `init_design`, and cannot be combined with any other option. You can add new macros, non-default rules, sites etc. using this option, but you cannot use it to modify any existing LEF data that is already loaded. The LEF files added using this option will be used when the saved design is loaded again using `read_db`. *Data_type*: string, required
`-add_oa_ref_libs` *lib1* [*lib2*]	Specifies the list of OpenAccess library names to be loaded incrementally. These library names are added in the `cds.lib` file, if not present. Use this parameter to specify standard cell libraries or I/O driver libraries that should all be loaded after the design is read. The specified library names are appended to the `init_oa_ref_libs` root attribute. *Data_type*: string, required
`-help`	Prints a brief description that includes type and default information for each `read_physical` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man read_physical`
`-lefs` *lib1* [*lib2*] ...	Specifies the list of LEF files to be loaded. The first LEF file must have the technology section present. The file names are saved to the `init_lef_files` root attribute. This option cannot be combined with `-oa_ref_libs`. **Note**: This option can only be used before `init_design` or `read-db`. If you specify this option after `init_design`, the tool will give an error. *Data_type*: string, required

`-oa_ref_libs` *lib1* [*lib2*] ...	Specifies the list of OpenAccess library names to be loaded. These names must also be listed in the `cds.lib` file. All the abstract views in the specified libraries are loaded. Use this parameter to specify standard cell libraries or I/O driver libraries that should all be loaded, even if some of the cells are not currently used in the netlist. The first OpenAccess library that is specified is also used to load the OpenAccess technology data. The specified library names are saved to the `init_oa_ref_libs` root attribute. *Data_type*: string, required
`-oa_lib_path` *libPath*	Specifies the path of oa reference libraries. This option can only be used with the `-add_oa_ref_libs` option. *Data_type*: string, required
`-oa_search_libs` *lib1* [*lib2*] ...	Specifies the list of OpenAccess libraries to be searched. This parameter can be specified only with `-oa_ref_libs`. As the netlist is read, these libraries are searched for cell abstracts to be load on demand for any Verilog module that does not have a lib_cell already defined. This parameter is typically used for libraries of block IP, such as RAMs, where only the abstracts that are actually used in the netlist need to be loaded. The specified library names are saved to the `init_oa_search_libs` root attribute. *Data_type*: string, optional

`-oa_tech_lib` *lib*	Specifies the OpenAccess library name to be loaded. This name must also be listed in the `cds.lib` file. This parameter can be specified only with `-oa_ref_libs`. Use this parameter to specify the library that is used to load the OpenAccess technology data. If not specified, the first library specified in the `-oa_ref_libs` list will be used. The specified library names are saved to the `init_oa_tech_lib` root attribute. *Data_type*: string, optional

Examples

- Use the following command before `init_design` to load LEFs:

  ```
  read_physical -lefs {tech.lef macro_a.lef macro_b.lef}
  ```

- Use the following command after `init_design` to add LEFs to the original LEF list:

  ```
  read_physical -add_lefs {macro_c.lef macro_d.lef}
  ```

- Use the following commands to load an OA cellview and `gpdk045_innovus` is the technological library,

  ```
  set_db init_power_nets  {dvdd avddlf avdd avddhf avdd_h VDDsw}
  set_db init_ground_nets {dgnd agndlf agnd agndhf agnd_h}
  read_mmmc scripts/LP_pll.viewDefinition.tcl
  read_physical -oa_ref_libs {gpdk045_innovus gsclib045}
  read_netlist -oa_cell_view {zambezi45_top LP_pll layout}
  ```

- Use the following commands to load a netlist

  ```
  set_db init_power_nets  {dvdd avddlf avdd avddhf avdd_h VDDsw}
  set_db init_ground_nets {dgnd agndlf agnd agndhf agnd_h}
  read_mmmc scripts/LP_pll.viewDefinition.tcl
  read_physical -oa_ref_libs {gsclib045} -oa_tech_lib {gpdk045_innovus} -oa_search_libs
  {zambezi45}
  read_netlist digital_block.v
  ```

Related Information

- `init_design`
- `read_mmmc`
- init Category Attributes

read_physical Category Attributes

The root attribute in the `read_physical` category is:

- read_physical_check_antenna
- read_physical_check_colored_shape
- read_physical_check_mask_shifts
- read_physical_extend_cell_obs_shapes_under_trim
- read_physical_merge_multi_port_to_single_port
- read_physical_must_join_all_ports
- read_physical_extend_polygon_cell_shapes

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `read_physical` category, use the following command:

```
get_db -category read_physical
```

read_physical_check_antenna

```
read_physical_check_antenna {true | false}
```

Default: `true`

Data_type: boolean, read/write

If you set `read_physical_check_antenna` to `true`, LEF or OA cells will have process antenna consistency checks done for LEF ANTENNA* data (or OA equivalent data) attached to their pins. Input pins with 0 gate-area, output pins with 0 diff-area, and inout pins with 0 gate-area or 0 diff-area values will generate warnings. If `false`, the tool will not perform consistency checking.

read_physical_check_colored_shape

```
read_physical_check_colored_shape {true | false}
```

Default: `false`

Data_type: boolean, read/write

Specifies to check and ignore colored shapes on colorless layers while reading the LEF or DEF data. When set to `true`, the tool errors out if a colored shape is on a colorless layer. When set to `false`, the tool gives error message and ignores the color.

read_physical_check_mask_shifts

```
read_physical_check_mask_shifts {on | off | bypass}
```

Default: `off`

Data_type: enum {on | off | bypass}, read/write

Checks conflicts between the LEF FIXEDMASK and LAYERMASKSHIFT values in the technology and MACRO sections when reading in any LEF files. You can set the following values:

- `on`: When the variable is set as on, the the tool will check for the conflict. In case of a conflict, the tool will give an error and stop running.
- `off`: When the variable is set to off, the tool will not check for the conflict.
- `bypass`: When the variable is set as bypass, the tool will give and error message and will continue running.

read_physical_extend_cell_obs_shapes_under_trim

```
read_physical_extend_cell_obs_shapes_under_trim listOfRoutingLayers
```

Default: `""`

Data_type: string

Specifies a list of routing layers. On each specified *layer* the LEF OBS shapes that are overlapped partially by a shape on the TRIMMETAL layer (that trims the routing layer), will be extended in the preferred routing direction to be fully covered by the trim shape. You can use this attribute for some advanced node libraries to avoid trim/OBS short violations.

read_physical_merge_multi_port_to_single_port

```
read_physical_merge_multi_port_to_single_port {true | false}
```

Default: `false`

Data_type: bool

When set to `true`, multiple ports in a LEF PIN are merged into a single port. However, the pin should not have the `MUSTJOINALLPORTS` attribute as it specifies that all of the ports must be connected individually.

read_physical_must_join_all_ports

```
read_physical_must_join_all_ports {true | false}
```

Default: `true`

Data_type: bool, read/write

If set to `false`, the LEF_MUSTJOINALLPORTS property on a LEF PIN auto-creates MUSTJOIN pins for each

PORT. If set to `true`, the MUSTJOIN pins are not created, but the router must connect to every port with a signal wire or signal via that physically overlaps all the ports.

read_physical_extend_polygon_cell_shapes

```
read_physical_extend_polygon_cell_shapes { {layer extension_amount}… }
```

Default: `""`

Data_type: string, read/write

Specifies a list of layer and a value for creating obs shape for 2D pin/obs shapes. Cells could have 2D objects, which require larger line-end spacing. You can use `read_physical_extend_polygon_cell_shapes` to automatically add SPACING 0 OBS for routing during LEF in.

For any 2D shapes, you can extend edges that are perpendicular to the preferred routing direction of the rectilinear shape by specifying the extension_amount in `read_physical_extend_polygon_cell_shapes`.

Related Command

`read_physical`

read_stream

```
read_stream
[-help]
-layer_map layer_map_files
{[-pvs_fill ] | [[in_files] [-cells cell_list [-offset {x y}]]]}
```

Reads in-stream files or a layer_map and outputs a summary of the cell names read in, and any layer/data types that have data with no map_file entry. The data is automatically scaled during reading to the correct DB units based on the stream units.

- It reads in the metal fill stream data (with top cell name and offset) to overlay on the design. The fill data is displayed to database fill shapes (equivalent to reading DEF FILL data) to allow editing or changing the fill data.
  Reading in fill data is done once per session.
- It reads in-stream cells that have the same names as Innovus cell names to display the stream cell data (for example, overlay or toggle between stream shapes and LEF shapes for the cells).
  If a stream cell name is repeated, it replaces any previous data for that cell.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `read_stream` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man read_stream`.
`-cells` *`cell_list`*	Reads only the specified cells from GDS files. *Data_type*: string, optional
`in_files`	Lists GDS and OASIS files. *Data_type*: list, optional
`-layer_map` *`layer_map_files`*	Specifies the layer map file map GDS layer to design layer. *Data_type*: string, required
`-offset` *`x y`*	Specifies, in microns, the offset for the top-level fill cell. *Data_type*: point, optional
`-pvs_fill`	Specifies to process the PVS FILL data in the read process. *Data_type*: bool, optional

Example

Parse stream cells with specified layer map display stream cell data on top of LEF cell data. The report output is redirected to read_stream.rpt.

```
>read_stream {stdcells.gds memory.gds} -layer_map gds_layer.map > read_stream.rpt
```

Read in metal-fill data and overlay it on the design. The report will be in the log file.

```
>read_stream fill.gds -cell top_fill -layer_map gds_layer.map
```

Example of output report

```
#Cell names read in:

top_fill

fill_1

fill_2

…

#Layer/dtype data in the stream file with no map-file entry

1    10

4    1, 9
```

...

Layer Map File Format

The `-layer_map` file maps stream layer/dtype data to Innovus layer and objects. Stream data does not have net ids, so you can only map stream data for display, or to fill, fill_opc or fill_blockage shapes.

The format for the layer map file is one line for each stream layer and dtype:

layer data_type layer_name object_type

Where

- *layer* is an stream layer number. It is an integer.
- *data_type* is a stream data_type number. It must be either an integer, or a range (e.g. 0-255).
- *layer_name* is normally must be a LEF (or OA tech) layer name. It can only be a "custom" layer name if the obj_type is "display" (e.g. this data is not on any of the LEF layers, but is useful for display purposes). Any custom layer data will be displayed like data created with add_gui_shape or add_gui_text. The *layer_name* is case-sensitive.
- *object_type* is one of these keywords:
  - `fill`: Equivalent to DEF FILL shapes
  - `fill_opc`: Equivalent to DEF FILL with + OPC shapes
  - `fill_blockage`: Equivalent to DEF BLOCKAGE + FILLS shapes
  - `display`: Is only for display purposes, and cannot be flattened.

  `fill`, `fill_opc`, and `display` can optionally be followed by
  `:mask:`*`mask_num`*
  where `mask_num` is the mask number for the shape for a multi-mask layer (equivalent of `DEF + MASK` *`mask_num`* for a shape).
  fill_blockage can optionally be followed by
  `:name:`*`blockage_name`*
  where *`blockage_name`* is the name given to all the blockages from this layer/dtype.

  Any text on the same layer/data_type will be mapped to the same DB layer as a text object on that layer. About the TEXT font and size, font 0 could be default (or other font decided by RD). Size could use the original size in GDS and scale it if dbu mismatch to Innovus.
  The *object_type* keywords are case insensitive. The tool ignores blank lines or lines beginning with #.
  A given layer/dtype combination can only appear once.

Example 1:

```
#Stream map-file for metal fill, via-fill and fill blockages

#only metal1 has two masks
```

```
#layer    dtype     layer_name     obj_type
1         1         metal1         fill:mask:1
1         2         metal1         fill:mask:2
51        1         cut1           fill
2         1         metal2         fill
52        1         cut2           fill
3         1         metal3         fill
…
101       1         metal1         fill_blockage:name:blkg1
101       2         metal1         fill_blockage:name:blkg2
101       3-255     metal1         fill_blockage
```

Example 2:

```
#Stream map-file for cell-data to display on top of LEF cell data
#Only routing layers and the cell-outline on custom layer “outline”
#are mapped. It does not show cut layers or layers below metal1.
#layer    dtype     layer_name     obj_type
1         0-255     metal1         display
2         0-255     metal2         display
...
#custom layer “outline” is created if it does not already exist
100       1         outline        display
```

Related Information

- write_stream
- write_stream Category Attributes

relink_db_files

```
relink_db_files
[-help]
-db_dir db_directory
-new_lib_dirs {new_lib_directory1 new_lib_directory2 ...}
```

Relinks symbolic links to library files inside a DB directory.

By default, `write_db` saves the location of library files as symbolic links under `<db_dir>/libs/…`. When a DB directory is copied to a new network where all the libraries are in a different location, or a new version of the library files are needed, you can use `relink_db_files` to change the symbolic links to new locations .

The `relink_db_files` command will search each `-new_lib_dirs` directory and the sub-directory tree below it for each library file name inside `<db_dir>`, and create a symbolic link to the new location. Only the base file name is used for the search (except for `qrcTechFile`). Therefore, two path names inside the new directory, such as `/timing/fast/std.lib` and `/timing/slow/std.lib`, will have duplicate names of "`std.lib`". The duplicate names are not supported and will cause an error. You can use the `read_db` command to update all the LEF full-path names or use a new MMMC files with all the new .lib full-path names if duplicate file names need to be updated. If there are missing library file names, the tool will show an error.

The `relink_db_files` command supports `.lib`, `.lef`, and `qrcTechFile` library file types.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `relink_db_files` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man relink_db_files`
`-db_dir` *db_directory*	The current db directory which contains incorrect library symbolic links.
`-new_lib_dirs` *{new_lib_directory1 new_lib_directory2 ...}*	The new directories to search for library files.

Example

If the current LEF files are all under`/libs/lefs_v1.0/` (or sub-directories) and the current `.lib` and `qrcTechFiles` are all under`/libs/timing_v1.0/` (or sub-directories), you use the following command to update the LEF files to use `/libs/lefs_v2.0/`:

```
>relink_db_files -db_dir my_db -new_lib_dirs {/libs/lefs_v2.0 /libs/timing_v1.0}
```

Note: The command must find every library file. Therefore, you need to list the top of the old timing directory tree

along with the top of the new LEF files directory tree.

Related Information

- write_db
- read_db

reset_design

```
reset_design [-help]
```

Removes library data and design data from the Innovus database. This allows you to reload the design in the same session while debugging some problem and provides faster debugging when repeatedly loading files to debug problems inside one session.

It does not reset the internal state of applications or global settings, so it is not reliable enough to use in a real flow. For example, it does not free collections but only invalidates them. If you try to access collections saved in TCL variables, you will not be able to see those collections. If you have saved pointers to DB objects in Tcl variables, they will be invalid and may even cause a crash if used.

If you have any unexpected problems, you should start a new session without using `reset_design`.

Parameters

`-help`	Prints a brief description of the `reset_design` command usage. For a detailed description of the command and all of its parameters, use the `man` command: `man reset_design`

Example

The intended usage model is given below:

```
init_design (or read_db)

<read some files that have problems (such as a Tcl script, MMMC file, LEF file)>

<fix the files based on error messages>

reset_design

init_design (or read_db)

<read modified files to see if they are ok now>
```

If there are still errors, make more modifications, and go back to `reset_design`.
If the final result is good, you should start over in a new session and repeat it without `reset_design` to continue with the flow.

Related Information

- `read_db`

run_abstract

```
 run_abstract
[-help]
-stream_files file_list
[-generate_script_only file.il]
[-lib_files file_list]
[-output_lef_file file.lef]
[-run_script_only file.il]
[-verilog_stub_files file_list]
```

Runs abstract to generate LEF from GDSII. The sequence of flow for the `run_abstract` command is as follows:

1. Checks if the executable “abstract” exists in the path. If not, it generates an error.
2. Generates “appropriate” configuration file.
3. Executes abstract with the configuration file.
4. Checks that the “abstract” exits with an exit code of “0”. If not, it generates an error.

The `run_abstract` command is run before loading a design.

The options for the `run_abstract` command are set using the run_abstract Category Attributes.

Note:

1. This command does not fully supports the block LEF abstract. Run 'ABSTRACT' standalone to generate LEF from block gds.
2. This command is under beta control. Contact your Cadence representative for more information related to this command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `run_abstract` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man run_abstract`
`-stream_files` *file_list*	Lists the GDSII files that need to be translated **Note**: It is important that only GDSII files of the same type are listed together. For example, std-cells, IO cells, and block cells should be listed in separate runs. *Data_type*: string, required
`-generate_script_only` *file.il*	Generates the SKILL script that can be given to the abstract tool but does not execute it. *Data_type*: string, optional
`-lib_files` *file_list*	Lists liberty (.lib) files. The .lib files can also be used to define pin directions by using the direction from the matching .lib cell and pin names. *Data_type*: string, optional
`-output_lef_file` *file.lef*	Outputs the LEF file that will have the LEF macro abstracts but not technology file information. *Data_type*: string, optional
`-run_script_only` *file.il*	Does not re-generate the script but just executes it with the specified file. *Data_type*: string, optional
`-verilog_stub_files` *file_list*	Defines the pin directions by using the direction from the matching Verilog module and pin names. *Data_type*: string, optional

run_abstract Category Attributes

The root attributes in the run_abstract category are:

- run_abstract_abstract_blockage_cut_around_pin
- run_abstract_antenna_connectivity
- run_abstract_antenna_diffusion_geometry
- run_abstract_antenna_gate_geometry
- run_abstract_blockage_detailed_layers
- run_abstract_boundary_layers
- run_abstract_cell_symmetry
- run_abstract_export_lef_version
- run_abstract_extract_layers_power
- run_abstract_extract_layers_signal
- run_abstract_extract_pin_layers_power
- run_abstract_extract_pin_layers_signal
- run_abstract_input_cell_type
- run_abstract_input_stream_layer_map_file
- run_abstract_input_lef_tech_file
- run_abstract_keep_output_files
- run_abstract_pins_analog_names
- run_abstract_pins_clock_names
- run_abstract_pins_ground_names
- run_abstract_pins_output_names
- run_abstract_pins_power_names
- run_abstract_pins_text_pin_map
- run_abstract_pre_abstract_script
- run_abstract_selected_cells
- run_abstract_site_name
- run_abstract_verbose

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `run_abstract` category, use the following command:

```
get_db -category run_abstract
```

run_abstract_abstract_blockage_cut_around_pin

`run_abstract_abstract_blockage_cut_around_pin` *layer_list*

Default: ""

Data_type: string, read/write

Specifies that obstruction should be cut around pin for standard cells.

By default, `run_abstract` creates obstructions on pin shapes.

- If `run_abstract_input_cell_type` is `std`, the default value for `run_abstract_abstract_blockage_cut_around_pin` is the list of all metal and via layer names. This means that abstract will not cover obstruction on pins for standard cells on all metal and via layers if `-abstract_blockage_cut_around_pin` is specified.
- If `run_abstract_input_cell_type` is `block` or `io`, the default value for `run_abstract_abstract_blockage_cut_around_pin` is the list of all via layer names. This means that abstract will not cover obstruction on pins for blocks and io pads on all via layers if `-run_abstract_abstract_blockage_cut_around_pin` is specified.

run_abstract_antenna_connectivity

`run_abstract_antenna_connectivity {`*layer1 connect_layer layer2*`}`

Default: ""

Data_type: string, read/write

Specifies the layers for which connectivity is to be extracted. The syntax is `{`*layer1 connect_layer layer2*`}`.

run_abstract_antenna_diffusion_geometry

`run_abstract_antenna_diffusion_geometry {{`*layer_name*`} {`*logical_expression*`}}`

Default: ""

Data_type: string, read/write

Specifies the diffusion layer, followed by the expression to remove the gate channel area from the diffusion region.

run_abstract_antenna_gate_geometry

```
run_abstract_antenna_gate_geometry
```

Default: ""

Data_type: string, read/write

Specifies the poly layer that forms a gate along with the layer expression to derive the gate area. This option also triggers the creation of antenna models.

run_abstract_blockage_detailed_layers

```
run_abstract_blockage_detailed_layers layer_list
```

Default: ""

Data_type: string, read/write

Specifies the layers for which a detailed blockage model is to be created. The detailed blockage model generates blockages only at those places on the layer where there are real shapes in the cell. This only applies to the IO and block cells and not to standard cells.

run_abstract_boundary_layers

```
run_abstract_boundary_layers layer_list
```

Default: ""

Data_type: string, read/write

Specifies the drawn layers to extract the cell boundary. If not specified, abstract uses the prBounbdary object as the boundary size.

By default, *layer_list* list is empty, and the prBoundary is used. The prBoundary comes from an explicit GDS layer that is used to compute the LEF SIZE (and OVERLAP OBS shapes for rectilinear boundaries). If there is no explicit GDS prBoundary layer, the boundary can be computed from the bounding box of geometries on this list of layers.

Note: This option will not normally work for core standard cells because they almost always have diffusion and metal shapes extending outside the real prBoundary. These shapes are usually shared with the row above or below for the power rails. This option can be useful for blocks that have no prBoundary and where a little lost area due to worst-case bounding box approximations is acceptable.

run_abstract_cell_symmetry

```
run_abstract_cell_symmetry {R0 | X | Y | R90 | X Y | X R90 | Y R90 | X Y R90}
```

Default: {X Y}

Data_type: string, read/write

Specifies a property value for cell symmetry. The valid values for the property symmetry are R0, X, Y, R90, X Y, X R90, Y R90, and X Y R9.

run_abstract_export_lef_version

```
run_abstract_export_lef_version {5.3 | 5.4 | 5.5 | 5.6 | 5.7 | 5.8}
```

Default: `5.7`

Data_type: enum {5.3 5.4 5.5 5.6 5.7 5.8}, read/write

Specifies the version of LEF to be exported. The default version is the same as the version of the technology LEF file being imported.

run_abstract_extract_layers_power

```
run_abstract_extract_layers_power layer_list
```

Default: `""`

Data_type: string, read/write

Specifies the layers through which the extractor extracts each power net. This is used to reduce the search space if abstract is taking too much run time for each cell.

Usually not applicable to standard cells. For blocks, it is common to only extract the power nets on the top one or two metal layers.

run_abstract_extract_layers_signal

```
run_abstract_extract_layers_signal layer_list
```

Default: `""`

Data_type: string, read/write

Specifies the layers through which the extractor extracts each net. This is used to reduce the search space if abstract is taking too much run time for each cell. Usually not applicable to standard cells.

run_abstract_extract_pin_layers_power

```
run_abstract_extract_pin_layers_power layer_list
```

Default: `""`

Data_type: string, read/write

Determines the shapes, which are found by the extractor, to be turned into pins. This argument is valid only if the associated layer, geometry specification and connectivity have been provided in the technology LEF. Usually not applicable to standard cells.

run_abstract_extract_pin_layers_signal

```
run_abstract_extract_pin_layers_signal layer_list
```

Default: ""

Data_type: string, read/write

Determines the shapes, which are found by the extractor, to be turned into pins. This argument is valid only if the associated layer, geometry specification and connectivity have been provided in the technology LEF. Usually not applicable to standard cells.

run_abstract_input_cell_type

```
run_abstract_input_cell_type {std | io | block}
```

Default: std

Data_type: enum {std io block}, read/write

Selects the cell type being translated with abstract. The tool adjusts its settings on the basis of the selected cell type.

run_abstract_input_stream_layer_map_file

```
run_abstract_input_stream_layer_map_file file.map
```

Default: ""

Data_type: string, read/write

Specifies the file that maps GDS layer number/data type to LEF layer names in the Virtuoso format.

For example, the GDS file is not colorized, you could use the common Virtuoso format GDS layer map to stream the GDS file.

```
#layer
name #purpose name #stream layer #stream data type
V0 drawing 35 0
V0 drawing 35 235
V0 drawing 35 236
M1 drawing 15 0
M1 drawing 15 235
M1 drawing 15 236
M1 drawing 15 239
```

```
For example, the gds file is colorized, you could specify the
mask color in gds layer map to stream gds file.
#layer name #purpose name #stream layer #stream data type #photo mask color #color state
V0 drawing 35 0
V0 drawing 35 235 mask1Color unlocked
V0 drawing 35 236 mask2Color unlocked
```

```
M1
drawing 15 0
M1 drawing 15 235 mask1Color unlocked
M1 drawing 15 236 mask2Color unlocked
M1 drawing 15 239 mask3Color unlocked
}
```

run_abstract_input_lef_tech_file

`run_abstract_input_lef_tech_file` *`file.lef`*

Default: ""

Data_type: string, read/write

Specifies the technology LEF file. This is used to get all the layer names and their types, such as routing, cut and the layer order for extracting connectivity.

run_abstract_keep_output_files

`run_abstract_keep_output_files {true , false}`

Default: false

Data_type: bool, read/write

Specifies to keep the temporary files/libraries that are created in the process after the `run_abstract` command finishes.

run_abstract_pins_analog_names

`run_abstract_pins_analog_names` *`pattern`*

Default: ""

Data_type: string, read/write

Identifies analog pin names based on label strings in the abstract to set the "USE ANALOG" property of LEF.

run_abstract_pins_clock_names

`run_abstract_pins_clock_names` *`pattern`*

Default: ""

Data_type: string, read/write

Identifies clock pin names based on label strings in the abstract to set the “USE CLOCK” property of LEF.

run_abstract_pins_ground_names

`run_abstract_pins_ground_names` *pattern*

Default: ""

Data_type: string, read/write

Identifies ground pins based on label strings in the abstract to set the “USE GROUND” property of LEF.

run_abstract_pins_output_names

`run_abstract_pins_output_names` *pattern*

Default: ""

Data_type: string, read/write

Identifies output pins based on label strings in the GDS to set the direction to OUTPUT property of LEF.

run_abstract_pins_power_names

`run_abstract_pins_power_names` *pattern*

Default: ""

Data_type: string, read/write

Identifies power pin names based on label strings in the abstract to set the “USE POWER” property of LEF.

run_abstract_pins_text_pin_map

`run_abstract_pins_text_pin_map` *pattern*

Default: ""

Data_type: string, read/write

Maps text labels to pins on nets. Specify the layer purpose pairs based on which you want the abstract generator to search for geometry of any given layer-purpose pair with a text label.

run_abstract_pre_abstract_script

`run_abstract_pre_abstract_script` *file.il*

Default: ""

Data_type: string, read/write

Specifies a skill file that will be executed in abstract before the auto-generated script is executed. Optional.

run_abstract_selected_cells

`run_abstract_selected_cells` *`pattern`*

Default: `""`

Data_type: string, read/write

Selects cells to create abstract for using regex style expressions.

run_abstract_site_name

`run_abstract_site_name` *`site_names`*

Default: ""

Data_type: string, read/write

Specifies the site to be used for macros. This site is added to all the cells.

run_abstract_verbose

`run_abstract_verbose {true , false}`

Default: `false`

Data_type: bool, read/write

Specifies the verbose mode with extra print.

set_cell_power_domain

```
set_cell_power_domain
[-help]
[-reset]
[-file file_name]
```

Defines domains for multi-VDD and multi-VSS cells. When reading an instance ASCII power file to perform power-rail analysis, if there are missing power values associated with ground pins, the software uses the information specified with the `set_cell_power_domain` command to derive domain association and distributes power to each ground net accordingly.

This domain information is stored in a side file that is used by power analysis to calculate power using the correct voltage for each domain. If you are specifying an external instance ASCII power file with pin information, this domain information is used to correctly distribute power to each pin.

Use this command before performing power and rail analysis.

Parameters

`-file file_name`	

	Specifies the name of the file containing the cell names and corresponding power-ground pairs.
	The format of the file is:
	`CELL: <cell name1>`
	`<power1> <gnd1>`
	`<power2> <gnd2>`
	`CELL: <cell name2>`
	`<power1> <gnd1>`
	`...`
	Data_type: string, optional

`-help`	Outputs a brief description for the `set_cell_power_domain` parameter. For a detailed description of the command, use the `man` command: `man set_cell_power_domain`.
`-reset`	Resets all specified options back to default values. *Data_type*: bool, optional

Examples

- The following command define two domains, `VDD:VSS` at `1v` and `VDDm:VSSm` at `0.84v`, of the cell `mycell` in the file `domain_file`:

  ```
  set_cell_power_domain -file domain_file
  ```

  The following is a snippet from `domain_file`:

  ```
  CELL: mycell
  VDD_1v  VSS_1v
  VDDm_0.84v  VSSm_0.84v
  ```

- "Dynamic Power and IRDrop Analysis" in the *Voltus Stylus Common UI User Guide*

set_library_unit

```
set_library_unit
[-help]
[-cap capUnit]
[-time timeUnit]
```

Sets the time and capacitance unit values for constraints and report generation.

The timing constraints (SDC) files do not contain any unit specification for capacitance and time values. Hence, the units for these values are considered to be same as those specified in the timing libraries. The commands, e.g., `report_timing`, require consistent units to generate reports. If an inconsistency occurs in the timing libraries, the default unit of time (as ns) and capacitance (as pf) is used.

You can use this command when you need to override the library units, or force the setting of units when libraries have different units.

Note: You must set the `set_library_unit` command before the design and constraints are read.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `set_library_unit` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man set_library_unit`.
`-cap` *capUnit*	Specifies the capacitance load unit in the timing library. *Default:* `1.0` pf *Data_type*: string, optional
`-time` *timeUnit*	Specifies the time unit to be used for timing constraints. The valid values are 1ns, 1ps, 10ps, 100ps. *Default:* `1.0` ns *Data_type*: string, optional

Example

- The following command sets the time unit for the design to `10`ps:

  ```
  set_library_unit -time 10ps
  ```

Related Information

- `report_timing`
- Timing Analysis chapter in the *Innovus Stylus Common UI User Guide*

set_power_lib_files

```
set_power_lib_files
[-help] [<in_file <file1[file2] ...>>] [-reset]
```

Specify the name of the timing library file(s) for dynamic power analysis. This command allows you to run the dynamic power analysis flow without reading a dotlib into design database to reduce background memory consumption. You must have an external TWF file to run this flow as the timing engine will not be invoked from within the software. This flow is recommended for large designs where front-end processing of timing libraries is high. Some of the database query commands will not work if `set_power_lib_files` is used.

This command works in conjunction with the `set_power_def_files` and `set_power_spef_files` commands.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_power_lib_files` parameter.
in_file <file1[file2] ...	
	List of timing library files. *Data_type*: string, optional
`-reset`	Resets all specified options back to default values. *Data_type*: bool, optional

Examples

- The following Tcl shows the use model of the **set_power_lib_files** command that works in conjunction with the set_power_def_files/set_power_spef_files flow to perform dynamic power analysis:

```
read_libs -lef tech1.lef tech2.lef
set_power_lib_files /../library1.lib /../library2.lib
set_power_def_files adder_routed.def
set_power_spef_files {test.spef }
read_twf test.twf2
read_netlist ../design/postRouteOpt.enc.dat/super_filter.v.gz -top super_filter
init_design
set_default_switching_activity -combinational_clockgate_ratio 1 -period 2.01ns -input_activity
0.2 -integrated_clock_gate_ratio 1
set_db power_default_supply_voltage 1.1 power_method dynamic_vectorless
report_power
```

trim_design

```
trim_design
[-help]
[-core_to_boundary distance]
[-dir output_dir_to_save_trimmed_design]
[-encrypt_name proc_name_to_encrypt]
[-name trim_design_name]
[-nets list_of_net_names]
[-place_only]
[-area {x1 y1 x2 y2} | -polygon list_of_points | -selected_route_blockage ]
```

Allows you to specify the coordinates of a box to create a small portion of the design as an independent design. This trimmed down version of the design can be then used for investigation and analysis. When you share the trimmed design for investigation of a localized issue, you do not need to share the whole third-party IP information, thereby ensuring confidentiality of the third-party data.

While the trimmed design completely preserves the physical data, it does not preserve the timing and the power domain data. Working on a small portion of the design offers a faster turnaround time and a lesser memory footprint.

Notes:

- The `trim_design` command retains the attributes and properties of all the standard cells and macros that are completely inside the trim box/area. All hard macros that overlap with the trim box/area are also preserved. It does not include any standard cells or macros that are completely outside the specified trim box/area.
- The `trim_design` command preserves all overlapping rows, sites, and colors.
- The `trim_design` command flattens all instances and net names. All instances in the trim box/areal lose their original logic hierarchy and appear ‘flat’ in the trimmed database. Any naming conflicts arising due to flattening are automatically resolved. For example, h1/h2/i1 in the full design will appear as i1 in the trimmed design. Also, h1/h4/i1 may appear as i1_uniquify1, to distinguish it from i1.
  Note: To resolve naming conflicts due to the loss of hierarchy, additional name uniquification is done. A mapping of original nets/instances names vs their trimmed design modified names, is written in a map file for book keeping purpose.
- The `trim_design` command maintains the design parameters such as instance location/orientation, regular/special wire and its connectivity relative to the original full design.
- The `trim_design` command retains the attributes and properties of all the nets having some instances inside the trim box/area. It also preserves (pushes down) the nets that are not connected to any instance in the trim box/area, but have some wires overlapping with trim box/area. Nets having all instances and wires outside of trim box/area are discarded.
- The `trim_design` command creates ports for all wires crossing the boundary of the trimmed design.
- The `trim_design` command preserves the tracks, attributes and colors of all wires that are completely inside the trim box/area. All wires that overlap with the trim box/area are also preserved. It does not include any wire that is completely outside the specified trim box/area.

- The `trim_design` command preserves the Power/Ground/Special wires that overlap with the boundary of the trim box by cutting them against the boundary. It creates additional PG ports at cross points these wires.
- The `trim_design` command discards fences, regions, guides, instance groups, and power domains.
- The `trim_design` command saves the `.globals` files. The `.globals` file has the .lef list copied from original full design's .globals file.
- The `check_place` command reports all violations that were there on instances in the box in the actual design. However, since hierarchical fences are not brought back, the trimmed design may not have the Region/Fence and Not-of-Fence Violations.
- The `check_drc` command reports all violations that were there on nets in the box of actual design. However, since only the net wires crossing box boundary are preserved, the trimmed design may have some extra violations.

Parameters

`-help`	Prints a brief description that includes type and default information for each trim_design parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man trim_design`
`-area {x1 y1 x2 y2}`	List of coordinates to represent a box for getting the trimmed design. **Note**: The specified box is snapped to the instance grid. All instances in the box lose their original logic hierarchy and appear flat in the new db. *Data_type*: string, required
`-core_to_boundary` *distance*	Specifies that any instance lying within the distance of coreToBoundary (in microns) to the trim box will be discarded. *Default*: 2 *Data_type*: string, optional
`-dir` *output_dir_to_save_trimmed_design*	Specifies the name of the directory in which the data related to the trimmed-design is saved. *Data_type*: string, optional
`-encrypt_name` *proc_name_to_encrypt*	Specifies that the names of instances and nets in the design will be encrypted when the trimmed design is saved. *Data_type*: string, optional

`-name` *trim_design_name*	Specifies the top-level name of the new trimmed design. *Data_type*: string, optional
`-nets` *list_of_net_names*	Species the nets that are to be completely enclosed by the specified shape by taking union of shape with net-boxes. *Data_type*: string, optional
`-place_only`	Specifies that only instances will be pushed. *Data_type*: bool, optional
`-polygon` *list_of_points*	List of coordinates to represent a polygon for getting the trimmed design. *Data_type*: string, required
`-selected_route_blockage`	Specifies that the selected routing blockages will be used to infer the box or polygon for getting the trimmed design. *Data_type*: bool, required

Examples

- The following command creates a trimmed design, `trim_db`, with the specified polygon coordinates and save the data in the DB file.

  ```
  trim_design -dir DB -name trim_db -polygon {{500.0 700.0} {500.0 900.0} {500.0 900.0} {700.0 900.0} {700.0 900.0} {700.0 800.0} {700.0 800.0} {800.0 800.0} {800.0 800.0} {800.0 700.0} {800.0 700.0} {500.0 700.0} }
  ```

- The following command creates a trimmed design, based on the selected routing blockage:
  ```
  trim_design -dir DB -name trim_db -selected_route_blockage
  ```

- The following command uses a `get_new_name` procedure to encrypt the names on the instances and nets in the trimmed design `trim_db`:
  ```
  trim_design -dir DB -name trim_db -area {300.0 200.0 800.0 700.0} -encrypt_name gen_new_name
  ```

  The following is a structure of the encryption procedure file. You can customize this procedure:

  ```
  proc gen_new_name {name} {
    global n
    if {![info exists n]} {
      set n 0
    }
    set new_name en_name__$n
    incr n
    return $new_name
  }
  ```

  - Trimming the Design

update_lef_macro

```
update_lef_macro
[-macros {listOfMacros}]
lef_file
```

Replaces the current MACRO information in the design with the MACRO information in the specified LEF file. You can use the update_lef_macro command to change the geometry information of a macro, such as boundary size, pin location, pin layer, and pin size. You cannot use the command to change the number or name of pins for a macro.

The update_lef_macro command only reads and replaces the MACRO information from the LEF file; it does not use any other information in the file.

Parameters

lef_file	Specifies the LEF file to read. *Data_type*: string, required
-macros {*listOfMacros*}	Replaces the information for the specified macros only. *Default:* Replaces the information for all macros in the LEF file. *Data_type*: string, optional

Related Information

- LEF Syntax chapter in the *LEF/DEF Language Reference*

write_db

```
write_db
[-help]
[-add_ignored_timing]
[-current_top_cell_only]
[-skip_file {metric cmd}]
[-no_fill]
[-no_pvs_fill]
[-no_wait out_file]
[-timing_graph [-no_constraint ]]
[{{dir_name [[-def][-verilog][-common]]} |
{{-oa_lib_cell_view {libname cellname viewname} | -oa_view {OAViewName}}[-oa_used_libs_only | -
oa_libs ]}}
[[-sdc ] [-rc ]]
[-gzip ]
[-lib]
[-lib_to_ldb]
[[-user_path [-keep_input_path ]] ]
```

Writes the complete design database in the native Innovus DB format if `<out_dir>` is given, or as an OpenAccess database (OA DB) if `-oa_lib_cell_view` or `-oa_view` is given.
The native Innovus DB format in `<out_dir>` must be used when you have LEF files for technology and physical library data in your original initialization script (e.g. `read_physical -lefs <files>`), while the OA DB output must be used if you use OA libraries (for example, `read_physical -oa_ref_libs <libs> -oa_search_libs <libs>`) during initialization.

There are different types of OA methodologies and flows supported that are controlled by root attributes. Use `get_db oa*` to see the attributes, and look at the *Mixed Signal Interoperability Guide* for more details on their effects on `write_db`/`read_db`.

You can write a design to the same location from which you read the design. The new data will overwrite the previous data.

You can use the `write_db` command at any time after `init_design`.

By default, external file references used inside *<out_dir>* (e.g. to library files, or SDC files that are not modified) are stored using a portable format that allows you to copy *<out_dir>* anywhere in the same network where the full path names are still valid, and then read it with `read_db`. This portable format is not supported for OA DBs that require the usage of a cds.lib file to find physical file locations.

Note:

- The `write_db` command does not save the state of the `timing_enable_simultaneous_setup_hold_mode` timing attribute. When the attribute is set to `true`, various physical design functions in the system are disabled. When the design is restored (using the `read_db` command), the physical design commands are required to be active so that the system can be properly initialized.
- You should not modify the contents of a saved DB (*.enc.dat or *.db) at any time. If the contents of the saved

DB are modified, restoring such modified DB might cause problems later or lead to DB corruption or crashes.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_db` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_db`.

`-add_ignored_timing`	If you use `read_db -no_timing` to read the DB, the timing data is not loaded. This option allows you to copy the ignored timing data from the original `read_db` location and add it back during `write_db` like this:
	
	`read_db -no_timing test1`
	
	`<physical editing commands ...>`
	
	`write_db -add_ignored_timing test2`
	
	This usage model is intended to allow faster physical-only editing, like DRC fixing, where the netlist is not modified. If you change the netlist, unpredictable results may occur when reading the `test2` DB using timing data copied from `test1`.
	
	Data_type: bool, optional

`-current_top_cell_only`	Specifies to only write current design module and its submodules in the netlist. By default, all the modules from the input netlist will be saved even if they do not belong to current design. *Data_type*: bool, optional
`-oa_lib_cell_view {`*`libname cellname viewname`*`}`	Saves the design in OpenAccess database format using the specified lib, cell, and view names. The design is saved in the *lib/cell/view* OA directory. **Note**: Usually, the cell name is the same as the design top cell name. If the cell name specified is different from the top cell name, it means that the top module created in OpenAccess would have the new cell name instead of the original name. *Data_type*: string, optional

`-common`	Saves the common-db design data to the specified directory. **Note**: Tool does not save the common-db when LEF is not available. *Data_type*: bool, optional
`-def`	Saves a DEF file, in addition to the normal DB files in the DB directory. This parameter is normally not used for flat or block flows and is not used by `read_db`. It can be useful in a hierarchical flow, where you want to use `assemble_design` to read only the netlist and the DEF files without opening up each design DB and writing out the Verilog and DEF files separately (see `-verilog`). *Data_type*: bool, optional
dir_name	Specifies the name of the output directory to write the DB using native Innovus formats. It is common to add a `.dat` extension to the directory name. This cannot be used with OA-based designs. *Data_type*: string, required
`-keep_input_path`	Saves the path same as the path in the input file. *Data_type*: bool, optional

`-lib_to_ldb`	Converts the `.lib` timing libraries referenced in the MMMC file to the `.ldb` format and writes them in a libs sub-directory inside the output design directory. References to the original .lib files in the MMMC file are changed to the corresponding `.ldb` files inside the libs sub-directory. This makes the design directory much larger because it has all the timing library data inside it and is not recommended for normal flows. Normally a user should setup `.ldb` files in an external library directory and have the MMMC files use them directly to avoid this overhead. Using `.ldb` files will make `read_db` faster when it reads the library data, so this option is useful for doing “throw-away” debugging experiments that require repeated sessions at the cost of a one-time conversion, and carrying the library data with the design. See the `write_ldb` command for more information about the usage of `.ldb` files. *Data_type*: bool, optional

`-lib`	Normally external file references, such as to the LEF, .lib, SDC, files are saved using full path-name, symbolic links to the original files inside a libs sub-directory inside the DB directory.This option forces copies of the files rather than symbolic links in the libs sub-directory so there are no external file references. That makes the DB directory much larger, but it is now suitable for sending to a different network where the library and external data files are not available. An OA DB will still have OA library references using the normal cds.lib methodology, but any other external file references will be copied inside the cellview directory. **Note:** Any future sessions that use `read_db` and then `write_db` will have references to files inside this design directory rather than to the original external locations. So, you must keep this DB directory around as long as any other DB references it (or you must use `write_db -lib` in the later session to force another local copy of the external files). *Data_type*: bool, optional
`-no_constraint`	This option requires the -timing_graph option, and saves the timing graph data without the SDC constraints data. This is useful to reduce the disk size, and speedup write_db, read_db. But the timing-graph data cannot be loaded by any other release version, and without the SDC files, the timing constraints would be lost if loaded by a different release version. Note, you can still load the timing-graph with the current release version, and then use `write_db` without the `-no_constraint` option, to regenerate the SDC files from the timing-graph and then use read_db with a later release. *Data_type*: bool, optional

`-no_fill`	Does not write any metal or via fill shapes inside the DB. This is useful if you did ECO routing, and the fill data is going to be regenerated anyway, so it is not worth saving the current fill data any more. All the fill data that would go to DEF FILLS section (floating fill data), or the DEF SPECIALNETS section with + SHAPE FILLWIRE or FILLWIREOPC will be ignored and not written. *Data_type*: bool, optional
`-no_pvs_fill`	Does not save the PVS fill data file. In some PVS flows, a stream (GDS) file from PVS is saved inside the Innovus DB directory (see the PVS documentation for more details). During read_db this file is not read, but can be optionally loaded or used later in the flow. By default, if the PVS fill file exists, write_db will copy it from the read_db location to the new DB directory. If ECO changes to the current design have made the PVS fill file invalid, use this option to stop it from being copied. *Data_type*: bool, optional

`-no_wait` *`out_file`*	Writes the design in a separate process. You can continue executing new commands simultaneously while the design is being saved. This is useful when you want to save intermediate results without waiting for the save to complete. Simultaneous commands that modify the DB will have no effect on the saved design. The memory is shared unless you modify it, so there is little or no increase in the memory usage for small changes, but if you completely changed everything in the DB, you would temporarily have up to double the total memory for both processes to run. Each process may use multiple CPUs up to the limits set by `set_multi_cpu_usage -local_cpu`. Therefore, if the simultaneous commands use multiple local CPUs, you may temporarily have up to double the max local CPU usage until `write_db` is complete. The actual number of CPUs used by `write_db` varies with design size and the type of data being saved. So, you would need to experiment with your specific design to find the number of CPUs used, or set the `-local_cpu` value temporarily lower to limit it. The output messages or error messages which normally go to stdout/stderr (e.g. the xterm) generated by `write_db` will be redirected to *out_file*. Any .log or .logv information is ignored and lost. You can check *`out_file`* to see if `write_db` completed successfully. If you give the `exit` command, the session will wait for `write_db -no_wait` to complete before exiting, while other commands will run simultaneously. This allows flow scripts that run multiple sessions to know any save from the previous session is complete before the next session uses it, without the need to poll or check *out_file*. **Example:** The following command writes the design into the `my_design.dat` directory, and any messages are written to `save.1`. `write_db my_design -no_wait save.1` *Data_type*: string, optional

`-oa_libs`	Saves all OA libraries specified in cds.lib under the directory libname/cellname/viewname/libs/oa/. **Note**: This parameter works only in OA designs. *Data_type*: bool, optional
`-oa_used_libs_only`	Saves only the libraries listed in the `init_oa_tech_lib`, `init_oa_ref_libs`, and `init_oa_search_libs`, which are referenced through the on-demand processing. On specifying this parameter, a new cds.lib file is created with only the specified libraries. The libraries are saved under directory libname/cellname/viewname/libs/oa/. **Note**: This parameter works only in OA designs. *Data_type*: bool, optional
`-rc_extract`	Writes RC extraction data, including data for incremental extraction. By default, Innovus does not automatically save RC extraction data to save disk space and run-time. The -rc_extract parameter does not save RC extraction data if the design is not extracted or if extract_rc_engine = pre_route. *Data_type*: bool, optional
`-sdc`	By default, if the SDC timing constraints have not been modified, a link to the original external SDC file is kept to reduce the disk size. If the SDC timing constraints were modified, then the SDC files are automatically stored in the DB directory. This option will force all SDC files to be copied locally inside the DB directory, even if they did not change. **Note:** Any future sessions that use read_db and then write_db will have references to SDC files inside this design directory rather than to the original external location. So, you must keep this DB directory around as long as any other DB references it (or you must use write_db -sdc in the later session to force another local copy of the SDC files). *Data_type*: bool, optional

`-skip_file {metric cmd}`	Removes the specified db files. • If you save a design with the `-skip_file {metric}` option, the tool does not save file db `inn.um.gz` and .metric.gz. • If you save a design with the `-skip_file {cmd}` option, the tool does not save the `inn.cmd.gz` file. • If you save a design with the `-skip_file {metric cmd}` option, all `inn.um.gz`, `.metric.gz`, and `inn.cmd.gz` files cannot be saved.
`-timing_graph`	Saves the timing graph data. When this parameter is specified, the `-rc_extract` parameter is also automatically enabled. This means that the RC extraction data is also saved along with the timing graph data at the post_route stage. At the pre_route stage, the RCs are not saved but all information is present to fully time the design without the need to rebuild the timing graph. Commands that use timing analysis results like `report_timing`, `opt_design`, etc. all use the saved timing graph. This can save significant CPU after `read_db`. A user can get the same timing seen previously without waiting for the timing analysis to be repeated. **Note**: This feature is dependent on the build version and tool. Tempus cannot read a timing-graph written by Innovus. You must write and read the timing graph using the same tool and build. You can still load the design with a different tool or build, but the timing-graph is lost and you must repeat the timing analysis. The timing graph data must be fully built (e.g. with `report_timing)` before calling `write_db -timing_graph`. *Data_type*: bool, optional

`-gzip`	Saves the design as a gzipped tar file. write_db writes *<out_dir>* and automatically turns on -libs and -sdc to force all external file references to be copied inside the DB directory (e.g. .lib, .lef, .sdc files, etc). Then it tars the directory and gzips it into a single portable Innovus design tar ball, by adding the .tar.gz extension to the *<out_dir>* name. So, `write_db myDesign.dat -gzip` results in a file named myDesign.dat.tar.gz. *Data_type*: bool, optional

`-oa_view` *OAViewName*	Specifies the name of the OA view. This view will be saved in the same lib/cell/ directory that you used with `read_db` or with `read_netlist` during initialization. This option provides a shortcut to save a view quickly in the same lib/cell structure that you read from.
	Example:
	`read_db -oa_lib_cell_view {designLib top layout}`
	`write_db -oa_lib_cell_view {designLib top place}`
	`write_db -oa_view place`
	Both the above `write_db` commands are equivalent.
	Data_type: string, optional

`-user_path`	By default all external file references (such as. library files) are stored as absolute paths without any symbolic-links. So, the DB directory is portable anywhere on the same network. This option stores external file references exactly as you entered it For example, full paths like /x/y or relative paths like ../x/y, ./x/y), and keeps any symlinks used inside the path names.
	Data_type: bool, optional
	Example:
	Consider that there are two library files a.lib and b.lib under:
	`/global/project1/libs/mmmc`
	And two lef files c.lef and d.lef under:
	`/global/project1/libs/lef`

There are two symlinks to the libs:

```
/usa/db1/libs1.0/mmmc/a.lib
→ /global/project1/libs/mmmc/a.lib

/usa/libs/mmmc/b.lib           →
/global/project1/libs/mmmc/b.lib

And two symlinks to the lefs:

/usa/db1/libs1.0/lef/c.lef
    → /global/project1/libs/lef/c.lef

/usa/libs/lef/d.lef            → /global/proj
ect1/libs/lef/d.lef
```

Your current work dir is /usa/db1.1/. You have an init script like:

```
read_mmmc ./mmmc.tcl

read_physical -lefs
{/usa/db1/libs1.0/lef/c.lef
../libs/lef/d.lef}

read_netlist design.v

init_design
```

Where mmmc.tcl has:

```
create_library_set -name test -timing
{/usa/db1/libs1.0/mmmc/a.lib
../libs/mmmc/b.lib }
```

Then after `write_db`, without `-user_path`, will save the libs and lefs to link to the real files.

```
> write_db db1.2
```

The ./mmmc.tcl file is always stored inside the DB dir, so no external reference is used.

By default, external file references are resolved to their fullpath name without any symlinks.

The .lib files inside the mmmc.tcl file will be referenced as:

```
{/global/project1/libs/mmmc/a.lib

/global/project1/libs/mmmc/b.lib}
```

The .lef files will be referenced as:

```
{/global/project1/libs/lef/c.lef
 /global/project1/libs/lef/d.lef}
```

This is portable and can be loaded by read_db anywhere on the same network.

```
/usa/db1.2/libs1.2/mmmc/a.lib    →
/global/project1/libs/mmmc/a.lib

/usa/db1.2/libs1.2/mmmc/b.lib    →
/global/project1/libs/mmmc/b.lib

/usa/db1.2/libs1.2/lef/c.lef    →
/global/project1/libs/lef/c.lef

/usa/db1.2/libs1.2/lef/d.lef    →
/global/project1/libs/lef/d.lef
```

With `-user_path` will save the libs and lefs to keep the symlinks of the current db.

```
> write_db db1.2 -user_path
```

The .lib files will be referenced as entered by the user: `{/usa/db1/libs1.0/mmmc/a.lib ../libs/mmmc/b.lib}`

The .lef files will referenced as entered by the user: `{/usa/db1/libs1.0/lef/c.lef ../libs/lef/d.lef}`

So `read_db` must be run in the same directory where `write_db` was run, or in a directory with the same ./y and /x directory structure.

```
/usa/db1.2/libs1.2/mmmc/a.lib   →
/usa/db1/libs1.0/mmmc/a.lib

/usa/db1.2/libs1.2/mmmc/b.lib   → ../../../libs/mmmc/b.lib

/usa/db1.2/libs1.2/lef/c.lef
→ /usa/db1/libs1.0/lef/c.lef

/usa/db1.2/libs1.2/lef/d.lef
→ ../../../libs/lef/d.lef
```

`-verilog`	Saves a Verilog file inside the DB directory, in addition to the normal DB files. This parameter is not normally used for flat or block flows, and is not used by read_db. It can be used in a hierarchical flow, where you want to use assemble_design to read only the Verilog and the DEF files without opening up each design DB and writing out the Verilog and DEF files separately (see -def). *Data_type*: bool, optional

Example

- The following command writes the current design into directory `test.dat`:

  ```
  write_db test.dat
  ```

- If you already ran timing analysis, you can save some run time during read like this:

  ```
  report_timing #first time usage, builds timing-graph
  write_db test.dat -timing_graph
  ```

  Then in a new session

  ```
  read_db test.dat
  report_timing #reports results, without repeating timing analysis
  ```

- For physical-only editing, you can do this to speedup read_db/write_db by ignoring the timing during read_db, and adding it back during write_db.

  ```
  read_db test1.dat -no_timing
  <physical-only editing>
  write_db test2.dat -add_ignored_timing
  ```

  Then in a new session

  ```
  read_db test2.dat #has timing from test1.dat
  ```

  If the logical netlist was modified during editing of test1.dat, then reading test2.dat may have unpredictable timing results.

write_db Category Attributes

The root attributes in the `write_db` category are:

- write_db_binary_timing_constraints
- write_db_create_read_file
- write_db_include_metal_fill_rules
- write_db_copy_timing_constraints_always
- write_db_save_unused_lef_block_names

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `write_db` category, use the following command:

```
get_db -category write_db
```

write_db_binary_timing_constraints

```
write_db_binary_timing_constraints {true | false}
```

Default: `true`

Data_type: bool, read/write

If set to `true`, `write_db` will save timing constraints in binary format. The value of the global should be persistent in subsequent `write_db` and `read_db` operations.

write_db_create_read_file

```
write_db_create_read_file {true | false}
```

Default: `false`

Data_type: bool, read/write

When set to `true`, `write_db my_db` will also create a '`my_db.read`' file with a '`read_db my_db`' command inside it. This is a Tcl file that can be passed to the Linux executable to make it easy to load the DB at startup like this: '`innovus -files my_db.read`'.

For OA usage, it would have the appropriate '`read_db -oa_lib_cell_view {<lib> <cell> <view>}`' command inside it.

When set to `false`, it only saves the design data (‘`my_db`’). User can read design as follows:

```
read_db my_db (innovus data)
read_db -oa_lib_cell_view {<lib> <cell> <view>} (OA data)
```

write_db_include_metal_fill_rules

```
write_db_include_metal_fill_rules {true | false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether metal fill settings are to be saved in the .init file when saving the design. Metal fill settings include `set_metal_fill`, `set_metal_fill_spacing_table`, and `set_via_fill` settings. By default, these metal fill settings are lost when you exit Innovus. To enable Innovus to record metal fill settings in the .init file, you must set the `write_db_include_metal_fill_rules` to `1` before saving the design. You can easily reload your settings by restoring the saved design:

```
set write_db_include_metal_fill_rules true

set_metal_fill -iterationName iter1 ...

write_db

read_db

#The previous metal fill settings are reloaded.
```

Related Commands

- `set_metal_fill`
- `set_metal_fill_spacing_table`
- `set_via_fill`
- `write_db`
- `read_db`

write_db_copy_timing_constraints_always

```
write_db_copy_timing_constraints_always {true | false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether SDC files are always copied to the DB directory rather than links to external SDC files. By default they are only copied if the constraints were modified.

This is the equivalent to always using the `-sdc` option whenever `write_db` is called.

Related Commands

- `write_db`
- `read_db`

write_db_save_unused_lef_block_names

```
write_db_save_unused_lef_block_names {true | false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether to remember a list of unused LEF block macros (CLASS BLOCK or RING) so they are not read back with `read_db`. If you have a large number of LEF blocks (for example, memories) that are not used in this design, this can speedup `read_db` and reduce memory by skipping those LEF cells. Small blocks with less then 10 pins are still read in, because they are sometimes added later in the flow.

write_def

```
write_def
[-help]
def_file
[-add_half_wire_extension_on_pin]
[-all_layers]
[-bump_as_pin]
[-cut_row]
[-flatten_via_pillar]
[-floorplan]
[-io_row]
[-netlist]
[-no_core_cells]
[-no_special_net]
[-no_std_cells]
[-no_tracks]
[-no_virtual_trim]
[-output_mask_layers layerNames]
[-scan_chain]
[-selected]
[-skip_trim_metal_layers]
[-special_route_user_class user_class]
[-trim_metal_gap_fill]
[-unit unit_per_micron]
[-unplaced]
[-use_eeq_cell_with_liberty_info]
[-used_via]
[-verilog_from_def_netlist_flow]
[-with_shield]
[-routing  [-routing_to_special_net  | -wrong_way_routing_to_special_net ]]
[-early_global_route]
```

Writes the specified information to a DEF file. By default, the `write_def` command writes floorplan, and all placed and unplaced standard cell information to the DEF file.

The `write_def` command does not support multiple groups per region. If you run Early Global Route before you run the `write_def` command, the software does not write information about `FIXED` status wires to the DEF file. The `write_def` command supports rectilinear die area.

By default, the `write_def` command does not write out any `NONDEFAULTRULE` or `VIA` defined in the LEF file. To write out a LEF via, set the `write_def_include_lef_vias` attribute to `true`. To write out a nondefault rule, set the `write_def_include_lef_ndr` attribute to `true`.

You can use the `write_def` command after importing a design.

Note: You can select the DEF version for your output file by setting the `write_def_lef_out_version` attribute to the version number. For example, to set the version number to 5.6, type the following command:

```
set_db write_def_lef_out_version 5.6
```

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_def` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_def`.
`-add_half_wire_extension_on_pin`	Typically, signal routing in the `NETS` section uses the default half-width wire extensions everywhere except for zero extensions on pins. This parameter forces the zero-extension on pins to the default half-width extension, and makes the DEF compatible for older tools that do not support DEF zero wire extensions. **Note:** Using this parameter can cause DRC violations. *Data_type*: bool, optional
`-all_layers`	Writes out any wires and shapes on non-routing layers to SPECIALNETS section. *Data_type*: bool, optional
`-bump_as_pin`	Writes bump cells as top-level pins in the `PINS` section. If a PORT in a block has a PASSIVATION layer, the tool treats it as an embedded bump. `write_def -bump_as_pin` outputs all the layer information for embedded bumps in the PIN section as for normal bumps. Use the `-bump_as_pin` parameter to generate a DEF file for use with Quantus gate-level extraction. A DEF file generated with this parameter cannot be read back into the Innovus software. *Data_type*: bool, optional
`-cut_row`	Cuts rows against placement obstructions, block halos, or power domain fence minimum gaps. *Default:* Placement blockages are written to the DEF file. *Data_type*: bool, optional
def_file	Specifies the DEF output file. If you add `.gz` as a suffix, the `write_def` command will automatically compress the generated file. *Data_type*: string, required

`-flatten_via_pillar`	Some advanced nodes that use SADP (self-aligned double patterning) use via-pillars. A via-pillar is a single via definition with two or more disjoint metal-shapes on the bottom (or top) routing layer of the via. This option will flatten the via pillar into several separate "normal" vias (e.g. a via with only a single metal shape on the top and bottom via layers). The multiple normal vias will be geometrically equivalent to the single via pillar. This can be useful for external tools that do not support a via pillar. **Note:** DEF created with this option should not be read back into Innovus. It should only be used for external tools that do not support via-pillars properly. *Data_type*: bool, optional
`-floorplan`	Writes the floorplan data to the DEF file. This information includes rows, chip size, `CLASS PAD` instances, `CLASS BLOCK` instances, and all placed standard cells. *Data_type*: bool, optional
`-io_row`	Generates I/O rows based on I/O pad placement, and writes the I/O row information to the DEF file. *Data_type*: bool, optional
`-netlist`	Writes the netlist (that is, the routing connectivity information) to the DEF file. This option is typically used after the design has been placed. **Note:** Use `-netlist` with `-unplaced` if the design has not been placed. *Data_type*: bool, optional
`-no_core_cells`	Excludes core cell information from the DEF file to reduce the data size for import into APD. *Data_type*: bool, optional
`-no_special_net`	Excludes special vias, special routes, and power from the DEF file. *Data_type*: bool, optional
`-no_std_cells`	Excludes placed and unplaced standard cell information from the DEF file. **Note:** If you specify this parameter with the `-floorplan` or `-unplaced` parameters, it overrides their setting. *Data_type*: bool, optional
`-no_tracks`	Excludes output track and gcell statements to the DEF file. *Data_type*: bool, optional
`-no_virtual_trim`	Excludes the trim metal shapes on a virtual trim metal layer. *Data_type*: bool, optional

`-output_mask_layers` *layerNames*	Outputs MASK data on specified layers only. *Data_type*: string, optional
`-routing`	Writes the routing information to the `NETS` section of the DEF file. If the `-routing` option is not specified, both power and signal vias are not written to the DEF file. **Note:** The `-routing` parameter implies the `-netlist` parameter; therefore, if you specify this parameter, you do not need to specify `-netlist`. *Data_type*: bool, optional
`-routing_to_special_net`	Writes all regular NETS routing to the SPECIALNETS section. *Data_type*: bool, optional
`-scan_chain`	Writes scan chain information to the DEF file. This option is mandatory to ensure that START/STOP instances of scan chain are preserved during timing/power closure when reloading the DEF in another session. *Data_type*: bool, optional
`-selected`	Writes out information for selected as follows: • If an instance or net is selected, writes only the DEF header and COMPONENT section for instances you have selected in the Innovus main window. If you specify the `-routing` parameter along with this parameter, the `write_def` command writes selected nets with their special routing and regular routing to the NETS section of the DEF file. • If a net is not selected but individual segments or vias are selected, writes only the selected vias to the DEF file. All LEF vias are excluded by default. If the `write_def_include_lef_vias` attribute is set to `true`, `write_def -selected` includes selected LEF vias when writing out selected vias. If the `-no_special_net` option is specified, special vias on the selected net will not be written out. • If a bump is selected, writes bump pin connection to the `SPECIALNETS` section of the DEF file. If a net is selected but bump pins are not individually selected, bump pin connection is not written. • If a blockage is selected in the main window, writes blockage information to the DEF file. • If a group is selected, all the instances in the selected groups are treated as selected and are writtten out. *Data_type*: bool, optional

`-skip_trim_metal_layers`	Specifies to not write trimmetal shapes in the FILLS section. *Data_type*: bool, optional
`-special_route_user_class`	Specifies the user class for special route. *Data_type*: string, optional
`-early_global_route`	Writes information about the wires generated by Early Global Router to the `NETS` section of the DEF file. This option implies the `-routing` parameter; therefore, if you specify this parameter, you do not need to specify `-routing`. *Data_type*: bool, optional
`-trim_metal_gap_fill`	Writes trimmetal gap fills to a dummy net _TRIMMETAL_FILLS_RESERVERD in SPECIALNETS section. *Data_type*: bool, optional
`-unit` *unit_per_micron*	Defines the units for the DEF file. *Data_type*: int, optional
`-unplaced`	Writes information about unplaced standard cells to the DEF file. *Data_type*: bool, optional
`-use_eeq_cell_with_liberty_info`	Specifies to use the EEQ cell with the timing library information as the master cell of a leaf instance. *Data_type*: bool, optional

`-used_via`	Specifies that only used vias should be written to the DEF file. Unused vias are ignored. All LEF vias are also excluded by default. To include used LEF vias in the DEF file, set the `write_def_include_lef_vias` attribute is set to `true` before specifying `write_def -used_via`. • If the `-routing` option is specified along with `-used_via`, used signal vias are also written out. • If the `-no_special_net` option is specified along with `-used_via`, used special vias are not written out. • If you specify both `-used_via` and `-selected`, the `-used_via` option is ignored and only selected vias are written to the DEF file. The following warning message is issued: `**WARN: (ENCDF-1039): Option -used_via will be ignored because option -selected is specified. Only selected vias will be output.` • If neither `-selected` nor `-used_via` is specified and the `write_def_include_lef_vias` attribute is set to `false` (default), all DEF vias are written out. • If neither `-selected` nor `-used_via` is specified and the `write_def_include_lef_vias` attribute is set to `true`, all DEF and LEF vias are written out. *Data_type*: bool, optional
`-verilog_from_def_netlist_flow`	
	Reconciles the names in the DEF and Verilog files generated by the `read_netlist -def` command. The `read_netlist -def` command generates a flat Verilog file in which all of the special characters are escaped. Use this parameter to convert the escaped names back to the original names in the DEF file. *Data_type*: bool, optional
`-with_shield`	By default, `write_def` does not write out the shielding routing on the power/ground net when outputting regular routing of selected nets in NETS section. When `-with_shield` is specified, `write_def` writes out those shielding routing (if any) on the power/ground net which is in the SPECIALNETS section. The `-with_shield` option must be used with the `-routing` and `-selected` options. **Note:** Multiple nets can be selected. If none of the selected nets have shielding routing, the `-with_shield` option has no effect. *Data_type*: bool, optional

`-wrong_way_routing_to_special_net`	Writes wrong way routing in the SPECIALNETS section. *Data_type*: bool, optional

Example

- The following command writes floorplanning data, and information on placed and unplaced standard cells to `TOPCHIP_SP.def`:

  ```
  write_def -floorplan -unplaced TOPCHIP_SP.def
  ```

- The following command also writes floorplanning data, and information on placed and unplaced standard cells:

  ```
  write_def test.def
  ```

- The following command writes floorplan and standard cell information to the DEF file. It does not write out unplaced standard cell information.

  ```
  write_def -floorplan
  ```

- The following command excludes all information on placed and unplaced standard cells from the DEF file:

  ```
  write_def -floorplan -no_std_cells
  ```

  The resulting DEF file contains floorplan data only.

- The following command writes the shield wires that are shielding the selected nets to the DEF file:

  ```
  write_def -selected -routing -with_shield test.def
  ```

- The following command writes bump cells as top-level pins in the PINS section of the `test.def` file:

  ```
  write_def -bump_as_pin test.def
  ```

  The PINS section in the test.def file is as follows:

  ```
  ++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
  PINS 102 ;
  - iot_schm_2m16m_3v + NET iot_schm_2m16m_3v + DIRECTION OUTPUT + USE SIGNAL

[-vias]
```

Writes information to specified sections in a DEF file. By default, it writes DIEAREA (and associated FE_CORE_BOX* properties), and the netlist part (not the placement or routing part) of the COMPONENTS and NETS sections that must be explicitly suppressed with options below if you do not want them. Other sections or sub-sections are only added based on option settings.

By default, the `write_def_by_section` command does not write out any via defined in the LEF file. If the `write_def_include_lef_vias attribute` is set to `1`, the `write_def_by_section` command writes out the via defined in LEF file.

You can use the `write_def_by_section` command after importing a design.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_def_by_section` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_def_by_section`
`-add_half_wire_extension_on_pin`	Forces the zero-extension on pins to the default half-width extension.
`-early_global_route`	Writes information about the wires generated by Early Global Route to the `NETS` section of the DEF file.
`-bump_as_pin`	Writes bump cells as top-level pins in the PINS section. Use this parameter to generate a DEF file for use with Quantus gate-level extraction. **Important**: A DEF file generated with this parameter cannot be read back into the Innovus software.
`-comp_placement`	Writes component placement and orientation information to the `COMPONENTS` section of the DEF file. The output is limited to instances with PLACED/FIXED/COVER status, unless `-unplaced` is also specified.
`def_file` *out_filename*	Specifies the name of the DEF output file.
`-fills`	Writes metal fill information to the `FILLS` section of the DEF file.
`-groups`	Writes group information to the `GROUPS` section of the DEF file. When you use this parameter, Innovus also writes information about regions.
`-io_row`	Generates I/O rows based on I/O pad placement and writes the I/O row information to the DEF file.
`-net_routing`	Writes routing data to the `NETS` section of the DEF file.
`-no_comp`	Excludes component information from the DEF file.
`-no_core_cells`	Excludes core cell information from the DEF file to reduce the data size for import into APD.

`-non_default_rules`	Writes non default rules (NDRs) to the NONDEFAULTRULES section of the DEF file. **Note**: The `-non_default_rules` parameter works only with `-no_nets`. As the NETS section is always dumped by default, so the NONDEFAULTRULE section is also dumped by default. However, if `-no_nets` is specified, the NONDEFAULTRULE section will be dumped only if -non_default_rules is also specified.
`-no_die_area`	Excludes the DIEAREA and associated FE_CORE_BOX* properties (FE_CORE_BOX_LL_X, FE_CORE_BOX_UR_X, FE_CORE_BOX_LL_Y, FE_CORE_BOX_UR_Y). You can use this option if you do not need some sections, such as SCANCHAINS or NONDEFAULTRULES, to be consistent with the DIEAREA or core-box settings.
`-no_nets`	Excludes net information from the DEF file. **Note**: If `-no_nets` is specified, the `-net_routing` and `-early_global_route` parameters are ignored.
`-no_group_regex`	Suppresses the use of regular expressions to represent instance names. You must also specify the `-groups` parameter.
`-no_virtual_trim`	Excludes the trim metal shapes on a virtual trim metal layer. *Data_type*: bool, optional
`-no_wildcard`	Suppresses the use of the wildcard format to represent special net connectivity. If specified, the `-compPlacement` parameter is ignored. **Note**: The `-no_wildcard` parameter must be used along with the `-special_nets` parameter to be effective. If you specify `-no_wildcard` without `-special_nets`, the software ignores it. *Default:* If you do not specify this parameter, Innovus writes connectivity information in the `SPECIALNETS` section in wildcard format, if possible.
`-output_mask_layers` *OutputMaskData*	Specifies the output MASK data on specified layers only.
`-pins`	Writes pin information to the `PINS` section of the DEF file.
`-place_blockages`	Writes placement blockage information to the `BLOCKAGES` section of the DEF file.
`-route_blockages`	Writes routing blockage information to the `BLOCKAGES` section of the DEF file.

`-rows`	Writes row information to the `ROWS` section of the DEF file.
`-scan_chains`	Writes scan chain information to the `SCANCHAINS` section of the DEF file.
`-selected`	Writes out information for selected as follows: • If a net or instance is selected, writes only the DEF header and `COMPONENT` section for instances or nets you have selected in the Innovus main window. If you specify the `-special_net_routing` parameter along with this parameter, the `write_def_by_section` command writes selected nets with their special routing to the NETS section of the DEF file. • If a net is not selected but individual segments or vias are selected, writes only the selected vias to the DEF file. All LEF vias are excluded by default. If the `write_def_include_lef_vias` attribute is set to 1, `write_def_by_section -selected` includes selected LEF vias when writing out selected vias. • If a bump is selected, writes bump pin connection to the `SPECIALNETS` section of the DEF file. If a net is selected but bump pins are not individually selected, bump pin connection is not written. • If a blockage is selected in the main window, writes blockage information to the DEF file. • If a group is selected, all the instances in the selected groups are treated as selected and are writtten out.
`-special_nets`	Writes the pin connections for special nets to the `SPECIALNETS` section of the DEF file. When specified along with `-selected`, writes out the pin connections for only selected nets. Does not write routing information.

`-special_net_routing`	Writes routing information for special nets to the `SPECIALNETS` section of the DEF file, when specified with the `-special_nets` parameter. Writes only the routes, without the pin connectivity information, to the `SPECIALNETS` section when specified without the `-special_nets` parameter. Use this parameter with `-selected` to write routing information of only selected nets. Use this parameter with `-special_route_user_class` to write routing information of only those special routes that have a `user_class` attribute from the specified list.
`-special_route_user_class` *`user_class`*	
	Writes out only the user class for special route.
`-special_shape` *`swire_type_list`*	Writes special routing information with specified shape types. **Note:** Use `write_def_by_section -special_shape` after you have used the `set_special_route_type` command to mark special wires and vias and set them to a specific shape type.
`-tracks`	Writes routing track information to the `TRACKS` and `GCELLGRID` statements of the DEF file.
`-unit unit_per_micron`	Defines the units for the DEF file.
`-unplaced`	Includes UNPLACED instances in the `COMPONENTS` section when combined with the `-compPlacement` option.

`-used_via`	Specifies that only used vias should be written to the DEF file. Unused vias are ignored. All LEF vias are also excluded by default. To include used LEF vias in the DEF file, set the `write_def_include_lef_vias` attribute to `1` before specifying `write_def_by_section -used_via`. • If you specify both `-used_via` and `-selected`, the `-used_via` option is ignored and only selected vias are written to the DEF file. The following warning message is issued: **WARN: (ENCDF-1039): Option `-used_via` will be ignored because option `-selected` is specified. Only selected vias will be output. • If neither `-selected` nor `-used_via` is specified and the `write_def_include_lef_vias` attribute is set to `0` (default), all DEF vias are written out. • If neither `-selected` nor `-used_via` is specified and the `write_def_include_lef_vias` attribute is set to `1`, all DEF and LEF vias are written out.
`-verilog_from_def_netlist_flow`	
	Reconciles the names in the DEF and Verilog files generated by the loadDefFile command. The loadDefFile command generates a flat Verilog file in which all of the special characters are escaped. Use this parameter to convert the escaped names back to the original names in the DEF file.
`-vias`	Writes via information to the `VIAS` section of the DEF file.

Example

- The following command writes component placement, pin, and special net information to the `test.def` file:

  ```
  write_def_by_section -comp_placement -pins -special_nets test.def
  ```

- In the following set of commands, `set_special_route_type` first traces special wires and vias that touch the named bump cells and sets them to `IOWIRE`. `write_def_by_section` then writes the special routing with IOWIRE shape type to the `test1.def` file.

  ```
  set_special_route_type -bump_cell {bc*} -stop_type_list {IOWIRE} -type IOWIRE

  write_def_by_section -special_shape {IOWIRE} test1.def
  ```

- With only the VDD net selected in the main window, the following command writes the routing information without pin connections for only those special routes in VDD that have the user_class attribute name as `attrA`.

  ```
  write_def_by_section -special_net_routing -special_route_user_class {attrA} -selected
  ```

write_def Category Attributes

The root attributes in the write_def category are:

- write_def_hierarchy_delimiter
- write_def_compress_vias
- write_def_include_lef_ndr
- write_def_include_lef_vias
- write_def_polygon_die_area
- write_def_lef_out_version

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `write_def` category, use the following command:

```
get_db -category write_def
```

write_def_hierarchy_delimiter

`write_def_hierarchy_delimiter` *`delimiter`*

Default: `NULL`

Data_type: string, read/write

Specifies the hierarchy delimiter character for the `write_def` and `write_def_by_section` commands.

For example, to set / as the delimiter, use the following code:

```
set write_def_hierarchy_delimiter /
```

Note:

- You cannot unset this attribute.
- `write_def_hierarchy_delimiter` is for the `write_def` and `write_def_by_section` commands only. It does not change the hierarchy delimiter character of Innovus.

The hierarchy delimiter used appears in the output DEF File as shown below.

```
DIVIDERCHAR "/" ;
```

Related Command

- write_def
- write_def_by_section

write_def_compress_vias

```
write_def_compress_vias number
```

Default: 0

Data_type: int, read/write

Compresses the via statement in SPECIALNETS section. This attribute controls write_def to sort vias with two dimension array, so it can use DO numX BY numY STEP stepX stepY statement.

The via array information is only preserved in the read_def session, but it will not be kept by write_db/read_db.

Related Command

- write_def

write_def_include_lef_ndr

```
write_def_include_lef_ndr {true | false}
```

Default: false

Data_type: bool, read/write

Controls whether write_def writes out the LEF non-default rule information in DEF. By default, write_def does not write out non-default rules defined in LEF. Set this attribute to true to output non-default rules defined in LEF.

Related Command

- write_def
- write_def_by_section

write_def_include_lef_vias

```
write_def_include_lef_vias {true | false}
```

Default: false

Data_type: bool, read/write

Controls whether `write_def` writes out LEF via information in DEF. By default, `write_def` does not write out vias defined in LEF. Set `write_def_include_lef_vias` to `true` to write out LEF vias in the DEF file.

Related Command

- `write_def`
- `write_def_by_section`

write_def_polygon_die_area

```
write_def_polygon_die_area {true | false}
```

Default: `true`

Data_type: bool, read/write

By default, `write_def` writes out polygon DIEAREA if the design is rectilinear. To write out rectangular DIEAERA along with blockages in cut-out area for a rectilinear design, set this attribute to `false`.

Related Command

- `write_def`

write_def_lef_out_version

```
write_def_lef_out_version {5.5 5.6 5.7 5.8}
```

Default: `5.8`

Data_type: enum {5.5 5.6 5.7 5.8}, read/write

Specifies LEF/DEF output version. Possible string values are `5.6, 5.7, and 5.8`. The default is `5.8`.

write_design

```
write_design
[-help]
directory_name
[-force_sdc]
[-pg_netlist]
[-prefix prefix_name]
[-rc_extract]
[-categories category_list]
[-signoff_eco]
-tempus
```

Exports all collateral of a design that is necessary to reconstitute the design intent in Tempus through import of discrete data files. These data files are normally gzipped, ASCII text files.

The write_design command exports the following data:

- The flat Verilog netlist for the design - optionally with power/ground
- The complete DEF for the design
- The CPF or UPF power intent
- Metrics data from Innovus
- Common preserve data
- Global and mode-level constraint data
- An MMMC configuration organizing the relevant data and establishing the timing intent
- SPEF RC parasitic files

The `write_design` command will generate the following template Tempus initialization scripts:

`designName.tempus_init.tcl`

`designName.tempus_setup.tcl`

These scripts will illustrate how to start a standard Tempus STA session using the data provided.

If the `-signoff_eco` option is also specified, then the following additional scripts will be generated:

`designName.tempus_eco_init.tcl`

`designName.tempus_eco_setup.tcl`

The `*init.tcl` scripts just have the bare minimum to load the netlist up through init_design. The `*setup.tcl` scripts include adding other side information, such metrics, modes, that might be helpful.

Parameters

`directory_name`	Specifies the name of the output directory to write the design files. *Data_type*: string, required
`-force_sdc`	The designName.mmmc.tcl file created by write_design includes references to the SDC constraint files. If the Innovus MMMC configuration is not pointing to golden SDCs, you can use this option to force the constraints to be written out locally to the write_design hierarchy. If the constraints have been modified during the Innovus session, the SDCs will automatically be saved locally. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes type and default information for each `write_design` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_design`.
`-pg_netlist`	By default, write_design exports a logical Verilog netlist. When this option is specified, the netlist will include additional PG pin and PG net information. You should use this option when the Tempus PGV flow is used to derive power intent directly from the netlist - rather than using CPF or UPF. *Data_type*: bool, optional
`-prefix` *prefix_name*	By default, files written to the output directory are prefixed by the design name (e.g. myChip.mmmc.tcl). You can use the -prefix option to specify an alternate prefix name. *Data_type*: string, optional

`-rc_extract`	Enables the output of **SPEF** formatted RC extraction data for each active rc_corner. write_design will only export parasitics that are currently available in the system. It does not invoke extraction if parasitic data is missing or try to configure/invoke sign-off level extraction. If the -rc_extract option is provided and parasitics are absent in the system, the tool will give a Warning or an Error. **Note**: RC data will not be saved if the design has not been extracted or the extract_rc_engine setting is 'pre_route'. *Data_type*: bool, optional
`-categories` *`category_list`*	By default, write_design will save key init settings to the Tempus template scripts from the current Innovus session. You can select additional settings belonging to various get_db attribute categories, such as timing, init, delay_cal, to be exported to a separate file for reference. *Data_type*: string, optional
`-signoff_eco`	Writes additional data (including DEF) to support Tempus physically-aware sign-off ECO flows. The ECO template script will also include the commands and file pointers for loading DEF and LEF. *Data_type*: bool, optional
`-tempus`	Saves the output for Tempus usage. *Data_type*: bool, required

write_do_lec

```
write_do_lec
[-help]
[output_filename | > output_filename]
[-checkpoint lec_checkpoint_file]
[-golden_design filename]
[-log_file filename]
[-no_exit]
[-pre_compare filename]
[-pre_exit filename]
[-pre_read filename]
[-revised_design filename]
[-verbose]
[-write_session lec_session_name]
[-hier | -flat]
```

Writes a script that can be used by Conformal® Logical Equivalence Checking tool to compare the specified golden and revised designs.

For formal verification of the Innovus-generated netlists, the `write_do_lec` command generates, within Innovus, the Conformal LEC scripts (such as dofile). These scripts are used for equivalence checking. You can generate a flat or a hierarchical comparison script. The dofile written out by this command contains standard Conformal flow commands and you will need to add the DFT constraints if netlist is scan inserted.

The `write_do_lec` command creates a verification directory, if does not already exist, in which the name mapping information file will be created. The name mapping file will usually contain the mapping information of MBIT flops against its split/single bit candidate. By default, the name of this verification directory is `fv/invs/%s`. You can use the `write_lec_directory_naming_style` attribute to change the directory name.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_do_lec` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_do_lec`
`-checkpoint lec_checkpoint_file`	Specifies the name of the LEC checkpoint file to save at the end. *Data_type*: string, optional
output_filename	Specifies the name for the output file to be written. *Data_type*: string, required

`-flat`	Creates a flat comparison script. *Data_type*: bool, optional
`-golden_design` *filename*	Specifies the user-written netlist file name to use as the golden design. *Data_type*: string, optional
`-hier`	Creates a hierarchical comparison script. *Data_type*: bool, optional
`-log_file` *filename*	Specifies the name of the LEC log file. *Data_type*: string, optional
`-no_exit`	Skips the exit command at end of dofile. *Data_type*: bool, optional
`-pre_compare` *filename*	Specifies an extra dofile to be sourced right before 'compare'. *Data_type*: string, optional
`-pre_exit` *filename*	Specifies an extra dofile to be sourced right before 'exit'. *Data_type*: string, optional
`-pre_read` *filename*	Specifies an extra dofile to be sourced right before reading library/design. *Data_type*: bool, optional
`-revised_design` *filename*	Specifies the user-written netlist file name to use as the revised design. *Data_type*: string, optional
`-write_session` *lec_session_name*	Specifies the name of the LEC session to save at the end. *Data_type*: string, optional
`-verbose`	Specifies whether the generated dofile will report verbosely. *Data_type*: bool, optional
`>` *output_filename*	Specifies the name for the output file to be written. *Data_type*: redirect_operator, optional

Example

The following command writes a script that can be used by Conformal® Logical Equivalence Checking tool to compare the `synth.v` golden design with the revised designs.

```
write_do_lec \
    -flat \
```

```
-golden_design synth.v \
-log_file lec.log \
-pre_compare dft_constraints.do \
lec.do
```

```

Generates design abstract (LEF) information for the current routed block-level design. By default, `write_lef_abstract` copies all the current design PG and signal pins to the LEF and creates cut-outs in the obstructions (OBS shapes) around the pins. The output LEF file contains process antenna information, if you run `check_process_antenna` before you run the `write_lef_abstract` command.

A routing blockage with a pushdown attribute (e.g. a DEF BLOCKAGE with + PUSHDOWN) is treated as an area of routing reserved for the level above this block. The LEF will have these blockages cut-out of the OBS. Other routing blockages shapes are ignored.

In a bottom-up flow (where the block was not created using the `create_partition` command), you normally create a simple LEF abstract that contains:

- one obstruction (`OBS`) shape per routing layer
- signal pins located along the block boundary
- add power pins for the top metal layer PG stripes (see –stripe_pins and –pg_pin_layers options)
- embedded bump pins shapes are also written out as LEF pin shapes

If the block used four routing layers out of a possible six layers, you would run the following command:

```
write_lef_abstract -no_cut_obs -stripe_pins -pg_pin_layers 4 -top_layer 4
```

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_lef_abstract` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_lef_abstract`
`-5.6 | -5.7 | -5.8 | -6.0`	Specifies the LEF version number. This value overrides any value you set with the `write_def_lef_out_version` attribute. *Default:* The software uses the current `write_def_lef_out_version` value. The default value for `write_def_lef_out_version` is `5.8`. *Data_type*: bool, optional
`-add_obs_layers` *layer_list*	Writes the shapes on on the specified layers as OBS shapes in the LEF. These layers cannot be routing or cut layers. *Data_type*: string, optional
`-cut_obs_min_spacing`	Creates cut outs in the blockages around pins using minimum width to calculate the spacing. This option cannot be used with `-no_cut_obs`. *Data_type*: bool, optional `-cut_obs_to_expose_routing` *distance_in_microns*	Exposes routing within the specified halo distance to a LEF model. *Data_type*: bool, optional

`-design_boundary` *point_list*	Specifies a list of points defining the design boundary polygon for the output LEF (a rectangle would use 4 points). It is used instead of the real design boundary to compute the LEF SIZE, OBS shapes to block routing layers, and OBS shapes on the OVERLAP layer if it is non-rectangular. The LEF will also include any special routes that are outside the design boundary as OBS shapes unless they are converted to PIN shapes based on other options. It does not matter if PIN shapes are inside or outside the design boundary, they are always written out. This is intended for a block that only has bumps and/or top-level RDL routing to the bumps that are outside the "real" block boundary. The real block boundary can be specified with this option to shrink the SIZE and OBS shapes to just include the active area of the block, and let the bumps and RDL routing stick outside. An important limitation is that any instances or regular routing shapes (for example, created by `route_design`) outside the design boundary will be ignored. It is assumed that placement and routing blockages are used to prevent this outside the "real" block boundary. *Data_type*: string, optional
`-exclude_obs_layers` *layer_list*	Ignores the specified layer when saving OBS in the macro LEF file. You can use this parameter to set the layer as the following format: ◦ One layer: For example, if you specify `-exclude_obs_layers {AP}`, the AP layer is not saved to OBS. ◦ Multiple layers: For example, if you specify `-exclude_obs_layers {M7 M8}`, M7, M8 layers are not saved to OBS. *Data_type*: (layer)+, optional
`-exclude_pin_layers` *layer_list*	Specifies not to create PIN shapes on the specified layers. *Data_type*: (layer)+, optional

`-extract_block_obs`	Extracts all obstruction (`OBS`) information from the instantiated `CLASS BLOCK`, `CLASS PAD AREAIO`, and `CLASS RING` macros and writes out the obstructions to the output LEF file. `OBS` information is extracted for layers that are not already being completely covered under the normal routing layer range and for cut layers between routing layers that are completely covered. *Data_type*: bool, optional
`-extract_block_pg_pin_layers` *layer_number_list*	

	Extracts the power and ground pin information from any `CLASS BLOCK`, `RING`, `PAD`, or `COVER` macros with pins on layers in the specified layer list and writes out the pin information to the LEF file.
	The layer names can be either names in the technology file like metal1, or technology independent names like 1 for the first routing layer, 2 for the second routing layer.
	For example, to create PG pins on layers `metal3` and `metal4`, use:
	`-extract_block_pg_pin_layers {metal3 metal4}`
	Or
	`-extract_block_pg_pin_layers {3 4}`
	Data_type: (layer)+, optional

`-extract_well_obs_from_rows` *margin*	Adds the bounding box of rows plus the *margin* to the bounding-boxes computed by -extract_well_layer_obs. This is useful if the std-cell LEFs do not have well shapes in them. The -extract_well_layer_obs option is required to use this option. *Data_type*: float, optional
`-extract_well_layer_obs` *well_layer_list*	Extracts the bounding-box of all the OBS and PIN shapes on all std-cells and blocks for each specified well layer. The bounding-box is trimmed to be inside the output LEF boundary and then written as a well-layer OBS shape to the output LEF file, This can be used for well spacing checks on the block at the next level if that is desired. *Data_type*: (layer)+, optional
fileName	Specifies the LEF output file. *Data_type*: string, required

`-ignore_bump_on_pin {all pg signal}`	By default, pin shapes of bump cells (e.g. LEF MACRO CLASS BUMP) are written out as LEF pin shapes. This option can be used to suppress those LEF pin shapes depending on the type of net they are connected to.
`-io_pad_pin`	Writes out the IO pads that are connected to the design pins as LEF pin shapes.
`-merge_connected_well_only`	Merges connected well shapes only, instead of merging all shapes into one bounding box. *Data_type*: bool, optional
`-no_cut_obs`	Creates a single obstruction shape for each routing layer. *Default:* Creates cut-outs (obstructions) in the blockages for signal pins, power and ground pins, vias, and power and ground stripes. *Data_type*: bool, optional This option cannot be used with `-cut_obs_min_spacing`.
`-obs_above_top_layer` *layer+*	Writes out OBS shapes rather than one large abstract OBS shape for special-routes on these layers that are not PIN shapes. The layers will have OBSSPACING FULLDRC added to the LEF so the OBS shapes on those layers are treated as 'real' shapes for DRC checking, and not abstract obstructions. This is intended for blocks that have some sparse special-routing above the blocks "normal" top-layer set with the `-top_layer` option (for example, it might be a few special-routes for clocks that match up with the chip clock distribution but must be visible inside the block). Only special-routes are currently supported. *Data_type*: layer+, optional

`-obs_spacing {val layers [val2 layers ...]}`	Writes out the LEF58_OBSSPACING property for the MACRO. This overrides the global USEMINSPACING OBS setting and sets the spacing required between routing and the OBS shapes of just this MACRO. This is equivalent to adding a SPACING *value* to every OBS RECT on the affected layers in the LEF. Note, it will only affect an OBS RECT that has no existing SPACING *value*.
	
	val = 'min' for min-spacing, and *layers* = {} for all layers.
	
	The order of the arguments is the order in the LEF file. In LEF, the last value for a given layer "wins" over previous values for that macro.
	
	For example, `-obs_spacing {min {} 1.0 {m2 m3} 2.0 {m5}}` would add this to the LEF:
	
	`PROPERTY LEF58_OBSSPACING "`
	`OBSSPACING MIN ;`
	`OBSSPACING 1.0 LAYER m2 LAYER m3 ;`
	`OBSSPACING 2.0 LAYER m5 ; " ;`
	
	So, OBS shapes in this MACRO on every layer would use SPACING <min-spacing> for that specific layer, then m2, m3 are changed to use SPACING 1.0, and finally m5 is changed to use SPACING 2.0.
	
	Data_type: string, optional

`-obs_spacing_per_layer`	Writes out the OBS SPACING values under each OBS LAYER statement rather than as a property that `-obs_spacing` uses by default. This parameter requires `-obs_spacing`.
	Data_type: bool, optional
	The following example sets the spacing of all layers as 1.0, except M2.
	`write_lef_abstract -obs_spacing {1.0 {} 2.0 {M2}} -obs_spacing_per_layer`
	`Macro A`
	`  ...`
	`  OBS`
	`    Layer M1` **SPACING 1.0** `;`
	`    RECT ... ;`
	`    Layer M2` **SPACING 2.0** `;`
	`    RECT ... ;`
	`    ...`
	`  END`
	`  ...`
	`END A`

`-property`	Writes out all the user-defined design properties.
`-pg_nets` *net+*	Writes out PG stripes only on these PG nets. If you specify a net name that does not exist in the design, or the net is not a PG net, tool will give an error and stop.
`-pg_pin_layers` *layer_number_list*	

	Writes out power and ground stripes on the specified layer numbers as power and ground pins.
	
	The layer names can be either names in the technology file like metal1, or technology independent names like 1 for the first routing layer, 2 for the second routing layer.
	
	For example, to create PG pins on layers metal3 and metal4, use:
	
	`-pg_pin_layers {metal3 metal4}`
	Or
	`-pg_pin_layers {3 4}`
	
	Note: You must specify the `-stripe_pins` parameter in order to use this parameter.
	
	Default: The top metal layer
	
	Data_type: (layer)+, optional

`-port_for_each_stripe_pin`	Creates a separate LEF port for each pin shape created by `-stripe_pins`. This means `check_connectivity` will check that every port is touching a PG routing shape at the next level. This is normally what users want for individual PG stripes on the top-layer of the block--each separate stripe shape should be connected to a top-level route or via somehow. This can help detect some missing power-mesh connections before running a complete IR drop analysis. *Data_type*: bool, optional
`-top_layer` *layer_number*	

	Creates obstructions (OBS shapes) covering the block only for layers up to the specified layer.
	
	The layer name can be either a name in the technology file like metal1, or a technology independent names like 1 for the first routing layer, 2 for the second routing layer etc.
	
	For example, to specify metal4 as the top layer, use:
	
	`-top_layer metal4`
	Or
	`-top_layer 4`
	
	By default, all routing layers in the technology file are fully obstructed with OBS shapes across the entire block (possibly cut around pin shapes). If this block does not use some of the highest routing layers, you should use this option to limit the OBS shapes to below layer.
	
	Data_type: (layer), optional

`-selected`	Writes out only the selected PG stripes as LEF pin shapes. *Data_type*: bool, optional
`-stripe_pins`	Writes out power and ground stripes on the top metal layer as power and ground pins. You can use this parameter in a bottom-up methodology, when you create abstracts for blocks that you will use at the next higher level of a hierarchical design. *Data_type*: bool, optional

Example

Suppose you have a design that was routed on only the first 5 routing layers, even though the technology has higher metal layers.

You would use the following command to include any PG stripes on metal5 as pins in the block LEF to allow connecting to them from above, and to only create OBS for routing layers up to layer 5.

```
write_lef_abstract my.lef -top_layer 5 -stripe_pins -pg_pin_layers 5
```

If your design also included a block inside that has PG pins on metal5 with no PG stripes in the current design covering them, you can include layer 5 PG pins from the internal blocks using the following command:

```
write_lef_abstract my.lef -top_layer 5 -stripe_pins -extract_block_pg_pin_layers 5
```

If you also want to include metal4 PG stripes as pins, and metal4 PG pins from the block, you would use the following command:

```
write_lef_abstract my.lef -top_layer 5 -stripe_pins -pg_pin_layers {4 5} -
extract_block_pg_pin_layers {4 5}
```

If you want to include some sparse special-route shapes on metal6, metal7 (for example, for a few manually routed clock nets) , you would use the following command:

```
write_lef_abstract my.lef -top_layer metal5  -obs_above_top_layer {metal6 metal7}
```

write_mmmc

```
write_mmmc
[-help]
[-library]
```

Writes out the MMMC file.

Parameters

`-help`	Prints out the command usage.
`-library`	Writes out only the library part of the MMMC file. *Data_type*: bool, optional

Related Information

- init_design
- `read_mmmc`
- read_physical

write_name_mapping

```
write_name_mapping
[-help]
[-bbox_pins]
[-hierarchical]
[-map_pins {input output all}]
[-pin_polarity]
[-enable_one_to_one_mapping | -report_power_format]
[-skip_clock_gate]
[-updated_only]
{output_filename | [[-output output_directory] -prefix filename_prefix]}
[-hdl | -initial | [-input_mapping_file mapping_file [-print_deleted]]]
```

Writes or updates the initial netlist key point names and corresponding current netlist key point names to a file. Mapping file consists of pin mapping information of all changes done during the flow (between comparison points) including polarity changes .

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_name_mapping` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_name_mapping`
`-bbox_pins`	Prints the pins of bbox in the output mapping file instead of inst names. • Prints bbox input pins if `-map_pins {input}` is specified. • Prints bbox output pins if `-map_pins {output}` is specified. • Prints both input and output pins if `-map_pins {all}` is specified.
`-enable_one_to_one_mapping`	When set to `true`, only one of the clones will be printed in the mapping file.
output_filename	Specifies the name of the output mapping file.
`-hdl`	Enables the generation of name mapping from current names to the names defined by the 'hdl_name' attribute. This will be used for power analysis.
`-hierarchical`	Specify if write out other post boundary optimizations mapping

`-initial`	Enables the generation of name mapping from current names to names defined by the 'initial_name' attribute. This will be used for verification of initial input netlist (post-synthesis) to any other netlist generated during the Innovus flow. The `write_do_lec` command in Innovus will call `write_name_mapping -initial` so that Conformal LEC do file and name mapping file are generated in one shot. The do file will source the name mapping file to facilitate key point mapping in LEC.
`-input_mapping_file` *`mapping_file`*	When provided Tool will read existing mapping file and write out updated mapping file.
`-map_pins {input output all}`	Specify type of pins to write out.
`-output` *`output_directory`*	Specify output directory
`-pin_polarity`	Specify if write out polarity information.
`-prefix` *`filename_prefix`*	Used for file name prefix.
`-print_deleted`	When `-print_deleted` is specified the mapping file will also print deleted instances.
`-report_power_format`	Specify if write out 1Pass power replay format
`-skip_clock_gate`	Filters out ICGs that are not in RTL. If you set `-skip_clock_gate` to `true` with `-hdl`, the tool skips the clock gate pins except the pins with hdl_name. If `-skip_clock_gate` is set to `true` and `-hdl` is not specified, the tool skips all clock gate pins.
`-updated_only`	Skips printing the pin that does not have any change/update during optimizations/flow.

[-use_eeq_cell_map {masterCell EEQcell1 EEQcell2}]
[-use_eeq_cell_with_liberty_info]
[-write_constant_for_signal_connection]
[-write_supply0_supply1]
```

Writes a netlist file of the design. By default, a logical netlist is saved. The netlist is in hierarchical Verilog format only if the original netlist loaded was hierarchical. The Innovus software saves the netlist from the top level of the hierarchy to the bottom level of the hierarchy if the original netlist is specified from top to bottom. If you run this command after using `loadDefFile`, it bundles bus pins to create busses in Verilog. Saving the netlist is done after running placement with timing driven option, clock tree synthesis, scan group re-order, or IPO.

You can use this command after importing the design.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_netlist` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_netlist`.
`-abstract`	Writes an empty Verilog module with port declarations for the specified module. You can the `-abstract` parameter with the following parameters: • `-include_pg` • `-exclude_top_pg_ports` • `-derive_pg_port_dir` • `-export_top_pg_nets` • `-module` • `-phys` *Default*: Top module
`-apply_maskshift`	Adds a suffix to the cell name of a leaf instance based on the color assignments of the instance. *Data_type*: bool, optional **Note**: • The netlist must be unique or `-flat` must specified for the option to take effect. • The mask shifted netlist cannot be read back into Innovus, as the cell names with suffix do not actually exist in LEF and timing libraries.
`-cell_instance_color {true | false}`	Specifies to use the instance-based color. *Data_type*: enum, optional
`-cell_master_color {true | false}`	Specifies to use the cell master-based color from the Innovus color engine. *Data_type*: enum, optional

`-derive_pg_port_dir`	Specifies whether to derive (vs. assume) directions of implicit PG ports in saving a physical netlist. *Data_type*: bool, optional
`-exclude_cell_def` *cellName*	Excludes the module definition of the specified cells. *Data_type*: string, optional
`-exclude_ilm`	Excludes the ILM module.
`-exclude_insts_of_cells` *cellName*	Excludes the instances of the specified cells from the netlist. You can exclude logical or physical instances. The *cellName* can be a single cell name or a list of cell names separated by a space and surrounded by braces (`{}`) or double quotation marks (`""`). For example: `-exclude_insts_of_cells {cell1 cell2}` or `"cell1 cell2"`. *Data_type*: string, optional
`-exclude_leaf_cells`	Writes I/O instances, macro or block instances, and standard cell instances to the netlist, but does not include leaf cell definitions in the netlist. *Data_type*: bool, optional
`-exclude_top_pg_ports` *portName*	Excludes specified power and ground port(s) from the top cell's module port list. The *portName* can be a single port name or a list of port names separated by a space and surrounded by braces (`{}`) or double quotation marks (`""`). For example: `-exclude_top_pg_ports {VSS VDD}` or `"VSS VDD"`. *Data_type*: string, optional
`-export_top_pg_nets`	Specifies to use top-cell PG nets as ports for the top module in a physical netlist created with the `-phys` or `-include_pg` option. *Data_type*: bool, optional
file_name	Specifies the name of the file where the netlist is written. *Data_type*: string, required

`-flat`	Writes a flattened Verilog netlist. *Data_type*: bool, optional *Default:* If you omit this parameter, and if the original netlist loaded was hierarchical, the netlist is written in hierarchical Verilog format.
`-flatten_bus`	Writes a flattened-bus Verilog netlist. When this parameter is used, a bus bit, such as "A[0]" is output as "\A[0]". If such conversions conflict with existing object names, `write_netlist` warns about such conflicts and returns an error: **WARN: (ENCDB-2156): Cannot rename bus-bit %s '%s' in cell '%s' because the name '%s' is already in use on %s in that cell. Change the design to remove the conflicting name or run the command without the `-flatten_bus` option. **ERROR: (ENCSYC-1279): Cannot output flatten-bus netlist due to the reported object-name conflicts. *Data_type*: bool, optional
`-follow_logical_module_order`	Follows the logical module order. The order of the modules, written without `-include_pg`, in a hierarchical logical netlist is different from that, written with the option, in a hierarchical PG netlist. If `-follow_logical_module_order` is specified together with `-include_pg` (but not `-flat`) the order of the modules in a physical netlist will be the same as that in a logical netlist. **Note**: The same order is for non-leaf modules only.
`-ignore_fixed_mask`	Ignores cell fixedMask when maskShift is applied. *Data_type*: bool, optional
`-ilm`	Writes out a netlist with ILM guts. *Data_type*: bool, optional **Note:** This parameter can be specified only in the `flattenIlm` state. If this parameter is specified in the unflatten state, the software returns an error message.

`-include_bump_cells`	Writes bump cell information to the netlist. *Data_type*: bool, optional **Note:** This parameter is effective only when used with either the `-phys` or `-flat` parameters.
`-include_phys_cells` *cellName*	Includes the physical instances of the specified cells in the netlist. With this parameter, 1'b1/1'b0-style, logical connections are used for tie-off pins. The *cellName* can be a single cell name or a list of cell names separated by a space and surrounded by braces (`{}`) or double quotes (`""`), for example, `-include_phys_cells {cell1 cell2}` or `"cell1 cell2"`. *Data_type*: string, optional *Default*: If you omit this parameter, no physical cell module definitions will be in the netlist file. **Note:** `-include_phys_cells` creates a netlist that should not be read back into Innovus.
`-include_pg`	By default, PG connections in the original logical Verilog netlist are already written out (unless -flat is given). You can add "physical only" global PG net connections and "physical only" PG nets added by IEEE1801 to the Verilog output with this option. It adds PG nets inside each module and PG ports on each module in order to thread the PG connections to each pin. Some physical tools like LVS prefer to have these explicitly in the hierarchical Verilog. *Data_type*: bool, optional
`-include_phys_insts`	Activates physical netlisting by including physical instances, such as fillers, in the netlist. With this parameter, GNC-based/physical connections, such as vss, are used for tie-off pins. *Data_type*: bool, optional
`-keep_all_backslash`	Keeps all backslashes in names.

`-line_length` *`characters_per_line`*	Specifies the maximum number of characters per line for module port lists and instance port connections. When a line length exceeds the specified value, the software wraps the line at the next opportunity. You must specify a non-negative integer for the value. *`Default:`* `0` (The software wraps lines at the earliest opportunity.) *Data_type*: bool, optional
`-maskshift_suffix` *`maskShiftSuffix`*	Adds a user suffix to the cell name of a leaf instance instead of the tool's default suffix. *Data_type*: string, optional The default suffix is `_<layer>_<mask>`. For example, BUFX1_M0_1 default suffix means the M0 color flipped from mask 0 to mask 1. The `-mask_shift_suffix` option works only when `-apply_mask_shift` is used. **Note**: The netlist must be unique or `-flat` must specified for the option to take effect.
`-module` *`moduleName`*	Saves the specified module of the netlist. *Data_type*: string, optional
`-omit_floating_ports`	Omits the unconnected instance ports from the saved netlist. *Data_type*: bool, optional
`-only_leaf_cells`	Writes only leaf cell definitions in the netlist. *Data_type*: bool, optional *Default:* If you do not specify this parameter, the software writes leaf cell definitions, standard cell instances, and macro/block instances in the netlist file.
`-only_blocks`	Writes only macro or block cell definitions to the netlist. *Data_type*: bool, optional *Default:* If you do not specify this parameter, the software writes leaf cell definitions, standard cell instances, and macro/block instances in the netlist file.

`-only_std_cells`	Writes only standard cell instances in the netlist. *Data_type*: bool, optional *Default:* If you do not specify this parameter, the software writes leaf cell definitions, standard cell instances, and macro/block instances in the netlist file.
`-phys`	Writes out physical cell instances, and inserts power and ground nets in the netlist. This is used for LVS and for designs with multiple supply voltages. Hierarchical power and ground nets are also supported. *Data_type*: bool, optional **Note:** `-phys` creates a netlist that should not be read back into Innovus.
`-remove_power_ground`	Removes PG ports, PG nets, PG pin connections, and replaces PG net connections on signal pins with 1'b1 or 1'b0. *Data_type*: bool, optional
`-replace_inout_with_output_for_pg_ports`	Changes the direction of inout P/G ports to output except for the ones defined by IEEE1801/UPF. Their directions remain unchanged. *Data_type*: bool, optional
`-replace_wor_wand_with_wire`	Replaces wor/wand with wire statement. *Data_type*: bool, optional

`-top_module` *cellName*	Saves a module and modules instantiated in the hierarchy rooted at the specified module. Without `-top_module`, all modules, instantiated or not, are written for a logical netlist but only instantiated modules are written for a PG netlist:
	`write_netlist logical.v`
	`write_netlist -include_pg pg.v`
	Data_type: string, optional

`-top_module_first`	Writes out top module first, followed by the rest of the modules. *Data_type*: bool, optional **Note**: This feature is not available for physical netlist writing. As a result, the `-top_module_first` option will be ignored if any of the following parameters is also specified: `-phys`, `-include_pg`, and `-include_phys_insts`.
`-update_tie_connections`	Replaces `1'b1` and `1'b0` constants with undriven nets in the output netlist. Use this parameter if you may want to save a Verilog netlist from Innovus without any `1'b*` constants. *Data_type*: bool, optional **Note:** By default, the `write_netlist` command writes a Verilog netlist file of the design using `1'b*` constants to represent Assign nets and ports. However, subsequent verification steps that you use outside Innovus might not be able to handle these `1'b*` constants. In such a case, use `-update_tie_connections`.
`-use_cds_thru_for_assign`	Replaces the assign statement with cds_thru, the output netlist will not be able to read back by Innovus. This is only for third party tool. *Data_type*: bool, optional
`-use_eeq_cell_map {`*masterCell EEQcell1 EEQcell2*`}`	Defines the master cell and the EEQ cells that need to be mapped to the master cell {{masterCell EEQcell1 EEQcell2} ...} *Data_type*: string, optional

`-use_eeq_cell_with_liberty_info`	Specifies to use EEQ cell with .lib info as the master cell of a leaf instance. *Data_type*: bool, optional
`-write_constant_for_signal_connection`	Writes constant value for tie pin connection. When this option is specified, tool can assign the tie net name to related signal pin. If this option is not specified, tool assigns the real net name to the signal pin.
`-write_supply0_supply1`	When `-write_supply0_supply1` is on, PG nets are written as "supply0" or "supply1" when a net declaration is needed. `-write_supply0_supply1` is off by default. When it is off, a PG net is written as "supply0/supply1" only if it defined in the original Verilog. *Data_type*: bool, optional The `-write_supply0_supply1` option must be specified together with `-phys` or `-include_pg` to take the effect.

Example

- The following command writes out the netlist in Verilog format of the current state of the design in Innovus to a file `mydesign_cts.v`:

  ```
  write_netlist mydesign_cts.v
  ```

- The following command saves the netlist with `dtmf_recvr_core` as the top module to the `output.v` file:

  ```
  write_netlist -top_module dtmf_recvr_core output.v
  ```

- The following command saves the physical netlist of ILM internals to the `output.v` file:

  ```
  write_netlist -ilm -phys output.v
  ```

  Use this combination of options to pass on power or ground (P/G) information correctly to the netlist in low power ILM flow.

- The following example shows the netlist generated by `write_netlist -abstract`.

  ```
  module test(in1, in2, out1, out2, clk1, clk2, clk3, se1, se2);
   input [3:0] in1;
   input [7:0] in2;
   input clk1, clk2, clk3, se1, se2;
   output [3:0] out1;
   output [7:0] out2;
  endmodule
  ```

write_netlist Category Attributes

The root attributes in the write_netlist category are:

- write_netlist_full_pin_out
- write_netlist_port_association_style

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `write_netlist` category, use the following command:

```
get_db -category write_netlist
```

write_netlist_full_pin_out

`write_netlist_full_pin_out {true | false}`

Default: `false`

Data_type: bool, read/write

Specifies whether to write out every instance port connection, including unconnected ports unused in the input netlist.

write_netlist_port_association_style

`write_netlist_port_association_style {true | false}`

Default: `false`

Data_type: bool, read/write

Writes out the netlist with implicit port mapping (that is, ordered port connections or position-based port connections) for hierarchical instances.

write_stream

```
write_stream
stream_file_name
[-area {x1 y1 x2 y2} [-strict][-enclosed_instances_only]]
[-attach_inst_name attributeNumber]
[-attach_net_name attributeNumber]
[-attach_net_attribute {{prop_name1 attr_num1} {prop_name2 attr_num2........}}]
[-die_area_as_boundary]
[-format {stream oasis}[-output_inst_name instNAme] [-output_net_name netName]]
[-help]
[-ignore_subtype {NETTYPE SHAPE}]
[-lib_name libraryName]
[-map_file mapFile]

[-merge {listOfExternalGDSOASISFiles} [-no_tsv tsv_name_list] [-uniquify_cell_names]]
[-report_file file_name]
[-mode {ALL | FILLONLY | NOFILL | NOINSTANCES}]
[-offset x y]
[-output_critical_net_color_from_file_only sideFile]
[-output_macros]
[-pvs_fill]
[-structure_name structureName | -no_structure_name]
[-unit {100 | 200 | 1000 | 2000 | 10000 | 20000}]
```

Creates a GDSII Stream file of the current database. Writes a summary of errors and warnings to the log file.

You can use the `write_stream` command after the design is placed, but is most commonly used only after the design is routed (which may also include metal fill shapes).

- If you do not specify a map file, the Innovus software creates a generic map file, in GDSII Version 3 format. The generic file shows the mapping that was used, if none was specified. You must customize the file to make it appropriate for your design. You can change the version by using the `write_stream_version` attribute.
- You must specify all layers to stream out. Layers that are not specified in the map file are not included in the file created by this command.
  Note: A cut layer in the map file (for a via) can have both MASK and SIZE at the same time.
- If you specify the `-merge` parameter and you want to merge files with a version number greater than `3`, the software generates a file with the highest version number from the merged files.
- If you do not specify `-output_macros`, `LEFPIN` and `LEFOBS` do not apply. If you do specify `-output_macros` and `LEFPIN` and `LEFOBS` are not specified in the map file for the layers in the LEF macros, the GDSII structures for those macros will be empty.

- If `MAXVOLTAGE` and `MINVOLTAGE` constructs are there in the layermap, `write_stream` will output a max voltage label and a min voltage label, for each net, to the GDSII file.

Parameters

`-area {x1 y1 x2 y2}`	Defines the area of the design to be output. Any shapes or instances enclosed, intersecting, or touching the specified area are output. So the data that is output can extend outside the specified area. By default the entire design is output. *Data_type*: rect, optional
`-attach_inst_name attributeNumber`	Specifies the instance name value added to the attribute on SREF of the specified attribute number. *Data_type*: int, optional *Range*: 1-127
`-attach_net_name attributeNumber`	Specifies that the net name will be added to the specified attribute number on the regular and special net wire shapes and vias SREF, but not on PIN shapes and pin vias. *Data_type*: int, optional *Range*: 1-127
`-attach_net_attribute {{prop_name1 attr_num1} {prop_name2 attr_num2........}}`	Specifies the attribute number on wiring shapes that will be used to store the value of the property associated nets in the design. For this option, you specify a list of property name and its attribute number. *Data_type*: string, optional **Note:** Multiple property names can be specified. Only wiring shapes associated with nets that contain one or more of the specified property names will have values assigned to their attributes. **Example:** `-attachPropName { {prop1 100} {prop2 101} }` In the above example, the attribute number `100` will be used to store the value of the property `prop1`, and the attribute number `101` will be used to store the value of the property `prop2`. It is a list of lists with a pair of property and its attribute number.

stream_file_name	Specifies the GDSII Stream output file. Include the `.gz` extension to enable file compression (for example, `GDS_file.gds.gz`). *Data_type*: list, required
`-die_area_as_boundary`	Forces the `write_stream` command to write the die area as a polygon (that is, a boundary). Otherwise, the `write_stream` command writes the die area as a rectangle (that is, a box). *Data_type*: bool, optional
`-enclosed_instances_only`	Specifies to stream out only those instances in which the shapes are fully enclosed by the specified area. *Data_type*: bool, optional
`-format {stream oasis}]`	Specifies the tape out file format. *Data_type*: enum, optional
`-help`	Outputs a brief description that includes type and default information for each `write_stream` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_stream`.

`-ignore_subtype {NETTYPE SHAPE}`	gnores the map file line containing the subtype keyword , and warning message is printed in the log file. *Data_type*: dict, optional For example, in the example below, with `-ignore_subtype {NETTYPE SHAPE}` the line 61, 62, and 63 of the map file will be ignored. • Line61: M2 SPNET:NETYPE:POWER:MASK:2 32 12 • Line62: M2 SPNET:SHAPE:STRIPE:MASK:2 32 22 • Line63: M2 SPNET: NETYPE:GROUND:SHAPE:STRIPE:MASK:2 32 32 • Line64: M2 SPNET:MASK:2 32 2
`-lib_name` *`libraryName`*	Specifies the library to convert to GDSII Stream format. *Default:* `DesignLib` *Data_type*: string, optional
`-map_file` *`mapFile`*	Specifies the file used for layer mapping. This file is required for successful stream out, and is read by the next tool used in the design flow.  If you do not specify a file with this parameter, the Innovus software will read a `write_stream.map` file if one exists. If a `write_stream.map`file does not exist, the software creates a generic map file that you must customize for your design. For information on the map file format, see "GDSII or OASIS Map File Format" in the Design Import and Export in Stylus chapter of the *Innovus Stylus Common UI User Guide*. *Data_type*: string, optional

`-merge_via_cell_map_file` *`cell_list`*	Specifies the list of cells that need merge via cell from an external file. *Data_type*: string, optional
`-merge` **{***`listOfExternalGDSOASISFiles`***}**	Specifies a single file or list of files to merge. Checks all merged files for name collisions, and generates a warning if any names are changed. Uses the following conventions for new names: • Replaces dot separators (`.`) with underscores (_). For example, `test.test_gds.gds` is renamed `test_test_gds_gds`. • Adds unique identifiers. For example, if more than one cell is named `test.test.gds.gds`, they are renamed `test_test_gds_gds_1`, `test_test_gds_gds_2`, and so on. *Data_type*: string, optional Supports the mixed format of the GDSII and OASIS files. You need to specify the merged files with mixed format using the `-merge` option. The tool will identify the files format, covert them, and merge them to a stream out file. Compressed files are acceptable (include the `.gz` extension to enable file compression). The Innovus software automatically creates blackboxes when merging and writing macro files. It ignores any cells in the merge files that are not used in the design. If you specify more than one file, separate the file names with spaces and enclose the list of file names in braces (`{}`) or double quotation marks (`"`) You can use a wildcard to read all `.gds` files in a specified directory. The usage is as follows: `write_stream -merge GDSIIdir/*.gds` where *`GDSIIdir`* is the name of the directory that contains the `.gds` files. ***Use caution when using wildcards, as they might affect the order in which the software reads merge files.***

`-mode {ALL | FILLONLY | NOFILL | NOINSTANCES}`	
	Identifies the layers to write. *Data_type*: enum, optional Specify one of the following: • `ALL`--Writes all layer information specified in mapFile as follows: ◦ All instances ◦ All via instances ◦ All generated via cells • `FILLONLY`--Writes only fill layers specified in mapFile as follows: ◦ No instances ◦ Only fill via instances ◦ Only generated fill via cells • `NOFILL`--Writes only non-fill layers specified in mapFile. • `NOINSTANCES`--Writes wiring (including vias) only; does not write out `COMPONENT` instances.
`-no_structure_name`	Enables you merge to files without loading an Innovus database when the `-merge` parameter is also specified. *Data_type*:
`-no_tsv` *`tsv_name_list`*	Specifies a list of TSV via names that should not be written out. *Data_type*: string, optional

`-offset` *x y*	Specifies, in microns, the location of the design in the GDSII output file. When the GDSII output file is saved, the design shifts to the specified location. *Data_type*: point, optional

`-output_critical_net_color_from_file_only` *sideFile*	Specifies the net list and the layer range through a side-file. The `write_stream` command outputs the object color on the specified layers and nets. Other objects remain gray in GDS.
	Here is an example of a side file:
	`<LAYERMAP>`
	`M5`
	`PIN:MASK:1,NET:MASK:1,SPNET:MASK:1,VIA:MASK:1`
	`35 271`
	`M5`
	`PIN:MASK:2,NET:MASK:2,SPNET:MASK:2,VIA:MASK:2`
	`35 272`
	`M6`
	`PIN:MASK:1,NET:MASK:1,SPNET:MASK:1,VIA:MASK:1`
	`36 271`
	`M6`
	`PIN:MASK:2,NET:MASK:2,SPNET:MASK:2,VIA:MASK:2`
	`36 272`
	`</LAYERMAP>`
	`<NETNAMELIST>`
	`TOP/NET1`
	`TOP/NET2`
	`...`
	`</NETNAMELIST>`

`-output_inst_name` *instNAme*	Writes the instance name to the oasis file. *Data_type*: string, optional

`-output_macros`	Writes LEF abstract information such as LEF pin geometries and obstructions for macros. Writes one text label per port within a LEF macro pin plus one text label per shape for feedthrough pins. Specify this parameter to create GDSII output that contains the LEF macro structures as well as the design data. You can also use this parameter to debug LEF macro definitions against verification DRC rules. The output contains macro pins and obstructions. **Note:** `LEFPIN` and `LEFOBS` apply only when you specify this parameter. If you specify this parameter and `LEFPIN` and `LEFOBS` are not specified in the map file for the layers in the LEF macros the GDSII structures for those macros will be empty. *Data_type*: bool, optional
`-output_net_name` *netName*	Writes the net name to the oasis file. *Data_type*: string, optional
`-pvs_fill`	Merges the PVS fill data attached to the current DB into the output GDS file and instantiates the PVS top fill cell at 0,0 R0 inside the top design cell. The PVS fill format must be GDS. *Data_type*: bool, optional
`-report_file file_name`	Outputs cell name changed to the file. *Data_type*: string, optional
`-strict`	Truncates the object outside the area. *Data_type*: bool, optional
`-structure_name` *structureName*	
	Specifies the superstructure that consists of all geometries that the map file writes out. *Default:* Current design's top cell name *Data_type*: string, optional

`-uniquify_cell_names`	Creates unique cell names if there are name collisions when the software merges files. Creates unique cell names if there are name collisions when the Innovus software merges files. *Data_type*: bool, optional ⓘ You must specify the `-merge` parameter if you specify this parameter. When you list the merge files, list the top-level file first, as the software uses the first name in the search path when renaming cells. When a cell name is repeated, the software renames the cell *`cellName_filename`*, where *`filename`* is the name of the merge file in which the cell name appears. The software changes the name of references to that cell in the merge file. The software changes the reference name if the referenced cell is defined in the same file, regardless of whether the cell is defined before or after the reference. If a reference in a merge file refers to a cell definition in a different merge file, then the reference is not changed in the GDSII Stream output file. *Default:* If you do not specify this parameter, the software ignores duplicate cell names. **Note:** You must specify the `-merge` parameter if you specify this parameter.
`-unit {100 | 200 | 1000 | 2000 | 10000 | 20000}`	Specifies the resolution for values in the GDSII file. Choose `100`, `200`, `1000`, `2000`, `10000`, or `20000`. *Default:* Units specified in LEF file *Data_type*: int, optional

Examples

- The following command creates a GDSII Stream file (merging cells from the ios.gds file):

```
write_stream amba_usb.gds -map_file write_stream.map -lib_name DesignLib
  -attach_inst_name 12 -merge {ios.gds}
  -attach_net_name 15
  -die_area_as_boundary
```

- The following command creates blackboxes for cells not found in the merge libraries and writes macros only for those cells:

  ```
  write_stream newFile.gds.gz -merge {myFile1 myFile2 myFile3} -output_macros
  ```

- The following command merges cells needed in the design from all files in `myDirectory` with the current database:

  ```
  write_stream myFile.gds.gz -merge myDirectory/*.gds
  ```

  If a merge file contains cells such as `A`, `B`, `C`, `D`, `X`, `Y`, and `Z`, and the design contains only cells `A`, `B`, and `D`, then the Innovus software merges only cells `A`, `B`, and `D`.

- The following example shows a stream out map file. The first column specifies the layer object name, and the second column specifies the layer object type. The third and fourth columns specify the GDS layer and data type to stream those objects, respectively. When the object name is "NAME", it indicates the text label for the object types specified in the second column.

  ```
  ==========original streamout.map file=============

  M1         NET          1         0

  M1         SPNET        2         0

  M1         PIN          3         0

  M1         LEFPIN       4         0

  M1         FILL         5         0

  M1         VIA          6         0

  M1         VIAFILL      7         0

  M1         LEFOBS       8         0

  NAME       M1/NET       1         0 <--- text for nets

  NAME       M1/SPNET     2         0 <--- text for special nets (i.e. power nets)

  NAME       M1/PIN       3         0 <--- text for pins including top level IO pins

  NAME       M1/LEFPIN    4         0 <--- text for LEF pins

  ================================================
  ```

Related Information

- write_stream Category Attributes
- Design Import and Export in Stylus chapter in the *Innovus Stylus Common UI User Guide*

write_stream Category Attributes

The root attributes in the write_stream category are:

- write_stream_allow_path_type4
- write_stream_cell_instance_color
- write_stream_cell_master_color
- write_stream_cell_name_prefix
- write_stream_cell_name_suffix
- write_stream_check_map_file
- write_stream_compatible
- write_stream_define_via_name
- write_stream_ignore_fixed_mask
- write_stream_label_all_pin_shape
- write_stream_oasis_compression
- write_stream_oasis_layer_name
- write_stream_oasis_cell_offset
- write_stream_merge_append
- write_stream_pin_text_orientation
- write_stream_remove_nets
- write_stream_snap_to_mfg
- write_stream_stream_convert_rect_to_path
- write_stream_stream_version
- write_stream_text_size
- write_stream_uniquify_cell_names_prefix
- write_stream_via_names
- write_stream_virtual_connection

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `write_stream` category, use the following command:

```
get_db -category write_stream
```

write_stream_allow_path_type4

`write_stream_allow_path_type4 {true | false}`

Default: `true`

Data_type: bool, read/write

Converts `PATHTYPE4` to `PATHTYPE0`. If you specify `write_stream_allow_path_type4 0`, the software converts `PATHTYPE4` paths to`PATHTYPE0` when outputting the path.

write_stream_cell_instance_color

`write_stream_cell_instance_color {true | false}`

Default: `false`

Data_type: bool, read/write

Streams out the instance-based color. The instance mask shift is honored in `write_stream`. When the option is on and the `-merge` option is used, the merged gds files with mask shift suffix must be provided through the `-merge` option.

write_stream_cell_master_color

`write_stream_cell_master_color {true | false}`

Default: `true`

Data_type: bool, read/write

Streams out the cell-based color from the Innovus color engine.

write_stream_cell_name_prefix

`write_stream_cell_name_prefix` *`prefix`*

Default: `""`

Data_type: string, read/write

Specifies to add a prefix to ALL cell names being written out, use user-specified prefix can avoid potential conflict when integrating different macros, which potentially two different cells (in two different libraries) with the same name.

write_stream_cell_name_suffix

`write_stream_cell_name_suffix` *`suffix`*

Default: `""`

Data_type: string, read/write

Specifies to add a prefix to ALL cell names being written out, use user-specified prefix can avoid potential conflict when integrating different macros, which potentially two different cells (in two different libraries) with the same name.

Specifies to add user specified suffix instead of appending color pattern to normal cell names. This applies to fixed color shift (flip) pattern only. This means that only single shift (flip) pattern is applied to the design.

write_stream_check_map_file

`write_stream_check_map_file {true|false}`

Default: `false`

Data_type: bool, read/write

Checks the specified map file. If the objects exist in Innovus and but therse objects are not mapped in the map file, the missed objects mapping and missed objects are printed in the log file. Tool checks only the main objects mapping.

write_stream_compatible

`write_stream_compatible {true | false}`

Default: `false`

Data_type: bool, read/write

Output instance only if `FOREIGN` is specified.

write_stream_define_via_name

`write_stream_define_via_name {default |` *`format_string`*`}`

Default: `%t_VIA%u` (This default value is used so that the names of the via cells are compatible with versions 4.2 and earlier versions of the Innovus software.)

Data_type: string, read/write

Specifies the naming convention that the `write_stream` command uses for via cells declared in the DEF file.

Note: When the version of the GDS file is 3 (this is the default version), via names are truncated if they are longer than 32 characters. The software automatically appends a unique identifier to names if there is a name conflict.

You can use any of the following characters to specify a format string to generate names that give you information about the cell contents. Separate the characters with underscores (_) to improve readability. You can list them in any order.

- `%c`
  Specifies the number of columns.
- `%l(lcu)`
  Specifies the via layers. For the lower layer, use `%l` or `%l(l)`. For the cut layer, use `%l(c)`. For the upper layer, use`%l(u)`. You can specify one, two, or all three layers. You must enclose the `l`, `c`, and `u` in parentheses, as in the following examples: `%l(c)`, `%l(lu)`.
- `%n`
  Specifies the number of cut rows and columns that make up a cut array.
- `%r`
  Specifies the number of cut rows.
- `%t`
  Specifies the top structure name.
- `%u`
  Specifies a unique number for the via.
- `%v`
  Specifies the via name in the DEF file.

For more information, see "Vias," in the DEF Syntax chapter of the *LEF/DEF Language Reference*.

write_stream_ignore_fixed_mask

```
write_stream_ignore_fixed_mask {true | false}
```

Default: `false`

Data_type: bool, read/write

Ignore macro FIXEDMASK keywords, enable color flip function.

write_stream_label_all_pin_shape

```
write_stream_label_all_pin_shape {true | false}
```

Default: `false`

Data_type: bool, read/write

Labels all pin shapes, whether or not they are physically connected, when set to `true`.

write_stream_oasis_compression

```
write_stream_oasis_compression {true | false}
```

Default: `true`

Data_type: bool, read/write

Reduces file size by using repetition compression. Repetition compression supports an 'array' of cell placements, geometries, or text elements, instead of write each the element separate only different in position, this can save duplicate information for an OASIS layout file size.

write_stream_oasis_layer_name

```
write_stream_oasis_layer_name {true | false}
```

Default: `false`

Data_type: bool, read/write

Support LAYERNAME in OASIS file.

write_stream_oasis_cell_offset

```
write_stream_oasis_cell_offset {true | false}
```

Default: `false`

Data_type: bool, read/write

Includes cell offset table to declare the byte offset from the beginning of the file (byte 0) to the corresponding CELL record location that appears in the file.

write_stream_merge_append

```
write_stream_merge_append {true | false}
```

Default: `false`

Data_type: bool, read/write

Append cell color information in current design to cell geometries that are from merging files. This option is for the fixed-mask design.

write_stream_pin_text_orientation

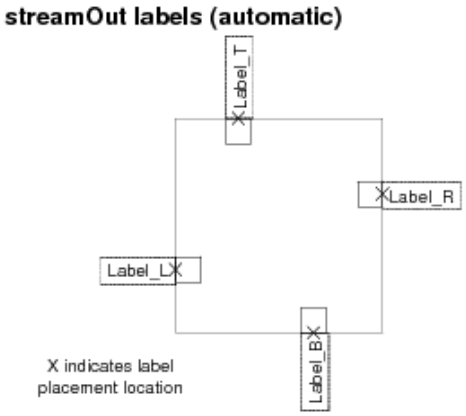
```
write_stream_pin_text_orientation {default | automatic}
```

Default: default

Data_type: string, read/write

Controls the pin text orientation, making it more readable.

- `default` implies that the labels are centered in the pin shapes and have `R0` orientation and `LowerLeft` justification.
- `automatic` implies that the labels for pin shapes that are abutted to the design boundary are centered on the edge of the pin shape.



write_stream_remove_nets

`write_stream_remove_nets {`*`list_of_nets`*`}`

Default: `""`

Data_type: string, read/write

Removes the specified nets from the output file.

write_stream_snap_to_mfg

`write_stream_snap_to_mfg {true | false}`

Default: `false`

Data_type: bool, read/write

Specifies whether to snap the nets' wires to the manufacturing grid.

write_stream_stream_convert_rect_to_path

`write_stream_stream_convert_rect_to_path {true | false}`

Default: `false`

Data_type: bool, read/write

Converts DEF SPECIALNETS path/rectangle and FILLS shapes to GDSII/stream PATH data instead of BOUNDARY data when enabled. Conversion to path data can result in significantly smaller output database when there are many rectangle shapes (example: after metal fill is included).

write_stream_stream_version

```
write_stream_stream_version version
```

Default: `3`

Data_type: int, read/write

Specifies the version for a created GDSII Stream file. If you use the `write_stream -merge` parameter, `write_stream` uses the highest version of the merged files, instead of the value specified by the parameter.

write_stream_text_size

```
write_stream_text_size value
```

Default: `1`

Data_type: double, read/write

Changes the size of the text used in the text labels in the GDSII Stream file written by the Innovus software.

- To increase the size of the text, specify a positive real number that is greater than 1, as in the following example:
  ```
  write_stream_text_size 10.0
  ```
- To decrease the size of the text, specify a positive real number that is less than 1, as in the following example:
  ```
  write_stream_text_size 0.5
  ```

Note: The write_stream_text_size attribute affects the size of only automatically created text. It does not affect text created through `create_custom_text`.

write_stream_uniquify_cell_names_prefix

```
write_stream_uniquify_cell_names_prefix {true | false}
```

Default: `false`

Data_type: bool, read/write

Adds a prefix, instead of a suffix, to uniquified cell names. The prefix is the source filename. If this parameter is not specified, the software adds a suffix (also the source filename) to uniquified cell names.

write_stream_via_names

```
write_stream_via_names {true | false}
```

Default: `false`

Data_type: bool, read/write

Determines the naming convention used for vias declared in the LEF file.

- Specify `true` to create unique names.
- Specify `false` to retain LEF via names.

write_stream_virtual_connection

```
write_stream_virtual_connection {true | false}
```

Default: `true`

Data_type: bool, read/write

Specifies whether a colon (`:`) label is appended to pin names for DEF pins with the `.extra`*N* syntax and to LEF pins with multiple ports (if `-output_macros` is specified for LEF pin ports that have disjoint shapes).
Default: `true`

- Specify `true` to append a colon to pin names.
- Specify `false` not to append a colon to pin names.

Note: For more information, see the DEF Syntax chapter of the *LEF/DEF Language Reference*.

write_via_defs

```
write_via_defs
[-help]
[-generate]
[out_file filename]
[-all_vias | -signal | -all_rules | -default | -ndr ]
```

Helps in debugging and testing. All the boolean options are default to false. If none is set, the vias are dumped out in LEF format.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `write_via_defs` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_via_defs`.
`-all_rules`	Dumps out vias from all routing rules. *Data_type*: bool, optional
`-all_vias`	Dumps out all vias. *Data_type*: bool, optional
`-generate`	Dumps out auto-generated vias. *Data_type*: bool, optional
`-default`	Dumps out vias of default routing rule.
`out_file filename`	Specifies the output file name. *Default*: `dump_via.out` *Data_type*: string, optional
`-ndr`	Dumps out vias of nondefault routing rules. *Data_type*: bool, optional
`-signal`	Dumps out signal vias. *Data_type*: bool, optional

Example

The following command dumps out all signal vias to the default output file, `dump_via.out`:

```
write_via_defs -signal
```

Here's the sample output:

```
#### Begin signal vias ####
VIA V01  # LEF
  LAYER POLY ; RECT -0.033 -0.033 0.033 0.033 ;

report_gates

```
report_gates
[-help]
[-hinst hInstName]
[-out_file fileName]
[-sort {name count area leakage_power internal_power total_power switching_power}] [-power | -
leakage_power ]
```

Reports the technology library cells that were implemented (and identifies their originating libraries), the area of the cell instances, and the break up of the instances into timing models, sequential cells, integrated clock-gating cells, inverters, buffers, and logic gate cells. Optionally power information can be reported.

The result is based on the cell_area calculated from LIB information. Use set_db use_area_from_lef true (default: false), if you want to get correlation between reports generated with `report_gates` command and `report_qor` or `report_utilization` commands. When a lef is read into Genus, the property "use_area_from_lef" is automatically set to `true`.

Timing models can refer to memory cells, IPs, and so on.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `report_gates` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_gates`
`-hinst hInstName`	Specifies the name of the hinst to collect the cell information. Only cells in the specified hinst will be considered.
`-leakage_power`	Provides leakage power statistic only.
`-out_file fileName`	Specifies the file in which report will be saved. If not specified, information is dumped in the log.
`-power`	Provides internal, switching, leakage and total power statistic.
`-sort {name count area leakage_power internal_power total_power switching_power}`	Specifies the sorting criteria to sort content of the tables to generate leakage_power/internal_power value only respected if the -power option is also specified.

Examples

```
>report_gates -sort name -out_file check.rpt
```

```

```

report_sequential

```
report_sequential
[-help]
[-deleted]
[-full]
[-hinst hInst_names]
[-mapped]
[-optimized]
[-out_file <string>]
```

Reports information about sequentials the design. Sequentials are the elements that have a library is_sequential tag. These can be flops, latches, and clock gates.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `report_sequential` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_sequential`
`-deleted`	Generates a report with the deleted flops and the reason.
`-full`	Generates a report with the sequential name, whether it was inferred or instantiated, the type of sequential, and the type of reset.
`-hinst` *`hInst_names`*	Hinst for the report. By default, the design is reported.
`-mapped`	Generates a report with synthesis requirements modified to map the sequential.
`-optimized`	Generates a report with sequentials optimized to constants or are unloaded, but have not been removed.
`-out_file` *`file_name`*	File to dump the report. Default is stdout

Example

- The following command reports the deleted flops:

```
innovus 1> report_sequential -deleted
Sequential elements: deleted flops
-------------------------------------

  Reason      Instance Name

-------------------------------------

unloaded       foo/bar/q_reg[15]
```

```
unloaded       foo/bar/q_reg[31]
unloaded       foo/bar/q_reg[47]
unloaded       foo/bar/q_reg[63]
unloaded       foo/bar/q_reg[79]
constant 0     moo/ff_reg_9
```

- The following command reports the optimized flops:

```
innovus 2> report_sequential -optimized
Sequential elements: optimized flops
----------------------------------------

  Reason      Instance Name

----------------------------------------
constant 0     RESULTS_CONV_INST/out_p1_reg[7]
constant 0     TDSP_CORE_INST/EXECUTE_INST/alu_cmd_reg[3]
constant 0     TDSP_CORE_INST/EXECUTE_INST/read_data_reg
constant 0     TDSP_CORE_INST/EXECUTE_INST/read_port_reg
```

check_design Category Attributes

The root attribute in the `check_design` category is:

- check_design_across_hierarchy
- check_design_report_async_pins
- check_design_report_scan_pins
- check_design_threshold_fanout

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `read_physical` category, use the following command:

```
get_db -category check_design
```

check_design_across_hierarchy

`check_design_across_hierarchy {true | false}`

Default: `true`

Data_type: boolean, read/write

Checks for undriven/multi-driven/unloaded/constant pins/ports by checking across hierarchical boundaries. By default checks are across hierarchy.

check_design_report_async_pins

`check_design_report_async_pins {true | false}`

Default: `true`

Data_type: boolean, read/write

Checks async pins in a netlist design.

check_design_report_scan_pins

`check_design_report_scan_pins {true | false}`

Default: `true`

Data_type: boolean, read/write

Checks scan pins in a netlist design.

check_design_threshold_fanout

check_design_threshold_fanout `{true | false}`

Default: `true`

Data_type: boolean, read/write

Checks for upper threshold in a netlist design.

add_io_buffers

```
add_io_buffers
[-help]
[-base_name baseName]
[-dishonor_power_intent_domain_boundary_check_for_iso_level_shifter_strategy]
[-exclude_clock_nets]
{[-in_cells cellNameList][-out_cells cellNameList]}
[-include_nets_file selNetFileName]
[-exclude_nets_file excNetFileName]
[-port]
[-pre_place]
[-suffix suffixName]
[-skip_refine_place]
[-status {placed fixed softfixed}]
```

Adds buffers/inverters to the I/O pins of a block and places the buffers/inverters near the I/O pins. When a top-level input (output) is connected to a power domain other than the default, the added buffer is matched to the hierarchy of the destination (source) cell and placed inside the power domain.

This command is power-domain aware. To take advantage of this feature when the netlist contains level shifters, load the shifter table before running this command.

Through the `-port` and `-suffix` parameters, you can control the instance and net names created when you use `add_io_buffers`.

You can use this command after loading a design.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `add_io_buffers` parameter. For a detailed description of the command and all of its parameters, use the man command: `man add_io_buffers`

`-base_name` *baseName*	Specifies the base name of the new nets. For nets with the same base name, you should consider the hierarchical index and add `1`. For example, if there are several nets with an `abc` base name, ending on `abc98`, then the first new net with the same base name is `abc99`. *Data_type*: string, optional
`-dishonor_power_intent_domain_boundary_check_for_iso_level_shifter_strategy`	Dishonors power-domain boundary check for isolation/level-shifter instances. *Data_type*: bool, optional
`-exclude_clock_nets`	Does not connect the buffer on clock nets. You must trigger the clock net markings prior to running `add_io_buffers`, with the `time_design` command. *Data_type*: bool, optional
`-exclude_nets_file` *excNetFileName*	Specifies the file that contains the names of nets to exclude from the buffer attachment operation. *Data_type*: string, optional

`-in_cells` *cellNameList*	Specifies the cell name or a list of cell names of the input (`-in_cells`) buffer. If the specified cell is an inverter, then the `add_io_buffers` command inserts an inverter pair. *Data_type*: string, optional **Note:** If the `-in` and `-out` parameters are specified together, both input and output pins will be attached buffers/inverters. If only `-in` (or `-out`) option is specified, then only input (or output) pins will be attached buffer. If a list of cells is specified, it will insert the first CPF compliant cell. It is recommended to give non-AO buffers/inverters before AO buffers/inverters in the list.

`-out_cells` *cellNameList*	Specifies the cell name or a list of cell names of the output (`-out_cells`) buffer. If the specified cell is an inverter, then the `add_io_buffers` command inserts an inverter pair. *Data_type*: string, optional **Note:** If the `-in` and `-out` parameters are specified together, both input and output pins will be attached buffers/inverters. If only `-in` (or `-out`) option is specified, then only input (or output) pins will be attached buffer. If a list of cells is specified, it will insert the first CPF compliant cell. It is recommended to give non-AO buffers/inverters before AO buffers/inverters in the list.
`-port`	Prepends the port name to the name of the net or instance created. *Data_type*: bool, optional

`-pre_place`	Specifies to legally place the inverter connected to the port and to leave the other inverter unplaced. *Data_type*: bool, optional
`-include_nets_file` *selNetFileName*	Specifies the file that contains the names of nets to include in the buffer attachment operation. *Data_type*: string, optional
`-skip_refine_place`	Skips legalization of the new buffer/inverter (incremental placement needs to be run later to legalize it). *Data_type*: bool, optional
`-status {placed fixed softfixed}`	Specifies the placement status of the added buffer as placed/fixed/softfixed. *Data_type*: enum, optional
`-suffix` *suffixName*	Appends a string to name of the net or instance created. *Data_type*: string, optional

Example

- The following command attaches buffers `bufx4` to the I/O pins. The new nets have a basename of `abc`:

  ```
  add_io_buffers -base_name abc -in_cells bufx4
  ```

- The following command prepends the port name and appends the `_buf` string to the name of the instance and net created by `add_io_buffers`:

  ```
  add_io_buffers -port -suffix "buf"
  ```

  Resulting instance name:

  ```
  port1_I_buf
  ```

  Resulting net name:

  ```
  port1_N_buf
  ```

Related Information

- `time_design`

add_notch_fill

```
add_notch_fill
[-help]
[-area {x1 y1 x2 y2}]
[-report filename]
[-use_existing_drc_result]
[-use_non_default_spacing]
```

Detects and fills notches, gaps, and holes, and corrects violations for rectangle notches. Also, the support is limited nodes 28nm and below.

Creates geometries in `DRCFILL` shapes as special wires attached to each net. Saves the geometries in DEF or GDSII Stream format. In a DEF file, the geometries are saved in the special net section. The software considers the geometries as active design objects.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `add_notch_fill` parameter. For a detailed description of the command and all of its parameters, use the man command: `man add_notch_fill`
`-area {x1 y1 x2 y2}`	Specifies the area to check and fill. For example, `add_notch_fill -area {0 0 100 100}`. *Data_type:* rect, optional
`-report filename`	Specifies the report file. The file includes the locations, types and number of violations corrected. For example, `add_notch_fill -report design_fill.rpt`. *Default:* `design.fill.rpt` *Data_type:* string, optional
`-use_existing_drc_result`	Allows fixing the `convexCornerSpacing` issues based on Verify Geometry markers. *Data_type:* bool, optional
`-use_non_default_spacing`	Honors nondefault spacing rules when filling notches. This behavior matches the behavior of `check_drc`; that is, when this parameter is specified, `add_notch_fill` honors both default and nondefault spacing rules. If this parameter is not specified, `add_notch_fill` honors default spacing rules but does not honor nondefault spacing rules. *Data_type:* bool, optional

Example

- The following commands check the notch issues and create drc markers with verify_drc, and add drc fill shapes on the drc marker location:

```
check_drc
add_notch_fill -use_existing_drc_result
```

Related Information

- `check_drc`

connect

```
connect
[-help]
port|pin|hpin|hport|pg_pin+
[-net net_object | -net_name net_name | -constant | -hnet hnet_object  ]
```

Connects objects together. If these objects exist in different levels of hierarchies, hpins/hport will be created to make these connections.

If more than one object has a driver (that is has a net connected), it creates a multi driver situation. If only one object has a net, all other objects will be connected to that net. If no object has a net, a net will be created and they all will be connected to that net and the `-net_name` option provides a mechanism to optionally name the new net. Otherwise, a new net will be created using n_<i> convention. If the `-net` option is used (along with a net object), then all objects will be disconnected from their existing connection and connected to the new net. For local connections, it returns then hnet object pointer used to make the connection. For hierarchical connection, it returns the parent net object pointer.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `connect` parameter. For a detailed description of the command and all of its parameters, use the man command: `man connect`
port|pin|hpin|hport|pg_pin+	List of objects to connect. Multiple pin/port objects are supported. Note that only object pointers like hport:h1/hport1 are allowed, and simple names like h1/hport1 are not allowed. All objects in the list will be connected together so if objects have existing drivers, then a multidriver situation can be created. *Data_type:* port| pin| hpin| hport| pg_pin)+, required

`-constant`	Connect the object to a constant (0 or 1). This option will only work for hpin/pin/hport/port objects. When specified, any existing net connections to the *objects* specified will be disconnected prior to connecting to the constant. It does not connect the objects together, but instead adds a constant to each separate object at the level of hierarchy where the object exists. If an hpin or a pin is connected to an hnet (e.g. is not dangling), the constant is added to the hnet, otherwise it is added directly to the hpin/pin. If a constant is added to a port/hport, it is always added to the hnet of the port/hport. If there are existing drivers or constants attached to any net of the hnets mentioned above, an error message is given, but the connection is done anyway. *Data_type*: bool, optional
`-hnet` *`hnet_object`*	Specifies the hnet object to be used for the connections. It is mutually exclusive with `-net` (and `-constant`, `-net`). Additionally, the `-hnet` option can only be used to make a local connection (i.e. at the same level of hierarchy) *Data_type:* hnet, optional
`-net` *`net_object`*	Net object to be used for the connections. The object will be connected to the hnet of the specified net at the same level of hierarchy as the object. If there is no hnet at the same level of hierarchy, hports/hpins will be created using the base_name of the net object. Also, when `-net` is specified, any existing net connections to the *objects* specified will be disconnected prior to connecting to this net (for example, equivalent to running disconnect on each object first). *Data_type:* (net), optional
`-net_name` *`net_name`*	Net name to create when only pins specified. Net name to create when only pins specified (i.e. when -net is not specified). This is the base_name of the net and will replace the name of all nets connected to the pins in the object list. If a hierachical connection is being made the base_name will also be used to name any hports/hpins that are created. If *`net_name`* has any illegal chars, it will be automatically escaped. Thus -name "i1/n2" will result in "i1\/n2" for the .escaped_name, since it uses DEF escaping semantics. This is equivalent to checking if *`net_name`* is a legal Verilog identifier, and if not, prepend \ and add a trailing space to the internal Verilog name. *Data_type:* string, optional

Examples

The following command connects two pins with the given net name:

```
connect {pin:H1/I1/Y pin:H1/I3/A} -net_name H1/N1
```

Related Information

- disconnect

connect_hpin

```
connect_hpin
[-help]
-hinst moduleName
-net netName
[-no_new_hpins]
-pin_name hpinName
```

Attaches an hpin in the specified hinst (or top level design) to a net.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `connect_hpin` parameter. For a detailed description of the command and all of its parameters, use the man command: `man connect_hpin`
`-hinst` *hinstName*	Specifies the hinst to that has the hpin. To specify the top design, enter '`-`'. *Data_type*: string, required
`-net` *netName*	Specifies the name of the net. *Data_type:* string, required
`-no_new_hpins`	Prevents the creation of new hpins. If the hpin cannot connect to the net in a different hierarchy through existing hpins, the software displays an error message and the command stops running. *Default*: If you do not specify this parameter, the software creates new hpins as required to reach the net. *Data_type*: bool, optional
`-pin_name` *pinName*	Specifies the base_name of the hpin on the hinst. *Data_type*: string, required

Examples

- The `connect_hpin` command connects the hpin with base_name `p1` on hinst named h1/h2 to the net `h1/h2/net3`:

  ```
  connect_hpin -hinst h1/h2 -pin_name p1 -net h1/h2/net3
  ```

Related Information

- disconnect_hpin

connect_pin

```
connect_pin
[-help]
[-hport portName]
-inst instName
[-module verilogModule]
-net netName
[-no_new_port]
-pin termName
[-reference_pin refInstName refTermName]
```

Attaches a pin to a net. If the pin already connects to a different net, the software first detaches the pin from the current net, then attaches it to the new net.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `connect_pin` parameter. For a detailed description of the command and all of its parameters, use the man command: `man connect_pin`
`-inst` *`instName`*	Specifies the instance containing the pin. If the instance name does not exist, the software displays an error message and the command stops. *Data_type:* string, optional
`-module` *`verilogModule`*	Attaches the pin to the specified verilog module. *Data_type*: string, optional
`-net` *`netName`*	Specifies the name of the net to attach to the pin. If the net name does not exist, Innovus displays an error message and the command stops. *Data_type*: string, required
`-no_new_port`	Prohibits Innovus from creating hierarchical ports when it attaches a pin. If the pin cannot connect to the net through existing ports, Innovus displays an error message and the command stops. *Default:* If you do not specify this parameter, Innovus creates hierarchical ports as needed *Data_type*: bool, optional
`-pin` *`termName`*	Specifies the name of the pin. *Data_type*: bool, optional
`-reference_pin` *`refInstName refPinName`*	Specifies the pin *`refPinName`* on instance *`refInstName`* connected to the net that Innovus connects to the pin. You cannot specify the `-hport` parameter if you use this parameter. *Data_type*: string, optional
`-hport` *`portName`*	Specifies the hierarchical port used to connect the pin with the net. If you specify this parameter, the hierarchical port must exist in the module that contains the instance. The hierarchical port must connect to the net. This parameter lets you use a specific hierarchical port to maintain the same netlist topology, which simplifies equivalence checking later in the design flow. You cannot specify the -reference_pin parameter if you use this parameter. *Default:* If you do not specify this parameter, Innovus uses existing hierarchical ports or creates new hierarchical ports as necessary to connect the pin to the net. *Data_type*: string, optional

Examples

- The following command attaches pin `in1` of instance `i1/i2/i3 to net i1/i2/net26`:
  ```
  connect_pin -inst i1/i2/i3 -pin in1 -net i1/i2/net26
  ```
  If `i1/i2/i3` does not exist, or if `in1` is not a pin of `i1/i2/i3`, or if `i1/i2/net26` does not exist, the software displays an error message and the command stops.

- The following command attaches pin `in2` of instance `i1/i2/i3` to net `net27`, using hierarchical port `myPort`:
  ```
  connect_pin -inst i1/i2/i3 -pin in2 -net net27 -hport myPort
  ```
  The hierarchical port `myPort` must exist in the module definition for `i1/i2`, and `myPort` must already connect to `net27`. If this is not the case, the software displays an error message and the command stops.

- The following command attaches pin `in3` on instance `i1/i2/i3` by re-using existing hierarchical ports to `net28`:
  ```
  connect_pin -no_new_port -inst i1/i2/i3 -pin in3 -net net28
  ```
  No new hierarchical ports is allowed to be created to make the connections. If no existing hierarchical ports can be re-used to complete the connection, the software displays an error message and the command stops.

- The following command attaches pin Y of instance `testInst` to the Verilog module `hier_t3` using the net `testnet`:
  ```
  connect_pin -module hier_t3 -inst testInst -pin Y -net testnet
  ```

Related Information

- `disconnect_hpin`

create_diode

```
create_diode
[-help]
[-prefix prefix]
-diode_cell diodeCellName
-pin instName termName
[-location x y
[-orient r0 r90 r180 r270 mx mx90 my my90]]
```

Adds an antenna diode to a post-routed design. Innovus places the diode as close as possible to the specified pin.

When *instName* is specified, the new instance is bound with the correct cell in the power domain.

When `-location` is specified, the location also gives a power domain, which is checked against the power domain of the pin. If the power domains are different, a warning is issued.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `create_diode` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_diode`
`-diode_cell` *diodeCellName*	Specifies the name of the diode cell master. *Data_type*: string, required
`-location` *x y*	Specifies the location of the lower left corner of the diode. *Data_type*: string, optional
`-orient r0 r90 r180 r270 mx mx90 my my90`	Specifies orientation of the placed diode. To specify this parameter, you must also specify `-location`. *Data_type*: string, optional
`-pin` *instName termName*	Specifies the pin associated with the diode. *Data_type*: string, required
`-prefix` *prefix*	Specifies the prefix name of the diode cell instances. Innovus appends integers to differentiate the instances. *Data_type*: string, optional

Example

- The following example adds a diode of type `D1` for `term2` on instance `i2`, at location `500`, `600`:

```
create_diode -diode_cell D1 -pin i2 term2 -location 500 600
```

create_hinst

```
create_hinst
[-help]
[-parent module|hinst|design]
{-name hinst_name }
{-module module|design}
```

Adds a hierarchical module to the design.

You can use this command after importing a design.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `create_hinst` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_hinst`
`-module module|design`	Specifies the module to use for the new hinst. The new hinst will have hports/hpins created based on the module ports as well as hnets of the same name. *Data_type:* (module|design), required
`-name hinst_name`	Specifies the name of the new hinst. If this is the full hierarchical path, then the parent will be derived from the name (i.e. the parent name is the string before the last "/". In this case, the base_name of the new hinst (i.e. the string after the last "/" should not have any special characters that require escaping. When the `-parent` option is used, then the name is the base_name of the new hinst. if the name has any illegal chars, it will be automatically escaped. Thus -name "i1/i2" will result in "i1\/i2" for the .escaped_name, since it uses DEF escaping semantics. This is equivalent to checking if <hinst_name> is a legal Verilog identifier, and if not, prepend \ and add a trailing space to the internal Verilog name. *Data_type*: string, required
`-parent module|hinst|design`	Specifies the parent for the new hinst. It supports both the object or the name for the specified object types. *Default*: Current design *Data_type*: (hinst|design|module), optional

Examples

The following example creates the module `module:carve/mod1` and instantiates it:

```
@innovus 1> create_module -name mod1
module:carve/mod1
@innovus 2> create_hinst -name H1 -module mod1
hinst:carve/H1
```

Related Information

- create_module
- delete_hinst

create_hnet

```
create_hnet
[-help]
[-bus msb:lsb]
{-name hnet_name}
[-parent module|hinst|design]
[-power | -ground ]
```

Creates a new hnet (and parent net) object and returns the newly created hnet object pointer.

Parameters

`-bus` *`msb:lsb`*	Specifies the bit range for bus nets. You must separate the start and end IDs with a colon (:). If there is an existing bus (for example, 3:0) then additional bits can be added provided they are adjacent to the existing bits (7:4 for example). By default, the tool creates a scalar hnet. *Data_type*: string, optional
`-ground`	Creates a ground net. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `create_hnet` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_hnet`
`-name` *`hnet_name`*	Specifies the name of the new hnet. If this is the full hierarchical path, then the parent will be derived from the name (i.e. the parent name is the string before the last "/". In this case, the base_name of the new hnet (i.e. the string after the last "/" should not have any special characters that require escaping. When the `-parent` option is used, the name is the base_name of the new hnet. If the name has any illegal chars, it will be automatically escaped. Therefore, `-name "i1/n2"` will result in "i1\/n2" for the .escaped_name, as it uses DEF escaping semantics. This is equivalent to checking if *`hnet_name`* is a legal Verilog identifier, and if not, prepend \ and add a trailing space to the internal Verilog name. *Data_type*: string, required
`-parent` *`module|hinst|design`*	Specifies the parent for the new hinst. It supports both the object or the name for the specified object types, *`module`*, *`hinst`*, *`design`*. *Default*: Current design *Data_type*: (hinst|design|module), optional
`-power`	Creates a power net. *Data_type*: bool, optional

Example

```
CPU
 |
 +-----------------+
```

```
 |                |
 H1 (alu)         H2 (fsm)
 |
 +----------------+
 |                |
+ H1 (add)        H2 (mult)
```

- The following command creates a scalar top level net/hnet named N1

  ```
  create_hnet -name N1
  ```

- The following command creates a 8-bit net/hnet named H1/H1/B1

  ```
  create_hnet -name B1 -bus 7:0 -parent module:add
  ```

- The following command creates an 8-bit net/hnet named H1/H1/B1

  ```
  create_hnet -name B1 -bus 7:0 -parent H1/H1
  ```

- The following commands add additional bits to an existing hnet:

  ```
  get_db hnets *CN1*
  {hnet:cpu/CH1/CN1[1]} {hnet:cpu/CH1/CN1[0]}
  create_hnet -parent CH1 -name CN1 -bus 4:2
  {hnet:cpu/CH1/CN1[4]} {hnet:cpu/CH1/CN1[3]} {hnet:cpu/CH1/CN1[2]} {hnet:cpu/CH1/CN1[1]}
  {hnet:cpu/CH1/CN1[0]}
  ```

create_hport

```
create_hport
[-help]
[-bus msb:lsb]
-direction {in out inout}
-name hport_name
[-parent module|hinst|design]
```

Create new hports and corresponding hpins for the parent object. It also implicitly creates hnet and net objects inside the parent object with the same name as the new hport. If the new hport is a bus, then the bus_bits objects are also created. The hnet object has no corresponding hnet or net object but is left dangling. It returns the newly created hport object pointer.

Parameters

`-bus msb:lsb`	Specifies the bit range for bus hports. You must separate the start and end IDs with a colon (:). If there is an existing bus (for example, 3:0) then additional bits can be added provided they are adjacent to the existing bits (7:4 for example). By default, the tool creates a scalar hport. *Data_type*: string, optional
`-direction {in out inout}`	Specifies the direction of the new port, in, out, inout. *Data_type*: enum, required
`-help`	Outputs a brief description that includes the type and default information for each `create_hport` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_hport`
`-name hport_name`	Specifies the name of the new hport. If this is the full hierarchical path, then the parent will be derived from the name (i.e. the parent name is the string before the last "/". In this case, the base_name of the new hport (i.e. the string after the last "/") should not have any special characters that require escaping. When the `-parent` option is used, then the name is the base_name of the new hport. If the name has any illegal chars, it will be automatically escaped. Therefore, `-name "hp1/2"` will result in `"hp1\/2"` for the .escaped_name, since it uses DEF escaping semantics. This is equivalent to checking if *hport_name* is a legal Verilog identifier, and if not, prepend \ and add a trailing space to the internal Verilog name. *Data_type*: string, required
`-parent module|hinst|design`	Specifies the parent for the new hport. *Data_type*: (hinst|design|module), optional

Example

```
CPU
 |
 +----------------+
 |                |
 H1 (alu)         H2 (fsm)
 |
 +----------------+
 |                |
+ H1 (add)        H2 (mult)
```

- The following command creates new scalar objects `hpin:CPU/H1/H1/P1`, `hport:CPU/H1/H1/P1`, and `hnet/net H1/H1/P1`.

  ```
  create_hport -name P1 -parent add -direction in
  ```

- The following command creates a new 8-bit objects `hpin:H1/H2/BP1`, `hport:H1/H2/BP1`, and `hnet/net H1/H2/BP1`.

  ```
  create_hport -name BP1 -parent H1/H2 -bus 7:0
  ```

- The following command creates new scalar objects `hpin:CPU/H1/H2/P2`, `hport:CPU/H1/H2/P2`, and `hnet/net H1/H1/P2`.

  ```
  create_hport -name H1/H2/P2 -direction out
  ```

- The following commands add a single bit to an hport:

  ```
  get_db hports *data_in*
  {hport:cpu/H1/data_in[3]} {hport:cpu/H1/data_in[2]} {hport:cpu/H1/data_in[1]}
  {hport:cpu/H1/data_in[0]}
  create_hport -parent H1 -name data_in -bus 4:4 -direction in
  ```

create_inst

```
create_inst
[-help]
[-dont_snap_to_placement_grid]
[-location {x y}]
[-orient {r0 r90 r180 r270 mx mx90 my my90}]
[-physical]
{-base_cell base_cell} {-name inst_name}
[-parent module|hinst|design]
[-place_status place_status]
```

Creates a new instance object, optionally places it in the design, and returns the newly created object pointer. You can run this command after the design is in memory.

For MSV designs, a cell specified using the `-base_cell` parameter should exist in libraries bound to the power domain of the newly added inst. When `-location` is specified, the location is checked for a power domain, which is checked against the power domain of the parent. If the power domains are different, a warning is issued.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `create_inst` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_inst`
`-physical`	Places a physical instance without updating the netlist. *Data_type*: bool, optional
`-base_cell base_cell`	Specifies the base_cell to use for the new instance. *Data_type*: (base_cell), required
`-dont_snap_to_placement_grid`	If `-dont_snap_to_placement_grid` is specified, Innovus places the instance at the specified location even if the location is off the placement grid. This parameter is used with `-location`. *Default*: false *Data_type*: bool, optional

`-name` *inst_name*	Specifies the name of the new inst. If this is the full hierarchical path, then the parent will be derived from the name (i.e. the parent name is the string before the last "/". In this case, the base_name of the new inst (i.e. the string after the last "/") should not have any special characters that require escaping. When the `-parent` option is used, then the name is the base name of the new inst. If the name has any illegal characters, it will be automatically escaped. Therefore, `-name "i1/i2"` will result in `"i1\/i2"` for the .escaped_name, since it uses DEF escaping semantics. This is equivalent to checking if *inst_name* is a legal Verilog identifier, and if not, prepend \ and add a trailing space to the internal Verilog name. *Data_type*: string, required
`-location {`*x y*`}`	Specifies the location of the placed instance. *Default:* If you do not specify a location, Innovus places the instance at the design origin. *Data_type*: point, optional
`-orient {r0 | r90 | r180 | r270 | mx | mx90 | my | my90}`	Specifies orientation of the placed instance. *Default:* If you do not specify an orientation, Innovus uses `r0`. *Data_type*: enum, optional
`-parent` *module|hinst|design*	Specifies the parent for the new instance. It supports both the object or the name for the specified object types. Only honored for logical instances and is ignored when used with `-physical`. Default: Current design *Data_type*: (hinst|design|module), optional

`-place_status` *place_status*	Specifies the placement status of the added instance. You can specify the following as the placement status: • `cover`: Specifies that the instance has a location and is a part of a cover macro. It cannot be moved by automatic tools or interactive commands. You must specify the instance's location and its orientation. • `placed`: The status of the added instance is placed. • `fixed`: The status of the added instance is fixed. • `soft_fixed`: The status of the added instance is soft_fixed. It cannot be moved by global placement and can only be moved by the legalization step of detail placement • `unplaced`: The status of the added instance is unplaced. *Default*: `unplaced` *Data_type*: enum, optional **Note:** This option is used along with the `-location` option. It should not be used along with the `-parent` option.

Examples

- The following command creates `inst:<design>/H1/I1`.
  ```
  create_inst -name I1 -parent H1 -base_cell BUF1
  ```
- The following command adds buffer instance `i1/i2` at location `100, 200`:
  ```
  create_inst -base_cell BUFX1 -name i1/i2 -location {100 200}
  ```
- The following command adds buffer instance `insta` to the verilog module `HIER_2`:
  ```
  create_inst -parent HIER_2 -base_cell BUFX2 -name insta
  ```

Related Information

- `delete_inst`

create_module

```
create_module
[-help]
-name module_name
```

Create new hports and corresponding hpins for the parent object. It also implicitly creates hnet and net objects inside the parent object with the same name as the new hport. If the new hport is a bus, then the bus_bits objects are also created. The hnet object has no corresponding hnet or net object but is left dangling. It returns the newly created hport object pointer.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `create_module` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_module`
`-name` *`module_name`*	Specifies the name of the new module. If the name has any illegal chars, it will be automatically escaped. Therefore, `-name "m1/m2"` will result in `"m1\/m2"` for the .escaped_name, since it uses DEF escaping semantics. This is equivalent to checking if *`hinst_name`* is a legal Verilog identifier, and if not, prepend \ and add a trailing space to the internal Verilog name. *Data_type*: string, required

Example

- The following command creates `module:<design>/mod1`.

  ```
  create_module -name mod1
  ```

- The following command creates `hinst:<design>/H1`.

  ```
  create_hinst -name H1 -module mod1
  ```

- The following command creates `hpin:<design>/H1/in`.

  ```
  create_hport -name in -module mod1 -input
  ```

- The following command creates `hpin:<design>/H1/out`.

  ```
  create_hport -name out -module mod1 -output
  ```

- The following command creates `inst:<design>/H1/I1`.

  ```
  create_inst -name I1 -parent H1 -base_cell BUF1
  ```

create_net

```
create_net
[-help]
[-bus startID:endID]
[-module verilogModule]
-name netName
[-power  | -ground ]
```

Creates a flat physical net, that is the parent is always the design. The net can optionally be tagged as a power or ground net. The .is_physical_only attribute will be set to `true` along with .is_power or .is_ground when specified. The net is not logical and will not be written as part of the verilog netlist unless `write_netlist -phys` is specified. Currently only pins and PG pins are supported. If a pin at any level of hierarchy is connected to a power or ground physical net, a local 1'b0 or 1'b1 will be connected to the pin at the same level of hierarchy as the pin, that is no hports or hpins will be created as it is treated as a global physical net.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `create_net` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_net`
`-bus` *`startID`*`:`*`endID`*	Specifies the bit range for bus nets. The *`startID`* and *`endID`* indicate the first and last bits on the bus. You must separate the start and end IDs with a colon (:). If the specified bus does not exist, tool will create a bussed Verilog net. If the specified bus already exists, tool will do bus net resizing. The specified bus bit range must be adjacent to the first or last bit of the existing bus. Also, it must have the same ascending or descending order as the existing bus. **Note**: PG bus net is not supported *Data_type*: string, optional
`-ground`	Adds a ground net. *Data_type*: bool, optional
`-module` *`verilogModule`*	Adds the new net to the specified verilog module. If the module name contains special characters, you need to start the module name with a backlash '\' and end it with a space. *Data_type*: (module|design), optional
`-name netName`	Specifies the net to add. If the net name contains special characters, you need to start the part of the net name, which contains special characters, with a backlash '\' and end it with a space. *Data_type*: string, required **Note:** You must specify *`-name`* before you specify other parameters. The software issues an error message if you do not specify the *`-name`* first.
`-power`	Adds a power net. *Data_type*: bool, optional

Examples

- The following command adds net `i1/n1`:

  ```
  create_net i1/n1
  ```

- The following command adds one bit i1/n1[6] to existing bus i1/n1[2:5]:

```
create_net -name i1/n1 -bus 6:6
```

- The following command adds three bits i1/n1[-1], i1/n1[0], i1/n1[1] to existing bus i1/n1[2:5]:
  ```
  create_net -name i1/n1 -bus -1:1
  ```
- The following command adds net with base name ant_net to hierarchy `DTMF_INST/TDSP_CORE_INST/TDSP_CORE_MACH_INST[0].g`:
  ```
  create_net {DTMF_INST/TDSP_CORE_INST/\TDSP_CORE_MACH_INST[0].g /ant_net}
  ```
  Here the "[" and "]" brackets between the backlash and the space are special characters.
- The following command adds net with base name `TDSP_CORE_INST/TDSP_CORE_MATCH_INST[0].g/ant_net` to hierarchy `DTMF_INST`:
  ```
  create_net {DTMF_INST/\TDSP_CORE_INST/TDSP_CORE_MATCH_INST[0].g/ant_net }
  ```
- The following command adds net with base name `ant_net[1]` to `module H[1]`:
  ```
  create_net {\ant_net[1] } -module {\H[1] }
  ```

Related Information

- `delete_nets`
- `write_netlist`

create_port

```
create_port
[-help]
[-bus msb:lsb]
-direction {in out inout}
-name port_name
```

Create new ports for a design object and returns the newly created port object pointer. It also implicitly creates hnet and net objects with the same name connected to the port.

Parameters

`-bus msb:lsb`	Specifies the bit range for bus ports. You must separate the start and end IDs with a colon (:). If there is an existing bus (for example, 3:0) then additional bits can be added provided they are adjacent to the existing bits (7:4 for example). Default is to create a scalar port. *Data_type*: string, optional
`-direction {in out inout}`	Specifies the direction of the new port, in, out, inout. *Data_type*: enum, required
`-help`	Outputs a brief description that includes the type and default information for each `create_module` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_module`. *Data_type*:
`-name module_name`	Specifies the name of the new port. If the name has any illegal chars, it will be automatically escaped. Therefore, `-name "p1/2"` will result in `"p1\/2"` for the .escaped_name, since it uses DEF escaping semantics. This is equivalent to checking if *port_name* is a legal Verilog identifier, and if not, prepend \ and add a trailing space to the internal Verilog name. *Data_type*: string, required

Example

- The following command creates a new input scalar port called P1:
  ```
  create_port -name P1 -direction in
  ```
- The following command creates a new 8-bit output port called BP1
  ```
  create_port -name BP1 -bus 7:0 -direction out
  ```

delete_assigns

```
delete_assigns
[-help]
[-add_buffer [-buffer_tie_assigns] ]]
[-buffer_name bufName]
[-honor_preserve]
[-ignore_port_constraints]
[-prefix bufNamePreFix]
[-nets netName [-net_buffer_name netBufName]]
[-report]
```

Removes assign statements from the Verilog as much as possible while keeping the same DEF netlist. This means that the placement and routing remain the same and timing is not disturbed.

The `delete_assigns` command removes all non-top module assign nets without adding buffers.There are cases where you do not want assign nets in your design. However, there are some assign nets in the original net list imported into Innovus, or you have a design with some unwanted assign nets. In such cases, you can use `delete_assigns` to remove all assigns or replace assigns with proper buffers that are automatically selected by the tool.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `delete_assigns` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_assigns`
`-add_buffer`	Used if assign net buffering feature is needed for command `delete_assigns`. *Data_type*: bool, optional
`-buffer_name bufName`	Specifies the name of the buffer for all assign nets, disables automatic buffer selection. *Data_type*: string, optional
`-buffer_tie_assigns`	Allows to buffer tie assigns. *Data_type*: bool, optional
`-honor_preserve`	Honors the preserve setting while doing the assignment removal. *Data_type*: bool, optional
`-ignore_port_constraints`	Allows to ignore all port constraints during assign removal. *Data_type*: bool, optional

`-nets` *netName*	Specifies the name of net (s). Supports removing or buffering assigns of a list of assign nets,
	For example, the following command removes all assigns of assign nets n1, n2 and n3.
	`delete_assigns -nets {n1 n2 n3}`
	The following command replaces all assigns of assign nets n1, n2 and n3 with buffers.
	`delete_assigns -add_buffer -nets {n1 n2 n3}`
	If "-net" is used, "-buffering" must also be used for buffering those assign nets specified in *netName*. Otherwise, `delete_assigns` will work same as no options are specified (as default).
	Whenever option "-net" is used, *netName* must be provided. Otherwise, a warning message is issued.
	You can specify any of the following as the *netName*:
	• Single net name
	• Multiple net names separated with space
	• Single wildcard name (all matched assign nets will be collected for buffering)
	• Multiple wildcard names separated with space (all match assign nets will be collected for buffering)
	• Single bus name
	• Multiple bus names
	Note: For each bus, all or portion of bus bits can be assign nets and the others can be non-assign nets. The buffering code replaces only those assign bus bits while leave those non-assign bus bits unchanged.
	Data_type: string, optional

`-net_buffer_name` *netBufName*	Specifies the name of the buffer for the specific net given in the `-nets` option. This option, if specified, should come after the `-nets` option. *Data_type*: string, optional
`-prefix` *bufNamePreFix*	Specifies the user-specified prefix for buffer names. If `-prefix` is used, you need to specify a prefix `bufNamePreFix` for buffer names that may be used in this command. The default prefix for added buffers is "`buf_dummy_`" if you do not specify it. *Data_type*: string, optional

`-report`	Reports list of all buffers and assign nets that were replaced by the buffers. If `-report` is used, a list of all buffers and assign nets that were replaced by the buffers will be reported in log file. If buffers are inserted to the netlist you may need to use Innovus to place and route them. *Data_type*: bool, optional

The `delete_assigns` command:

- Removes assigns that involve only internal "wires".
  For example, in the code below, `assign n2 = n1` is removed.

```
module top();
  wire n1, n2;
  assign n2 = n1;

  BUFX2 u1(.Y(n1));
  BUFX2 u2(.A(n2));
  endmodule
```

  becomes

```
module top();
  wire n1;

  BUFX2 u1(.Y(n1));
  BUFX2 u2(.A(n1));
  endmodule
```

- Removes assigns that involve only one port.
  For example, in the code below, `assign p1 = n1` is removed.

```
  module hier(p1);
  output p1;
  wire n1;
  assign p1 = n1;
   BUFX2 u1(.Y(n1));
  endmodule
```

becomes

```
module hier(p1);
output p1;
 BUFX2 u1(.Y(p1));
endmodule
```

- Rewires nets with feedthrough assigns that involve at least two ports, at some higher level:

```
module hier2 (
          i,
          o);
     input i;
     output o;
     assign o = i ;
     BUFX2 u1 (.A(i));
  endmodule
  module hier (
          i,
          o);
     input i;
     output o;

     hier2 u1 (.i(i),
          .o(o));
  endmodule
  module top ();
     // Internal wires
     wire i;
     wire o;
     BUFX2 u1 (.Y(i));
     hier u2 (.i(i),
          .o(o));
```

```
    BUFX2 u3 (.A(o));
  endmodule
```

becomes

```
module hier2 (
          i,
          o);
    input i;
    output o;

    BUFX2 u1 (.A(i));
  endmodule
  module hier (
          i,
          o);
    input i;
    output o;
    hier2 u1 (.i(i));
  endmodule
  module top ();
    // Internal wires
    wire i;

    BUFX2 u1 (.Y(i));
    hier u2 (.i(i));
    BUFX2 u3 (.A(i));
  endmodule
```

delete_bus_net

```
delete_bus_net
[-help]
[-module_based moduleName]
{-bus busName | -bus_from_bit busBitName}
```

Deletes bus net from a design.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `delete_bus_net`. For a detailed description of the command and all of its parameters, use the man command: man `delete_bus_net`
`-module_based moduleName`	Specifies the module name that contains the bus net which needs to be deleted. *Data_type*: string, optional
`-bus busName`	Specifies the base name of the top-level bus net, or the base name of a bus net in verilog module when used with `-module_based` option. *Data_type*: string, optional
`-bus_from_bit busBitName`	Specifies the bus bit name of a top level or a non-top level bus net, or a bus bit name of a bus net in verilog module when used together with the `-module_based` option. *Data_type*: string, optional

⚠ The `delete_bus_net` command does not support wildcards.

Examples

Non-top level bus net

- The following command deletes the bus net x/y/z.

  ```
  delete_bus_net -bus_from_bit x/y/z[2]
  ```

- The following command deletes a bus net from a verilog module, used with `-module_based` and `-bus_from_bit` *busBitName*.

  ```
  delete_bus_net -bus_from_bit z[2] -module_based Y
  ```

- The following command deletes a bus net from a verilog module, used with `-module_based` and `-bus` *busName*.

  ```
  delete_bus_net -bus z -module_based Y
  ```

Top level bus net

- The following command deletes the top-level bus net, using the option `-bus_from_bit` *busBitName*.

  ```
  delete_bus_net -bus_from_bit x[2]
  ```

- The following command deletes the top-level bus net, using the option `-bus` *busName*.

  ```
  delete_bus_net -bus x
  ```

delete_empty_hinsts

```
delete_empty_hinsts
-help
[-delete_empty_1801_hinsts]
```

Deletes modules and their instantiations. Modules and their instantiations are deleted if the following criteria are met:

- The netlist is unique
- The module does not contain any instances, or the module contains only unconnected instances of other empty modules
- The instances of the module are not connected to other instances or ports

Note: The `delete_empty_hinsts` command deletes only those modules that are below the top-level design module.

The `delete_empty_hinsts` command does not delete used empty modules, where there exists at least one connected instance of the empty cell. For example, black boxes typically are empty, but they are still connected to other instances or ports.

At times, the lowest hierarchy is connected to the immediate higher-level hierarchy but the module is dangling and should be deleted. You can delete the dangling modules by first deleting the dangling ports followed by the deletion of the empty modules as given below:

```
delete_dangling_ports

delete_empty_hinsts
```

Note: A design can contain empty modules for different reasons. Modules can become empty due to optimization processes. A design also can contain MCPO modules that were read in with the netlist. To convert empty modules into special leaf cells when reading in the netlist, see `init Category Attributes`.

Parameters

`-delete_empty_1801_hinsts`	Deletes empty UPF modules. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `delete_empty_hinsts` parameter.

Related Information

- delete_dangling_ports
- init Category Attributes

delete_feedthru_buffer

```
delete_feedthru_buffer
[-help]
[-dont_delete_dangling_hports]
[-non_preferred_keep_nets netNamePattern] [-preferred_keep_nets netNamePattern]
{{-inst bufInstName} | {-inst_prefix instPrefixName}
```

Removes the feedthrough buffer specified in the `-inst` option. It also removes all possible dangling horts/hnets that are associated with the buffer removed. The `delete_feedthru_buffer` command supports multiple-instantiated buffer cells.

Parameters

`-inst bufInstName`	Specifies the name of the feedthrough buffer to be removed. *Data_type*: string, optional
`-dont_delete_dangling_hports`	Is used if you do not want to remove the dangling ports created by this command. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `delete_feedthru_buffer` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_feedthru_buffer`
`-inst_prefix` *instPrefixName*	Specifies the prefix name for the feedthrough buffer. It removes all buffer instances that were created by the `add_partition_feedthrus` command if `add_partition_feedthrus` also used this option to specify the exactly same `instPrefixName`. Therefore, you need to specify exactly the same instance name prefix in the `-instPrefix` option of both the commands. *Data_type*: string, optional **Note**: The `-instPrefix` specified here must be unique to all instance names in the current design.
`-non_preferred_keep_nets` *netNamePattern*	Specifies the non-preferred keep net name pattern. The nets whose names match the pattern will not be used by buffer deletion. *Data_type*: string, optional
`-preferred_keep_nets` *netNamePattern*	Specifies the preferred keep net name pattern. The nets whose names match the pattern will be used by buffer deletion. *Data_type*: string, optional

Example

- The following command deletes feedthrough buffer with inst name as `i1/i2/FE_FEED_BUF_1`, and also keeps the dangling ports:
  ```
  delete_feedthru_buffer -inst i1/i2/FE_FEED_BUF_1 -dont_delete_dangling_hports
  ```

Related Information

- add_partition_feedthrus

delete_hinst

```
delete_hinst
[-help]
[-module | -modules ]
hinst_name+
```

Deletes a hierarchical instance and its module and optionally, its cell.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `delete_hinst` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_hinst`.
`hinst_name+`	Specifies the hierarchical instance to delete. *Data_type*: (hinst)+, required
`-module`	Deletes the module of the hierarchical instance. It only works when the specified hierarchical instance is the last one in the design that references this module. *Data_type*: bool, optional
`-modules`	Deletes all instances that are hierarchically inside the instance from which the given hierarchical instance, *`hinst_name`*, is instantiated. If a hierarchical instance is multi-referenced and all sibling hierarchical instances instantiated from the hierarchical instance are hierarchically inside *`hinst_name`*, the hierarchical instance will be deleted. Otherwise, the multi-referenced hierarchical instance will not be deleted. *Data_type*: bool, optional

Examples

- The following command deletes instance RESULTS_CONV_INST:
  ```
  delete_hinst DTMF_INST/RESULTS_CONV_INST
  ```

- The following command deletes instance RESULTS_CONV_INST and deletes its cell:
  ```
  delete_hinst DTMF_INST/RESULTS_CONV_INST -module
  ```

Related Information

- create_hinst

delete_hpin

```
delete_hpin
[-help]
[-bus startId:endId]
-hinst moduleName
-pin_name pinName
```

Disconnects the specified port from its net and deletes the port. Individual bits of a bus port cannot be deleted.

Parameters

`-bus startId:endId`	Specifies the startId and the endId of the bus bit. *Data_type*: string, optional **Note**: • When a bit port or bit net is connected to something else, the bit will not be removed. • Bus bit ports to be deleted must be adjacent to each other and adjacent to either msb or lsb of the existing bus.
`-help`	Outputs a brief description that includes the type and default information for each `delete_hpin` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_hpin`
`-hinst moduleName`	Specifies the name of the hierarchical instance whose port is to be deleted. Specify "-" for the top hierarchical instance. *Data_type*: string, required
`-pin_name pinName`	Specifies the name of the port to be deleted. Wildcards are not accepted. *Data_type*: string, required

Examples

- The following command deletes the port 'rst_i' from the top hierarchical instance:
  ```
  delete_hpin -hinst - -pin_name rst_i
  ```
- The following command deletes all bits of the bus port '`data_i`' of the hierarchical instance `moduleB_inst`:
  ```
  delete_hpin -hinst moduleA_inst/moduleB_inst -pin_name data_i
  ```
- The following command deletes bus bits out[7], out[6], out[5], and out[4] from existing top-level bus port out[7:0]:
  ```
  delete_hpin -hinst - -pin_name out -bus 7:4
  ```

Related Information

- `create_hport`

delete_inst

```
delete_inst
[-help]
-inst instName
[-module moduleName ]
[-verbose]
```

Deletes instances from the current design. Innovus checks whether the instance is physical or logical, and deletes the instance accordingly.

Note: The `delete_inst` command cannot be used in the post-mask ECO. Please use `read_eco <eco_files> -post_mask` to delete instances in the post-mask ECO.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `delete_inst` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_inst`
`-inst` *instName*	Specifies the list of instances to delete. Does not accept *inst* dual ported objects. *Data_type*: string, required
`-module` *moduleName*	Specifies the name of the Verilog module. *Data_type*: string, optional
`-verbose`	Prints out the deleted instance message. *Data_type*: bool, optional

Example

- The following command deletes instance `i1/i2`:

  ```
  delete_inst -inst i1/i2
  ```

- The following command deletes all instances whose base names begin with `i` inside hierarchical instance `i1`:

  ```
  delete_inst -inst i1/i*
  ```

- The following command deletes the instance `insta` from the verilog module `HIER_2`:

  ```
  delete_inst -module HIER_2 -inst insta
  ```

- The following command deletes all instances in the `SPGM` module:

  ```
  delete_inst -inst * -module SPGM
  ```

Related Information

- `create_inst`
- `delete_obj`
- `delete_filler`
- `eco_batch_mode` in `eco Category Attributes`
- `read_eco`

delete_nets

```
delete_nets
[-help]
net
[-bus startId:endId]
[-module verilogModule]
```

Logically deletes nets from a design. If a net is routed, wire segments associated with the net are also deleted.

If you plan to call `route_eco -route_only_layers bottomLayer:topLayer` later, ensure that the net to be deleted only has wire segments on the specified layer.

Note: To delete wire segments associated with a net without deleting it logically, use the `delete_routes` command.

You can use wildcards (`*?`) to specify the nets you want Innovus to delete.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `delete_nets` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_nets`
`-bus startId:endId`	Deletes the specified bus bits. The specified bus bit net must be a one pin net, which means that the bus bit net is floating on the other side. The specified range must be adjacent to the most significant bit or the least significant bit of the existing bus. Also, it must have the same ascending or descending order as the existing bus. **Note**: PG bus net is not supported. *Data_type*: string, optional
`-module verilogModule`	Deletes the net from the specified verilog module. *Data_type*: string, optional
net	Specifies the name of the net to delete. *Data_type*: string, required

Example

- The following command deletes `net1`:

  ```
  delete_nets net1
  ```

- The following command deletes all nets whose name begin with `net1`:

  ```
  delete_nets net1*
  ```

- The following command deletes one bit h1/net2[3] from existing bus h1/net2[3:0]:

  ```
  delete_nets h1/net2 -bus 3:3
  ```

- The following command deletes two bits h1/net2[3], h1/net2[2] from existing bus h1/net2[3:0]:

  ```
  delete_nets h1/net2 -bus 3:2
  ```

Related Information

- `create_net`
- `delete_routes`
- `route_eco`

delete_notch_fill

`delete_notch_fill`

Deletes all gap, notch, and hole geometries.

- A gap is a minimum spacing violation with two edges without a common adjacent side.
- A notch is a minimum spacing violation with two edges with a common adjacent side.
- A hole is a minimum enclosure violation.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `delete_notch_fill` parameter.

Related Information

- ECO Flows chapter in the *Innovus Stylus Common UI User Guide*

disconnect

```
disconnect
[-help]
pin|hpin|port|hport|pg_pin+
[-keep_dangling_net]
```

Disconnects pins, ports, hports, or hpins from any hnet or net. For example, if A, B, and C are connected to net N , and you disconnect A, then B and C remain connected to N, but A is now left unconnected. For hpin/hport objects, they are disconnected only from the local hnet they are connected to. So, for an hpin, it will be disconnected from the hnet above the hpin (outside the hinst of the hpin). For hports, it will be disconnected from the hnet below the hport (the hnet inside the hinst of the hport) but the associated hpin/hport to hnet connection is not affected. You need to disconnect them both if you want both connections removed. Also, if an hpin/pin is directly connected to a constant (e.g. has .constant 0/1 and no hnet), the .constant attribute on the hpin/pin will be cleared, and return “no_constant”.

By default, dangling hnets that have no port, hport, hpin, or pin attached to it are deleted. Any constants like 1’b0/1’b1 are ignored, so a constant hnet is considered dangling if there are no port, hport, hpin or pin objects attached to it.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `disconnect` parameter. For a detailed description of the command and all of its parameters, use the man command: `man disconnect`
`-keep_dangling_net`	Keeps the net object even if it has no loads or drivers. Default is to delete dangling nets. *Data_type*: bool, optional
pin|hpin|port|hport|pg_pin+	List of objects to disconnect (port/pin/hpin/hport/pg_pin). Only objects are supported, no simple names. *Data_type*: (pin |hpin |port |hport |pg_pin)+, required

Example

Consider the following example:

```
@innovus1>get_db hport:H1/B1 .hnet

hnet:H1/B1

@innovus2>get_db hpin:H1/B1.hnet
```

```
hnet:P1
```

If the following command is run, the tool will disconnect hport:H1/B1 from hnet:H1/B1, but leave hpin:H1/B1 connected to hnet:P1

```
@innovus2>disconnect hport:H1/B1
```

Related Information

- connect

disconnect_hpin

```
disconnect_hpin
[-help]
-hinst hinstName
-pin_name portName
```

Detaches the net connected to the specified port on the specified hierarchical instance.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each disconnect_hpin parameter. For a detailed description of the command and all of its parameters, use the man command: `man disconnect_hpin`
`-hinst hinstName`	Specifies the name of the hierarchical instance. To detach a top-level port, specify "-" as the *hinstName*. For example, the following command detaches the port 'a' from the net connected to it: `>disconnect_hpin -hinst - -pin_name a` *Data_type*: string, required
`-pin_name portName`	Specifies the port on the module. *Data_type*: string, required

Example

- The following command detaches port `p1` from `moduleA`:
  ```
  disconnect_hpin -hinst moduleA -pin_name p1
  ```

Related Information

- connect_hpin

disconnect_pin

```
disconnect_pin
[-help]
[-module verilogModule]
-inst instName
-pin
[-net]
```

Disconnects a pin from a net.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `disconnect_pin` parameter. For a detailed description of the command and all of its parameters, use the man command: `man disconnect_pin`
`-inst instName`	Specifies the instance that contains the pin you want to detach. *Data_type*: string, required
`-module verilogModule`	Detaches pin of the specified instance inside the Verilog module. *Data_type*: string, optional
`-net`	Specifies the net that is already connected to the pin. If the pin does not connect to the specified net, or if the net does not exist, the software displays an error message and the command stops. The software uses this parameter for error checking only. *Data_type*: string, optional
`-pin`	Specifies the pin to disconnect. If the pin does not exist on the specified instance, the software displays an error message and the command stops. *Data_type*: string, required

Example

- The following command disconnects pin `in1` of instance `i1/i2/i3`:

  ```
  disconnect_pin -inst i1/i2/i3 -pin in1 -net i1/i2/net26
  ```

  If instance `i1/i2/i3` does not exist, or `in1` is not a pin of `i1/i2/i3`, the software displays an error message and the command stops. The net `i1/i2/net26` is specified, so if net `i1/i2/net26` does not exist, or if the pin is not already connected to net `i1/i2/net26`, the software displays an error message and the command stops.

Related Information

- `connect_pin`

eco_add_repeater

```
eco_add_repeater
[-help]
{-net netName | -pins {term1 term2} }
[-hinst_guide hinstName | -spread_distance distance| -spread_count number ]
[-name instName | -spread_distance distance | -spread_count number ]
[-spread_distance distance | -spread_count number ]
[-new_net_name netName | -spread_distance distance | -spread_count number ]
[-location {xLoc yLoc} | { xLoc yLoc inv_xLoc inv_yLoc} | -off_load_at_location {x1a y1a x1b y1b
x2a y2a x2b y2b ....} | { xLoc yLoc inv_xLoc inv_yLoc} | -off_load_slack slack | -spread_distance
distance | -spread_count number ]
[-radius radius | -logical_change_only | -spread_distance distance | -spread_count number ]
[-off_load_at_location {x1a y1a x1b y1b x2a y2a x2b y2b ....} | { xLoc yLoc inv_xLoc inv_yLoc} | -
off_load_slack slack | -spread_distance distance | -spread_count number ]
[{[-location {xLoc yLoc} | { xLoc yLoc inv_xLoc inv_yLoc}] [-relative_distance_to_sink sinkWeight]
[-off_load_at_location {x1a y1a x1b y1b x2a y2a x2b y2b ....} | { xLoc yLoc inv_xLoc inv_yLoc}]}
[-radius radius ] ]
[-location {xLoc yLoc} | { xLoc yLoc inv_xLoc inv_yLoc} [-buffer_orient {R0 | R90 | R180 | R270 |
MX | MX90 | MY | MY90}]]
[-net netName [-spread_distance distance]]
[-cells {list of cells} ]
[-relative_distance_to_sink sinkWeight | -off_load_at_location {x1a y1a x1b y1b x2a y2a x2b y2b
....} | { xLoc yLoc inv_xLoc inv_yLoc} | -off_load_slack slack | -spread_distance distance | -
spread_count number ]
[-location {xLoc yLoc} | { xLoc yLoc inv_xLoc inv_yLoc} | -no_place]
```

Adds either a single buffer or two inverters on a net. This allows you to optionally specify the location and radius, the location relative to the sink pin, and the buffer insertion based on the slack. This command also checks for and observes power domains based on the specified instance name and location. This command cuts wires by default.

This command does not modify `dont_touch` nets if `-eco_honor_dont_touch` is set to `true`.

Notes:

- The `eco_add_repeater` command is simultaneous setup/hold and MMMC aware. To make the command simultaneous setup/hold aware, set the global variable `set_global timing_enable_simultaneous_setup_hold_mode` to `true`. The simultaneous setup/hold mode can only be used for timing analysis. It cannot be used for any physical implementation steps.
  By default, if you specify an inverter as the master cell, `eco_add_repeater` adds a pair of inverters.
- `eco_add_repeater` can return new instance and net name: `newInstName inputNet outputNet`
  Example
  ```
  set result [eco_add_repeater -net s2_hresp0 -cells inv_32 -pins \
  arm926p_test/wrapper_1_out_reg/d -location 1069.018666 128.2435714]
  ```

```
set newInstName [lindex $result 0]
set inputNetName [lindex $result 1]
set outputNetName [lindex $result 2]
```

If a pair of inverter is added then the return list could be the following, assuming `inv1OutputNet` drives the input pin of `inv2InstName`:

```
{inv1InstName inv1InputNet inv1OutputNet inv2InstName inv2OutputNet}
```

- When `eco_add_repeater` is used in the post-mask ECO, ensure that it is used with the `-no_place` option to avoid base layer change. Also, call `place_eco -use_spare_cells` or `eco_swap_spare_cell` to map the new repeater to the spare cell. If you plan to call `route_eco -route_only_layers bottomLayer:topLayer` later, ensure that the added repeater can be connected through the specified layer. Otherwise, please do not use the `eco_add_repeater` command. You can also use `read_eco <eco_files> -post_mask` to add repeaters in the post-mask ECO.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `eco_add_repeater` parameter. For a detailed description of the command and all of its parameters, use the man command: `man eco_add_repeater`
`-buffer_orient` *orientation*	Specifies the legalized orientation for the instance. Valid orientation values are: R0, R90, R180, R270, MX, MX90, MY, MY90. *Data_type*: string, optional For more information on orientation keys, see "Orientation Key" in the *Floorplanning the Design* chapter of the *Innovus User Guide*.
`-cells` *listOfCells*	Specifies the master name for the cell to be inserted. Either a buffer or an inverter can be specified as the master cell. If an inverter is specified, two inverters in series will be added. The cell should have timing information in the library. *Data_type*: string, optional
`-hinst_guide` *hinstName*	Indicates the module hierarchy in which the `inst` is inserted by Tempus or a third party tool so that Innovus is able to make the association in case the instance appears in the `-pinsList` option of an ECO command at a later stage. This option can be only used when `set_db eco_batch_mode true` is specified. You also need to specify the `-name` option along with it. *Data_type*: string, optional

`-location {xLoc yLoc} | { xLoc yLoc inv_xLoc inv_yLoc}`	Specifies the x and y coordinates for the location of the buffer or inverter pair to insert. If no location is specified, the tool will automatically determine a location. • If the cell is a buffer and location is specified, the newly created buffer is placed at the specified location (x, y). • If the cell is an inverter pair and two locations are specified, the first inverter will be placed at location (x1, y1) and the second inverter will be placed at location (x2, y2). • If the cell is an inverter pair and only one location is specified, both inverters will be placed at the same location (x, y). *Data_type*: (point)+, optional
`-logical_change_only`	Specifies that buffer/inverter addition should be done in the logical-only mode. *Data_type*: bool, optional
`-name` *instName*	Specifies the base name for the repeater to be inserted. *Data_type*: string, optional
`-net` *netName*	Specifies the name of the net where the buffer will be inserted. *Data_type*: string, optional
`-new_net_name` *netName*	Specifies the base name for the new net created for the repeater insertion. *Data_type*: string, optional
`-no_place`	Specifies that the inserted cells should not be placed. Only the logical change in connectivity will be made. *Data_type*: bool, optional
`-off_load_at_location {x1a y1a x1b y1b x2a y2a x2b y2b ....}`	Specifies the location(s) at which buffer (or inverter-pair) should be inserted to drive the sinks downstream from the location(s). *Data_type*: (point)+, optional
`-off_load_slack` *slack*	Inserts a buffer to offload the paths with less than the specified slack threshold from the driver of a net with multiple cells. This option ignores the *term* option, if it is provided. This option is used to connect the added buffer to drive only noncritical receivers, selected By Slack. This checks the timing graph for noncritical receivers and offloads those from the critical path, and could improve critical path timing by penalizing noncritical path delays. *Data_type*: float, optional

`-radius` *radius*	Specifies the radius in which the added instances are free to move. If no legal location can be found in the specified radius, the cells would be placed at the specified location resulting in an overlap with other cells. In that case, you should perform legalization. *Data_type*: float, optional
`-relative_distance_to_sink` *sinkWeight*	Specifies the location of the buffer based on its distance from the sink or the driver pin. The value is a number between 0 and 1. A low value (0.1) places the buffer near the sink; a high value (0.9) places the buffer near the driver. The fraction is based on the length of the wire. *Data_type*: float, optional *Minimum*: 0 *Maximum*: 1 This option works: • When one `term` is provided; it does not work if no `term` or multiple terms are specified. • When `-net` with 1-sink net is provided. It does not work if the specified net is not a 1-sink net.
`-pins` *term1 term2..*	Specifies a list of terms. The terms specified in the list should be connected to a common net and the tool adds buffer to the common net. If `-pins` is not specified, all the terms of the net will be buffered. *Data_type*: string, optional
`-spread_count` *number*	Specifies the number of repeaters to be added for buffering. *Minimum*: 1 *Maximum*: INT_MAX *Data_type*: int, optional
`-spread_distance` *distance*	Specifies the distance (starting from the driver) after which repeaters are to be added. *Minimum*: 2.2250738585072e-308 *Maximum*: 1073741.823 *Data_type*: float, optional

Note: You can specify the following ECO attributes:

```
set_db eco_honor_fixed_status false #to modify FIXED instance.

set_db eco_honor_dont_use false #to modify instances which have dontUse attribute on cells.
```

```
set_db eco_honor_dont_touch false #to modify instance/nets which are marked dontUse.
```

Examples

- The following command adds a buffer near the receiver:
  ```
  eco_add_repeater -net wire_I13 -relative_distance_to_sink 0.1 -cells BUFX4
  ```
- The following command adds a buffer near the driver:
  ```
  eco_add_repeater -net wire_I13 -relative_distance_to_sink 0.9 -cells BUFX4
  ```
- The following command adds a buffer in a specified location
  ```
  eco_add_repeater -net wire_I10 -location 51.5 85.67 -cells BUFFX4
  ```
- The following command adds an inverter by specifying the terminal list:
  ```
  eco_add_repeater -net n1 -cells INVX4 -pins {i1/i2/in1 i1/i2/in2 i1/i2/in3}
  ```
- The following command adds an inverter by specifying the slack time:
  ```
  eco_add_repeater -net wire1_B2 -cells INVX4 -off_load_slack -0.1
  ```

eco_compare_netlist

```
eco_compare_netlist
[-help]
[-logical]
-out_file fileName
[-output_physical_inst_in_file physicalInstFile]
{-def_file referenceFileName [-reference_data {in_memory | external}]}
```

Compares a specified netlist with the design in the database for structural or logical equivalence, and creates a file containing the differences found.

If the `eco_disable_change_net_name_for_flat_netlist` attribute of the `eco` category is set to `true`, there would not be any net renaming for flat netlist. Net renaming will take place if the net name is hierarchical and the terms it connects to do not fall under the same hierarchy or lies up in the hierarchy. Do `set eco_disable_change_net_name_for_flat_netlist 1` before running the `eco_compare_netlist` command to disable net renaming for flat netlist.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `eco_compare_netlist` parameter. For a detailed description of the command and all of its parameters, use the man command: `man eco_compare_netlist`
`-def_file` *`referenceFileName`*	Specifies the name of the DEF file that Innovus uses to compare with the design. *Data_type*: string, required
`-reference_data [in_memory | external]`	Specifies the data from where the post-ECO netlist is to be compared. • `in_memory` compares the post-ECO netlist to the netlist in memory. `in_memory` is the default behavior. • `external` compares the post-ECO netlist to an external netlist. *Data_type*: enum, optional
`-logical`	Compares the netlists for logical equivalence. *Data_type*: bool, optional
`-out_file` *`fileName`*	Specifies the file that contains the differences between the specified DEF file and the design in the database. If the directory specified to save the file does not exist, the tool creates the directory. For example, in the following command if `a/` does not exist, the tool will create it: `eco_compare_netlist -def_file test.def -out_file ./a/test.rpt` *Data_type*: string, required
`-output_physical_inst_in_file` *`physicalInstFile`*	
	When this option is specified, physical instance ECO command is also written to ECO file, and the added physical instances names one per line are dumped into the *`physicalInstFile`* file. *Data_type*: string, optional

Example

- The following command compares the `myFile.def` file against the design, and writes the results to `differences.file`:

  ```
  eco_compare_netlist -def_file myFile.def -out_file differences.file
  ```

Related Information

- eco Category Attributes

eco_delete_repeater

```
eco_delete_repeater
[-help]
[-logical_change_only]
{-insts {list_of_instances} | -inverter_pair {pairs_of_inverters} }
```

Deletes a buffer or pair of inverters connected back-to-back. This command merges wires after ECO.

This command does not modify `dont_touch` nets if `set_db eco_honor_dont_touch` is set to `true`.

Note:

- The `eco_delete_repeater` command is simultaneous setup/hold and MMMC aware. To make the command simultaneous setup/hold aware, set the `timing_enable_simultaneous_setup_hold_mode` attribute to `true`. The simultaneous setup/hold mode can only be used for timing analysis. It cannot be used for any physical implementation steps.
- The `eco_delete_repeater` command cannot be used in the post-mask ECO. Please use `read_eco <eco_files> -post_mask` to delete repeaters in the post-mask ECO.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `eco_delete_repeater` parameter. For a detailed description of the command and all of its parameters, use the man command: `man eco_delete_repeater`
`-insts` *`list_of_instances`*	Specifies a buffer or inverter to delete. If you specify an inverter, the command finds another inverter on the net and deletes the back-to-back pair in order to preserve the logical equivalence. Instances are deleted only if they are tied to each other. To specify a pair of instances, enclose the instances in braces. `-insts` {*`inst1 inst2`*} *Data_type*: string, optional
`-inverter_pair` {*`pairs_of_inverters`*}	Specifies pairs of inverters to be deleted/evaluated for deletion. *Data_type*: string, optional
`-logical_change_only`	Specifies that buffer/inverter deletion should be done in the logical-only mode. *Data_type*: bool, optional

Note: You can specify the following using the `set_db` command:

- `set_db eco_honor_dont_use false` to modify instances which have dontUse attribute on cells.
- `set_db eco_honor_dont_touch false` to modify instance/nets which are marked dontTouch.

Examples

- The following command deletes the specified buffer, `A/inst1`:
  ```
  eco_delete_repeater -insts A/inst1
  ```
- The following command deletes a back-to-back inverter pair containing `A/inv1`:
  ```
  eco_delete_repeater -insts A/inv1
  ```
- The following command deletes instances `DTMF_INST/RESULTS_CONV_INST/FE_PHC845_r1644_2_` and `DTMF_INST/RESULTS_CONV_INST/FE_PHC845_r1643_3_`:
  ```
  eco_delete_repeater -insts {DTMF_INST/RESULTS_CONV_INST/FE_PHC845_r1644_2_
  DTMF_INST/RESULTS_CONV_INST/FE_PHC845_r1643_3_}
  ```

eco_design

```
eco_design
[-help]
sessionDirectoroy
{design name}
net_list_file
[-allow_to_load_binary_timing_file]
[-add_hport_for_tie_off]
[-cpf_file newCPFFile | -1801_file new1801File]
[-def defFile]
[-eco_mmmc newMMMCFile]
[-eco_sdc newSDCFile]
[-keep_inst_location]
[-lef_files LEFFilesName]
[-no_add_filler]
[-filler_prefix prefix | -no_delete_filler]
[-route_only_layers MLb:MLt]
[-no_eco_place]
[-no_eco_route]
[-no_timing]
[-post_mask]
[-report_file reportFile]
[-skip_ccopt]
[-spare_cells spareCellName]
[-suffix suffix]
[-tie_cells cellNameList]
[-use_gate_array_cells GACoreSite | -use_gate_array_filler_cells list_of_filler_cells]
```

Takes an Innovus database and a modified netlist as input and performs ECO operations. It restores the {design name}, examines the changes in the new netlist, and automatically implements the required changes with `place_eco` and `route_eco`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `eco_design`. For a detailed description of the command and all of its parameters, use the man command: man `eco_design`
`-1801_file new1801File`	Specifies the name of the new CPF file. *Data_type*: string, optional

`-add_hport_for_tie_off`	Allows the added tie cells to connect to the tie pins across hierarchical boundaries if other constraints, such as maximum fanout and maximum distance, allow it. This parameter can be used only with `-post_mask` and `-tie_cells` options. *Data_type*: bool, optional
`-allow_to_load_binary_timing_file`	Allows the tool to load the binary timing graph or the timing constraint file. If you execute `eco_design` based on binary timing graph or timing constraints, the tool will give an error and stop loading the new design. This is because the timing graph or the timing constraints file from the loaded design is a binary file, and if you keep on loading it, it may cause fatal error. In such a case, you need to restore the original design and then save a new design with the no-binary timing file. Then, execute `eco_design` based on the new design. If you still want to load the current design, you need to run `eco_design -allow_to_load_binary_timing_file 1` to turn on the control.
`-cpf_file` *newCPFFile*	Specifies the name of the CPF file. *Data_type*: string, optional
`-def` *fileName*	Specifies the DEF file you want the software to load automatically when performing ECO. This parameter automatically assigns the location of the new ECO cells. As a result, you do not need to run `place_eco` after performing the ECO. *Data_type*: string, optional
{*design name*}	Specifies the top cell name of the {design name}. *Data_type*: string, required
`-eco_mmmc` *newMMMCFile*	Specifies the name of the ECO view definition file. *Data_type*: string, optional
`-eco_sdc` *newSDCFile*	Specifies the name of the new SDC file. *Data_type*: string, optional

`-filler_prefix` *prefix*	Specifies the filler cell instance prefix. The `eco_design` command removes all filler cells before placing the ECOs. If you do not specify a prefix, `deleteFiller` removes filler instances based on the `add_fillers` category settings. If you have not set `add_fillers` category attributes, then no filler cells are removed. *Data_type*: string, optional
`-keep_inst_location`	Keeps the instance location of changed cells. *Data_type*: bool, optional
`-lef_files` *LEFFilesName*	Specifies the LEF files name for loading. Use this option if you want to replace the existing LEF files in the original design with new LEF files. Refer to `read_db -lef_files` for more details and limitations. For example, tech.lef, A.lef are the existing LEFs used in original design. You can change A.lef to A_v2.lef using the following command: `eco_design original.enc.dat myDesign myDesign.new.v -lef_files {tech.lef A_v2.lef}` *Data_type*: string, optional
`-no_add_filler`	Skips filler insertion in the pre-mask eco flow. *Data_type*: bool, optional
`-route_only_layers` *MLb:MLt*	Specifies the layers to be modified during the ECO process. *Data_type*: string, optional
net_list_file	Specifies the name of new netlist file. *Data_type*: string, required
`-no_delete_filler`	Specifies to not remove physical cell instances, such as filler cells, end-cap cells, and well-tap cells. *Data_type*: bool, optional
`-no_eco_place`	Prevents placement during the ECO process. *Data_type*: bool, optional

`-no_eco_route`	Prevents routing during the ECO process. *Data_type*: bool, optional
`-no_timing`	Ignores timing libraries and MMMC configuration.
`-post_mask`	Specifies that the changes are being made on a post-mask {design name}. `-post_mask` is required when the `-suffix`, `-spare_cells`, `-modifyOnlyLayers`, `-tie_cells`, or `-add_hport_for_tie_off` option is specified. *Data_type*: bool, optional
`-report_file` *reportFile*	Specifies the name of the report file. *Data_type*: string, optional **Note**: By default, `eco_design` creates the default `ecoRestoreDesign.rpt` file. However, this default file will be overwritten by the file name specified using the `-report_file` option in next eco RUN.
session_directory	Specifies the .dat directory from which to load the files. *Data_type*: string, required
`-skip_ccopt`	Skips restore ccopt config for `time_design_signoff`.
`-spare_cells` *spareCellName*	Specifies the name of the spare cell to use during the ECO process. *Data_type*: string, optional
`-suffix` *suffix*	Specifies the suffix to be appended to the spare cells. You can specify this parameter only if you specify `-post_mask`. *Default:* `_SPARE` *Data_type*: string, optional

`-tie_cells "cellName1 cellName2"`	Specifies the existing tie cells to be reused to make tie connections for newly created SPARE instance in the {design name}. You can only specify a maximum of two tie-cells, where one cell must be a tie-high driver, and the other a tie-low driver. The two tie-cell names must be surrounded by quotation marks. This parameter can be used only with `-post_mask` option. *Data_type*: string, optional
`-use_gate_array_cells GA_site`	Specifies the site name of the GA cell. Check the site name defined in the LEF file. *Data_type*: string, optional
`-use_gate_array_filler_cells list_of_filler_cells`	Specifies a list of Gate Array (GA)-style filler cells that the tool can replace with GA cells during post-mask ECO. You can only use this parameter in a post-mask ECO flow. *Data_type*: string, optional **Note:** You cannot specify the `-use_gate_array_cells` parameter if you use this parameter.

Examples

- The following command performs a pre-mask ECO:
  ```
  eco_design original.enc.dat myDesign myDesign.new.v
  ```
- The following command and options are used to implement a post-mask ECO:
  ```
  eco_design -post_mask -route_only_layers 2:3 -spare_cells *spare* original.enc.dat myDesign
  myDesign.new.v
  ```

eco_oa_design

```
eco_oa_design
[-help]
lib
cell
view
-eco_verilog_file input_fileName
[-post_mask [-suffix suffixName]]
[-use_gate_array_cells GACoreSite]
[-report_file output_fileName]
```

Imports an OpenAccess database and an ECO-modified netlist. Restores the physical objects in the database, examines the changes in the new netlist, and implements the required connectivity changes in the logical database without making changes to the physical objects. It preseves the spare cell markings in the old `lib`/`cell`/`view`.

For more information, refer to the Innovus-Based ECO Flow section of the `Chip Finishing and ECO Flows` chapter of *Innovus Stylus Common UI Mixed Signal (MS) Interoperability Guide*.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `eco_oa_design` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man eco_oa_design`.
`cell`	Specifies the OpenAccess cell name of the top cell to import. *Data_type*: string, required
`lib`	Specifies the OpenAccess library name. *Data_type*: string, required
`-eco_verilog_file` *`input_fileName`*	Specifies the changed Verilog netlist. *Data_type*: string, required **Note:** The original netlist must be written out from the original *`lib cell view`* and it must be hand-modified to incorporate the required ECO changes.

`-report_file` *output_fileName*	Specifies a report file that shows the additions and removals of instances and nets in the new Verilog netlist. *Default:* eco.log *Data_type*: string, optional
`-post_mask`	Specifies that eco_oa_design works in the post-mask mode. If this parameter is not specified, then Innovus considers the mode as pre-mask by default. By default, the suffix is _SPARE. *Data_type*: bool, optional
`-suffix` *suffixName*	Specifies the suffix name for the spare cells. *Default*: _SPARE *Data_type*: string, optional
`-use_gate_array_cells` *GACoreSite*	The `-use_gate_array_cells` parameter is valid only in the post-mask mode. *Data_type*: string, optional 1. For cells that match the specified GA core site: ◦ Newly added GA cells that exist in memory but not in the OpenAccess database are left unplaced. ◦ GA cells that exist in the OpenAccess database but not in the memory are deleted in the new database. 2. For cells that do not match the specified GA core site, Innovus treats them as standard cells as described in post-mask mode.
view	Specifies the OpenAccess view name to import. *Data_type*: string, required

Examples

The following command reads the modified Verilog from the `eco.v` file, complete physical pre-ECO database from the `lib/cell/view designLib/TOP/final` in the post-mask mode:

```
eco_oa_design designLib TOP final -eco_verilog_file eco.v -post_mask
```

In post-mask mode, no physical database changes are allowed and the new logical changes coming through `eco.v` are incorporated using spare cells in successive `place_eco` and `eco_route` commands.

Related Information

- Chip Finishing and ECO Flows chapter of *Innovus Stylus Common UI Mixed Signal (MS) Interoperability Guide*.

eco_read_def

```
eco_read_def
[-help]
[-post_mask [-suffix suffixName]]
[-use_gate_array_cells GACoreSite]
[-report_file in_file]
[-drc_clean_data]
[-keep_inst_location]
[-merge_floating_route_to_pg_net netName]
[-eco_def_file {new_DEF_in_file}]
filename
```

Restores physical information from an old design and compares this information with the design in memory. This command uses the specified DEF file in the following ways for pre-mask and post-mask ECO:

- Used in pre-mask mode (without the `-post_mask` parameter) this command behaves as follows:
    - New cells and nets
      Cells that exist in memory but not in the DEF file become unplaced.
    - Deleted cells or nets
      Cells and nets that exist in the DEF file but not in memory are discarded.
    - Modified nets
      Nets found both in the DEF file and in memory, but whose connections are different, are marked as "modified" for further processing during `route_eco`.
    - Matched cells/nets
      Nets and cells that exist both in the DEF file and in memory, and have the same connections, are placed as described in the DEF file. This includes the soft matching capability used in `read_def`.

Soft matching happens when a DEF net name does not have an equivalent name and another net is found in memory, that has the same connections as described in the DEF file.

The most common case for soft matching is when nets have multiple aliases in a hierarchical design `"net1" = "inst1/net2" = "inst1/inst2/net3"` and so on. Any of these net names can be used in the DEF and can have the same connections.

Without soft matching, net `a', for example, is removed and net `b' is created in it's place, resulting in ripping of the wire.

- In post-mask mode (with the -post_mask parameter), the software can only change nets, not cells. This command behaves as follows:
    - New added cells and nets
      Cells that exist in memory but not in the DEF file become unplaced. Later, these cells will be mapped to spare cells when you use `place_eco -use_spare_cells`.

- Deleted cells
  Cells and instances that exist in DEF but not in memory are added to a spare cell list in Innovus: They are not discarded. Deleted cells are renamed with their original name and the suffix you specify. The default suffix is `_SPARE`. For example, `cellA` is renamed `cellA_SPARE`. The software retains deleted nets and their routing, which `route_eco` reroutes later.
- Deleted nets
  Nets that exist in DEF but not in memory are kept and processed later when you use the `route_eco` command.
- Modified nets
  Same behavior as in the pre-mask mode.
- Matched cells and nets
  Same behavior as in the pre-mask mode.
- Physical cells
  Cells that exist in the DEF file but not in memory, which are marked with `+SOURCE DIST` in the DEF file, are restored.

If you specify `-use_gate_array_cells`, this implies a post-mask mode. This option behaves as follows:

- For cells that match the specified GA core site:
  - New added GA cell that exists in memory but not in the DEF file are left unplaced.
  - New GA cells that exist in the DEF file but not in memory are deleted.
- For cells that do not match the specified GA core site, the software treats them as standard cells as described in `-post_mask` mode.

If you specify a report filename, this command reports the following information:

- New cells and nets found in memory but not in the DEF file
- Deleted cells and nets found in DEF but not in memory
- Nets whose connection does not match
- Cells and nets that match in Innovus and DEF

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `eco_read_def` parameter. For a detailed description of the command and all of its parameters, use the man command: `man eco_read_def`

`-drc_clean_data`	Specifies that the routed data is DRC clean. ECO routing will skip routing analysis. *Data_type*: bool, optional
`-eco_def_file {`*`new_def_in_file`*`}`	Specifies the name of a partial DEF file. The tool compares the original routed DEF file or Innovus database with this file and marks the changed instances, changed location of the existing instances, and changed segments or wires. *Data_type*: string, optional
`in_file`	Specifies the name of the routed/original DEF file to load. *Data_type*: string, required
`-keep_inst_location`	Applies the placement status and location of the instance in the DEF file to the instance in db. *Data_type*: bool, optional This option is only applicable in the following special situation: When an instance in DEF file and an instance in db have the same name but the master cell of the instance in the DEF and in the db do not match, then the instance in DEF is considered as deleted while the instance in db is added. In this case, if the option is not specified, the general rule for addition or deletion of an instance is applied as described earlier. For the added instance, the placement status is set to unplaced. If the option is specified, the placement status and location of the instance in the DEF file is applied to the instance in db.
`-merge_floating_route_to_pg_net` *`netName`*	Merges the routing data to the specified PG net. In this case, the physical-only net will not be created. When this parameter is not specified, if a net is deleted in the new netlist but exists in the DEF file, then the `eco_read_def` command discards the net in pre-mask ECO and creates a physical-only net in post-mask ECO to preserve the routing data on the net. *Data_type*: string, optional
`-post_mask`	Runs this command in post-route mode. *Data_type*: bool, optional
`-report_file` *`in_file`*	Specifies the name for the report generated by the `eco_read_def` command. *Default:* `eco_read_def.rpt` *Data_type*: string, optional

`-suffix` *suffixName*	Appends the specified suffix to cells that appear in the DEF file but have been deleted in the new netlist. *Default:* `_SPARE` *Data_type*: string, optional
`-use_gate_array_cells` *GACoreSite*	Specifies the GA Core Site. *Data_type*: string, optional

Examples

The following example reads a DEF file, `myOld.def`, for post-mask ECO.

```
eco_read_def -post_mask -suffix _SPARE -report_file eco_read_def.rpt myOld.def
```

When the software converts a deleted instance to a spare cell, it adds the `_SPARE` suffix to the instance. This command generates a report `eco_read_def.rpt`.

The following example shows a report file:

```
DELINST DTMF_INST/TDSP_CORE_INST/PROG_BUS_MACH_INST/i_9649 INVX1
(converted to spare cell
DTMF_INST/TDSP_CORE_INST/PROG_BUS_MACH_INST/i_9649_SPARE)

ADDINST DTMF_INST/TDSP_CORE_INST/PROG_BUS_MACH_INST/i_9649 BUFX8
MODIFYNET dtmf_chip_TIELO_Y_r2c1
ADDNET DTMF_INST/UNCONNECTED_000
ADDNET DTMF_INST/UNCONNECTED_001
ADDNET DTMF_INST/TDSP_CORE_INST/UNCONNECTED_000
ADDNET DTMF_INST/TDSP_CORE_INST/UNCONNECTED_009
ADDNET DTMF_INST/TDSP_CORE_INST/UNCONNECTED_010
```

```

Remaps or restructures gates that have inputs connected to the same net. These gates are remapped into functionally equivalent logic such that none of the new gates has inputs tied together. Usually, such optimization is good in all objectives. For example, a 4-input OR gate with 3 of its inputs tied together (implementing function a+b+b+b) can safely be replaced with a 2-input OR gate (implementing a+b). This move is likely to be better in terms of area, power, and delay. However, in case of complex gates, it may not be possible to restructure a gate in a way that improves delay, but it may be possible to decompose it into smaller discrete gates, none of which has inputs tied together. Area and/or delay may be worse, but in some libraries, it is preferable to not have instances with inputs tied together. The `eco_remove_tied_inputs` command fixes any gate with two or more inputs connected to the same net regardless of the improvement in delay/area/power. It tries to find improving moves, but it may accept moves that worsen delay/area/power.

The command can also insert buffers in nets tying inputs together. Inserting buffers should be used for the gates that cannot be automatically fixed or that are preserved. You need to specify which buffer cell(s) must be inserted before which input(s). There must be as many buffer cells specified as there are inputs specified. The only exception is specifying a single buffer cell; in that case it is understood that all inputs will be untied by using instances of that same buffer cell.

The command honors `opt` category settings for timing update and legalization. It does not call `route_eco` if run in the postRoute/ECO stages.

Note: MBFF cells are ignored by default as they always have tied inputs.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `eco_remove_tied_inputs` parameter. For a detailed description of the command and all of its parameters, use the man command: `man eco_remove_tied_inputs`
`-base_cells libCell/ptnCell+`	Specifies the buffer cells to be used for fixing. *Data_type*: (base_cell)+, optional
`-ignore_base_cells libCell/ptnCell+`	Specifies to ignore instances of these cells from fixing. *Data_type*: (base_cell)+, optional

`-ignore_insts` *inst+*	Specifies to ignore these instances from fixing. *Data_type*: (inst)+, optional
`-insts` *inst+*	Specifies to fix only these instances. *Default*: All design minus ignored instances/cells. *Data_type*: (inst)+, optional
`-relaxed_placement`	Accepts moves even if instances cannot be placed. *Data_type*: bool, optional You do not need to set this option if `eco_remove_tied_inputs` can successfully fix all violations. In some cases, for example if an instance with tied inputs is in a very congested area, the tool may not be able to place the new instances. In such cases, you can use the `-relaxed_placement` option to fix such instances. However, the final placement may not be legal, and the new instances will likely overlap. For this, you can perform incremental placement to legalize the placement.
`-term` *term_list*	Specifies the terms to be buffered. *Data_type*: string, optional
`-verbose`	Reports existing tied inputs, but does not provide fixing details by any method. *Data_type*: bool, optional
`-report`	Specifies to increase the detail of reports and fixing. *Data_type*: bool, required

Related Information

- `opt Category Attributes`
- `route_eco`

eco_swap_spare_cell

```
  eco_swap_spare_cell
[-help]
instName
spareInstName
[-keep_scan]
[-no_scan_trace]
[-preserve_pins {list_of_spare_cell_pins}]
[-suffix suffix]
```

Swaps an unplaced or placed cell with a cell in the spare cell list.

You can specify this command only after you have run `set_spare_insts`.

This command can swap cells of the same cell type (same footprint and identical pin name). Cells of different sizes can also be swapped. The spare cell is connected according to the specified global net connections.

If the cell to be swapped is unplaced, it is mapped to the spare cell. *instName* is deleted, and its connection is transferred to the spare cell. If the cell to be swapped is placed, it is swapped with the spare cell and is renamed to *instName suffix* if the `-suffix` option is used. If a suffix is not specified, the *inst name* cell is renamed to *spareInstName*. The *instName* cell's connections are transferred to *spare instName*. The input of *instName* is `tielo`, based on the global connection definition.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `eco_swap_spare_cell` parameter. For a detailed description of the command and all of its parameters, use the man command: `man eco_swap_spare_cell`
`-keep_scan`	Keeps the scan connection for both the spare cell and the specified instances. Before you can use this parameter, you must first identify the scan connections by running a scan trace. *Data_type*: bool, optional
`instName`	Specifies the name of the cell to swap. *Data_type*: (inst), required
`-no_scan_trace`	Disables scan tracing while swapping. *Data_type*: bool, optional
`-preserve_pins {`*`list_of_spare_cell_pins`*`}`	Specifies a list of pins whose connection you want to preserve while swapping spare cells. The same pin on both the spare cell and specified instances is preserved. If both the instance and the spare cell are placed instances, the `-preserve_pins` parameter is effective for both cells. If the instance is unplaced, `-preserve_pins` only affects the spare cell because the instance is deleted. *Data_type*: string, optional
`spareInstName`	Specifies the spare cell in the spare cell list to swap with the placed cell. *Data_type*: (inst), required
`-suffix` *`suffix`*	Specifies a string that is appended to the *`instName`* after swapping. *Data_type*: string, optional

Examples

The following example swaps a placed cell, `DTMF_INST/TDSP_CORE_INST/PROG_BUS_MACH_INST/i_9649`, with spare cell `spare1`:

```
set_spare_insts -inst *spare*
place_eco -use_spare_cells
check_place

eco_swap_spare_cell DTMF_INST/TDSP_CORE_INST/PROG_BUS_MACH_INST/i_9649 spare1
```

Related Information

- check_place
- set_spare_insts
- place_eco

eco_update_cell

```
eco_update_cell
[-help]
-cells list_of_cells |-up_size | -down_size
[-orient {r0 | r90 | r180 | r270 | mx | mx90 | my | my90}]
-insts instNames
[-location {xLoc yLoc}]
[-pin_maps oldpin1 newpin1 oldpin2 newpin2 ...]
```

Upsizes or downsizes the specified instance based on the available footprint. Cell mapping is also possible as long as the output pins are functionally the same. This command also checks for and observes power domains.

This command does not modify `dont_touch` nets if the `eco` attribute `eco_honor_dont_touch` is set to `true`.

Notes:

- If you use the `eco_update_cell` command to modify a `` `fixed' `` instance, the software issues a warning message.
  Instead, you can specify the following using the `eco` category attributes:
  `eco_honor_fixed_status` to `false`, to modify FIXED instance.
  `eco_honor_dont_use` to `false` to modify instances which have dontUse attribute on cells.
  `eco_honor_dont_touch` to `false` to modify instance/nets which are marked dontTouch.
- `The eco_update_cell` command is simultaneous setup/hold and MMMC aware. To make the command simultaneous setup/hold aware, set the `timing_enable_simultaneous_setup_hold_mode` attribute to `true`. The simultaneous setup/hold mode can only be used for timing analysis. It cannot be used for any physical implementation steps.
- When resizing instances inside multiple-instantiated blocks, the resize would be applied to all instantiations of the block.
- You can change a buffer to a pair of inverters using the `eco_delete_repeater` and `eco_add_repeater` commands. You can change a buffer to an inverter by first using the `eco` attribute `eco_check_logical_equivalence false` and then using `eco_update_cell`. However, please note that it results in the change in logic.
- The `eco_update_cell` command cannot be used in the post-mask ECO. Please use `read_eco <eco_files> -post_mask` to change cells in post-mask ECO.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `eco_update_cell` parameter. For a detailed description of the command and all of its parameters, use the man command: `man eco_update_cell`
`-orient {r0 | r90 | r180 | r270 | mx | mx90 | my | my90}`	Specifies the legalized orientation for the instance. You can specify this parameter with the `-location` parameter only. *Data_type*: string, optional
`-insts` *instNames*	Specifies the names of the instances to be added. *Data_type*: string, optional
`-location {xLoc yLoc}`	Specifies the legalized location where the instance will be placed. *Data_type*: point, optional
`-up_size`	Upsizes the specified instance with the next available cell in the same footprint unless the specified cell is already of the highest driving strength. Upsizing an instance that drives a large load can improve the driver delay and the transition time at the receivers. *Data_type*: bool, optional
`-down_size`	Downsizes the specified instance with the next available cell in the same footprint unless the specified cell is already of the lowest driving strength. Downsizing an instance on the noncritical path can reduce the loading of its driver on the critical path. *Data_type*: bool, optional
`-cells` *list_of_cells*	Specifies the name of a specific cell(s) to be substituted in the design. The function of the original cell has to match the function of the new cell for all the outputs used by the old cell. The original master cell and the new master cell must have exactly same number of pins. *Data_type*: string, optional
`-pin_maps` *oldpin1 newpin1 oldpin2 newpin2*	Specifies the pin mapping for the new cell based on the old cell. This option is required if the new master cell has different pin names than the original cell. The net connected to *oldpin1* of the original cell should be connected to *newpin1* of the new cell, and so forth. *Data_type*: string, optional

Examples

- Upsizes the specified instance:
  ```
  eco_update_cell -insts Top_I18 -up_size
  ```

- Downsizes the specified instance:

  ```
  eco_update_cell -insts Top_I18 -down_size
  ```

- Modifies the specified instance according to the specified cell:

  ```
  eco_update_cell -insts Top_I18 -cells BUFX20
  ```

- Changes to another cell with a different pin name:

  ```
  eco_update_cell -insts Top_I27 -cells TXOR2X2 -pin_maps A X B Y Y Z
  ```

- Downsizes the specified instance:

  ```
  eco_update_cell -insts Top_I18 -down_size
  ```

Related Information

- eco_add_repeater
- eco_delete_repeater
- eco Category Attributes
- read_eco

eco Category Attributes

The root attributes in the eco category are:

- eco_add_ports
- eco_batch_mode
- eco_delay_calculation_effort
- eco_disable_change_net_name_for_flat_netlist
- eco_honor_dont_touch
- eco_honor_dont_use
- eco_honor_fixed_status
- eco_honor_fixed_wires
- eco_honor_power_intent
- eco_inherit_net_attribute
- eco_check_logical_equivalence
- eco_prefix
- eco_preserve_hpin_function
- eco_refine_place
- eco_spread_inverter
- eco_update_only_layers
- eco_update_timing

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `eco` category, use the following command:

```
get_db -category eco
```

eco_add_ports

`eco_add_ports {true|false}`

Default: `true`

Data_type: bool, read/write

Controls whether timing optimization adds ports to the lower-level hierarchies of the design. It only works during ECO and overwrites the value of `opt_add_ports` for ECO commands, `eco_add_repeater`, `eco_update_cell`, and `eco_delete_repeater`.

eco_batch_mode

```
eco_batch_mode {true|false}
```

Default: `false`

Data_type: bool, read/write

Speeds up the runtime in case the user performs lots of interactive ECO operations. When the user specifies `eco_batch_mode true`, various ECO operations are performed in a batch and initialization steps are not performed for every ECO call. In addition, updating timing is performed only once for all the ECO operations. Tool will only perform timing initialization at the first ECO command in the batch mode and timing update at the time of exiting the batch mode. User needs to set batch mode false to exit the batch mode.

The batch mode is activated by `set_db eco_batch_mode true` and exited by `set_db eco_batch_mode false`, and only `eco_add_repeater`, `eco_delete_repeater` and `eco_update_cell` could be given in between `set_db eco_batch_mode true` and `set_db eco_batch_mode false`:

```
set_db eco_batch_mode true
eco commands (eco_add_repeater, eco_delete_repeater, eco_update_cell)

set_db eco_batch_mode false
```

If a user activates the batch mode, then the user needs to remember to exit it. If the user does not exit the batch mode, the user might see some unexpected results. For example, if the tool automatically added cell padding for blocks when `place_detail` is called by ECO commands for some reason, the cell padding will not be removed and the block size will change unless the user exits the batch mode.

All other settings should be made prior to activating the batch mode. If you would like to change settings, you need to exit the batch mode first.

Note: This option supports all commit ECO commands. Evaluation commands are not supported.

Related Command

- `place_detail`

eco_delay_calculation_effort

```
eco_delay_calculation_effort {low | medium | high}
```

Default: `high`

Data_type: string, read/write

Specifies delay calculation effort level { low | medium | high} used in timing update.

eco_disable_change_net_name_for_flat_netlist

`eco_disable_change_net_name_for_flat_netlist`

Default: `0`

Data_type: int, read/write

Specifies whether nets would be renamed in ECO report of `eco_compare_netlist`. When set to 1, there will not be any net renaming for flat netlist. The net renaming will take place if net name is hierarchical and the terms it connects to do not fall under the same hierarchy or lies up in the hierarchy. You need to set `eco_disable_change_net_name_for_flat_netlist` to `1` before `eco_compare_netlist` command is issued to disable net renaming for flat netlists.

eco_honor_dont_touch

`eco_honor_dont_touch {true|false}`

Default: `true`

Data_type: bool, read/write

Checks for the don't touch attribute on nets and instances. If you specify a terminal list, this parameter checks each terminal for the don't touch attribute. The `eco_add_repeater` command honors the don't touch nets. The `eco_delete_repeater` and `eco_update_cell` commands honor don't touch instances.

Related Commands

- `eco_delete_repeater`
- `eco_update_cell`

eco_honor_dont_use

`eco_honor_dont_use {true|false}`

Default: `true`

Data_type: bool, read/write

Checks for the don't use attribute on cells. The `eco_add_repeater`, `eco_delete_repeater`, and `eco_update_cell` commands honor don't use cells.

Related Commands

- `eco_add_repeater`
- `eco_delete_repeater`
- `eco_update_cell`

eco_honor_fixed_status

`eco_honor_fixed_status {true|false}`

Default: `true`

Data_type: bool, read/write

Checks for fixed instances.

It restricts the resize or deletion of fixed instances.

eco_honor_fixed_wires

`eco_honor_fixed_wires {true|false}`

Default: `true`

Data_type: bool, read/write

Checks for fixed net wires.

It restricts the addition or deletion on fixed net so that the fixed status of the wires is not altered.

When `eco_honor_fixed_wires` is set to `false`, `eco_add_repeater` can insert a cell on the wires with the FIXED/COVER status and change the status of these wires from FIXED/COVER to ROUTED.

eco_honor_power_intent

`eco_honor_power_intent {true|false}`

Default: `true`

Data_type: bool, read/write

Performs MSV checks during ECO. When set to `true`:

- `eco_update_cell` does not allow:
  - Resizing a regular cell with an always-on cell (and vice-versa).
  - Resizing with cells belonging to different power domains.
- `eco_add_repeater` does not allow:

  - Adding buffer to a power domain it does not belong to.
  - Buffering a cross power domain net if it can cause MSV violations.
  - Adding a regular buffer to a net that requires an always-on buffer.
  - Adding an always-on buffer to a net that does not require an always-on buffer.
- `eco_delete_repeater` does not allow deletion of a buffer or an inverter-pair that will cause:
  - A redundant isolation cell.
  - A CPF-constrained net to be deleted.

Note: To prevent buffer insertion failure due to MSV constraints, you need to set `eco_honor_power_intent` to `false`.

eco_inherit_net_attribute

```
eco_inherit_net_attribute {true|false}
```

Default: `true`

Data_type: bool, read/write

Inherits the net attribute.

eco_check_logical_equivalence

```
eco_check_logical_equivalence {true|false}
```

Default: `true`

Data_type: bool, read/write

Enables functionality checking when swapping cells. The software can swap cells that are logically equivalent.

When `eco_check_logical_equivalence` is `true`:

- `eco_add_repeater` adds inverter pair if the specified cell is inverter.
- `eco_delete_repeater` deletes inverter pair if the specified instance is inverter.
- `eco_update_cell` changes cell to another cell type with the same function as long as they have same number of pins.

When `eco_check_logical_equivalence` is set to `false`:

- `eco_add_repeater` can add only one single inverter if the specified cell is inverter.
- `eco_delete_repeater` can delete only one single inverter if the specified instance is inverter.
- `eco_update_cell` can perform nonequivalent cell change as long as they have same number of pins.

Related Commands

- `eco_add_repeater`
- `eco_delete_repeater`
- `eco_update_cell`

eco_prefix

`eco_prefix` *`prefix`*

Default: `ECO`

Data_type: string, read/write

Adds a prefix to the inserted cells.

eco_preserve_hpin_function

`eco_preserve_hpin_function {true|false}`

Default: `false`

Data_type: bool, read/write

Determines whether to preserve logical functions at hierarchical module ports. It only works for manual ECO commands and overwrites the value of `opt_preserve_hpin_function` for the ECO commands, `eco_add_repeater`, `eco_update_cell`, and `eco_delete_repeater`.

eco_refine_place

`eco_refine_place {true|false}`

Default: `true`

Data_type: bool, read/write

Legalizes placement whenever `eco_add_repeater` or `eco_update_cell` are used. If `false`, you must run `place_detail` after ECO if you want to legalize placement.

Note: Specifying `eco_refine_place true` can affect performance when large numbers of cells are added or modified.

Example

The following command does not legalize placement whenever `eco_add_repeater` or `eco_update_cell` are used:

```
set_db -eco_refine_place false
```

Related Commands

- `eco_add_repeater`
- `eco_update_cell`
- `place_detail`

eco_spread_inverter

```
eco_spread_inverter {true|false}
```

Default: `true`

Data_type: bool, read/write

Distributes an inverter pair evenly between the driver and the sink. It works when the buffering nets have only one driver and one sink. The design must be routed before you use this parameter.

eco_update_only_layers

```
eco_update_only_layers bottom_layer:top_layer
```

Default: `""`

Data_type: string, read/write

Modify routes only on metal layers in this range (both inclusive).

eco_update_timing

```
eco_update_timing {true|false}
```

Default: `true`

Data_type: bool, read/write

Controls whether to `eco*` commands recompute timing. If `true`, the eco* commands recompute timing. If `false`, the commands do not recompute timing, and us can later use `report_timing` to recompute timing.

ECO Without Category Attributes

The ECO root attributes without any category are:

- bit_blasted_port_style
- group_instance_suffix

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

bit_blasted_port_style

```
bit_blasted_port_style %s_%d
```

Default: `%s_%d, persistent`

Data_type: string, read/write

Defines the bus bit blasted port name.

Specifies the naming style to be used if mapped ports are bit blasted with the command `bitblast_ports`. The values of this global need to contain elements %s and %d.

The following rules apply:

- A port name always starts with the base name (represented by %s)
- The suffix is appended to the base name to form port name, according to the format specified in the global value.
- %d represents the bit information.

Example

The default of %s_%d will convert a bus-bit A[0] to A_0.

If you want to keep the original bus-bit name but have it turned into an escaped scalar name you can use:

```
set_db bit_blasted_port_style {%s\[%d\]}
```

This will convert a bus-bit A[0] to an escaped scalar name A\[0\] in Tcl, so the port .name would be “A[0]”, the .escaped_name would be “A\[0\]”, the dual-ported-object name would look like {port:top/A\[0\]} with Tcl adding the {} around it to protect the \ chars, and the Verilog port would look like “\A[0] “.

One advantage of this is that SDC commands and Innovus Tcl commands that use port names with A[0] will still “soft-match” the new A\[0\] name, so they do not have to change. However, using escaped names may require

careful Tcl scripting to make sure you do not inadvertently lose the escaped \ chars when you want them.

group_instance_suffix

`group_instance_suffix` *`suffix`*

Default: `i`

Data_type: string, read/write

This suffix is added to a new hinst name created by the `group` command. So, `group -name abc` creates a new module named `abc`, and a new `hinst` named `abci`. If you do not want any suffix, you need to set the value to the empty string “”.

end_eco

```
end_eco
[-help]
```

Ends logging ECO operations.

Parameters

None

Examples

- The following commands show the usage of `initECO` and `endECO`.

  ```
  init_eco File1
  ....
  <ECO commands>
  ....
  end_eco
  ```

  All operations performed by ECO Commands are logged in *`File1`*.

fix_multi_drivers

```
fix_multi_drivers
[-help]
[-exclude_net netName | netNameList]
[-replace_bus_bit]
[-report_only]
```

Fixes multi-drive issues by disconnecting driving ports that do not have a real driver.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `fix_multi_drivers` parameter. For a detailed description of the command and all of its parameters, use the man command: `man fix_multi_drivers`
`-exclude_net` *netName* `|` *netNameList*	Specifies the list of nets to be excluded.
`-replace_bus_bit`	Replaces all bus ports with wrong directions, if any, by new scalar ports. If not specified, just report without such replacement. *Data_type*: bool, optional
`-report_only`	Reports, but does not fix, ports with wrong directions. *Data_type*: bool, optional

group

```
group
[-help]
inst|hInst+
[[-module_name module_name -hinst_base_name hinst_base_name ]]
```

Creates a new module and hinst from a group of the specified hinsts or insts. You can only group hinsts and insts that belong to the same hierarchy (the same hinst parent). Returns the newly created hinst.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `group`. For a detailed description of the command and all of its parameters, use the man command: `man group`
inst|hInst+	Specifies the hinst(s) or inst(s), in the same hierarchy, to be grouped. *Date_type*: (inst|hinst)+, required
`-hinst_base_name` *hinst_base_name*	Specifies the hinst base name of the new group instantiation. *Data_type*: string, required
`-module_name` *module_name*	Specifies the module name of the new group. *Data_type*: string, required

Example

The following command groups two hinsts, `h1` and `h2`, at the top-level into a new module named `test`. The new hinst is named testi by default.

```
>group -name test {h1 h2}
```

Related Information

- `group_instance_suffix` attribute in ECO Without Category Attributes
- `ungroup`

gui_show_buffer_tree

```
gui_show_buffer_tree
[-help]
-net netName
[-out_file fileName]
```

Displays a buffer tree associated with the specified net.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `gui_show_buffer_tree` parameter. For a detailed description of the command and all of its parameters, use the man command: `man gui_show_buffer_tree`
`-net netName`	Specifies the name of the net for which you want to display the buffer tree. *Data_type*: string, required
`-out_file fileName`	Specifies the text file containing buffer locations. *Data_type*: string, optional

Example

- The following command highlights instances and wires in the buffer tree associated with the net `reset` in the design display area:
  ```
  gui_show_buffer_tree -net reset
  ```

init_eco

```
init_eco
[-help]
eco_file_name
```

Logs ECO operations in a log file.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `init_eco` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man init_eco`.
`eco_file_name`	Specifies the name of the ECO log file. *Data_type*: string, required

Examples

- The following commands show the usage of `init_eco` and `end_eco`.

  ```
  init_eco File1
  ....
  <ECO commands>
  ....
  end_eco
  ```

  All operations performed by ECO commands are logged in *`File1`*.

Related Information

- `end_eco`

place_eco

```
place_eco
[-help]
[-fix_placed_insts {true|false}]
[-timing_driven {true|false}]
[-use_gate_array_cells GACoreSite]
[-use_gate_array_filler_cells GAFillerCells]
[-use_gate_array_filler_groups {true|false}]
[-use_spare_cells {true|false}]
```

Incrementally places the unplaced standard cells. In a pre-mask flow, this command moves the unplaced standard cells into the core area. During an ECO loop, some new unplaced standard cells may get introduced. If you need to move the unplaced standard cells into the core area and place them without disturbing the original placement (pre-mask flow), it is recommended to run `place_eco` at this stage. In a post-mask flow, if you specify `-use_spare_cells`, the software can map the unplaced cells to the available spare cells. When `-use_gate_array_filler_cells` is provided in a post-mask flow, the command can map existing unplaced cells to placed GAFillers in the design.

You can use this command after the `eco_read_def` command when some newly added cells are still unplaced.

Parameters

`-fix_placed_insts {true | false}`	
	Specifies that instances with the PLACED status are not moved. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes type and default information for each `place_eco` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man place_eco`.
`-timing_driven {true|false}`	Turns on the slack-driven placement for ecoPlace. *Default*: `false` *Data_type*: bool, optional
`-use_gate_array_cells GACoreSite`	

	Selects and places the unplaced instances with techSite matching the provided GACoreSite. It is expected that there is free space to place the instances. If not, GA fillers could be deleted before `place_eco -use_gate_array_cells` and re-inserted after the command. You can use this parameter only for post-mask ECO. *Data_type*: string, optional **Note:** You cannot specify the `-use_gate_array_filler_cells` parameter if you use this parameter.
`-use_gate_array_filler_cells` *GAFillerCells*	
	Specifies a list of Gate Array (GA)-style filler cells that the tool can replace with GA cells during post-mask ECO. You can only use this parameter in a post-mask ECO flow. The new logic instances adding during a post-mask flow must already be present in the netlist. *Data_type*: string, optional **Note:** You cannot specify the `-use_gate_array_cells` parameter if you use this parameter.
`-use_gate_array_filler_groups {true|false}`	
	Specifies that filler cell instances will only be replaced by logic instances that belong to the same GA groups. This option can only be used when there is a filler group created by `create_gate_array_filler_group`. `place_eco -use_gate_array_filler_groups` first finds the optimal location for each instance based on its connectivity, then searches for the nearest GA filler cell that is included in the same filler group, places a GA cell at the GA filler location, and deletes the original GA filler. If the GA cell is smaller than the GA filler, the placer creates a new GA filler instance using the list of GA filler cells in the same filler group and places the filler in the gap. If there is only one filler group created, it equals to `place_eco -use_gate_array_filler_cells`. *Default*: `false` *Data_type*: bool, optional

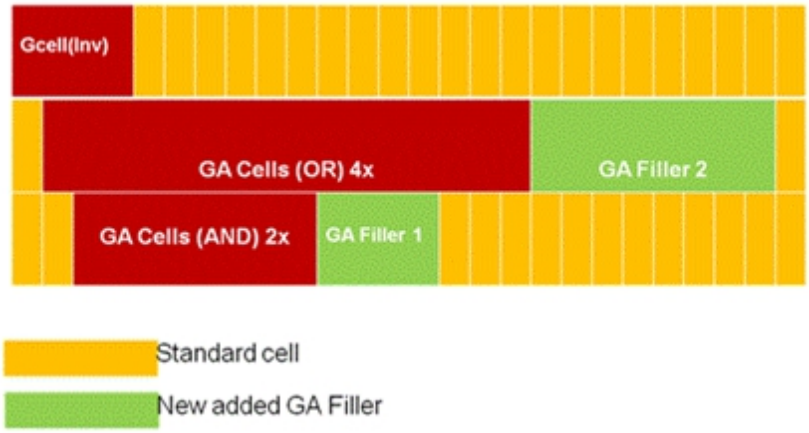
`-use_spare_cells {true|false}`	Maps unplaced cells to spare cells during placement. First, checks whether all unplaced cells match spare cells. Next, chooses a spare cell and changes the connections from the unplaced cell to the selected spare cell. Finally, deletes the unplaced cell. You can use this parameter only for post-mask ECO. This option observes the power domain when selecting the spare cell and maps an unplaced cell to the spare cell in the power domain, based on the instance name of the cell. For example, if module A/B is defined for power domain PD2, this option will map an unplaced cell A/B/inst1 to a spare cell in module A/B. *Data_type*: bool, optional

Examples

- The following command performs incremental placement:
  ```
  place_eco -use_spare_cells true
  ```
- The flowing command will place the GA-ECO cells on GACORE site.
  ```
  place_eco -use_gate_array_cells site_name
  ```
- The following command will place GA-ECO cells on specified GA-Fillers and fill remaining gaps with GA-Fillers.
  place_eco -use_gate_array_filler_cells {GAFiller1 GAFiller2 …}

  Before

  
  After



- The following commands create GA Filler group that associates GA-Function cells with GA-Fillers. Then `place_eco` will place GA-ECO cells on same group GA-Fillers.

```
create_gate_array_filler_group -group GROUP1
-gate_array_cells {GA_Cell1 GA_Cell2… }
-gate_array_fillers {GA_Filler1 GA_Filler2…}
place_eco -use_gate_array_filler_groups true
```

read_eco

```
read_eco
[-help]
[-post_mask | -use_gate_array_cells GACoreSiteName]
[-suffix suffix]
[-verbose]
eco_files
```

Reads a file containing ECO directives and applies the changes to the current netlist.

You can use this command at any time after you import the design.

This command also performs consistency checks while the ECO commands are applied and after the changes are complete. It also checks for and observes power domains. This command produces results compatible with `eco_read_def`, so you will use `place_eco` and `route_eco` to complete the ECO process.

The ECO directives do not affect routing, except in the following cases:

- `DELETENET` deletes routing attached to a specified deleted net.
- `DELETEINST` deletes an instance but leaves the wires attached to the instance dangling. You can then repair dangling wires with the router after ECO is complete.

If you want to reroute the entire design, delete routing before running the `read_eco` command.

This command supports ECOs for gate array designs through the `-use_gate_array_cells` and `-post_mask` parameters.

If an error occurs when the `read_eco` command reads the ECO file, the `read_eco` command stops without reading more commands from the file, and writes error messages to the `innovus.log` file.

Note: The first line of the ECO file you read must be the following:

```
FORMATVERSION 2
```

For information on the commands you can include in the ECO command file, see "ECO Directives," in the *Innovus User Guide*.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `read_eco` parameter. For a detailed description of the command and all of its parameters, use the man command: `man read_eco`
`eco_files`	Specifies the name of the file that contains the ECO directives. You can specify more than one file. File names must be separated by one space. *Data_type*: string, required
`-suffix`	Specifies the suffix this command adds to spare cells created by deleting instances. The default suffix is `SPARE`. *Data_type*: bool, optional
`-use_gate_array_cells` *`GACoreSite`*	Uses gate array cells when adding or deleting instances. This parameter applies to gate array designs only. If `ADDINST` is specified in the ECO file, the default behavior for `ADDINST` applies. If `DELETEINST` is included in the ECO file, the software deletes an instance if the instance master uses the same site as the specified *`GACoreSite`*, which can be the name of any gate array site defined in the LEF file. If you do not specify this parameter, `DELETEINST` removes the instance from the netlist. *Data_type*: string, required
`-post_mask`	When adding an instance, the new cell will be unplaced. The unplaced cell will map to the spare cell during placement with the `place_eco -use_spare_cells` command. When the software deletes an instance, it renames the instance to an instance name at the original level of hierarchy, and appends the specified suffix. If you do not specify the `-suffix` parameter, this parameter appends `SPARE`. *Data_type*: bool, optional
`-verbose`	Provides a report for nets without drivers and the instance input pins with no net connections. *Data_type*: bool, optional

Example

- The following command reads `myfile` and runs the ECO commands it contains:

  ```
  read_eco myfile
  ```

- The `read_eco` command issues a summary report on completion, for example:

```
***************** Load ECO Summary *****************
    Number of New Nets:                             0
    Number of New Instances:                        0
    Number of New Ports:                            0
    Number of New Assigns:                          0
    Number of New Feedthroughs:                     0
    Number of Changed Connections:                  0
    Number of Changed Instances:                    0
    Number of Deleted Nets:                         0
    Number of Deleted Instances:                    1
    Number of Deleted Ports:                        0
    Number of Deleted Assigns:                      0
    Number of Deleted Feedthroughs:                 0
```

- The following ECO summary is the output of the `read_eco` command with `-verbose` options:

```
    ***************** Load ECO Summary *****************
    Number of New Nets:                               0
    Number of New Instances:                          1
    Number of New Ports:                              0
    Number of New Assigns:                            0
    Number of New Feedthroughs:                       0
    Number of Changed Connections:                    0
    Number of Changed Instances:                      0
    Number of Deleted Nets:                           0
    Number of Deleted Instances:                      0
    Number of Deleted Ports:                          0
    Number of Deleted Assigns:                        0
    Number of Deleted Feedthroughs:                   0
    Nets With No Driver:
            n_23
            u_counter_1/cnt[30]
```

```
Number of Nets With No Drivers:                    2

Input Instance Pins With No Net Connection:

        A of inst newInst

        TE of inst u_counter_2/ECO_reg_iflg_reg

Number of Input Instance Pins With No Net Connection:   2
```

For an example of an ECO file, see *Example ECO File* in the ECO Directives chapter of the *Innovus Stylus Common UI User Guide.*

ungroup

```
ungroup
[-help]
hInst+
[-exclude hinst+]
[-flatten]
[-honor_dont_touch]
[-threshold instance_count]
[-verbose]
[-simple  | -prefix prefix | -escaped ]
```

Ungroups the specified hinsts. Ungrouping dissolves the hinsts and moves the contents into its parent directory. By default, an hinst or an inst inside one of the ungrouped hinsts is renamed by concatenating its name to its parent's name with "_". for example, "ungroup h1", would rename h1/i1 to h1_i1. Name collisions are resolved by appending _1, _2, etc. until a unique name is found. If a given hinst cannot be ungrouped, a warning is issued about why it cannot be ungrouped.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `ungroup` parameter. For a detailed description of the command and all of its parameters, use the man command: `man ungroup`
`hInst+`	Specifies the hinst(s) to be ungrouped. *Data_type*: (hinst)+, required
`-escaped`	Flattened names use escaped hinst names. For example, h1/i1 becomes \h1/i1 in Verilog and h1\/i1 in DEF. *Data_type*: bool, optional
`-exclude` *`hinst+`*	Excludes specified hinst(s) as ungroup targets. *Data_type*: (hinst)+, optional
`-flatten`	Ungroups recursively below the specified hinst(s). *Data_type*: bool, optional
`-honor_dont_touch`	Skips the hinst that is marked as dont touch. *Data_type*: bool, optional
`-prefix` *`prefix`*	Flattened names use a prefix. For example, h1/i1 becomes <prefix>_i1. *Data_type*: string, optional
`-simple`	Flattened names use the base_name. For example, h1/i1 becomes i1. *Data_type*: bool, optional
`-threshold` *`instance_count`*	Ungroups only those hinsts that have an instance count less than or equal to the specified integer. *Data_type*: int, optional
`-verbose`	Prints the names of the hierarchies that are being ungrouped. *Data_type*: bool, optional

Example

- The following command will flatten h1, h2/h3. It will recursively flatten any lower hinsts that have an inst count <= 10 and do not have 'cpu' in their name.

  ```
  >ungroup {h1 h2/h3} -exclude *cpu* -flatten -threshold 10 -prefix test
  ```

- This command ungroups all hinsts matching `h1*` and uses escaped names for the flattened names. This is useful so external SDC files that only refer to inst and pin names will still work but it may cause problems in down-stream tools that do not support escaped names. Note that hpins and hnets of ungrouped hinsts will disappear, so usage of those names will no longer work.

  ```
  >ungroup h1* -escaped
  ```

  An inst named `h1/i1` will become `h1\/i1`. Various commands like `get_db` will still "soft-match" `h1/i1` to the escaped `h1\/i1` name.

update_inst

```
update_inst
[-help]
-base_cell base_cell
[-dont_snap_to_placement_grid]
[-location {x y}] -name inst_name
[-orient {r0 r90 r180 r270 mx mx90 my my90}]
[-place_status {fixed soft_fixed placed unplaced cover}]
```

Updates the base cell of an existing instance object and returns the updated inst object pointer. The new base cell and existing base cell must have the identical pins.

This command only updates the netlist not the timing graph. For timing eco, `eco_update_cell` is the recommended command to use.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `update_inst` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man update_inst`
`-base_cell` *`base_cell`*	Specifies the base cell to use for the new instance. *Data_type*: (base_cell), required)
`-dont_snap_to_placement_grid`	If `-dont_snap_to_placement_grid` is specified, Innovus places the instance at the specified location even if the location is off the placement grid. This parameter is used with `-location`. *Default*: false *Data_type*: bool, optional
`-name` *`instName`*	Specifies the name of the instance to update. *Data_type*: (inst), required
`-location {`*`x y`*`}`	Specifies the location of the changed instance. *Default:* Default is the same location. *Data_type*: point, optional
`-orient {r0 r90 r180 r270 mx mx90 my my90}`	Specifies orientation of the changed instance. *Default:* Default is the same orientation. *Data_type*: enum, optional
`-place_status {fixed soft_fixed placed unplaced cover}`	Specifies the placement status of the changed instance. *Default*: Default is the same place_status. *Data_type*: enum, optional

Example

- The following command updates the base_cell of `inst i1/i2` from `BUFX2` to `BUFX4`, and then marks it as fixed:
  ```
  update_inst -name i1/i2 -base_cell BUFX4 -place_status fixed
  ```

Related Information

bitblast_ports

```
bitblast_ports
[-help]
topCell|vCell|hInst+
[-bus busname]
```

Bitblasts the specified port bus (or hport bus) of the specified design, module, or module of the specified hinst, so they are scalars rather than bus-bits. This can be useful to allow optimization for flexibility such as changing the inversion of just some bits of the bus. The name of the bitblasted ports will follow the nomenclature specified by the bit_blasted_port_style global variable. The default style is:

%s_%d

where %s is the bus name, and %d is the bus-bit value. Each bus-bit that is renamed is reported for each module that is changed.

Names used for SDC timing constraints can only be modified if they are loaded into the memory. So, you must ensure that all the timing views are loaded with `set_analysis_view` before running this command. You can either write out the modified SDC files with the new names for later usage or write constraints and Tcl scripts in a way that does not use the original bus-bit names.

There is a limitation that port names used inside a CPF power_intent file cannot be changed. CPF usage assumes that the CPF file is golden and should not be modified. If you need to change names used inside a CPF file, you need to update the CPF file manually, and then read in the new CPF file after running `bitblast_ports`. In contrast, an IEEE1801 power_intent file is allowed to change during the design flow, so changing any port names with bitblast_ports will automatically update the IEEE 1801 names. You can write out the new IEEE1801 file with the updated names.

For non-uniquified netlist, if you bit-blast the hinst, the module and the cloned hinsts also get bit-blasted.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `bitblast_ports`. For a detailed description of the command and all of its parameters, use the man command: `man bitblast_ports`
`topCell|vCell|hInst+`	Specifies the list of design|module|hinst.
`-bus` *`busname`*	Bit-blasts just the specified bus (just “A” not “A[3:0]”), rather than all busses for the module.

Examples

- In the following example, the design top has two-bit input port AI:

```
AI[1:0]
@Innovus> bitblast_ports design:top
#New bitblasted names
Module: top
AI[0]      AI_0
AI[1]      AI_1
@Innovus> get_db ports .name
> AI_0 AI_1
```

- In the following example, hinst1 has two-bit port IN:

```
IN[1:0]
@Innovus> bitblast_ports hinst:top/hinst1 -bus IN
#New bitblasted names
Module: mod1
IN[0]      IN_0
IN[1]      IN_1
@Innovus> get_db hinst:top/hinst1 .hports.name
> hinst1/IN_0 hinst1/IN_1
```

- In the following example, design top has 2 two-bit input ports AI, BI:

```
AI[1:0] BI[1:0]
@Innovus> bitblast_ports design:top -bus AI
#New bitblasted names
Module: mod1
IN[0]      IN_0
IN[1]      IN_1
@Innovus> get_db ports .name
> AI_0 AI_1 BI[0] BI[1]
```

You can bit-blast all ports of two different hinsts:

```
>bitblast_ports {hinst:top/h1 hinst:top/h2} > bitblast.rpt
```

```
>
```

Related Information

- set_analysis_view

delete_unintantiated_modules

```
delete_uninstantiated_modules
[-help]
[-report_only]
```

Deletes uninstantiated modules.

Parameters

Parameters

`-help`	Prints out the command usage. For a detailed description of the command, use the man command: `man delete_uninstantiated_modules`
`-report_only`	Reports all uninstantiated vcells instead of deleting them. All uninstantiated vcells will be deleted if `-reportOnly` is not specified. *Data_type*: bool, optional

```

The `add_power_switches` command supports five type of cells: switch cells, filler cells, breaker cells, corner cells (for the ring style only), and buffer cells. You can define a cell pattern when you create power switch rings.

The parameters of this command are categorized as below in the Parameters table depending upon their functionality based on how they are to be used:

- Column Type Insertion Parameters
- Power Switch Prototyping Parameters
- Ring Type Insertion Parameters

Column Type Insertion Parameters

Before you insert power switches in a column style, you must assign power switch cells to `CLASS CORE` and the correct `SITE` in the `.lef` file and connect power/ground nets and pins of the power switch cells. The distance between columns of switches (the horizontal pitch value) must be in µm. You might need to use `create_shifter_rows` to create a new set of rows based on the SITE name if the power switch cell in unique.

The column style is favorable for channel-less designs. In this case, all blocks are abutted and there is no space for rings. In ring style, you must have a space greater than the max ring cell height between the power domain and the adjacent power domain. This space is primarily occupied by ring switch cells and power routing.

If you create power switch columns within a specified power domain the distance between the columns of switches is determined by the `-horizontal_pitch`. The first (left-most) column of switches is located `-left_offset` from the power domain's left boundary. The `-enable_net_in`, which might consist of one or more enable nets, drives the `-enable_pin_in` of the first switch cell of each column.

In column style, nets are assigned to pins sequentially if more nets than number of pins are specified. For example, if the list consists of three nets, and there are five columns of switches, net `1` drives the pin of the first switch in column `1` and `4`, net `2` connects to column `2` and `5`, and net `3` only drive the `-enable_pin_in` of the first switch in column `3`.

Power Switch Prototyping Parameters

These are the parameters, which are used for power switch prototyping.

Ring Type Insertion Parameters

If you insert power switches in ring style, the power switches are added around the selected power domain in the minimum gap available. Unless specified, the power switches are added to the top level hierarchy but the user has a choice to specify to which level in the hierachy should the power switches be added. The command creates a switch ring on the top, bottom, left, and right sides of the specified power domain unless you assign a specific side.

Before you insert power switches in a ring style, you must assign power switch cells to `CLASS RING` in the `.lef` file (SYMMETRY X Y r90, recommended, but not required for switch cells) and connect power/ground nets and pins of the power switch cells. You must have existing enable nets to drive the buffer inside the power switch cells and acknowledge nets exiting the power switch cell. You need these net names when you specify `-enable_net_in` and `-enable_net_out`.

Rectilinear power domains are supported in both ring-style and column-style switch insertion.

Regardless of whether you insert columns or a ring, the software ties the `-enable_pin_out` of the first switch cell to the `-enable_pin_in` of the next switch cell in the same column or on the same side of a ring. All the enable pin of the switch cells in the same column/side are daisy-chained together. For the last switch of the column, the `-enable_pin_out` is tied to `-enable_net_out`.

Note: The parameters which are applicable to both Column Type Insertions and Ring Type Insertions are listed in both sections.

The Syntax Conventions and Examples are listed out before apart from the description the the parameters. For conventions and examples, see:

- Syntax Conventions
- Syntax Examples

For Power Switch Chaining Unchaining Instances, see the description of the `reorder_power_switch_chains` command.

Parameters

-help	Outputs a brief description that includes the type and default information for each `add_power_switches` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man add_power_switches`

`-get_switch_instances` *string*	Returns the existing power switch instances previously added by `add_power_switches`. It returns all the power switches in the current design without any other option, and can be used with `-power_domain`, `-column`, `-ring` and `-area` options to return specific power switches. By default, the command returns a Tcl list. Use the `-report_file` option if you want to list the power switch information into a file. **Example** `add_power_switches -get_switch_instances -power_domain TDSPCore -area {189.0 31.36 318.0 190.36}` *Data_type*: string, optional
Column Type Insertion Parameters	
`-1801power_switch_rule_name` *string*	Specifies the power switch rule name defined in the 1801 power intent file. By default, `add_power_switches` uses the first defined rule. *Data_type*: string, optional
`-acknowledge_tree_cell` *cell_name*	Specifies the name of cell to use in acknowledge tree synthesis. If you specify this parameter but do not specify `-acknowledge_tree_hinst`, the tool builds the acknowledge tree at the top level of the design. This parameter provides control over the time it takes to switch a power domain off and on. *Data_type*: string, optional
`-acknowledge_tree_hinst` *hier_instance*	Inserts an enable net out signal tree of specified cell instances in the specified hierarchical instance in the design. This parameter provides a power domain off and on; and works with option `-acknowledge_tree_cell`. *Data_type*: string, optional
`-allow_partial_stripe_row_overlap`	Allows placement of power switch cells on nearest row location even if crossing stripes do not completely overlap the power switch cells. Use the option with the option `-place_by_net_wire_intersection`. *Data_type*: string, optional
`-area {`*x1 y1 x2 y2*`}`	Defines an area within a power domain where the tool can insert power switches. The option applies to rectangular area. *x1 y1* is the lower left coordinate of the rectangular area. *x2 y2* is the upper right coordinate corner of the rectangular area. You can specify `-left_offset`, `-right_offset`, `-top_offset`, or `-bottom_offset` to offset the switches from the boundaries of the area. **Note:** The power switch instances snap to placement grid so the actual location is slightly different from the specified coordinate. *Data_type*: string, optional

`-back_to_back_chain {LtoR | RtoL}`	Connects the `enable_net_out` at the top of a column to the `enable_net_in` at the top of the next column, and connects the `enable_net_out` at the bottom of the column to the `enable_net_in` at the bottom of the next column. The chain proceeds left to right or right to left. By default, the `enable_net_in` is connected to the bottom of each column, and the `enable_net_out` exits from the top of each column, in parallel. This parameter is optional. *Data_type*: string, optional
`-bottom_offset` *float*	Specifies the distance between the bottom-most switch in the switch column and the bottom fence boundary of the power domain. You can use this parameter along with `-width`, `-height`, and other offsets to define a unique, specific area within the power domain for placing switches. By default, the switch column can abut the bottom fence boundary. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-buffer_switch_same_direction` *string*	Used for chaining daisy chain with power switch cell having two enabled pins. The option usage is as follows: • `buffer_switch_same_direction 0` (Default) Input Enable net `EnIn_1` and `EnIn_2` connect first switches at opposite ends; output `EnOut_1` and `EnOut_2` come out as last switch cells in daisy chain. • `buffer_switch_same_direction 1` Input Enable net `EnIn_1` and `EnIn_2` connect first switches at the same end; output `EnOut_1` and `EnOut_2` come out as last switch cells in daisy chain. *Data_type*: string, optional

`-cell_enable_pin`	Specify this option to define/provide the pin names of PSO cells used in `add_power_switches` when the PSO cells pin names are different than given in the parameters `-enable_pin_in` and `-enable_pin_out`. This option can be used with ring as well as column insertion. The option usage is as follows for defining different cell pin signature: `-cell_enable_pin {{cellname {enableInputPinList}\ {enableOutputPinList}}}` In the following example the I/O pin names of switch cells `Cell65_SW_type1` and `Cell65_SW_type2` are different. You can use the `-cell_enable_pin` option to mention the pin name for switch cell `Cell65_SW_type2`. `add_power_switches -column -power_domain PDoff \ -enable_pin_in { SLEEPIN } \ -enable_pin_out { SLEEPOUT } \ -global_switch_cell_name { {Cell65_SW_type1 T1}\ {Cell65_SW_type2 T2} } \ -enable_net_in {Ctrl1_In } \ -enable_net_out { Ctrl1_Out } -global_pattern { T1 T2 } -cell_enable_pin { {Cell65_SW_type2 { SLEEPIN_1 } {SLEEPOUT_1 } }}` In the above example the two pins specified in `-cell_enable_pin` are different from those specified in `-enable_pin_in { SLEEPIN }` and `-enable_pin_out { SLEEPOUT }` *Data_type*: string, optional
`-chain_by_row` *LtoR RtoL*	Gives additional control if you need to enable horizontal signal chaining. For example, in rows. By default, signal chaining is enabled from bottom to top. The signal chaining by this option can be: • LtoR: Signal chaining is enabled from Left to Right direction • RtoL: Signal chaining is enabled from Right to Left direction *Data_type*: string, optional
`-chain_direction_x` *LtoR|RtoL*	Defines the direction of the chain along X axis. *Data_type*: string, optional
`-chain_direction_y` *BtoT|TtoB*	Defines the direction of the chain along Y axis. *Data_type*: string, optional
`-checker_board` *string*	Places the power switches in a checkerboard pattern within a power domain. *Data_type*: string, optional

`-connect_bottom_switch_enable_pins {`*`LtoR	RtoL`*`}`	Connects the first switch of the first column to the enable net specified. The software connects the first switch in the remaining columns to the output enable net of the first switch in the previous column. The following figure illustrates the `LtoR` option (default) for a rectilinear power domain.  **Note:** This parameter applies to power switch column creation only. *Default:* The enable pin of the first switch of each column is connected directly to the enable net signal specified. *Data_type*: string, optional
`-cpf_power_switch_rule_name` *`rule_name`*	Specify this option when there are multiple power switch rules specified for a power domain in CPF. By default, `add_power_switches` uses the first defined rule. *Data_type*: string, optional

`-enable_net_in {listOfnets}`	Specifies the list of input nets that the software attaches to the enable input pins. The order in which you specify these nets determines the sequence in which nets are assigned to pins. Enable nets and pins are connected automatically if they reside at the same level in the hierarchy. If you have already specified `update_power_switch_rule -enable_condition` or `create_power_domain -shutoff_condition` in your CPF file, you do not need to specify this parameter. `update_power_switch_rule -enable_condition` takes precedence over `create_power_domain -shutoff_condition` for enable net In connection. For automatic enable connection to work, you should also specify `update_power_switch_rule -acknowledge_receiver` info in CPF for `enable_net_out` connection. Otherwise you should provide enable net connections using `-enable_net_in` and `-enable_net_out` options. If you specify `-enable_net_in`, it will override `create_power_domain -shutoff_condition`. *Data_type*: string, optional **Note:** You need to specify the `-enable_net_in` and `-enable_pin_in` parameters of the `add_power_switches` command while using the `commit_power_intent -power_switch` parameter for making logical connections between switches.
`-enable_net_out {netBaseName | {listOfNets}}`	Specifies the enable output nets that the software attaches to the enable output pins. The order in which you specify these nets determines the sequence in which nets are assigned to pins. If enable nets and pins reside at the same level in the hierarchy they are connected automatically. The `-enable_pin_out` of the last switch of the last column is tied to `-enable_net_out`. If you have already specified `update_power_switch_rule -acknowledge_receiver` in your CPF file, you do not need to specify this parameter. For automatic enable connection to work, you should also specify `update_power_switch_rule -enable_condition` or `create_power_domain -shutoff_condition` in the CPF file. For `enable_net_in` connection you should provide enable net connections using `-enable_net_in` and `-enable_net_out` options. You must specify *`netBaseName`* for columns or a list of nets for rings. Automatic `enable_net_out` connection works if there is only one enable net out after insertion. *Data_type*: string, optional

`-enable_pin_in {listOfPins}`	Specifies the list of enable input pins of the buffers inside the switch cell. The order in which you specify these nets determines the sequence in which nets are assigned to pins. If enable nets and pins reside at the same level in the hierarchy they are connected automatically.The software ties the `-enable_pin_out` of the first switch cell to the `-enable_pin_in` of the next switch cell in the same ring: All the enable pin of the switch cells in the same column are daisy-chained together. The `-enable_pin_in` of the first switch of the first column, is tied to `-enable_net_in`. *Data_type*: string, optional **Note:** You need to specify the `-enable_net_in` and `-enable_pin_in` parameters of the `add_power_switches` command while using the `commit_power_intent -power_switch` parameter for making logical connections between switches.
`-enable_pin_out {listOfPins}`	Specifies the list of enable output pin(s) of the buffer(s) inside the switch cell. The order in which you specify these pins is important because nets are assigned to pins sequentially. The software ties the `-enable_pin_out` of the first switch cell to the `-enable_pin_in` of the next switch cell in the same column: All the enable pin of the switch cells in the same column are daisy-chained together. For the last switch of the column, the `-enable_pin_out` is tied to `-enable_net_out`. *Data_type*: string, optional
`-first_instance_name` *instanceName*	Specifies the instance name of an existing switch cell in the netlist to use as the first cell in the column or ring. Usually, there is at least one switch instantiated in a module (specified by `-switch_module_instance`) in the netlist. The software creates a unique instance name for each switch inserted. This parameter is optional. If the netlist does not contain switches, then this parameter is invalid. *Data_type*: string, optional
`-global_buffer_cell_name` *cell_syntax*	Specifies the cell name of the buffer cell to insert in the power switch ring surrounding the specified power domain, or in the columns inside the power domain, if there are spaces available. *Data_type*: string, optional
`-global_filler_cell_name` *cell_syntax*	Specifies the cell name of the filler cell to insert in the power switch ring surrounding the specified power domain, or in the columns inside the power domain, if there are spaces available. *Data_type*: string, optional
`-global_pattern` *pattern_syntax*	Specifies a pattern of cells to repeat either in the switch rings or switch columns. The pattern consists of a group of different types of cells in a specified order. *Data_type*: string, optional
`-global_switch_cell_name` *cellName*	Specifies the cell name of the switch cell to insert in the power switch ring surrounding the specified power domain, or in the column inside the power domain. This parameter is required. *Data_type*: string, optional

`-ground {(GND:GND1 GND2...)...}`	Specifies a list of ground nets and pin connections. If `-ground` has multiple ground nets, the software uses the last one in the list for tie-hi/lo connections. For example, specify `-ground (VSS:gnd vss!)` to indicate that the `gnd` and `vss!` pins of all the instances in a given power domain are connected to the `VSS` net. *Data_type*: string, optional
`-height length_in_um`	Specifies the height of an area inside the power domain where switches can be placed. You can use this parameter along with `-width`, `-bottom_offset`, and `-left_offset` to define a unique, specific area in the power domain for placing switches. *Data_type*: string, optional
`-honor_non_regular_pitch_stripe`	Honors the option`-skip_rows` when the pitch/distance between the power stripe specified in `-place_under_vertical_net` option is not regular. This option is related to column insertion. *Data_type*: string, optional
`-horizontal_pitch float`	Specifies the distance between switch columns in µm. This parameter is required. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Data_type*: string, optional
`-ignore_shifter_rule`	Ignores the level shiftier rules, which are applied to the power switches in both CPF and UPF. *Data_type*: string, optional
`-ignore_soft_blockage`	With this option `add_power_switches` can insert power switch cells in areas with soft or partial blockages. By default, `add_power_switches` does not add power switch cells in areas with any type of placement blockage: hard, soft, or partial. *Data_type*: string, optional
`-incremental`	Inserts switches to the power domain without removing the existing switches. *Default:* Running the `add_power_switches` command removes the existing placed switches and inserts new switches. *Data_type*: string, optional
`-instance_prefix prefix`	Adds prefix to power switch instances. **Note**: `-instance_prefix` overwrites the prefix specified in CPF by `update_power_switch_rule`. *Data_type*: string, optional

`-left_offset` *float*	Specifies the distance between the left-most switch in the switch column and the right fence boundary of the power domain. You can use this parameter along with `-width`, `-height`, and `-bottom_offset` to define a unique, specific area within the power domain for placing switches. By default, the switch column can abut the right fence boundary. **Note:** When you create a power domain, a `minGap` exists for this power domain, and the switches are inserted within this `minGap`. However, if the specified `minGap` is less than the switch dimension, then the tool automatically extends the `minGap` for this power domain. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document., and refer to commands `-bottom_offset`, `-right_offset`, `-top_offset`, `-vertical_offset`, and `-horizontal_offset`. *Default:* `0` The switches abut the power domain fence if possible. *Data_type*: string, optional
`-logical`	Inserts a logical power switch to the partition block so that the software writes out correct PG direction in dumped PG netlist. *Data_type*: bool, optional
`-loopback_at_end`	Connects the `enable_pin_out` of the last cell in the chain to the `enable_pin_in` of the same cell. This option useful or can be used when a power switch has two `enablePin In` and `Out` pins. *Data_type*: string, optional
`-max_chain_depth` *integer*	Specifies the maximum number of instances in the enable chain. After the specified maximum, `add_power_switches` starts a new enable chain from the next power switch cell. This feature provides fine control over the time it takes to switch a power domain off and on. *Data_type*: string, optional
`-max_distance` *distance_in_microns*	During power switch insertion, `max_distance` is the maximum distance within which the `add_power_switches` looks for the next switch to enable net connections to form an enable signal chain connection. *Data_type*: string, optional
`-max_fanout` *integer*	During power switch insertion, max_fanout is the maximum number of PSO cell enable input pins that a PSO cell enable output pin may connect to. This option is to be used with max_distance. *Data_type*: string, optional
`-no_enable_chain`	Inserts and places power switches without adding enable signal chaining. *Data_type*: string, optional
`-no_fixed_std_cell_overlap`	Avoids placing PSO instances over fixed physical instances already placed on rows. *Data_type*: string, optional

`-no_double_height_check`	Allows double height power switch insertion even if when SITE name is same for double height as well as single height cells. The recommended flow is to use different SITE names for single and double height cells. *Data_type*: string, optional
`-no_row_verify`	Allows you to not verify row coverage at end of a column insertion. By default, the command verifies row coverage. *Data_type*: string, optional
`-offset_x`	Specifies the offset number of intersections in X direction. With this, power switch instances can be inserted in checker board style with specified offset value. **Note:** This must used with `-place_by_net_wire_intersection` and `-skip_x`, options. The value should not be more than the value of `-skip_x`. *Data_type*: string, optional
`-orient` *orientation_syntax*	Specifies the orientation of the switch to be placed in the row. The software checks the specified orientation of the switch against the legal orientation of the row in which the switch is to be placed. The software uses the row site information and the row orientation to determine whether the specified orientation is legal. *Default:* Follows the row orientation. *Data_type*: string, optional
`-parallel_enable`	Connects a power switch's input pin in parallel style rather than daisy-chaining. You do not have to specify `-enable_pin_out` or `-enable_net_out`. *Data_type*: string, optional
`-place_by_net_wire_intersection {`*h_net h_layer v_net v_layer*`}`	Places switches at the intersection of specified horizontal net and vertical net on the respective LEF layers of a pre-existing power grid. You must specify the horizontal net and layer first, then the vertical net and layer. By default, the switches are placed at the bottom-left intersection of the grid. You can offset the switches from the grid intersection by specifying `-place_adjustment_x`, `-place_adjustment_x_y`, or `-place_adjustment_y` in addition to this parameter. *Data_type*: string, optional
`-place_adjustment_x {`*delta_in_x*`}`	Specifies the horizontal offset (in micrometers) from the grid intersection specified by `-place_by_net_wire_intersection`. The value can be positive or negative. *Data_type*: string, optional
`-place_adjustment_x_y {`*delta_in_x delta_in_y*`}`	Specifies the x-y offset (in micrometers) from the grid intersection specified by `-place_by_net_wire_intersection`. The values can be positive or negative. *Data_type*: string, optional
`-place_adjustment_y {`*delta_in_y*`}`	Specifies the vertical offset (in micrometers) from the grid intersection specified by `-place_by_net_wire_intersection`. The values can be positive or negative. *Data_type*: string, optional

`-place_under_vertical_net {vert_net vert_layer}`	Places switches under the vertical net of the specified LEF layer of a pre-existing power grid. By default, the switches are placed at the bottom-left intersection of the grid and row but in addition to this option, you can offset the switches from the row by specifying options like -place_adjustment_x. *Data_type*: string, optional
`-power {(VDD:VDD1 VDD2...)...}`	Specifies a list of power nets and pin connections. For example, specify `-power (Vdd1:Vdd Pwr) (Vdd2:VDD vdd!)` to indicate that the `Vdd` and `Pwr` pins of all the instances in a given power domain are connected to the `Vdd1` net, and the `VDD` and `vdd!` pins are connected to the `Vdd2` net. If `-power` has multiple power nets, the software uses the last one in the list for tie-hi/lo connections. For example, if `-power {(vdd1:VDD1) (vdd2:VDD2)}` is specified, then the software uses net `vdd2` for tie-hi connection. **Note:** You must specify both `-ground` and `-power` to ensure that the instance being moved contains the correct `(net:pin)` connections in the new power domain. *Data_type*: string, optional
`-power_domain power_domain_name`	Specifies the power domain that shuts off through the inserted power switches. *Data_type*: string, optional
`-report_file filename`	Writes switch instances and their corresponding input/output enable signal pin/net connections to the specified file name. *Data_type*: string, optional
`-right_offset`	Specifies the distance between the right-most switch in the switch column and the right fence boundary of the power domain. You can use this parameter along with `-width`, `-height`, and `-left_offset` to define a unique, specific area within the power domain for placing switches. By default, the switch column can abut the right fence boundary. **Note:** When you create a power domain, a `minGap` exists for this power domain, and the switches are inserted within this `minGap`. However, if the specified `minGap` is less than the switch dimension, then the tool automatically extends the `minGap` for this power domain. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-skip_x`	Specifies the number of intersections to skip in X direction. **Note:** This option is to be used with `-place_by_net_wire_intersection`. *Data_type*: string, optional

-skip_y	Specifies the number of intersections to skip in Y direction. **Note:** This option is to be used with `-place_by_net_wire_intersection` *Data_type*: string, optional
`-skip_rows` *integer*	Specifies the number of rows to skip when placing a switch in a column. For example, `-skip_rows 2` skips two rows before placing the next switch in a column. You can use this parameter with or without the `-checker_board` parameter. *Data_type*: string, optional
-snap_to_nearest	Snaps the cell placement to the nearest legal location. This parameter can be used when a hard macro blocks part of a column. The switches that would overlap the hard macro blockage are placed at legal locations nearest to the expected original location. You must specify either `-skip_rows` or `-checker_board` in order to create enough space for the cells to snap. If you specify `-skip_rows`, you must set the value greater than zero. *Data_type*: string, optional
`-spacerCellName` *cell_syntax*	Specifies the spacer cells to place on either side of power switch cells within a power domain to prevent the tool from placing standard cells next to the switch cells. *Data_type*: string, optional
`-switch_module_instance` *instanceName*	Specifies module instance where all the switches will be instantiated. This parameter is required. *Data_type*: string, optional

-tap_from_nearest_enable_net	Enables `add_power_switches` to use the enable net from the nearest, already inserted/placed power switch instance. This option can be used during incremental power switch insertions.
	Example :
	`add_power_switches -column \`
	`-power_domain PD1 -enable_pin_in {PinIn} \`
	`-enable_pin_out {PinOut} \`
	`-global_switch_cell_name PSO_SWITCH\`
	`-enable_net_in {pwr_on} -enable_net_out {pwr_ack}\`
	`-horizontal_pitch 100 \`
	`-left_offset 5 \`
	`-area { x1 y1 x2 y2 } -incremental \`
	`-tapfromnearesEnableNet`
	Data_type: string, optional

-top_down	Adds switches from the top down rather than from the bottom up. The following figure shows how the software places switches from top to bottom.  *Data_type*: string, optional
`-top_offset` *value*	Specifies the distance between the top-most switch in the switch column and the top fence boundary of the power domain that shuts off. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-width` *length_in_um*	Specifies the width of an area inside the power domain where switches can be placed. Specifies the distance between the bottom-most switch in the switch column and the bottom fence boundary of the power domain that shuts off. You can use this parameter along with `-bottom_offset`, `-height`, and `-left_offset` to define a unique, specific area in the power domain for placing switches. *Data_type*: string, optional
Power Switch Prototyping Parameters	

`-buffer_delay {value_in_seconds | {value_in_seconds value_in_seconds}}`	Specifies the delay of the enable buffer in switch. If the switch is a mother-daughter type (with two enables), you can specify two values corresponding to the stage-1 and stage-2 enable buffers respectively. *Data_type*: string, optional
`-cell_em value_in_amps`	Specifies the maximum current that can pass through the switch due to the electromigration limit of the cell. *Data_type*: string, optional
`-commit_proto string`	Adds the number of switches determined by `-proto_number_switches`. This parameter does not work with any other prototyping commands. *Default*: If you specify `-commit_proto` but do not specify a value, the default is 1. If you do not specify `-commit_proto`, the default is 0. *Data_type*: string, optional
`-device_threshold_voltage value_in_volts`	Specifies the device threshold voltage for ramp up prototyping. If you do not specify this parameter, the tool computes a default value based on the switch characterization parameters. *Data_type*: string, optional
`-idSat {value_in_amps | value_in_amps value_in_amps}`	Specifies the switch current when the switch is operated in saturation mode. If the switch is a mother-daughter type (with two enables), then you can specify two values corresponding to the stage-1 and stage-2 enables respectively. *Data_type*: string, optional
`-iLeak value_in_amps`	Specifies the switch cell leakage current when the switch is off. *Data_type*: string, optional
`-load_capacitance value_in_farads`	Specifies the total captive load of the domain for ramp-up analysis. *Data_type*: string, optional
`-max_ir_percentage float`	Specifies the maximum IR drop allowed inside power domain. *Default*: 2 percent *Data_type*: string, optional
`-max_leakage_current value_in_amps`	Specifies the maximum leakage current constraint of the power domain. *Data_type*: string, optional
`-max_leakage_percentage float`	Specifies the maximum domain leakage constraint as a percentage of the total domain leakage current. *Default*: 50 percent *Data_type*: string, optional
`-max_ramp_up_current value_in_amps`	Specifies the maximum ramp up current value used in chain depth and switch delay prototyping. Use this parameter with `-proto_chain_depth_given_ramp_up_current` or `-proto_delay_given_ramp_up_current`. *Data_type*: string, optional
`-max_switch_ir value_in_volts`	Specifies the maximum voltage drop allowed across the switch. *Data_type*: string, optional

`-netPrefix` *prefix*	Adds a prefix to power switch enable nets.
	For example:
	`add_power_switches -instance_prefix myInst_ -netPrefix myNet_ \`
	`-column -power_domain MPY -enable_net_in swcontrol_2 \`
	`-enable_net_out swack_2 -global_switch_cell_name CDN_COLUMN_SW \`
	`-enable_pin_in A0 -enable_pin_out Z0 -left_offset 10 \`
	`-horizontal_pitch 50 -skip_rows 2 -report_file PSWmpy.rpt \`
	`-switch_module_instance DTMF_INST_4/TDSP_CORE_INST/MPY_32_INST`
	`## From PSWmpy.rpt file`
	`DTMF_INST_4/TDSP_CORE_INST/MPY_32_INST/myInst_psoI_MPY_1_CDN_COLUMN_SW_1415_330`

	Data_type: string, optional

`-no_pg_capacitance_estimate` *string*	Omits power grid capacitance estimation during ramp up analysis. *Default:* `0` *Data_type*: string, optional
`-no_pg_decap_estimate` *string*	Omits decoupling capacitance estimation during ramp up analysis. *Default:* `0` *Data_type*: string, optional
`-number_simultaneous_ramp_up_chain` *integer*	Specifies the number of simultaneous ramp up chains for ramp up analysis. *Data_type*: string, optional
`-proto_report_file` *fileName*	Specifies the file containing prototyping results. *Data_type*: string, optional
`-pg_capacitance` *value_in_farads*	Specifies the total power grid capacitance for ramp up analysis. *Data_type*: string, optional
`-pg_capacitance_factor` *float*	Specifies the ratio of the power grid capacitance as a factor of the total load capacitance. *Data_type*: string, optional
`-pg_inductance` *value_in_henrys*	Specifies the effective power grid inductance associated with the power grid and package. *Data_type*: string, optional
`-proto_chain_depth` *string*	Performs prototyping on chain depth given maximum ramp up current. You must specify -ramp_up_time when you specify this parameter. *Data_type*: string, optional

`-proto_chain_depth_given_ramp_up_current` *string*	Performs prototyping on chain depth given maximum ramp up current. You must specify `-max_ramp_up_current` when you specify this parameter. *Data_type*: string, optional
`-proto_delay_given_ramp_up_current` *string*	Analyzes optimum ramp up time given maximum ramp up current. You must specify `-max_ramp_up_current` when you use this command. *Data_type*: string, optional
`-proto_ignore_leakage` *string*	Ignores leakage constraints during prototyping. *Data_type*: string, optional
`-proto_max_chain_depth` *string*	Performs maximum chain depth prototyping based on ramp up time. You must specify `-ramp_up_time` when you specify this parameter. *Data_type*: string, optional
`-proto_min_chain_depth` *string*	Performs minimum chain depth prototyping based on ramp up time. You must specify `-ramp_up_time` when you specify this parameter. *Data_type*: string, optional
`-proto_number_switches` *string*	Determines the optimum number of switches based on switch characteristics and domain constraints. *Data_type*: string, optional
`-proto_ramp_up_time` *string*	Performs prototyping on ramp up time based on chain depth. You must specify `-ramp_up_chain_depth` when you specify this parameter. *Data_type*: string, optional
`-proto_sweep_chain_depth {`*min_integer max_integer increment_integer*`}`	Explores various chain depths from minimum to maximum in specified increments, and reports ramp up metrics for each setting. *Data_type*: string, optional
`-proto_sweep_switch_number {`*min_integer max_integer increment_integer*`}`	Explores the number of switches from minimum to maximum in specified increments, and reports corresponding power domain operation metrics. *Data_type*: string, optional
`-ramp_up_chain_depth` *integer*	Specifies the chain depth used in ramp up time prototyping. Specify this parameter when you specify `-proto_ramp_up_time`. *Data_type*: string, optional
`-ramp_up_rail_voltage_percentage` *float*	Specifies the percentage of the full domain voltage upon which the power domain is considered operable when ramping up. *Default*: 90 percent *Data_type*: string, optional
`-ramp_up_time {`*min_value_in_seconds max_value_in_seconds*`}`	Specifies the minimum and maximum ramp up time settings for chain depth prototyping. This parameter is required for `-proto_chain_depth`, `-proto_min_chain_depth`, and `-proto_max_chain_depth`. *Data_type*: string, optional

`-power_switch_cell` *`fileName`*	Specifies the file containing the switch characterization data. The file contains a list of characterization data per cell, on one line. If you do not put all of the information for a cell on one line, the tool issues an error message. The format is as follows:
	`CELL cell_name SUPPLY pin_name SWITCHED pin_name RON value_in_ohms idSat value_in_mA iLeak value_in_mA`
	`CELL2...`
	For power switch prototyping, the tool only reads and uses the first line of the file and uses only one cell type.
	Data_type: string, optional

`-resistance_on` *`value_in_ohms`*	Specifies the resistance when the switch is operated in linear mode. If the switch is a mother-daughter type (with two enables), you can specify two values corresponding to the stage 1 and stage 2 enables respectively. *Data_type*: string, optional
`-total_leakage_power` *`value_in_watts`*	Specifies the total leakage power of the power domain before switches are added. *Data_type*: string, optional
`-total_power` *`value_in_watts`*	Specifies the total power consumed by the domain. If you do not specify this parameter, `report_power` computes power consumption. *Data_type*: string, optional
`-voltage` *`value_in_volts`*	Specifies the primary rail voltage of the power domain. *Data_type*: string, optional
Ring Type Insertion Parameters	
`-1801power_switch_rule_name` *`string`*	Specifies the power switch rule name defined in the 1801 power intent file. By default, `add_power_switches` uses the first defined rule. *Data_type*: string, optional

`-bottom_num_switch` *integer*	Specifies the number of switches to insert on the bottom side(s) of the power domain. **Note:** This parameter applies to power switch ring creation only. Three scenarios can occur: • If the spaces available match the number specified, the software fills these spaces with switches. • If the number exceeds the spaces available, the software issues a warning message. • If the number is less than the spaces available, the tool inserts the switches, then inserts filler cells to fill the space. Also, if you specify `f` instead of an integer, the tool automatically fills the bottom side with switches and filler cells. This parameter is optional. See `-horizontal_num_switch`, `-vertical_num_switch`, `-left_num_switch`, `-right_num_switch`, and `-top_num_switch`. *Default:* `f` *Data_type*: string, optional
`-side_num_switch_list` `{`*integer ...*`}`	Specifies the list of switches to insert at the side(s) of the power domain. *Data_type*: string, optional
`-bottom_offset` *float*	Specifies distance from the bottom edge outside of the power domain fence and the bottom side(s) of the power switch ring. See `-horizontal_offset`, `-vertical_offset`, `-left_offset`, `-right_offset`, and `-top_offset`. **Note:** When you create a power domain, a `-min_gap` exists for this power domain, and the switches are inserted within this `-min_gap`. However, if the specified `-min_gap` is less than the switch dimension, then the tool automatically extends the `-min_gap` for this power domain. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-bottom_orient` *orientation_syntax*	Specifies the cell orientation for all bottom side(s) of the power switch ring. *Data_type*: string, optional
`-bottom_pattern` *pattern_syntax*	Defines a pattern for the bottom side(s) of the ring only. *Data_type*: string, optional

`-bottom_side` *string*	Inserts switches on the bottom side(s) of the power domain. If you do not specify a side, the software creates a full power switch ring around the specified power domain. If you specify a side, the software inserts switches on that side. In this case, the tool sets `-bottom_side` to 1 and sets the other sides to `0`. You can specify multiple sides and the software inserts switches only on the sides you specify. The tool sets the specified sides to `1` and sets the unspecified sides to `0`. *Default:* `1` *Data_type*: string, optional
`-buffer_cell_name_bottom` *cell_syntax*	Specifies the buffer cells to use on the bottom side(s) of the switch ring. *Data_type*: string, optional
`-buffer_cell_name_horizontal` *cell_syntax*	Specifies the buffer cells to use on the horizontal side(s) of the switch ring. *Data_type*: string, optional
`-buffer_cell_name_left` *cell_syntax*	Specifies the buffer cells to use on the left side(s) of the switch ring. *Data_type*: string, optional
`-buffer_cell_name_right` *cell_syntax*	Specifies the buffer cells to use on the right side(s) of the switch ring. *Data_type*: string, optional
`-buffer_cell_name_top` *cell_syntax*	Specifies the buffer cells to use on the top side(s) of the switch ring. *Data_type*: string, optional
`-buffer_cell_name_vertical` *cell_syntax*	Specifies the buffer cells to use on the vertical side(s) of the switch ring. This parameter applies to power switch ring creation only. *Data_type*: string, optional

`-buffer_cell_side_list {`*cell_syntax …*`}`	Specifies that the buffer cells are inserted on each side of a power domain. The first value of the list indicates the first side related to `Corner 0`, which is the lower left corner of the ring. If the `-counterclockwise` parameter is specified, the first side is considered from from `Corner 0` in the counterclockwise direction. The following example shows the buffer cells specified for an eight-sided power switch ring:
	`-define_side_list {1 0 1 0 1 0 1 0}`
	`-buffer_cell_side_list {cell1 cell1 cell2 cell2 cell3 cell3 cell4 cell4}`
	The `cell1` value is used for the first side. Specify `cell1` again to provide a valid cell type, even when there are no cells on the second side.
	Note: A space must be inserted between the list values. Additionally, only a valid cell name must be specified for each side, even if no cells can be specified for a side. The tools checks whether the number of specified cells is the same as the number specified with `-define_side_list`. In case of any discrepancy, an error message is displayed.
	Data_type: string, optional

`-cell_enable_pin` *string*	Specify this option to define/provide the pin names of PSO cells used in `add_power_switches` when the PSO cells pin names are different than given in the parameters `-enable_pin_in` and `-enable_pin_out`. This option can be used with ring as well as column insertion. The option usage is as follows for defining different cell pin signature: `-cell_enable_pin {{cellname {enableInputPinList}\ {enableOutputPinList}}}` In the following example the I/O pin names of switch cells `Cell65_SW_type1` and `Cell65_SW_type2` are different. You can use the `-cell_enable_pin` option to mention the pin name for switch cell `Cell65_SW_type2`. `add_power_switches -ring -power_domain PDoff \ -enable_pin_in { SLEEPIN } \ -enable_pin_out { SLEEPOUT } \ -global_switch_cell_name { {Cell65_SW_type1 T1}\{ Cell65_SW_type2 T2} } \ -enable_net_in {Ctrl1_In } \ -enable_net_out { Ctrl1_Out } -global_pattern { T1 T2 }- cell_enable_pin { {Cell65_SW_type2 { SLEEPIN_1 } { SLEEPOUT_1 } }}` In the above example the two pins specified in `-cell_enable_pin` are different from those specified in `-enable_pin_in { SLEEPIN }` and `-enable_pin_out { SLEEPOUT }` *Data_type*: string, optional
`-center_tap_pins` *pinname_list*	Enables the center tap capability, and specifies the pins to use as center taps. You must use breaker cells to terminate the buffer signal propagation on both sides of the center tap buffer. The following figure shows that, depending on the specified pin name list, the software assigns a pin name to the enable net. This feature can be useful for debugging the enable signal. **Note:** This parameter applies to power switch ring creation only.  *Data_type*: string, optional
`-continue_pattern`	Continues a specified pattern from one side of the ring to the next side. You must also specify `-global_pattern` when you use this parameter. *Default:* If you do not use this parameter, the software stops the pattern at the end of a side and restarts the pattern from the beginning on the next side. *Data_type*: string, optional

`-corner_cell_list {listOfCornerCells}`	Specifies the list of available corner cells that can be used by the tool to fill the corners of the ring. This parameter is optional. If user specifies only one corner cell, that same cell is used on all four corners with the appropriate orientation for a rectangular power domain. *Data_type*: string, optional

`-corner_cell_list_by_corner corner_cells_name_per_corner`	Specifies the corner cells to be used at different corners. This is applicable for ring only. This option is optional.
	In an example of a rectangular power domain with four corners and two different corner cells, we name the cells: `CORNER_cell1` and `CORNER_cell2` using the option `-corner_cell_list` and then we map them to each corner as shown below:
	`add_power_switches -power_domain PSO -ring \`
	`-global_switch_cell_name {{VDDISWITCH } \`
	`-global_filler_cell_name {{FILLERCELL } \`
	`-specifySides {1 1 1 1 } \`
	`-global_offset 4 \`
	`-corner_cell_list { CORNER_cell1 CORNER_cell2 } \`
	`-corner_cell_list_by_corner { CORNER_cell1\ CORNER_cell2 CORNER_cell1 CORNER_cell2 }\`
	`.... \`
	Data_type: string, optional

`-corner_orient_list {orientation_syntax …}`	Specifies cell orientations for the tool to use for each corner of switch ring, starting with Corner 0 (the lower left corner). List the orientations in a list, with the first orientation corresponding to the first side, the second orientation to the second side, and so on. If you do not specify this parameter, the software determines the corner cell orientations. *Data_type*: string, optional
`-cpf_power_switch_rule_name rule_name`	Specify this option when there are multiple power switch rules specified for a power domain in CPF. By default, `add_power_switches` uses the first defined rule. *Data_type*: string, optional
`-device_threshold_voltage value_in_volts`	Specifies the device threshold voltage for ramp up prototyping. *Data_type*: string, optional
`-distribute`	Distributes switches of different types as evenly as possible on a ring side. For example, if there are 40 available slots, and there are 20 switches and 20 fillers, the software will alternate switches and fillers in the available slots. Use this option together with `-horizontal_num_switch`, `-vertical_num_switch`, `-left_num_switch`, `-right_num_switch`, `-top_num_switch`, or `-bottom_num_switch`. *Data_type*: string, optional

`-enable_net_in {listOfnets}`	Specifies the list of input nets that the software attaches to the enable input pins. The order in which you specify these nets determines the sequence in which nets are assigned to pins. Enable nets and pins are connected automatically if they reside at the same level in the hierarchy. If you have already specified `update_power_switch_rule -enable_condition` or `create_power_domain -shutoff_condition` in your CPF file, you do not need to specify this parameter. `update_power_switch_rule -enable_condition` takes precedence over `create_power_domain -shutoff_condition` for enable net In connection. For automatic enable connection to work, you should also specify `update_power_switch_rule -acknowledge_receiver` info in CPF for `enable_net_out` connection. Otherwise you should provide enable net connections using `-enable_net_in` and `-enable_net_out` options. If you specify `-enable_net_in`, it will override `create_power_domain -shutoff_condition`. *Data_type*: string, optional **Note:** You need to specify the `-enable_net_in` and `-enable_pin_in` parameters of the `add_power_switches` command while using the `commit_power_intent -power_switch` parameter for making logical connections between switches.
`-enable_net_out {`*`netBaseName`*` | {listOfNets}}`	Specifies the enable output nets that the software attaches to the enable output pins. The order in which you specify these nets determines the sequence in which nets are assigned to pins. If enable nets and pins reside at the same level in the hierarchy they are connected automatically. For the last switch of the ring, the `-enable_pin_out` is tied to `-enable_net_out`. If you have already specified `update_power_switch_rule -acknowledge_receiver` in your CPF file, you do not need to specify this parameter. For automatic enable connection to work, you should also specify `update_power_switch_rule -enable_condition` or `create_power_domain -shutoff_condition` in the CPF file. For `enable_net_in` connection you should provide enable net connections using `-enable_net_in` and `-enable_net_out` options. You must specify *`netBaseName`* for columns or a list of nets for rings. Automatic `enable_net_out` connection works if there is only one enable net out after insertion. *Data_type*: string, optional

`-enable_pin_in {listOfPins}`	Specifies the list of enable input pins of the buffers inside the switch cell. The order in which you specify these nets determines the sequence in which nets are assigned to pins. If enable nets and pins reside at the same level in the hierarchy they are connected automatically.The software ties the `-enable_pin_out` of the first switch cell to the `-enable_pin_in` of the next switch cell in the same ring: All the enable pin of the switch cells in the same column are daisy-chained together. For the first switch of the ring, the `-enable_pin_in` is tied to `-enable_net_in`. *Data_type*: string, optional **Note:** You need to specify the `-enable_net_in` and `-enable_pin_in` parameters of the `add_power_switches` command while using the `commit_power_intent -power_switch` parameter for making logical connections between switches.
`-enable_pin_out {listOfPins}`	Specifies the list of enable output pin(s) of the buffer(s) inside the switch cell. The order in which you specify these pins is important because nets are assigned to pins sequentially. The software ties the `-enable_pin_out` of the first switch cell to the `-enable_pin_in` of the next switch cell in the same column: All the enable pin of the switch cells in the same column are daisy-chained together. For the last switch of the column, the `-enable_pin_out` is tied to `-enable_net_out`. *Data_type*: string, optional
`-end_offset value`	Places the last switch on every side of the power domain at the specified distance from the end of each side. The side end is not necessarily determined by the power domain boundary. You can use `-left_offset`, `-right_offset`, `-top_offset`, `-bottom_offset`, `-horizontal_offset`, and/or `-vertical_offset` to determine the side end relative to the power domain boundary. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default*: `0` *Data_type*: string, optional
`-end_offset_bottom value`	Places the last switch on bottom side of the power domain at the specified distance from end of the side. The side end is not necessarily determined by the power domain boundary. You can use `-left_offset`, `-right_offset`, and/or `-vertical_offset` to determine the side end relative to the power domain boundary. • If the value is positive, the software places the switch to the right of the end location. • If the value is negative, the software places the switch to the left of the end location. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional

`-end_offsetHoriztonal` *value*	Places the last switch on the horizontal side of the power domain at the specified distance from end of the side. The side end is not necessarily determined by the power domain boundary. You can use `-left_offset`,`-right_offset`, and/or `-vertical_offset` to determine the side end relative to the power domain boundary. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-end_offset_left` *value*	Places the last switch on the left side of the power domain at the specified distance from end of the side. The side end is not necessarily determined by the power domain boundary. You can use `-top_offset -bottom_offset` and/or `-horizontal_offset` to determine the side end location relative to the power domain boundary. • If the value is positive, the software places the switch below the end location. • If the value is negative, the software places the switch above the end location. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-end_offset_right` *value*	Places the last switch on the right side of the power domain at the specified distance from end of the side. The side end is not necessarily determined by the power domain boundary. You can use the `-top_offset`, `-bottom_offset`, or `-horizontal_offset` to determine the side end relative to the power domain boundary. • If the value is positive, the software places the switch above the end location. • If the value is negative, the software places the switch below the end location. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional

`-end_offset_top` *value*	Places the last switch on the top side of the power switch ring at the specified distance from end of the side. The side end is not necessarily determined by the power domain boundary. You can use `-left_offset`, `-right_offset` or `-vertical_offset` to determine the side end relative to the power domain boundary. • If the value is positive, the software places the switch to the left of the end location. • If the value is negative, the software places the switch to the right of the end location. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-end_offset_vertical` *value*	Places the last switch on the vertical sides of the power switch ring at the specified distance from end of the side. The side end is not necessarily determined by the power domain boundary. You can use `-top_offset`, `-bottom_offset`, and/or `-horizontal_offset` to determine to the side end relative to the power domain boundary. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-filler_cell_name_bottom` *cell_syntax*	Specifies the filler cell used for the bottom side(s) of the ring. You can specify a different filler cell for each side of the ring. This parameter is optional. *Default:* The filler cell specified by `-global_filler_cell_name`. *Data_type*: string, optional
`-filler_cell_name_horizontal` *cell_syntax*	Specifies the filler cell used for the horizontal side(s) of the ring. You can specify a different filler cell for each side of the ring. This parameter is optional. *Default:* The filler cell specified by `-global_filler_cell_name`. *Data_type*: string, optional
`-filler_cell_name_left` *cell_syntax*	Specifies the filler cell used for the left side(s) of the ring. You can specify a different filler cell for each side of the ring. This parameter is optional. *Default:* The filler cell specified by `-global_filler_cell_name`. *Data_type*: string, optional
`-filler_cell_name_right` *cell_syntax*	Specifies the filler cell used for the right side(s) of the ring. You can specify a different filler cell for each side of the ring. This parameter is optional. *Default:* The filler cell specified by `-global_filler_cell_name`. *Data_type*: string, optional

`-filler_cell_name_top` *cell_syntax*	Specifies the filler cell used for the top side(s) of the ring. You can specify a different filler cell for each side of the ring. This parameter is optional. *Default:* The filler cell specified by `-global_filler_cell_name`. *Data_type*: string, optional
`-filler_cell_name_vertical` *cell_syntax*	Specifies the filler cell used for the vertical side(s) of the ring. You can specify a different filler cell for each side of the ring. This parameter is optional. *Default:* The filler cell specified by `-global_filler_cell_name`. *Data_type*: string, optional

`-filler_cell_side_list {`*cell_syntax …*`}`	Specifies the filler cells to insert on each side of a power domain. The first member of the list indicates the first side relative to Corner 0, which is the lower left corner of the ring.
	The following example shows the filler cells specified for an eight-sided power switch ring:
	`-define_side_list {1 0 1 0 1 0 1 0}`
	`-filler_cell_side_list {cell1 cell1 cell2 cell2 cell3 cell3 cell4\ cell4}`
	`cell1` is used for the first side. You can then specify `cell1` again to provide a valid cell type, even though there can be no cells on the second side.
	Info: You must include a space between each item in the list.
	You *must* specify a valid cell name for each side, even if no cells can be specified for a side. The tools checks that the number of cells you specify is the same number you specified with `-define_side_list`, and issues an error message if it finds a discrepancy.
	Data_type: string, optional

`-first_instance_name` *instanceName*	Specifies the instance name of an existing switch cell in the netlist to use as the first cell in the column or ring. Usually, there is at least one switch instantiated in a module (specified by `-switch_module_instance`) in the netlist. The software creates a unique instance name for each switch inserted. This parameter is optional. If the netlist does not contain switches, then this parameter is invalid. *Data_type*: string, optional
`-force_offset`	Forces the software to place ring switches at the exact offset you specify for all sides. Sides with unspecified offsets are forced to 0.0 µ. When you specify any other offset without specifying `-force_offset`, the tool places switches at the smallest distance that is greater than or equal to the specified offset for each side, in order to maintain a contiguous ring. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. **Note:** Using this parameter might result in gaps in the ring. *Data_type*: string, optional

`-global_buffer_cell_name` *cell_syntax*	Specifies the cell name of the buffer cell to insert in the power switch ring surrounding the specified power domain, or in the columns inside the power domain, if there are spaces available. *Data_type*: string, optional
`-global_filler_cell_name` *cell_syntax*	Specifies the cell name of the filler cell to insert in the power switch ring surrounding the specified power domain, or in the columns inside the power domain, if there are spaces available. *Data_type*: string, optional
`-global_offset` *value*	Offsets all sides of the power switch ring the specified distance from the power domain boundary. Specify the offset in µm. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-global_pattern` *pattern_syntax*	Specifies a pattern of cells to repeat either in the switch rings or switch columns. The pattern consists of a group of different types of cells in a specified order. In the ring style, you can use the `-continue_pattern` parameter to continue the pattern around the corner, from one side of the ring to another. *Data_type*: string, optional
`-global_switch_cell_name` *cellName*	Specifies the cell name of the switch cell to insert in the power switch ring surrounding the specified power domain, or in the column inside the power domain. This parameter is required. *Data_type*: string, optional
`-ground {(`*GND:GND1 GND2*`...)...}`	Specifies a list of ground nets and pin connections. If `-ground` has multiple ground nets, the software uses the last one in the list for tie-hi/lo connections. For example, specify `-ground (VSS:gnd vss!)` to indicate that the `gnd` and `vss!` pins of all the instances in a given power domain are connected to the `VSS` net. *Data_type*: string, optional
`-horizontal_num_switch` *value*	Specifies the number of switches to insert on the horizontal side(s) of the power domain. **Note:** This parameter applies to power switch ring creation only. Three scenarios can occur: • If the spaces available match the number specified, the software fills these spaces with switches. • If the number exceeds the spaces available, the software issues the following error message. • If the number is less than the spaces available, the tool inserts the switches, then inserts filler cells to fill the space. This parameter is optional. See `-left_num_switch`, `-right_num_switch`, and `-top_num_switch`. *Data_type*: string, optional

`-horizontal_pattern` *pattern_syntax*	Specifies a pattern of cells to repeat on the horizontal side(s) of the power domain when switches are inserted. The pattern consists of a group of different types of cells in a specified order. *Data_type*: string, optional
`-horizontal_offset` *value*	Offsets the switch ring from the horizontal edge of the power domain. Specify the offset in µm. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-horizontal_orient` *orientation_syntax*	Specifies the cell orientation for all horizontal side(s) of the power switch ring. *Data_type*: string, optional
`-horizontal_side` *string*	Inserts switches on all horizontal side(s) of a power domain. You cannot specify this parameter in conjunction with `-vertical_side`, `-bottom_side`, `-top_side`, `-left_side`, or `-right_side`. *Default:* `1` *Data_type*: string, optional
`-ignore_soft_blockage`	With this option `add_power_switches` can insert power switch cells in areas with soft or partial blockages. By default, `add_power_switches` does not add power switch cells in areas with any type of placement blockage: hard, soft, or partial. *Data_type*: string, optional
`-incremental`	Inserts switches to the power domain without removing the existing switches. *Default:* Running the `add_power_switches` command removes the existing placed switches and inserts new switches. *Data_type*: string, optional
`-inside_corner_cell_list {`*cellName …*`}`	Specifies a list of cells for the tool to choose for the inside corners of the power domain. The following example specifies the corner cells any power switch ring: `-inside_corner_cell_list {cell1 cell2}` **Note:** You do not need to list a specific cell for a specific corner. The tool selects from the list you provide. *Data_type*: string, optional
`-instance_prefix` *prefix*	Adds prefix to power switch instances. The option applies to column and ring insertion.

`-left_offset` *float*	Specifies distance from the right edge outside of the power domain fence and the right side of the power switch ring. See `-horizontal_offset`, `-vertical_offset`, `-right_offset`, `-bottom_offset`, and `-top_offset`. **Note:** When you create a power domain, a `-min_gap` exists for this power domain, and the switches are inserted within this `-min_gap`. However, if the specified `-min_gap` is less than the switch dimension, then the tool automatically extends the `-min_gap` for this power domain. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document, and see `-bottom_offset`, `-right_offset`, `-top_offset`, `-vertical_offset`, and `-horizontal_offset`. *Default:* `0` The switches abut the power domain fence if possible. *Data_type*: string, optional
`-left_num_switch` *integer*	Specifies the number of switches to insert on left side(s) of the power domain. Three scenarios can occur: • If the spaces available match the number specified, then the software fills these spaces with switches. • If the number exceeds the spaces available, the software issues a warning message. • If the number is less than the spaces available, the tool inserts the switches, then inserts filler cells to fill the space. This parameter is optional. See `-bottom_num_switch`,`-right_num_switch`, and `-top_num_switch`. *Default:* `f` *Data_type*: string, optional
`-left_orient` *orienation_syntax*	Specifies the cell orientation for all left side(s) of the power switch ring. *Data_type*: string, optional
`-left_pattern` *pattern_syntax*	Defines a pattern for the left side(s) of the ring only. You can use this parameter with `-bottom_pattern`, `-top_pattern`, and `-right_pattern`. *Data_type*: string, optional
`-left_side` *string*	Inserts switches on the left side(s) of the power domain. If you do not specify a side, the software creates a full power switch ring around the specified power domain. If you specify a side, the software inserts switches on that side. In this case, the tool sets `-left_side` to 1 and sets the other sides to `0`. You can specify multiple sides and the software inserts switches only on the sides you specify. The tool sets the specified sides to `1` and sets the unspecified sides to `0`. *Default:* 1 *Data_type*: string, optional

`-no_filler`	Suppresses the addition of filler cells in power switch rings. *Data_type*: string, optional
`-no_min_gap_adjustment`	Can be used when the user does not want to extend the minimum power domain gaps to form the power switch ring. *Data_type*: string, optional
`-no_enable_chain`	Inserts and places power switches without adding enable signal chaining. *Data_type*: string, optional
`-num_switches`	Defines total number switches to be added around a power domain. This is applicable to ring type insertion only. *Data_type*: string, optional
`-parallel_enable`	Connects a power switch's input pin in parallel style rather than daisy-chaining. You do not have to specify `-enable_pin_out` or `-enable_net_out`. *Data_type*: string, optional
`-power {(`*`VDD:VDD1 VDD2`*`...)...}`	Specifies a list of power nets and pin connections. For example, specify `-power (Vdd1:Vdd Pwr) (Vdd2:VDD vdd!)` to indicate that the `Vdd` and `Pwr` pins of all the instances in a given power domain are connected to the `Vdd1` net, and the `VDD` and `vdd!` pins are connected to the `Vdd2` net. If `-power` has multiple power nets, the software uses the last one in the list for tie-hi/lo connections. For example, if `-power {(vdd1:VDD1) (vdd2:VDD2)}` is specified, then the software uses net `vdd2` for tie-hi connection. **Note:** You must specify both `-ground` and `-power` to ensure that the instance being moved contains the correct `(net:pin)` connections in the new power domain. *Data_type*: string, optional
`-power_domain` *`power_domain_name`*	Specifies the power domain that shuts off through the inserted power switches. *Data_type*: string, optional
`-report_file` *`filename`*	Writes switch instances and their corresponding input/output enable signal pin/net connections to the specified file name. *Data_type*: string, optional

`-right_offset`	Specifies distance from the right edge outside of the power domain fence and the right side of the power switch ring. See `-horizontal_offset, -vertical_offset, -left_offset, -bottom_offset, and -top_offset`. **Note:** When you create a power domain, a `-min_gap` exists for this power domain, and the switches are inserted within this `-min_gap`. However, if the specified `-min_gap` is less than the switch dimension, then the tool automatically extends the `-min_gap` for this power domain. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-r0_corner` *corner_syntax*	Specifies the side where the corner cell instance can be placed in the `r0` orientation without rotation. • `UL` = Upper left • `LL` = Lower left • `LR` = Lower right • `UR` = Upper right The orientation rotates the corner cell 90 degrees for each corner, proceeding counterclockwise. *Default:* `UL` The corner cell in the upper left position in the ring is placed with orientation r0. Default orientations: • `UL = r0` • `LL = mx` • `LR = r180` • `UR = my` *Data_type*: string, optional

`-r0_inside_corner {LT | TR | RB | BL}`	Specifies the inside corner where to place the corner cell instance in the r0 orientation. Use this parameter for rectilinear switch rings containing inside corners. • `LT` = Corner of the left and top sides • `TR` = Corner of the top and right sides • `RB` = Corner of the right and bottom sides • `BL` = Corner of the bottom and left sides *Default:* `LT` The corner cell in the left top position in the ring is placed with the orientation r0. • `LT = r0` • `BL = mx` • `RB = r180` • `TR = my` *Data_type*: string, optional
`-r0_side {L | T | R | B}`	Specifies the side where the switch or filler instance can be placed in the `r0` orientation without rotation. The command adjusts the orientation of the remaining sides so that the switches form a continuous ring. The orientation rotates 90 degrees for each side, proceeding counterclockwise. • `L` = Left side • `T` = Top side • `R` = Right side • `B` = Bottom side The orientation rotates 90 degrees for each side, proceeding counterclockwise. *Default:* `T` The switch and filler cells in the top row are placed with orientation `r0`. Default orientations: • `T = r0` • `L = r90` • `B = r180` • `R = r270` *Data_type*: string, optional
`-r0_side_orient` *orientation_syntax*	Enables the software to rotate or mirror the switch instances on the `r0` side. The software automatically adjusts the orientation of the other sides of the domain to form a continuous ring. *Data_type*: string, optional
`-ring`	Specifies ring style power switch insertion. Power switches are placed outside the power domain. *Data_type*: bool, optional

`-right_num_switch` *integer*	Specifies the number of switches to insert on right side(s) of the power domain. Three scenarios can occur: • If the spaces available match the number specified, then the software fills these spaces with switches. • If the number exceeds the spaces available, the software issues a warning message. • If the number is less than the spaces available, the tool inserts the switches, then inserts filler cells to fill the space. Also, if you specify `f` instead of an integer, the tool automatically fills the right side with switches and filler cells. This parameter is optional. See `-bottom_num_switch`, `-left_num_switch`, and `-top_num_switch`. *Default:* `f` *Data_type*: string, optional
`-right_orient` *orientation_syntax*	Specifies the cell orientation for all right side(s) of the power switch ring. *Data_type*: string, optional
`-right_pattern` *pattern_syntax*	Defines a pattern for the right side(s) of the ring only. You must use this parameter with `-bottom_pattern`, `-top_pattern`, and `-left_pattern`. *Data_type*: string, optional
`-right_side` *string*	Inserts switches on the right side(s) of the power domain. If you do not specify a side, the software creates a full power switch ring around the specified power domain. If you specify a side, the software inserts switches on that side. In this case, the tool sets `-right_side` to 1 and sets other sides to `0`. You can specify multiple sides and the software inserts switches only on the sides you specify. The tool sets the specified sides to `1` and sets the unspecified sides to `0`. *Default:* `1` *Data_type*: string, optional
`-side_end_offset_list` `{`*value* `...}`	Places the last switch at the specified distance from the end of the sides. Use this parameter with rectilinear power domains to specify a value for each side. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional

`-side_offset_list {value …}`	Lists the offset values representing the distance between the power domain fence boundary and each side of the power switch ring. Each value in the list corresponds to a side specified with `-define_side_list`.
	
	The following example show that all sides of an eight-sided power domain can have switches:
	
	`-define_side_list {1 1 1 1 1 1 1 1}`
	
	The following example shows an offset of 8 µm from side1, 8 µm from side2, 8 µm from side 3, 6 µm from side 4, 3 µm from side 5, 3 µm from side 6, 3 µm from side 7, and 6 µm from side 8.
	
	`-side_offset_list {8 8 8 6 3 3 3 6}`
	
	Note: When you create a power domain, a `-min_gap` exists for this power domain, and the switches are inserted within this `-min_gap`. However, if the specified `-min_gap` is less than the switch dimension, then the tool automatically extends the `-min_gap` for this power domain.
	
	Info: You must include a space between each item in the list.
	
	You *must* specify a valid cell name for each side, even if no cells can be specified for a side.
	
	The tools checks that the number of cells you specify is the same number you specified with `-define_side_list`, and issues an error message if it finds a discrepancy.
	
	For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document.
	
	Default: `0`
	
	Data_type: string, optional

`-side_orient_list {orientation_syntax …}`	Lists the orientations for cells in each side of the power switch ring. Each orientation in the list corresponds to a side specified
	
	The following example shows which sides of an eight-sided power domain can have switches:
	
	`-define_side_list {1 1 1 1 1 1 1 1 }`
	
	Ring switches can be placed on any side.
	
	The following example shows that cells in side 1 have orientation r90, r180 in side 3, r270 in side5, and r0 in side 7:
	
	`-side_orient_list {r90 r90 r180 r180 r270 r270 r0 r0}`
	
	Info: You must include a space between each item in the list.
	
	You *must* specify a valid cell name for each side, even if no cells can be specified for a side.
	
	The tools checks that the number of cells you specify is the same number you specified with `-define_side_list`, and issues an error message if it finds a discrepancy.
	
	Data_type: string, optional

`-side_pattern_list {pattern_syntax …}`	Specifies the cell pattern per side of a power switch ring. Each pattern in the list corresponds to a side specified with `-define_side_list`.
	The following example shows which sides of an eight-sided power domain can have switches:
	`-define_side_list {1 0 1 0 1 0 1 0}`
	Ring switches can be placed at sides 1, 3, 5, and 7.
	The following example shows that cells in side 1 have orientation r90, r180 in side 3, r270 in side5, and r0 in side 7:
	`-side_pattern_list {{cell1 cell2 {cell3 * 6}} {cell1 cell2 {cell3 * 6}} {cell2 cell3 {cell4 * 6}} {cell2 cell3 {cell4 * 6}} {cell1 cell2 {cell3 * 6}} {cell1 cell2 {cell3 * 6}} {cell2 cell3 {cell4 * 6}}{cell2 cell3 {cell4 * 6}}`
	Info: You must include a space between each item in the list.
	You must include a valid pattern for each side, regardless of whether the side has any switches.
	The tools checks that the number of cells you specify is the same number you specified with `-define_side_list`, and issues an error message if it finds a discrepancy.
	Data_type: string, optional

`-start_offset value`	Places the first cell on every side of the power domain at the specified distance from the beginning of each side. The beginning of each side is not necessarily determined by the power domain boundary. You can use `-left_offset`, `-right_offset`, `-top_offset`, `-bottom_offset`, `-horizontal_offset`, and/or `-vertical_offset` to determine the beginning of each side relative to the power domain boundary. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default*: 0 *Data_type*: string, optional
`-side_end_offset_list {value ...}`	Places the last cell at the specified distance from the ending location of the sides. Use this parameter with rectilinear power domains to specify a value for each side. *Data_type*: string, optional
`-side_start_offset_list {value ...}`	Places the first cell at the specified distance from the starting location of the sides. Use this parameter with rectilinear power domains to specify a value for each side. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional

`-define_side_list` *string*	Specifies the sides of a power switch ring that can and cannot contain ring switches. In the list, 1 indicates that the side can contain ring switches, and 0 indicates that the side cannot contain ring switches. The list must contain either 0 or 1 for each side of the shape. The first member of the list indicates the first side relative to Corner 0, which is the lower left corner of the ring. The following example shows which sides of an eight-sided power domain can have sw itches: `-define_side_list {1 0 1 0 1 0 1 0}` Ring switches can be inserted at sides 1, 3, 5, and 7. **Note:** You must include a space between each item in the list. *Data_type*: string, optional
`-start_enable_chain_at_corner` *integer* or *corner_syntax*	Specifies the corner where the switch ring insertion begins. This parameter can accept corner syntax or an integer, which accommodates more than four corners in a rectilinear power domain. The corner numbering starts with corner 0 at the lower left corner, and proceeds clockwise around the switch ring. For example, `-start_enable_chain_at_corner 1` starts the enable chain at the first corner found in a clockwise direction from corner 0. *Data_type*: string, optional
`-start_offset_bottom` *value*	Places the first cell on the bottom side of the power domain at the specified distance from the beginning location of the side.The beginning location of the side is not necessarily determined by the power domain boundary. You can use `-left_offset`, `-right_offset` or `-vertical_offset` to determine the beginning location of the side relative to the power domain boundary. • If the value is positive, the software places the cell to the left of the starting location. • If the value is negative, the software places the cell to the right of the starting location. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional

`-start_offset_horizontal` *value*	Places the first cell on the horizontal side of the power domain at the specified distance from the beginning location of the sides. The beginning location of the side is not necessarily determined by the power domain boundary. You can use `-left_offset`, `-right_offset` or `-vertical_offset` to determine the beginning location of the side relative to the power domain boundary. • If the value is positive, the software places the cell to the left of the starting location. • If the value is negative, the software places the cell to the right of the starting location. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-start_offset_left` *value*	Places the first cell on the left side of the power domain at the specified distance from the beginning location of the side. The beginning location of the side is not necessarily determined by the power domain boundary. You can use `-bottom_offset`, `-top_offset`, or`-horizontal_offset` to determine the beginning location of the side relative to the power domain boundary. • If the value is positive, the software places the cell above the starting location. • If the value is negative, the software places the cell below the starting location. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-start_offset_right` *value*	Places the first cell on the right side of the power domain at the specified distance from the beginning location of the side. The beginning location of the side is not necessarily determined by the power domain boundary. You can use `-top_offset`, `-bottom_offset`, or `-horizontal_offset` to determine the beginning location of the side relative to the power domain boundary. • If the value is positive, the software places the first cell below the beginning location of the side. • If the value is negative, the software places the first cell above the beginning location of the side. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional

`-start_offset_top` *value*	Places the first cell at the specified distance from the starting location of the top offset. Use this parameter with `-left_offset`, `-right_offset`, or `-vertical_offset` to determine the beginning location of the side. • If the value is positive, the software places the first cell to the right of the beginning location of the side. • If the value is negative, the software places the first cell to the left of the beginning location of the side. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-start_offset_vertical` *value*	Places the first cell on the vertical sides of the power switch ring at the specified distance from beginning location of the vertical sides. The beginning location of the side is not necessarily determined by the power domain boundary. You can use `-top_offset`, `-bottom_offset`, or `-horizontal_offset` to determine the beginning location of the side relative to the power domain boundary. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-top_switch_cell` *cell_syntax*	Specifies a top switch cell for the power switch ring. *Data_type*: string, optional
`-switch_cell_name_bottom` *cell_syntax*	Specifies a different switch cell for the bottom side(s) of the power switch ring. *Default:* The switch cell specified by `-global_switch_cell_name`. *Data_type*: string, optional
`-switch_cell_name_horizontal` *cell_syntax*	Specifies a different switch cell for the horizontal side(s) of a power switch ring. *Default:* The switch cell specified by `-global_switch_cell_name`. *Data_type*: string, optional
`-switch_cell_name_left` *cell_syntax*	Specifies a different switch cell for the left side(s) of the power switch ring. *Default:* The switch cell specified by `-global_switch_cell_name`. *Data_type*: string, optional
`-switch_cell_name_right` *cell_syntax*	Specifies a different switch cell for the right side(s) of the power switch ring. *Default:* The switch cell specified by `-global_switch_cell_name`. *Data_type*: string, optional

`-switch_cell_name_top` *cell_syntax*	Specifies a different switch cell for the top side(s) of the power switch ring. *Default:* The switch cell specified by `-global_switch_cell_name`. *Data_type*: string, optional
`-switch_cell_name_vertical` *cell_syntax*	Specifies a different switch cell for the vertical side(s) of a power switch ring. *Default:* The switch cell specified by `-global_switch_cell_name`. *Data_type*: string, optional

`-switch_cell_side_list {`*cell_syntax …*`}`	Specifies the switch cells to insert on each side of a power domain. The first member of the list indicates the first side relative to Corner 0, which is the lower left corner of the ring.
	The following example shows the switch cells specified for an eight-sided power switch ring:
	`-define_side_list {1 0 1 0 1 0 1 0}`
	`-switch_cell_side_list {cell1 cell1 cell2 cell2 cell3 \ cell3 cell4 cell4}`
	`cell1` is used for the first side. You can then specify `cell1` again to provide a valid cell type, even though there can be no cells on the second side.
	Info: You must include a space between each item in the list.
	You *must* specify a valid cell name for each side, even if no cells can be specified for a side. The tools checks that the number of cells you specify is the same number you specified with `-define_side_list`, and issues an error message if it finds a discrepancy.
	Data_type: string, optional

`-switch_module_instance` *instanceName*	Specifies module instance where all the switches will be instantiated. This parameter is required. *Data_type*: string, optional
`-switch_pitch`	Specifies the global switch pitch value. You cannot use this parameter with the `-switch_pitch` parameters (left, right, top, bottom, horizontal, and vertical). For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-switch_pitch_bottom` *value*	Places the a switch the specified distance from the right edge of the previous cell on the bottom side of the power domain. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional

`-switch_pitch_horizontal` *value*	Places the a switch the specified distance from the left edge of the previous cell on the horizontal side of the power domain. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-switch_pitch_left` *value*	Places the a switch the specified distance from the bottom edge of the previous cell on the left side of the power domain. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-switch_pitch_right` *value*	Places the a switch the specified distance from the top edge of the previous cell on the right side of the power domain. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-switch_pitch_top` *value*	Places the a switch the specified distance from the left edge of the previous cell on the top side of the power domain. You can use this parameter with `-switch_pitch*`, `-end_offset*`, and `-*Offset` parameters. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-switch_pitch_side_list {`*value* `...}`	Places the a switch the specified distance from the edge of the previous cell on the sides specified in the list. Use this parameter for rectilinear power domains. You can use this parameter with `-switch_pitch*`, `-end_offset*`, and `-*offset` parameters. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-switch_pitch_vertical` *value*	Places the a switch the specified distance from the bottom edge of the previous cell on the vertical sides. You can use this parameter with `-switch_pitch*`, `-end_offset*`, and `-*offset` parameters. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional

`-top_offset` *float*	Specifies the minimum offset from the top edge outside of the power domain fence boundary where the software can insert switches. See `-bottom_offset`, `-right_offset`, and `-left_offset`. **Note:** When you create a power domain, a `-min_gap` exists for this power domain, and the switches are inserted within this `-min_gap`. However, if the specified `-min_gap` is less than the switch dimension, then the tool automatically extends the `-min_gap` for this power domain. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` The switches abut the power domain fence if possible. Otherwise, the switches are placed as close as possible to the power domain. *Data_type*: string, optional
`-top_num_switch` *integer*	Specifies the number of switches to insert on the top side(s) of the power domain. **Note:** This parameter applies to power switch ring creation only. Three scenarios can occur: • If the spaces available match the number specified, then the software fills these spaces with switches. • If the number exceeds the spaces available, the software issues a warning message. • If the number is less than the spaces available, the tool inserts the switches, then inserts filler cells to fill the space. Also, if you specify `f` instead of an integer, the tool automatically fills the top side with switches and filler cells. This parameter is optional. See `-horizontal_num_switch`, `-vertical_num_switch`, `-bottom_num_switch`,`-left_num_switch`, and `-right_num_switch`. *Default:* `f` *Data_type*: string, optional
`-top_orient` *orientation_syntax*	Specifies the cell orientation for all top side(s) of the power switch ring. *Data_type*: string, optional
`-top_pattern` *pattern_syntax*	Defines a pattern for the top side(s) of the ring only. You must use this parameter with `-horizontal_pattern`, `-vertical_pattern`, `-bottom_pattern`, `-left_pattern`, and `-right_pattern`. *Data_type*: string, optional

`-top_side` *string*	Inserts switches on the top side(s) of the power domain. If you do not specify a side, the software creates a full power switch ring around the specified power domain. If you specify a side, the software inserts switches on that side. In this case, the tool sets `-top_side` to 1 and sets the other sides to `0`. You can specify multiple sides and the software inserts switches only on the sides you specify. The tool sets the specified sides to `1` and sets the unspecified sides to `0`. *Default:* `1` *Data_type*: string, optional
`-total_leakage_power` *value_in_watts*	Specifies the total leakage power of the power domain before switches are added. *Data_type*: string, optional

`-total_number_patterns` *number_of_patterns*	Adds the defined number of patterns around a power domain in a ring-type insertion. The pattern type for the insertion can be defined by the option `-global_pattern`.
	
	 	
	Example:
	
	`add_power_switches -ring -power_domain MPY -define_side_list {1 1 1\ 1 1 1 } \`
	`-enable_net_in swcontrol_1 -enable_net_in swack_1 \`
	`-global_switch_cell_name {{CDN_RING_SW1 s} {CDN_RING_SW2 b}} \`
	`-global_filler_cell_name {{CDN_RING_FILLER f}} \`
	`-corner_cell_list CDN_RING_CORNER_UL \`
	`-inside_corner_cell_list CDN_RING_CORNER_InCell \`
	`-switch_module_instance DTMF_INST_3 \`
	`-enable_pin_in A0 -enable_pin_out Z0 -side_offset_list { 3 3 3 3 3 \ 3 } \`
	`-global_pattern { {s}*5 {b} } \`
	`-distributePattern 1 \`
	`-continue_pattern 1 \`
	`-total_number_patterns 19 \`
	`-report_file MPY.rpt`
	
	Data_type: string, optional

`-vertex {x1 y1 x2 y1 x2 y2 x3 y2 x3 y3 x1 y3 ... xn yn}`	Allows you to insert power switches in ring style around the power domain by specifying vertex locations around the power domain. In the ring the cells are towards the outer side of the edge.
	 	
	`add_power_switches \`
	`-ring -vertex \`
	
	`{478.90 461.50 478.90 511.70 444.50 511.70 \ 444.50 578.70 535.40 578.70 535.40 461.50 \ 478.90 461.50} -power_domain TDSPCore...`
	
	Data_type: string, optional

`-vertical_num_switch value`	Specifies the number of switches to insert on all vertical side(s) of the power domain. Three scenarios can occur: • If the spaces available match the number specified, the software fills these spaces with switches. • If the number exceeds the spaces available, the software issues the following error message. • If the number is less than the spaces available, the tool inserts the switches, then inserts filler cells to fill the space. Also, if you specify `f` instead of an integer, the tool automatically fills the bottom side with switches and filler cells. This parameter is optional. See `-left_num_switch`, `-right_num_switch`, and `-top_num_switch`. *Default:* `f` *Data_type*: string, optional
`-vertical_offset value`	Offsets the switch ring from the vertical edge of the power domain. Specify the offset in µm. For more information, see the Using Pitch Control and Offsets chapter of the *Innovus User Guide* document. *Default:* `0` *Data_type*: string, optional
`-vertical_orient orientation_syntax`	Specifies the cell orientation for all vertical side(s) of the power switch ring. *Data_type*: string, optional

`-vertical_pattern` *pattern_syntax*	Specifies a pattern of cells to repeat on all vertical side(s) of the power domain. The pattern consists of a group of different types of cells in a specified order. *Data_type*: string, optional
`-vertical_side` *string*	Inserts ring switches on all vertical side(s) of a power domain. *Default:* 1 *Data_type*: string, optional

  pattern_syntax
  {id1 id2 {id * n}} (Example: n=integer -> repeat id n times)
  - id, id1, id2 are defined in *cell_syntax*
  - Default id is the same as the cell name if *cell_syntax* does not define it.

Syntax Examples

Guidelines for Examples

switch cell name: CDN_SWT_CELL

Filler cell name: CDN_FLL_CELL

Buffer cell name: CDN_BUF_CELL

Breaker cell name: CDN_BRE_CELL

cell_syntax

cell (single cell): CDN_SWT_CELL

{*cell1 cell2*}: {CDN_SWT_CELL1X CDN_SWT_CELL2X …}

{{*cell id*}}: {{CDN_SWT_CELL S}} <- S can be any alphabetic character from A to Z or a to z, or any combination of alphabetic characters or numerals. The id must always start with an alphabetic character.

Precedence Rules

For the -*direction*_side parameters, the software applies their settings in the following precedence rules:

- -specify_sides
- -top_side, -right_side, -left_side, -bottom_side
- -horizontal_side, -vertical_side

Higher precedence parameters override lower precedent parameters.

Examples

- The following command creates a power switch column within power domain `PD`:

  ```
  add_power_switches -column -power_domain PD -global_switch_cell_name switch_cell -switch_module_instance switch_block \
  -enable_pin_in A0 -enable_pin_out Z0 -enable_net_in {enable_net_on} -enable_net_out {enable_net_out} \
  -left_offset 30 -bottom_offset 0 -horizontal_pitch 240
  ```

  In this example, the software inserts `switch_cell` into power domain `PD`. This switch cell has only one buffer inside. This example specifies one `-enable_net_in (enable_net_on)` and one `-enable_net_out` (`enable_net_out`). The input pin `A0` on the first switch of every column is driven by the net `enable_net_on`. The `enable_pin_out` (`Z0`) drives the `enable_pin_in` pin of the next switch cell in the same column. The nets for this connection are created internally and the names are unique. The `enable_pin_out` pin of the last switch for each column is tied to the net `enable_net_out`. The first switch cell is placed 30 microns from the left side boundary of the selected power domain. The spacing between the columns is 240 microns.

- The following command creates a power switch ring around power domain `PD`.

  ```
  add_power_switches -ring -power_domain PD -switch_module_instance switch_block \
  -enable_pin_in {A0 A1} -enable_pin_out {Z0 Z1} -enable_net_in enIn -enable_net_out enOut \
  -global_switch_cell_name switchCell -global_filler_cell_name filler_cell -first_instance_name u1_switchCell \
  -left_num_switch -right_num_switch 28 -top_num_switch 40 -bottom_num_switch 50
  ```

  In in this example, all `switchCell` switches are instantiated in the `switch_block` module.

  Note: The bottom offset is zero in this example. The first switch cell is placed in the column in or on the bottom-most switch cell row. If the row sites are different for switch cells, you can create them with the `create_shifter_rows -site switch_cell_site` command.

  This example inserts the switches as follows:

- Switches are inserted in a full ring pattern (left, top, right, and bottom)
  The switch ring encircles the `PD` power domain fence. `PD` is the power domain that shuts off.
- A specified number of switches are inserted on each side of the ring. The `-num_switch_left` parameter has a value of `f` (autofill), so the tool fills the left side with as many switches as possible in the available space, then inserts filler cells.
- If the spaces available match the number of switches specified, then the software fills these spaces with switches. If the number of switches is less than the spaces available, the tool inserts the switches, then inserts filler cells `filler_cell` to fill the space. If the number exceeds the spaces available, then the software issues the following error message:

  ```
  ERROR: number of switches exceeded space availability.
  ```

  Also in this example, the original netlist already has a switch instantiated inside the module `switch_block`. The switch is fixed as the first instance in the ring by `-first_instance_name u1_switch_cell`. The tool then generates a unique instance name for each switch.

  You must specify the input and output enable pin names of the switch. You must specify the pins in order because the software attaches them to the enable nets you specify. In this example, there is a loopback type of enable nets, so you must specify one net for input (`-enable_net_in`) and one net for output (`-enable_net_out`). The input net (`enIn`) attaches to the first variable specified in the `-enable_pin_in` list (`A0`) of the first switch, and the output net (`enOut`) attaches to the last variable specified in the `-enable_pin_out` list (`Z1`) of the next switch inserted.

check_power_domains

```
  check_power_domains
[-help]
[-all_inst_in_power_domain]
[-always_on_buffer_type]
[-cell_bind {cell ...}]
[-drc_file string]
[-global_connection [module_name_list] [-always_on_bias]]
[-ignore_net_to_port_iso]
[-ignore_net_to_port_shifter]
[-lib_binding_voltage]
[-lib_cell_binding]
[-nets_missing_iso [fileName]
[-nets_missing_shifter [fileName]
[-place [-place_report report_name]]
[-power_switch]
[-power_within_min_gap]
[-retention {fileName ...}]
```

Verifies whether the power domains are set up correctly in terms of timing library binding and PG connection. This command also checks whether any power domains overlap. The `check_power_domains` command checks that libraries specified for each power domain of each `dc_corner` are complete for each power domain member list. The command also checks if the inserted isolation is consistent with the isolation rule.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `check_power_domains` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man check_power_domains`
`-all_inst_in_power_domain`	Verifies all instances are in the power domain. *Data_type*: bool, optional
`-always_on_bias`	Checks the `always_on_bias` net connection. *Data_type*: bool, optional
`-always_on_buffer_type`	Checks if the AO buffer in each domain has correct type in terms of AO Nwell design and IEEE1801 Nwell specification. *Data_type*: bool, optional
`-cell_bind {cell ...}`	Checks if the specified cells are bound in the domain's library set for all active views and domains. *Data_type*: string, optional

`-drc_file` *fileName*	Creates the Design Rule Checking (DRC) violation markers and save those in the specified file. *Data_type*: string, optional
`-ignore_net_to_port_iso`	Ignores the nets connecting to I/O when verifying isolation using `-nets_missing_iso`. *Data_type*: bool, optional
`-ignore_net_to_port_shifter`	Ignores the nets connecting to I/O when verifying shifter using `-nets_missing_shifter`. *Data_type*: bool, optional
`-lib_binding_voltage`	Checks voltage against the binding library. *Data_type*: bool, optional
`-lib_cell_binding`	Verifies that all cells are bound to correct timing library cells. *Data_type*: bool, optional
`-global_connection` *module_name_list*	
	Verifies that power and ground pins of instances within the power domain are connected to the power and ground nets of that power domain. In addition, this parameter verifies that the tie-high and tie-low connections of an instance are connected to the same power and ground nets of the power domain to which the cell belongs. If you do not specify a list of module names, all modules are verified. *Data_type*: string, optional
`-nets_missing_iso`	Verifies if the nets are missing isolation instances according to the power intent file. It also checks if the isolation uses right type of cell specified in the IEEE1801 `map_isolation_cell` command (if any). *Data_type*: string, optional
`-nets_missing_shifter`	Verifies if the nets are missing level shifter according to the power intent file. It also checks if the level shifter uses right type of cell specified in the IEEE1801 map_level_shifter_cell command (if any). *Data_type*: string, optional
`-place`	Verifies if the instances are placed in the boundary of their power domain. *Data_type*: bool, optional
`-place_report` *report_name*	
	Specifies a name and location for the report generated when you use this command with the `-place` parameter. *Data_type*: string, optional

`-power_switch`	Verifies whether each row in the power domains contain at least one power switch. The command issues a warning message detailing which rows do not contain at least one switch. It also checks if the power switch uses right type of cell specified in the IEEE1801 `map_power_switch_cell` command (if any). *Data_type*: string, optional
`-power_within_min_gap`	
	Verifies that the power domain ring is within the distance specified by the `modifyPowerDomainAttr -minGaps` or `createPowerDomain -minGaps` command. *Data_type*: bool, optional
`-retention {`*`fileName ...`*`}`	
	Specifies a name for storing the verify retention information. It checks if the retention uses the right type of cell specified in the IEEE1801 map_retention_cell command (if any). *Data_type*: string, optional

Example

The following command issues warning messages if instances that are not members of a power domain are placed within that power domain boundary, or if any power domains overlap:

```
check_power_domains -place
```

check_power_intent

```
check_power_intent
[-help]
-1801
-hierarchical
[-out_file string]
[-verbose]
```

Checks the IEEE1801 power intent coding style for the IEEE1801 partitioning. This command also reports potential IEEE1801 coding style, which is unsuitable for partitioning.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `check_power_intent` parameter. For a detailed description of the command and all its parameters, use the man command: `man check_power_intent`
`-1801`	Specifies that the power intent is IEEE 1801. *Data_type*: bool, required
`-hierarchical`	Specifies the input power intent style. *Data_type*: bool, required
`-out_file string`	Specifies the output filename. *Data_type*: string, optional
`-verbose`	Prints the detailed information related to the `check_power_intent` command. *Data_type*: bool, optional

Related Information

check_power_switches

```
check_power_switches
[-help]
[-power_domain powerDomain]
[-check_floating_input]
[-check_floating_output]
[-check_floating]
[-check_overlap]
[-check_place]
[-check_loop]
[-check_row_coverage]
[-check_all]
[-highlight]
[-report_longest_chain]
[-starting_net]
```

Verifies power switch placement and enable connections, including the row coverage for column insertion. The command issues a warning message detailing which rows do not contain power switches. The options also enable reporting for the longest signal chain starting from a given enable net. If the start of the enable net is not available, all enable nets of all domains will be used as starting points and all chains will be reported. Both the length of the chain and the switch instances involved in the longest chain will be reported.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `check_power_switches` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man check_power_switches`
`-check_all`	To verify all the checks. *Data_type*: bool, optional
`-check_floating`	To check both floating input and output enable pins. *Data_type*: bool, optional
`-check_floating_input`	To check floating input enable pins. *Data_type*: bool, optional
`-check_floating_output`	To check floating output enable pins. *Data_type*: bool, optional
`-check_loop`	To check for accidentally created enable signal loops. *Data_type*: bool, optional
`-check_overlap`	To check any overlap among the pins. *Data_type*: bool, optional
`-check_place`	To check for unplaced power switches. *Data_type*: bool, optional
`-check_row_coverage`	To check if every row is covered by power switch. *Data_type*: bool, optional
`-highlight`	To select the violation. *Data_type*: bool, optional
`-power_domain powerDomain`	Verify only the specified power domain. *Data_type*: string, optional
`-report_longest_chain`	Reports the longest chain starting from the given enable net. If`-starting_net` is not given, all enable nets of all domains will be used as the starting point and all chains will be reported. The report will include both: the length of the chain, and the switch instances involved in the longest chain. *Data_type*: bool, optional
`-starting_net`	*Data_type*: string, optional

Examples

- The following command verifies the placement status of power switch cells and checks the row coverage by power switch cells for the `powerDomain TDSPCore`:

```
check_power_switches -power_domain TDSPCore -check_place -check_row_coverage
Verifying domain: TDSPCore.
Verifying power switch row coverage ...
Verifying power switch placement status ...
Switch verification completed on domain: TDSPCore.
Number of warnings on domain TDSPCore : 0.
Power switch verification completed with 0 warnings..
1
```

- The following command reports the longest switch chains starting from `net psw_en`:

```
check_power_switches -power_domain PD2 -report_longest_chain -starting_net psw_en
```

clone_msv_gate

```
clone_msv_gate
[-help]
[-iso]
[-shifter]
[-instances inst1 inst2 .... ]
[-max_fanout integer]
[-max_transition num]
[-max_cap num]
[-honor_pre_placed]
[-honor_dont_touch]
```

Ensures that the cloned isolation or level shifter can drive a group of the receivers and be placed close to this group of receivers. By doing this, the timing QoR can be improved.

Note: The command will not automatically update your CPF file to match the new netlist. It is advised that you run Conformal Low Power to check for any issues. When the enable signal for isolation cells is cloned (creating new ports on the boundary of the power domain) the users may need to update the `create_isolation_rule` in CPF by defining the isolation control differently.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `clone_msv_gate` parameter. For a detailed description of the command and all its parameters, use the man command: `man clone_msv_gate`
`-honor_dont_touch`	Does not clone don't touch instances or cells. The default is to clone don't touch instances. *Data_type*: bool, optional
`-honor_pre_placed`	Does not clone pre-placed (fixed) instances. The default is to clone fixed instances. *Data_type*: bool, optional
`-instances` *inst1 inst2 ...*	Clones specified instances. *Data_type*: string, optional
`-iso`	Clones only the isolation cells. *Data_type*: bool, optional
`-max_cap` *num*	An optional check to clone instances with maximum capacitance violation. The default is not to use `-max_cap` violation. *Data_type*: string, optional
`-max_fanout` *integer*	Specifies the maximum fanout count. *Data_type*: int, optional
`-max_transition` *num*	Cloning will be only on instances with maximum transition time violation. The default is `2ns`. *Data_type*: string, optional
`-shifter`	Clones only the level shifters. *Data_type*: bool, optional

commit_power_intent

```
  commit_power_intent
[-help]
[-clp_log string]
[-eco string]
[-isolation]
[-keep_rows]
[-level_shifter]
[-power_domain]
[-power_switch]
[-state_retention]
[-verbose]
```

Commits IEEE1801 power intent specifications for the design for use in verification and implementation of the structure and behavior of the design in context of a given power management architecture. The method supports incremental refinement of power intent specifications required for IP-based design flows.

Note: It is needed to commit the power intent using the `commit_power_intent` command after running the `init_design` command for design initialization.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `commit_power_intent` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man commit_power_intent`
`-clp_log` *string*	Specifies the CLP log file for CPF only. *Data_type*: string, optional
`-eco` *string*	Specifies the eco CPF file. **Note:** The `-eco` option is available only for the CPF flow. *Data_type*: string, optional
`-isolation`	Specifies the commit isolation. *Data_type*: bool, optional
`-keep_rows`	Specifies the pre-existing rows to be retained. By default, rows are recreated based on the power domain information. The new rows might not match the original rows. *Data_type*: bool, optional
`-level_shifter`	Specifies the commit level shifter. *Data_type*: bool, optional
`-power_domain`	When specified, the command creates the power domains, makes the pg connection and saves the rules such as level shifter, isolation and state retention rule. **Note**: The command does not commit the rules. *Data_type*: bool, optional
`-power_switch`	Specifies the commit power switch. **Note:** You need to specify the `-enable_net_in` and `-enable_pin_in` parameters of the `add_power_switches` command while using the `commit_power_intent -power_switch` parameter for making logical connections between switches. *Data_type*: bool, optional
`-state_retention`	Specifies the commit state retention. *Data_type*: bool, optional
`-verbose`	Prints the detailed information related to the `commit_power_intent` command. *Data_type*: bool, optional

compare_power_intent

```
compare_power_intent
[-help]
[-domain_attributes]
[-domain_boundary_port_constraints]
[-domain_map_file file_name]
[-file_prefix prefix]
-golden_1801 file_name
-hier_1801 file_name
[-pin_effective_domain]
[-power_domains list_of_domains]
[-verbose]
```

Compares the golden IEEE1801 and the hierarchical IEEE1801 files generated by the Innovus hierarchical partition flow in terms of the low power database, and reports the mismatched category. If there is no mismatch, the two IEEE1801 files are considered to be equivalent in the Innovus low power flow.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `compare_power_intent` parameter. For a detailed description of the command and all its parameters, use the man command: `man compare_power_intent`
`-domain_attributes`	Compares low power attributes and properties of all the attributes, which include instance count, low power cell count, primary supply, available supply, boundary, port low power constraint, and effective domain counter for the leaf instance pin, and port. *Data_type*: bool, optional
`-domain_boundary_port_constraints`	Compares the domain boundary port IEEE1801 constraint against the golden IEEE1801. *Data_type*: bool, optional
`-domain_map_file` *file_name*	Specifies the domain map file saved during partition. The domain map file maps the golden IEEE1801 domain/supply set/low power signal with the hierarchical IEEE1801 domain/supply set/low power signal. *Data_type*: string, optional
`-file_prefix` *prefix*	Specifies the file prefix for the report files. *Data_type*: string, optional
`-golden_1801` *file_name*	Specifies the golden IEEE1801. *Data_type*: string, optional
`-hier_1801` *file_name*	Specifies the hierarchical IEEE1801 to be compared. *Data_type*: string, optional
`-pin_effective_domain`	Compares only the domain for leaf instance pin and port. *Data_type*: bool, optional
`-power_domains` *list_of_domains*	Specifies the list of specific power domains to be compared. *Data_type*: string, optional
`-verbose`	Displays the detailed information related to each category. *Data_type*: bool, optional

cut_box_list_from_power_domain

```
cut_box_list_from_power_domain
[-help]
-power_domain
-box_list
```

Cuts out default power domains from a non-default power domain. This command is mainly used to solve buffering related issues.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `cut_box_list_from_power_domain` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man cut_box_list_from_power_domain`
`-power_domain`	Specifies the power domain in which you want to create the shifter rows. You can create rows for the default power domain in addition to creating rows for the non-default power domains. *Data_type*: string, required
`-box_list`	Specifies the list of boxes to be cut. *Data_type*: string, required

Examples

```
cut_box_list_from_power_domain -power_domain pd -box_list {(list1{ {list2}......}
```

The list is numbers in the format: `{llx1 lly1 urx1 ury1}`

```
cut_box_list_from_power_domain -power_domain 1.0V_Domain \
-box_list {{10 10 20 20} {35 60 45 70}}
```

This will cut box `{10 10 20 20}` and `{35 60 45 70}` from the domain `1.0V_Domain`, and these two boxes will become the default domain.

cut_power_domain_by_overlaps

```
cut_power_domain_by_overlaps
power_domain_name
[-help]
```

When you want to floorplan one power domain (inner domain) completely inside the other power domain (outer domain), use this command to cut the outer domain as a hollow or donut shape.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `cut_power_domain_by_overlaps` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man cut_power_domain_by_overlaps`
power_domain_name	Specifies the outer power domain where the nested power domain will reside. *Data_type*: string, required

Related Topics

- `cut_box_list_from_power_domain`

delete_power_intent

```
 delete_power_intent
[-help]
[-keep_fence]
```

The command deletes all the power intent data stored by the `commit_power_intent` command in current session and cleans up the design.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `delete_power_intent` parameter. For a detailed description of the command and all its parameters, use the man command: `man delete_power_intent`
`-keep_fence`	Retains domain groups and their fences at the time of removing the the power intent. Use `read_power_intent` and `commit_power_intent -keep_rows` to reload power intent after using this parameter.

Related Topics

- `commit_power_intent`
- `read_power_intent`
- `write_power_intent`

delete_power_switches

```
delete_power_switches
[-help]
[-1801_power_switch_rule_name rule_name]
{{-column | -ring}
-power_domain powerDomainName}
[-instance_list {instName ...}]
```

Removes all switches and filler cells that were inserted by the `add_power_switches` command, from either columns or rings, or removes specified power switch defined in CPF.

This command retains and unplaces switches added by `add_power_switches -switch_instances`, whose cells were already instantiated in the `netlist`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `delete_power_switches` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man delete_power_switches`
`-1801_power_switch_rule_name` *`rule_name`*	Removes power switches based on the specified IEEE 1801 rule. *Data_type*: string, optional
`-column`	Removes all switches and filler cells that were inserted by the `add_power_switches` command, from columns in the specified power domain. *Data_type*: bool, optional
`-instance_list {`*`instName`* `…}`	Specifies the power switch cell instances to delete. *Data_type*: string, optional
`-power_domain` *`powerDomainName`*	Specifies the power domain next to which the columns are placed. *Data_type*: string, optional
`-ring`	Removes all switches and filler cells that were inserted by the `add_power_switches` command, from the ring around the specified power domain. *Data_type*: bool, optional

Examples

- The following command removes instances `psoI_TDSP3_instA` and `psoI_TDSP3_InstB` that were added by the `add_power_switches` command:
  ```
  delete_power_switches -instance_list {psoI_TDSP3_instA psoI_TDSP3_InstB}
  ```
- The following command removes all power switch instances that were inserted by `add_power_switches` in columns inside the power domain `PD2`:
  ```
  delete_power_switches -column -power_domain PD2
  ```

- The following command removes all power switch instances that were inserted by `add_power_switches` in the ring around `PD1`:
  ```
  delete_power_switches -ring -power_domain PD1
  ```

get_cpf_user_attributes

```
get_cpf_user_attributes
[-help]
-domain domainName | -net netName
```

Reports the `user_attributes` of the power domain or net specified in the CPF file. If the domain or net has no `user_attributes` in the CPF file, then this command reports an empty string.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `get_cpf_user_attributes` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man get_cpf_user_attributes`
`-domain`	Specifies the name of the power domain containing the user_attributes. *Data_type*: string, optional
`-net`	Specifies the name of the net having the `user_attributes`. *Data_type*: string, optional

- Overview
- Power Domain Shutdown and Scaling
- Support for the Common Power Format

get_pg_pins_use_signal_route

```
get_pg_pins_use_signal_route
[-help]
```

Returns all the existing MSV settings that were set by the `set_pg_pins_use_signal_route` command in the current database. Use this command to identify the cell PG pins, which are routed by the signal router.

Parameters

`-help`	Prints out the command usage. For a detailed description of the command and all its parameters, use the `man` command: `man get_pg_pins_use_signal_route`

get_upf_port_attr

```
  get_upf_port_attr
[-help]
hport
```

Returns UPF port attributes from UPF or for the specified values. Run this command before design partitioning. Following is the output format of this command:

```
list of {attr_name val}
```

Parameters

`-help`	Prints a brief description that includes the type and default information for each `get_upf_port_attr` parameter. For a detailed description of the command and all its parameters, use the man command: `man get_upf_port_attr`
hport	Specifies the module term name for which UPF port attributes need to be returned. *Data_type*: string, required

Example

The following command returns UPF port attributes for the `iC/in hport`:

```
get_upf_port_attr iC/in
```

Following is the output of the above command:

```
{-driver_supply supplySetName} {attr_name value2} {is_analog FALSE} …
```

Related Information

Low Power Design chapter in the *Innovus User Guide*

get_valid_power_switch_location

```
get_valid_power_switch_location
-help
-cell cell_name
-loc location
[-orient string]
[-search_area string]
```

Returns a valid location of the power switch cells according to the specified placement grid, cell name, and nearest location. This valid location of the power switch cells can be used to specify offsets while using the `add_power_switches` command.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `get_valid_power_switch_location` parameter. For a detailed description of the command and all its parameters, use the man command: `man get_valid_power_switch_location`
`-cell` *cell_name*	Specifies the name of the power switch cell whose valid location needs to be identified. *Data_type*: string, required
`-loc` *location*	Specifies the nearest location from where the valid location needs to be identified. *Data_type*: string, required
`-orient` *string*	Specifies the orientation. The orientation can be one of the following: `r0`, `r90`, `r180`, `r270`, `mx`, `mx90`, `my`, and `my90`. *Data_type*: string, optional
`-search_area` *string*	Specifies the area within which the valid location needs to be identified. *Data_type*: string, optional

Example

The following command identifies a valid location for the `HSWX1` power switch cell:

```
get_valid_power_switch_location -cell HSWX1 -orient MX -loc {382 970}
```

Following is the output of the above command:

```
382.0350 970.0750 MX
```

`add_power_switches`

identify_physical_power_domains

```
identify_physical_power_domains
[-help]
{-domains physical_domain_list | -reset | -check_only}
[-group_physical_logical_domains {{phyPd lpd1 lpd2 ...} ...}]
```

Marks the physical power domains that need fences in case the power domains share the same primary supply net and the available supply net setting (if specified). The command also enables the logical domains to exist without any fence.

Note: `identify_physical_power_domains` needs to be called again (after the initial use), whenever the tool reads in an power intent file. Else, the file content is not recognized.

Parameters

`-help`	Prints out the command usage. For a detailed description of the command and all its parameters, use the `man` command: `man identify_physical_power_domains`
`-check_only`	Checks the fence sharing against Power/Ground (P/G) nets. *Data_type*: bool, optional
`-domains physical_domain_list`	Marks listed power domains as physical domains (a physical power domain must have a fence). Once a physical domain is marked, the power domain sharing the same P/G nets (not marked in this command) are recognized as logical domain (or fenceless domain). Therefore, this domain can be implemented without a fence. The instances within logical domain are placed within the fence of its corresponding physical domain. This parameter also executes the`-checkOnly` parameter, by default. **Note:** Default power domain is not required to be marked, it is marked by default. This command needs to be called after each run of `commit_power_intent`. Otherwise the physical/logical power domain information will be lost in the database. *Data_type*: string, optional
`-group_physical_logical_domains {{phyPd lpd1 lpd2 ...} ...}`	Groups a list of physical and logical domains for the `identify_physical_power_domains` command. *Data_type*: string, optional
`-reset`	Resets the status marking settings after running `commit_power_intent`. *Data_type*: bool, optional

Example

The following command marks `PDdefault` as physical domain:

```
identify_physical_power_domains -domains {PDdefault}
```

move_power_switches

```
move_power_switches
[-help]
[-area {x1 y1 x2 y2}]
[-column_x string]
[-fix_overlap]
[-honor_soft_blockage]
[-power_domain string]
[-report_file string]
[-selected]
[-switch_instances string]
[-x_offset float]
[-y_offset float]
```

The command is used to move power switch instances by offset value in X or Y direction. You can specify multiple power switch instances to be moved in the same offset value.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `move_power_switches` parameter. For a detailed description of the command and all its parameters, use the man command: `man move_power_switches`
`-area {x1 y1 x2 y2}`	Specifies moving the switches inside the indicated area. *Data_type*: rect, optional
`-column_x string`	Specifies moving columns at the indicated x locations. *Data_type*: string, optional
`-fix_overlap`	Internally checks any overlap and fixes it with the suggested offset value. *Data_type*: bool, optional
`-honor_soft_blockage`	When used, prevents the `move_power_switches` command from moving power switch cells in areas having soft placement blockage. *Data_type*: bool, optional
`-power_domain string`	Specifies moving the switches found in the indicated power domain. *Data_type*: string, optional
`-report_file string`	Specifies the name of the report file that stores information about the moved switches. *Data_type*: string, optional
`-selected`	Specifies moving the selected switches. *Data_type*: bool, optional
`-switch_instances string`	Specifies moving the switches in the list. *Data_type*: string, optional
`-x_offset float`	Specifies moving switches by the indicated amount in the x direction. *Data_type*: float, optional
`-y_offset float`	Specifies moving switches by the indicated amount in the y direction. *Data_type*: float, optional

power_intent Category Attributes

The root attributes in the `power_intent` category are:

- power_intent_allow_power_domain_min_gap_zero
- power_intent_allow_shifter_voltage_mismatch
- power_intent_honor_power_domain_for_domain_crossing_route
- power_intent_honor_power_domain_for_intra_domain_route
- power_intent_do_not_use_top_domain_for_port_voltage
- power_intent_allow_back_to_back_isolation
- power_intent_allow_nested_default_domain
- power_intent_assume_iso_enable_pin_is_always_on
- power_intent_check_all_nets_for_domain_crossing
- power_intent_include_dot_lib_related_pg_pin
- power_intent_share_well_always_on_buffering_support
- power_intent_use_cpf_global_connect_for_always_on_buffer
- power_intent_use_cpf_global_connect_for_shifter
- power_intent_use_effective_domain_for_iso_shifter_insertion

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `power_intent` category, use the following command:

```
get_db -category power_intent
```

power_intent_allow_power_domain_min_gap_zero

```
power_intent_allow_power_domain_min_gap_zero int
```

Default: `true`

Data_type: bool, read/write

Allows users to set power domain zero `minGap`.

power_intent_allow_shifter_voltage_mismatch

```
power_intent_allow_shifter_voltage_mismatch {true | false}
```

Default: `true`

Data_type: bool, read/write

When set to false, it prevents insertion of level shifters by allowing voltage tolerance.

power_intent_honor_power_domain_for_domain_crossing_route

```
power_intent_honor_power_domain_for_domain_crossing_route {true | false}
```

Default: `true`

Data_type: bool, read/write

Routes nets belonging to more than one power domain so that the routing does not violate power domain boundaries, in addition to routing intra-power domain and global nets using the specifications of the power domains.

For example, when you specify `power_intent_honor_power_domain_for_domain_crossing_route true`, if a net belongs to power domains PD1 and PD3, but not PD2, Early Global Route routes the net without going over the PD2 power domain boundary.

power_intent_honor_power_domain_for_intra_domain_route

```
power_intent_honor_power_domain_for_intra_domain_route {true | false}
```

Default: `true`

Data_type: bool, read/write

Routes intra-power domain and global nets using the specifications of the power domains. If you specify `power_intent_honor_power_domain_for_intra_domain_route true`, Early Global Route routes intra-power domain nets only within their power domains. Global nets that do not connect with a power domain do not get routed through that power domain.

power_intent_do_not_use_top_domain_for_port_voltage

```
power_intent_do_not_use_top_domain_for_port_voltage {true | false}
```

Default: `false`

Data_type: bool, read/write

Controls voltage using top fterm domain for IO pin voltage.

power_intent_allow_back_to_back_isolation

```
power_intent_allow_back_to_back_isolation {true | false}
```

Default: `false`

Data_type: bool, read/write

Supports back-to-back isolation insertion along one cross-domain net based on the CPF ISO rule. Set true to enable.

power_intent_allow_nested_default_domain

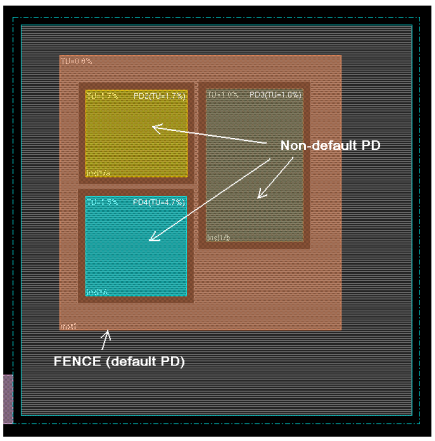
```
power_intent_allow_nested_default_domain {true | false}
```

Default: `true`

Data_type: bool, read/write

Allows a non-default power domain member to be logically nested in a default power domain. This default power domain member has fence constraint.

By default, due to grouping, the fence constraint is lost for the non-default power domain member. Set true to enable.



In the netlist: modules `HInst11` and `HInst12` are under `HInst1`; and `HInst1` is under the top.

You have the following:

```
create_power_domain -instances HInst1

create_power_domain -default -instances {HInst11 HInst12}...
```

That means `HInst11` and `HInst12` are cut from `HInst1` to default power domain. If there is a fence/region constraint for `HInst11` and `HInst12` in default power domain, then please turn this global on. Otherwise, the fence/region for `HInst11` and `HInst12` will be lost.

power_intent_assume_iso_enable_pin_is_always_on

```
power_intent_assume_iso_enable_pin_is_always_on {true | false}
```

Default: `true`

Data_type: bool, read/write

Insert ISO/LS for all the inter-domain nets using effective domain based on the CPF rules. Set `true` to enable.

power_intent_check_all_nets_for_domain_crossing

```
power_intent_check_all_nets_for_domain_crossing {true | false}
```

Default: `true`

Data_type: bool, read/write

Checks all the nets for domain crossings. Set `true` to enable.

power_intent_include_dot_lib_related_pg_pin

```
power_intent_include_dot_lib_related_pg_pin {true | false}
```

Default: `true`

Data_type: bool, read/write

Honors library related PG pins. Set true to enable.

power_intent_share_well_always_on_buffering_support

```
ower_intent_share_well_always_on_buffering_support {true | false}
```

Default: `false`

Data_type: bool, read/write

Shares the isolated Nwell AO buffers.

power_intent_use_cpf_global_connect_for_always_on_buffer

```
power_intent_use_cpf_global_connect_for_always_on_buffer {true | false}
```

Default: `false`

Data_type: bool, read/write

Honors connection pecs for AO buffer based on the CPF rules. Set `true` to enable.

power_intent_use_cpf_global_connect_for_shifter

```
power_intent_use_cpf_global_connect_for_shifter {true | false}
```

Default: `false`

Data_type: bool, read/write

Honors connection specs for shifters based on the CPF rules. Set `true` to enable.

power_intent_use_effective_domain_for_iso_shifter_insertion

```
power_intent_use_effective_domain_for_iso_shifter_insertion {true | false}
```

Default: `true`

Data_type: bool, read/write

Honors effective domains for ISO/LS insertions. Set `true` to enable.

read_power_intent

```
read_power_intent
[-help]
power_intent_file
{-cpf | -1801 | -msv_db }
```

Reads-in power intent file and do syntax check. The method supports incremental refinement of power intent specifications required for IP-based design flows.

Note: It is needed to read the power intent using `read_power_intent [-cpf|-1801] file` before running the `init_design` command for design initialization.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `read_power_intent` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man read_power_intent`
power_intent_file	Specifies the name of the power intent file to be read. *Data_type*: string, required
`-cpf`	Specifies that the CPF format power intent file will be used. *Data_type*: bool, required
`-1801`	Specifies that the IEEE1801 format power intent file will be used. *Data_type*: bool, required
`-msv_db`	Specifies that the IEEE1801 data format `(.cpfdb)` power intent file will be used. **Note:** `-msv_db` is for partition flow and must be read for power intent in partition implementation. *Data_type*: bool, required

read_power_switches

```
read_power_switches
[-help]
[-power_domain powerDomainName]
[-in_file fileName]
```

Imports power switch databases. The need for this commands arises in case of defIn-based flows where power switch database required for power switch related operations is not loaded through `defOut`.

So, using `write_power_switches` a user can save power switch database after power switch insertion using `add_power_switches` for later use and it can be loaded back using `read_power_switches`.

Note: The enable net IN and OUT connections should remain the same in the netlist in power switch database export/import process and the commands need not be run when `save_design` is run because the power switch database is automatically saved and restored.

PSO File Generation and Usage

A PSO file gets generated as an output of the `write_power_switches` command, which can be used in a future session, if needed. One scenario where this file can be needed is when a DEF file containing a power switch chain is not used in the power switch synthesis and hence the incoming netlist to Innovus would not have any power switches. The power switch chain is then created at the `init` stage of Innovus using the `add_power_switches` command in such a run. A database saved using `write_db` after running the `add_power_switches` command, will have the power switch chain saved in a `<design.pso>` file. When restored, this database can also be used to write out the saved PSO file using the `write_power_switches` command. When the power switches are added using the `add_power_switches` command, the `report_power_switches` command can be used to validate their addition.

To avoid regenerating power switches in future implementation runs, save the power switch chain using the `write_power_switches` command along with the floorplan DEF. Ensure that the `-routing` parameter of the `write_def` command is also used along with `-floorplan` and `-no_std_cells` to save the power switch network under the NETS section of the DEF.

Refer to the following flows to understand the usage of the PSO file:

Innovus Session 1:

```
<init Design1 - incoming design has no power switches>
add_power_switches
write_power_switches test.pso
write_def -floorplan -no_std_cells -routing test.def
```

Innovus Session 2:

```
<init Design2 - incoming design has no power switches>
read_power_switches -in_file test.pso
read_def test.def
```

While reading the DEF file, you can identify the power switches using the database commands, even without using the `read_power_switches` command. Following is a usage example of such a database command:

```
get_db [get_db insts -if {.name == inst1/psoI_PD1_1_HSWX1_200_1582_0} ] .base_cell.is_power_switch
```

Here, `inst1/psoI_PD1_1_HSWX1_200_1582_0` is the instance name of the switch cell.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `read_power_switches` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man read_power_switches`
`-power_domain` *`powerDomainName`*	Specifies the power domain whose power switch information is to be imported. *Data_type*: string, optional
`-in_file` *`fileName`*	Specifies the name of the import file. *Data_type*: string, optional

read_power_switches_for_floorplan

```
read_power_switches_for_floorplan
[-help]
[-file string]
```

Restores the information stored in the power switch databases. You can use this command to load back the power switch information only after completing power switch insertion using the `add_power_switches` command and then saving the database information using the `write_power_switches_for_floorplan` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `read_power_switches_for_floorplan` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man read_power_switches_for_floorplan`
`-file string`	Specifies the name of the file from which the power switch database information will be restored.

Related Information

- `add_power_switches`
- `write_power_switches_for_floorplan`

reorder_power_switch_chains

```
reorder_power_switch_chains
[-help]
[-back_to_back_chains string]
[-cascade]
[-cell_enable_pins string]
[-chain_by_instances]
[-chain_by_rows]
[-chain_direction_x LtoR|RtoL]
[-chain_direction_y BtoT|TtoB]
[-chain_style {min_length_tree single_output_chain}]
[-chain_x_before_y]
[-chain_y_before_x]
[-enable_nets_in {listOfnets}]
[-enable_nets_out  {netBaseName | {listOfNets}}]
[-enable_pins_in  {listOfPins}]
[-enable_pins_out  {listOfPins}]
[-max_distance_x um]
[-max_distance_y um]
[-merge_distance_x um]
[-merge_distance_y um]
[-parallel_enable]
[-out_file string]
[-reverse_order]
[-selected]
[-switch_insts string]
[-unchain_by_insts]
```

Enables flexible power switch enable chaining and unchaining after power switch insertion.

Note: It is recommended that you use this command for PSO enable chaining.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `reorder_power_switch_chains` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man reorder_power_switch_chains`
`-back_to_back_chains` *string*	Connects the `enable_nets_out` at the top of a column to the `enable_nets_in` at the top of the next column, and connects the `enable_nets_out` at the bottom of the column to the `enable_nets_in` at the bottom of the next column. The chain proceeds left to right or right to left. By default, the `enable_nets_in` is connected to the bottom of each column, and the `enable_nets_out` exits from the top of each column, in parallel.  This parameter is optional. *Data_type*: string, optional

`-cascade`	Connects switches in cascade  *Data_type*: bool, optional

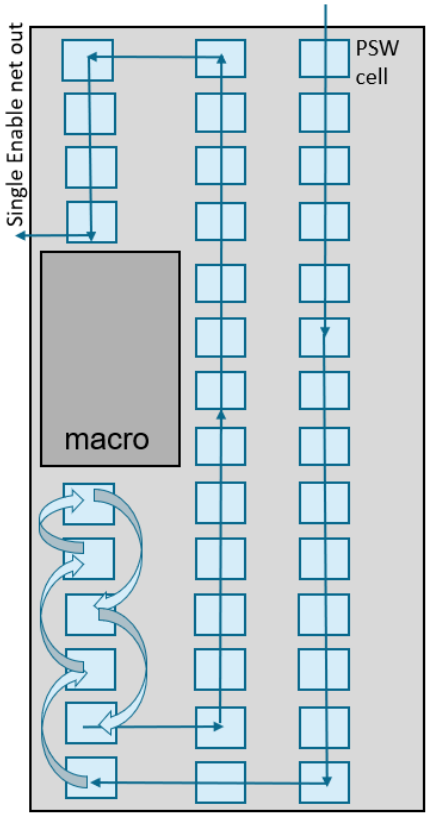
`-cell_enable_pins` *string*	Provides the pin names of power switch cells when the power switch cell pin names are different than the specified instance's cell. This option is also useful in cases where all enable pins of instances are not connected by enabling a way to provide pin map.
	Example:
	`set INST [ add_power_switches -get_switch_instances -power_domain PD1 -column ]`
	`reorder_power_switch_chains -chain_by_instances -chain_y_before_x \`
	`-unchain_by_insts -enable_pins_in SW_IN -enable_pins_out SW_OUT \`
	`-enable_nets_in NETin -enable_nets_out NETout \`
	`-chain_direction_x RToL -out_file pd1_chain.rpt \`
	`-back_to_back_chains \`
	`-cell_enable_pins { { SW_withDiff_pinNames {SW_IN_1} {SW_OUT_1} }} \`
	`-switch_insts $INST`
	Data_type: string, optional

`-chain_by_instances`	To chain the instances. This option is used for chaining the instances defined by `-selected` or instances given in `-switch_insts`.
	 	
	Select all PSO instances of power domain ALU
	`set ALUinst [add_power_switches -column -get_switch_instances -power_domain ALU]`
	The below command make the changes in the connection of the switch enable
	`reorder_power_switch_chains -unchain_by_insts\`
	`-chain_by_instances \`
	`-switch_insts $ALUinst -enable_pins_in A -enable_pins_out Y \`
	`-enable_nets_in swcontrol_2 -enable_nets_out swack_2 \`
	`-cascade -chain_direction_y BtoT`
	Data_type: bool, optional

`-chain_by_rows`	Gives additional control if you need to enable horizontal signal chaining. For example, in rows. By default, signal chaining is enabled from bottom to top. *Data_type*: bool, optional

`-chain_direction_x` *`LtoR|RtoL`*	Defines the direction of the chain along X axis. *Data_type*: enum, optional
`-chain_direction_y` *`BtoT|TtoB`*	Defines the direction of the chain along Y axis. *Data_type*: enum, optional

`-chain_style {min_length_tree single_output_chain}`	Specifies the chain style for enabling power switches and making enable chain connections. The specified chain styles help in optimizing the wire length with longer enable chains, and connecting all the power switches in single pass to avoid blockages. Following are the chain style values specified by this parameter:
	• `min_length_tree`: Connects the enable pin of the switches with a chain, which has multiple branch outputs. The following command presents the usage of this parameter value:
	`reorder_power_switch_chains -power_domain PD1 -selected \`
	`-chain_style min_length_tree \`
	`-max_distance_x 40 -max_distance_y 100 -start_loc "200 6400" \`
	`-enable_nets_in pso1 -enable_nets_out pso1_out ….`
	 	
	• `single_output_chain`: Connects the enable pin of the switches with a chain, which has single branch output. This parameter value can be specified with `-max_distance_x` and `-max_distance_y` parameters. The following command presents the usage of this parameter value:
	`reorder_power_switch_chains -power_domain PD1 -selected \`
	`-chain_style single_output_chain \`
	`-max_distance_x 40 -max_distance_y 100 -start_loc "200 6400" \`
	`-enable_nets_in pso1 -enable_nets_out pso1_out ….`



Data_type: enum, optional

`-chain_x_before_y`	Defines row chain over column. *Data_type*: bool, optional
`-chain_y_before_x`	Defines column chain over row. This is the default option. *Data_type*: bool, optional
`-enable_nets_in {listOfnets}`	Specifies the list of input nets that the software attaches to the enable input pins. The order in which you specify these nets determines the sequence in which nets are assigned to pins. Enable nets and pins are connected automatically if they reside at the same level in the hierarchy. *Data_type*: string, optional
`-enable_nets_out {`*`netBaseName`*` | {listOfNets}}`	Specifies the enable output nets that the software attaches to the enable output pins. The order in which you specify these nets determines the sequence in which nets are assigned to pins. If enable nets and pins reside at the same level in the hierarchy they are connected automatically. For the last switch of the ring, the `-enable_pins_out` is tied to `-enable_nets_out`. *Data_type*: string, optional
`-enable_pins_in {listOfPins}`	Specifies the list of enable input pins of the buffers inside the switch cell. The order in which you specify these nets determines the sequence in which nets are assigned to pins. If enable nets and pins reside at the same level in the hierarchy they are connected automatically.The software ties the `-enable_pins_out` of the first switch cell to the `-enable_pins_in` of the next switch cell in the same ring: All the enable pin of the switch cells in the same column are daisy-chained together. For the first switch of the ring, the `-enable_pins_in` is tied to `-enable_nets_in`. *Data_type*: string, optional

`-enable_pins_out {listOfPins}`	Specifies the list of enable output pin(s) of the buffer(s) inside the switch cell. The order in which you specify these pins is important because nets are assigned to pins sequentially. The software ties the `-enable_pins_out` of the first switch cell to the `-enable_pins_in` of the next switch cell in the same column: All the enable pin of the switch cells in the same column are daisy-chained together. For the last switch of the column, the `-enable_pins_out` is tied to `-enable_nets_out`. *Data_type*: string, optional
`-max_distance_x` *um*	Maximum X distance a switch can drive. *Data_type*: float, optional
`-max_distance_y` *um*	Maximum Y distance a switch can drive. *Data_type*: float, optional
`-merge_distance_x` *um*	To consider switches within this in the same column. *Data_type*: float, optional
`-merge_distance_y` *um*	To consider switches within this in the same row. *Data_type*: float, optional
`-parallel_enable`	Connects enable Net In to all switches in parallel type connection.  *Data_type*: bool, optional
`-out_file` *string*	Writes switch instances and their corresponding input/output enable signal pin/net connections to the specified file name. *Data_type*: string, optional
`-reverse_order`	The reverse order of the `-switch_insts`. *Data_type*: bool, optional
`-selected`	Selects switches to be chained and unchained. **Note:** This option must be used with `-chain_by_instances` and `-unchain_by_insts`. *Data_type*: bool, optional
`-switch_insts` *string*	Specifies the instances to be chained/unchained. When chaining is requested, the sequence of the final chain is taken from the sequence of the instance names given in the provided list. *Data_type*: string, optional
`-unchain_by_insts`	To unchain the instances. This option is used for unchaining the instances defined by `-selected` or instances given in `-switch_insts`. *Data_type*: bool, optional

report_isolation

```
report_isolation
[-help]
[-highlight]
[-out_file fileName]
[-from powerDomain]
[-to powerDomain]
```

Reports or shows the added isolation cells and instances.

Note: Use this command after you add isolation cells.

Parameters

-help	Outputs a brief description that includes the type and default information for each `report_isolation` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man report_isolation`
`-from`	Reports all the isolation instances connected to the output pins of the power domain specified in `-from` option. *Default:* Reports all isolation cells. *Data_type*: string, optional
`-highlight`	Highlights isolation instances in the main window. *Data_type*: bool, optional
`-out_file` *fileName*	Writes isolation cell and instance names to a report. *Default:* The software writes the report to a default file: *designName*`.isolation.rpt` *Data_type*: string, optional
`-to`	Reports all the isolation instances connected to the input pins of the power domain specified in `-to` option. *Default:* Reports all isolation cells. *Data_type*: string, optional

Example

The following command highlights isolation cells and writes the cell names to `isolationCellReport`:

```
report_isolation -highlight -out_file isolationCellReport
```

report_partition_boundary_ports

```
report_partition_boundary_ports
-pins
```

The `report_partition_boundary_ports` command prints out the boundary pins' debug information during partition (through `commit_partitions`) in a log which shows how to assign the power domain for the partition pins.

This is useful when debugging CPF partitions as you get the information about how Innovus assigns the power domain for the partition boundary pins during debugging.

Parameters

-pins	Specifies a list of the partition pins. If wildcard * is specified, it means all partition pins. *Data_type*: string, required

Example

Specify the partition pins(Hterm) you want to debug:

```
report_partition_boundary_ports "I2/d I2/clk"
```

After partition, the command will execute the partition command to print the following DBG info in the log file:
DBG: deriving hterm I2/d power domain
DBG: ….

Low Power Design chapter in the *Innovus User Guide*

report_power_domains

```
report_power_domains
[-help]
[-bind_lib]
[-insts inst_name]
[-iso_inst]
[-modules {list_of_modules}
[-nets net_name]
[-out_file outFile]
[-partition_hports pin | port | hpin+]
[-pg_nets]
[-pins]
[-power_domain powerDomainName [-check_pg_scope]]
[-power_domain_boundary_port string]
[-power_domain_coverage pd1 pd2]
[-shifter]
[-supply_crossing supp1 supp2]
[-verbose]
[-voltage]
```

Reports information about power domains. The report includes the following attributes:

- Power domain name
- Power domain bounding box
- Timing library
- Mingap
- RS extension
- Row type
- Row spacing

The command also reports whether the power domain is always on.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `report_power_domains` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man report_power_domains`
`-bind_lib`	Reports the timing library bound to each instance of a power domain. *Data_type*: bool, optional
`-check_pg_scope`	Checks if there are any PG connections that cross UPF-defined scope. All PG connections for UPF scope should be at the boundary PG port. This parameter is used with the `-power_domain` parameter. *Data_type*: bool, optional

`-insts inst_name`	Reports the power domain-related information for the specified instance: the input, output, and power/ground connections. *Data_type*: string, optional
`-iso_inst`	Reports all isolation cells in the power domain. *Data_type*: bool, optional
`-modules {list of modules}`	Checks whether the specified instances or hierarchical instances are in the power domain. *Default:* The software does not perform this check. *Data_type*: string, optional
`-nets net_name`	Reports power domain-related information for the specified net: • The driver instance of the net and its power domain. • The receiver instances of the net and their power domains. *Data_type*: string, optional
`-out_file outFile`	Specifies the name of the output file. *Default:* `designName-powerdomain.rpt` *Data_type*: string, optional
`-partition_hports pin | port | hpin+`	Reports the hierarchical partition (Hinst) boundary port's domain at the time of partitioning. *Data_type*: (pin|port|hpin)*, optional
`-pg_nets`	Reports all the power/ground nets in the power domain. *Data_type*: bool, optional
`-pins pin1, pin2 ...`	Lists the pins and the option is of type string. This option is optional. *Data_type*: string, optional
`-power_domain powerDomainName`	Specifies the power domain whose attributes you want to report. *Default:* If you do not specify the power domain, this command report data about all power domains. *Data_type*: string, optional
`-power_domain_boundary_port string`	Reports if the specified port name of the power domain boundary has an IEEE1801 constraint. *Data_type*: string, optional

`-power_domain_coverage` *pd1 pd2*	Reports the coverage between two specified domains. *Data_type*: string, optional
`-shifter`	Reports all shifters in the power domain. *Data_type*: bool, optional
`-supply_crossing` *supp1 supp2*	Reports if the two specified supplies have the on/off and low/high crossing. *Data_type*: string, optional
`-verbose`	Prints out the detail information and is optional. *Data_type*: bool, optional
`-voltage`	Reports domain voltage. *Data_type*: bool, optional

Examples

- The following command checks the `I1/PD1` instances to identify if there are any PG connections that do not use the `UPF I1` PG nets. If those are found, an error occurs specifying the instance name and its out-of-scope PG connection.
  ```
  report_power_domains -check_pg_scope true -power_domain I1/PD1
  ```
- The following command reports all shifter cells, all isolation cells, and all power/ground nets in power domain `PD1`. The command also checks whether HInst `instA` is contained in `PD1`, and reports all results to `myDesign-powerdomain.rpt`.
  ```
  report_power_domains -power_domain PD1 -out_file myDesign-powerdomain.rpt -modules {instA} -shifter -iso_inst -pg_nets
  ```
- The following example shows how output file `outfile` contains the binding between the timing libraries and instances in power domain VCORE:
  ```
  report_power_domains -bind_lib -power_domain VCORE -out_file outfile

  Timing library for instance(s):
  ============================
  INST = uLSCVSocDownVCore/uACLKEND/uLVHL (lvl_slow_1v08_1v08)
  INST = uLSCVSocDownVCore/uACLKENI/uLVLHL (lvl_slow_1v08_1v08)
  INST = uLSCVSocDownvCore/uaCLKENP/uLVLHL (lvl_slow_1v08_1v08)
  INST = uLSCVSocDownvCore/uaCLKENRW/uLVLHL (lvl_slow_1v08_1v08)
  INST = uLSCVSocDownvCore/uaBIGENDINIT/uLVHlL (lvl_slow_1v08_1v08)
  INST = uLSCVSocDownvCore/uaCLKIN/uLVHL (lvl_slow_1v08_1v08)
  INST = uLSCVSocDownvCore/uCP15SDISABLE/uLVHL (lvl_slow_1v08_1v08)
  ```
- The following command reports the power domain-related information about instance `PM_INST/state_inst/g45`:
  ```
  report_power_domains -insts PM_INST/state_inst/g45
  ```

  Result:

  ```
  Analyzing PM_INST/state_inst/g45 (Cell: AN2D1) power domain:AO
  ------from side ------
  Pin A2 => Net PM_INST/state_inst/n_28
  PM_INST/state_inst/g71/ZN in power domain A0
  Pin A1 => Net PM_INST/state_inst/n_25
  PM_INST/state_inst/g47/Z in power domain A0
  ```

```
------to side ------
Pin Z => Net PM_INST/state_inst/n_36
PM_INST/state_inst/fsm_reg[1]/qi_reg/D in power domain A0
==========PG pins =============
VDD conneted to Net: VDD
VSS connected to Net:VSS
```

report_power_switches

```
report_power_switches
[-help]
-out_file file_name
```

Reports each power switch instance, the location, and pin/net connections. The report format is as follows:

```
#InstName (x,y)
#   (pin1): net1
#   (pin2): net2
```

Parameters

`-help`	Outputs a brief description that includes the type and default information for each report_power_switches parameter. For a detailed description of the command and all its parameters, use the `man` command: `man report_power_switches`
`-out_file file_name`	Specifies the name of the report file where the information is written. *Data_type*: string, required

Related Topics

report_shifters

```
report_shifters
[-help]
[-cell cellName]
[-from powerDomainName]
[-to powerDomainName]
[-out_file fileName]
[-highlight]
```

Reports the level shifters that have been read into or defined for the Innovus software. In CPF flow, the level shifters are inserted.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `report_shifters` parameter. For a detailed description of the command and all its parameters, use the man command: `man report_shifters`
`-cell`	Reports shifters with the specified cell. *Default:* Reports all level shifters. *Data_type*: string, optional
`-from powerDomainName`	Reports all the shifter instances connected to the output pins of the power domain specified in the `-from` option. *Default:* Reports all level shifters. *Data_type*: string, optional
`-highlight`	Highlights placed level shifters. *Data_type*: bool, optional
`-out_file fileName`	Reports all instances in an output file. *Default:* The instances will be reported to a default output file `designName.shifter.rpt`. A warning message is printed to indicate a default output file is created. *Data_type*: string, optional
`-to powerDomainName`	Reports shifter instances connected to the input pins of the power domain specified in the `-to` option. *Default:* Reports all level shifters. *Data_type*: string, optional

report_voltage

```
report_voltage
[-help]
[-early]
[-inst string]
[-late]
[-net string]
[-pin string]
[-quiet]
[-view string]
```

This command reports the voltage for the net/pin (term)/inst in the specific view under a specific corner.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `report_voltage` parameter. For a detailed description of the command and all its parameters, use the man command: `man report_voltage`
`-early`	Specifies that the voltage is reported in the early mode. *Data_type*: bool, optional
`-inst string`	Specifies the instance power domain voltage (PVT). *Data_type*: string, optional
`-late`	Specifies that the voltage is reported in the late mode. *Data_type*: bool, optional
`-net string`	Specifies the net voltage (driver's pin voltage). *Data_type*: string, optional
`-pin string`	Specifies the term voltage. *Data_type*: string, optional
`-quiet`	Displays only the pin voltage-related information without other additional unnecessary information to avoid huge log size. *Data_type*: bool, optional
`-view string`	Specifies the analysis view. *Data_type*: string, optional

Low Power Design chapter of the *Innovus User Guide* document

route_secondary_pg_pins

```
route_secondary_pg_pins
[help]
[-all]
[-max_pins_per_trunk number]
[-nets {listofNets}]
[-non_default_rule ruleName]
[-pattern {trunk | steiner}]
[-well]
```

Routes the secondary power/ground pins of always-on cells to the specified power/ground nets in signal route. You can also control the routing pattern and wire by specifying the pattern, the maximum number of pins per cluster, and non-default rules.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `route_secondary_pg_pins` parameter. For a detailed description of the command and all its parameters, use the man command: `man route_secondary_pg_pins`
`-all`	Routes non-primary power/ground pins of all the cells. *Data_type*: bool, optional
`-max_pins_per_trunk` *number*	Specifies the maximum number of pins per cluster in the trunk rotating pattern. *Default:* 5 *Data_type*: int, optional
`-nets` *listOfNets*	Specifies the power/ground nets to be connected to the secondary power/ground pins. *Data_type*: string, optional
`-non_default_rule` *ruleName*	Specifies the non-default rule the signal router uses to route the secondary power/ground pins. *Default:* Regular signal routing rule is used by default. *Data_type*: string, optional
`-pattern {trunk | steiner}`	Specifies how the signal router routes the secondary power/ground pins. `Trunk`: When the `max_pins_per_trunk` option's value is 1, it routes the pins to nearest power grid. When the value is more than 1, routes all pins per cluster to the trunk. `Steiner`: Routes all pins to a trunk. *Default:* `trunk` *Data_type*: enum, optional
`-well`	Includes nwell and pwell pins. *Data_type*: bool, optional

Related Topics

The following sections in the Low Power Design chapter of the *Innovus User Guide*:

- Overview
- Power Domain Shutdown and Scaling

set_pg_pins_use_signal_route

```
  set_pg_pins_use_signal_route
[-help]
[-reset]
[-all]
{cell1:pin1 [cell2:pin2 ...]} cellName:pinName cellName:pinName2 ...
[-well]
```

Sets the internal bit for a given cell/pin pair to be routed by the signal router. Use this command to enable NanoRoute to route always-on-pins in SRPG (state retention power gating) or always-on buffer cells.

Parameters

`-help`	Prints out the command usage.
`-all`	Routes all backup and non-main_rail primary power/ground pins. *Data_type*: bool, optional
`{cell1:pin1 [cell2:pin2 ...]}` *cellName*	Specifies the cell containing the pin for NanoRoute to route. You can use a wildcard to specify all cells of certain type. *Data_type*: list, optional
`-reset`	Resets this feature. *Data_type*: bool, optional
`{cell1:pin1 [cell2:pin2 ...]}` *pinName*	Specifies the pin to be routed. *Data_type*: list, optional
`-well`	Includes nwell and pwell pins. *Data_type*: bool, optional

Examples

- The following example sets both the `vddo` and `vsso` pins for the signal router, but NanoRoute will only route `vddo`:

  ```
  set_pg_pins_use_signal_route SDRFF:vddo SDRFF:vsso
  set_pg_pins_use_signal_route -nets VDD
  ```

- The following example sets NanoRoute to route the `VDD1` pin of all `NAND` cells:

  ```
  set_pg_pins_use_signal_route NAND*:VDD1
  ```

swap_cell_with_always_on_cell

```
swap_cell_with_always_on_cell
[-help]
[-cell_map_file file_name]
[-default_always_on_cell ao_cell_names]
[-nets lp_error_net_list]
[-verbose]
```

Identifies the regular buffer/inverter and swaps it with always-on buffer/inverter. The regular buffer/inverter causes the LP error. Hence, this command fixes the LP error through the regular to always-on buffer/inverter swapping.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `swap_cell_with_always_on_cell` parameter. For a detailed description of the command and all its parameters, use the man command: `man swap_cell_with_always_on_cell`
`-cell_map_file` *file_name*	Specifies the map file name. The map file provides the equivalent driving strength between the regular buffer/inverter and AO buffer/inverter. This means that the timing will not be degraded with using this parameter, when the mapped always-on cell is swapped in. Following is the map file format: `regularBufCellName AoBufCellName` *Data_type*: string, optional
`-default_always_on_cell` *ao_cell_names*	Specifies the default always-on buffer/inverter to be used to replace the regular buffer/inverter. When using default always-on buffer/inverter, this parameter just corrects the LP error. Additionally, this parameter may degrade the timing, and you need to run optimization in flow. *Data_type*: string, optional
`-nets` *lp_error_net_list*	Specifies the list of LP-error nets. By default, the `swap_cell_with_always_on_cell` command works on all the buffer/inverter trees. When this parameter is used, the command works on the buffer/inverter tree for the specified nets. *Data_type*: string, optional
`-verbose`	Displays the detailed trace information for the specified nets. *Data_type*: bool, optional

Examples

- The following command swaps the incorrect regular buffer with `AoBuf1`, and the incorrect regular inverter with `AoInverter1`:
  `swap_cell_with_always_on_cell -default_always_on_cell "AoBuf1 AoInverter1"`
- The following command swaps the incorrect regular buffer/inverter using the specified mapping cells or the default always-on cells:
  `swap_cell_with_always_on_cell -cellMapFile mapfile1 -default_always_on_cell "AoBuf1 AoInverter1"`
- The following command swaps the incorrect regular buffer/inverter using the default always-on cells for the buffer/inverter trees along with the `net1` and `net2` paths:
  `swap_cell_with_always_on_cell -nets "net1 net2" -default_always_on_cell "AoBuf1 AoInverter1"`
- The following command swaps the incorrect buffer/inverter along with the `net1` and `net2` paths and displays the detailed trace information:
  `swap_cell_with_always_on_cell -nets "net1 net2" -default_always_on_cell "AoBuf1 AoInverter1 -verbose"`

update_power_domain

```
update_power_domain
[-help]
[-add_block_box string]
[-core_to_bottom valueInMicron]
[-core_to_left valueInMicron]
[-core_to_right valueInMicron]
[-core_to_top valueInMicron]
[-default_tech_site string]
[-disjoint_hinst_box_list string]
[-first_row_site_index integer]
[-gap_sides {values}|-gap_edges {values}]
[-last_row_site_index integer]
power_domain_name
[-power_extend_sides {values}|-power_extend_edges {values}]
[-row_flip {first second noflip auto}]
[-row_pattern_site site_name]
[-row_space_type {0 1 2}]
[-row_spacing float]
```

Renames a power domain or changes its structure.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `update_power_domain` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man update_power_domain`
`-add_block_box`	Adds a hard block to the disjoint power domain. `-add_block_box` supports both rectangular and rectilinear macros. *Data_type*: string, optional
`-core_to_bottom valueInMicron`	Specifies the row margin from bottom boundary. *Data_type*: float, optional
`-core_to_left valueInMicron`	Specifies the row margin from left boundary. *Data_type*: float, optional
`-core_to_right valueInMicron`	Specifies the row margin from right boundary. *Data_type*: float, optional
`-core_to_top valueInMicron`	Specifies the row margin from top boundary. *Data_type*: float, optional
`-default_tech_site string`	Allows selection of one of the tech sites to be not picked by the software, in case there are two smallest tech sites of the same size in a power domain. **Note:** The specified `-default_tech_site` size value must be same as the current default tech site in the power domain.

`-disjoint_hinst_box_list`	Specifies a region for an Hinst. It is defined as an Hinst and Region pair. *Data_type*: string, optional
`-first_row_site_index` *integer*	Specifies the first row site index value. *Data_type*: int, optional
`-gap_edges`	Specifies the minimum space value to other domain by power domain edge in microns. You can specify the value per edge in clockwise order, starting with the vertical edge at the lower-left corner (smallest Y, and then smallest X). *Data_type*: string, optional
`-gap_sides` *T B L R*	Defines the distance, in microns, that must be reserved from the power domain boundary edges for power routing. You can specify four values, one for each edge. *Data_type*: string, optional
`-last_row_site_index` *integer*	Specifies the last row site index value. *Data_type*: int, optional
power_domain_name	Specifies the current name of the power domain to be modified. This is a positional parameter, and you must specify this value immediately after the command name. *Data_type*: (power_domain), required
`-power_extend_edges`	Specifies the maximum search distance for power extension connections by domain edge in microns. You can specify the value per edge in clockwise order, starting with the vertical edge at the lower-left corner (smallest Y, and then smallest X). *Data_type*: string, optional
`-power_extend_sides` *T B L R*	Specifies the boundary for legal targets to be used by the power planning and routing commands, in conjunction with the power domain boundary. You can specify four values, one for each edge. *Data_type*: string, optional

`-row_flip {first | second | noFlip | auto}`	Flips the orientation of either the first or second row, then follows the flipped and abutted row pattern.
	`first`
	(from bottom to top). MX -> R0 -> MX -> R0 - > …
	`second`
	(from bottom to top). R0 -> MX -> R0 - > MX -> …
	`noFlip`
	(from bottom to top). R0 -> R0 -> R0 - > R0 -> …
	The noFlip option preserves the R0 orientation for all rows (above).
	`auto`
	Detects orientation of row outside of power domain and aligns with power domain bottom. Orientation is applied to the first row at the bottom of power domain.
	So if row on left is R0, the pattern will be (from bottom to top). R0 -> MX -> R0 - > MX -> …
	If row on left is MX, the pattern will be (from bottom to top). MX -> R0 -> MX -> R0 - > …
	The `auto` option resets the software for this automatic behavior if you have previously specified `first`, `second`, or `noFlip`.
	Default: `auto`
	Note: *saveRowImage* resets the option `-row_flip` to `auto`. In this case, try moving the power domain and check the row changes.
	Data_type: enum, optional

`-row_pattern_site site_name`	Specifies the site name for the row pattern. *Data_type*: string, optional
`-row_space_type {0|1|2}`	Determines whether the row spacing value applies between no row (0), each row (1), or each pair of rows (2). *Data_type*: enum, optional
`-row_spacing value`	Specifies the row spacing between each row (1) or each pair of rows (2) as specified in `-row_space_type`. *Data_type*: float, optional

Examples

The following command changes the route search extension values of `PowerDomain1` to 15 µm on each side:

```
update_power_domain PowerDomain1 -power_extend_sides 15 15 15 15
```

Low Power Design chapter in the *Innovus User Guide*

update_power_switches

```
update_power_switches
[-help]
-insts inst_name_list
-cell cell_name
[-x_offset value_in_microns]
[-y_offset value_in_microns]
[-orient orienation_syntax]
[-cell_enable_pins {{cellname {enableInputPinList} {enableOutputPinList}}}]
[-x_y_range_from_center_inst]
```

Replaces the cell of a power switch instance. You can also change the orientation of the instance after cell substitution, and provide a new location for the instance origin relative to the original instance origin.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `update_power_switches` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man update_power_switches`
`-cell` *`cell_name`*	Specifies the cell to substitute for the instance's cell. *Data_type*: string, required
`-cell_enable_pins` {{*`cellname`* {*`enableInputPinList`*} {*`enableOutputPinList`*}}}	Provides the pin names of power switch cell specified thru `-cell` option in `update_power_switches` when the power switch cell pin names are different than the specified instance's cell. This option is also useful in cases where all enable pins of instances are not connected by enabling a way to provide pin map. *Data_type*: string, optional
`-insts` *`inst_name_list`*	Specifies the instance whose cell you want to replace. *Data_type*: string, required
`-orient` *`orientation_syntax`*	Specifies the orientation of the instance after the cell substitution. Choose one of the following values: `r0`, `r90`, `r180`, `r270`, `mx`, `my`, `mx90`, and `my90`. *Default:* The same orientation as the original instance. *Data_type*: enum, optional
`-x_offset` *`value_in_microns`*	Specifies the instance placement in the `x` direction after the cell substitution. A positive value moves the instance to the right of the original instance origin. A negative value moves the instance to the left of the original instance origin. *Data_type*: float, optional

`-x_y_range_from_center_inst`	Selects the power switch instances whose lower left corner is in the range from lower left corner of the specified instance (`-insts`) for replacement with switch cell (`-cell`). **Note:** The first instance specified in the `-insts` will be used for the area computation. The rest of the instances in the `-insts` list will be ignored and will not be replaced. For Example: `update_power_switches -insts psoI_TDSP2_1_CDN_COLUMN_SW_669_1622_3 \ -x_y_range_from_center_inst { 60.3 20 } -cell \ CDN_COLUMN_SW` *Data_type*: string, optional
`-y_offset` *value_in_microns*	Specifies the instance placement in the y direction after the cell substitution. A positive value moves the instance above the original instance origin. A negative value moves the instance above the original instance origin. *Data_type*: float, optional

Examples

- The following example substitutes cell `CDN_RING_SW1` for the original cell for instance `pso1_TDSP2_1_CDN_RING_SW_636_1309_6`:
  `replacePowerSwtich -insts pso1_TDSP2_1_CDN_RING_SW_636_1309_6 -cell CDN_RING_SW1`
- The following example substitutes cell `CDN_RING_SW1` for the original cell for instance `pso1_TDSP2_1_CDN_RING_SW_636_1315_8` and changes the orientation of the instance to `my90`:
  `update_power_switches -insts pso1_TDSP2_1_CDN_RING_SW_636_1315_8 -cell CDN_RING_SW1 -orient my90`

write_power_intent

```
write_power_intent
[-help]
file_name
-incremental_1801
{-cpf [[-hinsts -top_hier] | [-hinst_only]] | -1801}
[-no_extra_connects]
```

Writes the CPF/IEEE1801 file. The command options help to write the file for CPF as well as for the IEEE1801 standard.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_power_intent` parameter. For a detailed description of the command and all its parameters, use the man command: `man write_power_intent`
`file_name`	Specifies name of the IEEE1801 input file. *Data_type*: string, required
For CPF	
`-cpf`	When specified, Innovus writes out the CPF file. *Data_type*: bool, required
`-hinst_only`	Specifies the hierarchical instance name. Writes (partitions) the CPF for the hierarchical instance specified in this option. **Note:** Must be used along with `-cpf` option. *Data_type*: string, optional
`-hinsts`	Writes top-level CPF where the hierarchical instances specified in `-hinsts` option are hard blocks when specified together with `-top_hier -cpf`. *Data_type*: string, optional
`-top_hier`	Writes top-level CPF when specified together with `-hinsts` and `-cpf`. *Data_type*: bool, optional
For IEEE1801	

`-1801`	Writes the IEEE1801 file from the low-power database. It filters out the non-existing instances from the original IEEE1801 file and appends to it the following: • PG connection for the newly-inserted always-on buffers • Nwell/Pwell connections for the low-power cells • `-no_isolation`/`shifter` for the isolation/level shifter strategies for the newly-created ports along the power domain boundary *Data_type*: bool, required
`-incremental_1801`	Specifies the incremental IEEE1801 power intent. *Data_type*: bool, required
`-no_extra_connects`	If this parameter is specified, `write_power_intent -1801` does not write out any extra `connect_supply_net` (PG connection). For example: `write_power_intent -1801 -no_extra_connects out.upf` **Note:** Extra connects means that the extra `connect_supply_net` commands appended by the tool, which are not included in the original UPF. *Data_type*: bool, optional

write_power_switches

```
  write_power_switches
[-help]
[-power_domain powerDomainName]
[out_file fileName]
```

Exports power switch databases. The need for this command arises in case of defIn-based flows where power switch database required for power switch related operations is not loaded.

So, using `write_power_switches` a user can save power switch database after power switch insertion using `add_power_switches` for later use and it can be loaded back.

Note: The enable net IN and OUT connections should remain the same in the `netlist` in power switch database export/import process and the commands need not be run when `save_design` is run because the power switch database is automatically saved and restored.

PSO File Generation and Usage

A PSO file gets generated as an output of the `write_power_switches` command, which can be used in a future session, if needed. One scenario where this file can be needed is when a DEF file containing a power switch chain is not used in the power switch synthesis and hence the incoming netlist to Innovus would not have any power switches. The power switch chain is then created at the `init` stage of Innovus using the `add_power_switches` command in such a run. A database saved using `write_db` after running the `add_power_switches` command, will have the power switch chain saved in a `<design.pso>` file. When restored, this database can also be used to write out the saved PSO file using the `write_power_switches` command. When the power switches are added using the `add_power_switches` command, the `report_power_switches` command can be used to validate their addition.

To avoid regenerating power switches in future implementation runs, save the power switch chain using the `write_power_switches` command along with the floorplan DEF. Ensure that the `-routing` parameter of the `write_def` command is also used along with `-floorplan` and `-no_std_cells` to save the power switch network under the NETS section of the DEF.

Refer to the following flows to understand the usage of the PSO file:

Innovus Session 1:

```
<init Design1 - incoming design has no power switches>
add_power_switches
write_power_switches test.pso
write_def -floorplan -no_std_cells -routing test.def
```

Innovus Session 2:

```
<init Design2 - incoming design has no power switches>
read_power_switches -in_file test.pso
read_def test.def
```

While reading the DEF file, you can identify the power switches using the database commands, even without using the `read_power_switches` command. Following is a usage example of such a database command:

```
get_db [get_db insts -if {.name == inst1/psoI_PD1_1_HSWX1_200_1582_0} ] .base_cell.is_power_switch
```

Here, `inst1/psoI_PD1_1_HSWX1_200_1582_0` is the instance name of the switch cell.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_power_switches` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man write_power_switches`
`-power_domain` *`powerDomainName`*	Specifies the power domain whose power switch information is to be exported. *Data_type*: string, optional
`out_file fileName`	Specifies the name of the export file. *Data_type*: string, optional

write_power_switches_for_floorplan

```
write_power_switches_for_floorplan
[-help]
out_file
```

Stores the power switch database information, which can later be restored in the same floorplan through the `read_power_switches` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_power_switches_for_floorplan` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man write_power_switches_for_floorplan`
`out_file`	Specifies the output file for storing the power switch database information. *Data_type*: string, optional

Machine Learning Commands

- init_ml
- write_ml_design
- write_ml_library
- write_ml_timing_graph
- write_ml_timing_path

init_ml

```
init_ml
[-help]
[-comment string]
[-flow_phase string]
[-name string]
-prefix string
[-scenario string]
```

Initializes the environment to start writing data for JedAI. Run this command before using any of the following commands to ensure that content is properly labeled for big data ingestion and registration:

- `write_ml_design`
- `write_ml_library`
- `write_ml_timing_graph`
- `write_ml_timing_path`

Parameters

`-help`	Prints a brief description that includes the type and default information for each `init_ml` parameter. For a detailed description of the command and all of its parameters, use the man command `man init_ml`.
`-comment` *`string`*	Specifies a comment. *Data_type*: string, optional
`-flow_phase` *`string`*	Specifies the flow phase. *Data_type*: string, optional
`-name` *`string`*	Specifies the design name. *Data_type*: string, optional
`-prefix` *`string`*	Specifies the prefix for the output files. *Data_type*: string, required
`-scenario` *`string`*	Specifies the scenario. *Data_type*: string, optional

Example

- The following command the environment to start writing data for JedAI for the `cts` flow phase with the `default` scenario for the `dtmf` design.

  ```
  init_ml -prefix out/ -name dtmf -flow_phase cts -scenario default -comment "This is a demo."
  ```

Related Information

- write_ml_design
- write_ml_library
- write_ml_timing_graph
- write_ml_timing_path

write_ml_design

```
write_ml_design
[-help]
[-no_power]
[-objects object_list]
-prefix string
[-verbose]
[-views view_list]
```

Writes design-related data for JedAI to csv files with specified prefix. It includes data that is design specific and relates to logical, physical, and timing type objects.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_ml_design` parameter. For a detailed description of the command and all of its parameters, use the man command `man write_ml_design`.
`-no_power`	Specifies that power attributes should not be dumped. *Data_type*: bool, optional
`-objects` *object_list*	

	Specifies the list of db object(s) to be dumped, which could include one or more of the following values:
	`analysis_view arc base_cell base_pin blockage clock congestion constraint_mode`
	`delay_corner design gcell_grid hinst hnet hpin hport inst layer marker net netlist`
	`opcond option p2p partition patch_wire pg_base_pin pg_pin pin pin_shape port`
	`rc_corner route_rule row site skew_group special_net timing_condition track_pattern unit_parasitic via_def`
	Use curly braces to enclose multiple values.
	Data_type: tcl_obj, optional

`-prefix` *string*	Specifies the prefix for the output files. *Data_type*: string, required
`-verbose`	Displays a more detailed message. *Data_type*: bool, optional
`-views` *view_list*	
	Dumps the data for the specified analysis view(s). *Data_type*: tcl_obj, optional

Example

- The following command writes the attributes of all design objects to csv files with the specified prefix:

```
write_ml_design -prefix out/
```

Related Information

- `init_ml`
- `write_ml_library`
- `write_ml_timing_graph`
- `write_ml_timing_path`

write_ml_library

```
write_ml_library
[-help]
[-objects object_list]
-prefix string
```

Writes library-related data for JedAI to csv files with the specified prefix. It includes data that is library specific and relates to lib_cells, timing_tables, and power_tables.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_ml_library` parameter. For a detailed description of the command and all of its parameters, use the man command `man write_ml_library`.
`-objects object_list`	
	Specifies the list of db object(s) to be dumped, which could include one or more of the following values: `lib_arc lib_cell lib_feature lib_pin library library_set power_table timing_table` Use curly braces to enclose multiple values. *Data_type*: tcl_obj, optional
`-prefix string`	Specifies the prefix for the output files. *Data_type*: string, required

Example

- The following command writes library-related data for JedAI to csv files with the specified prefix:

  ```
  write_ml_library -prefix out/
  ```

Related Information

- init_ml
- write_ml_design
- write_ml_timing_graph
- write_ml_timing_path

write_ml_timing_graph

```
write_ml_timing_graph
[-help]
[-noedge]
-prefix string
[-register_only]
[-views view_list]
```

Writes timing-related data for JedAI to csv files. It includes data representing the complete timing graph for a given set of analysis views.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_ml_timing_graph` parameter. For a detailed description of the command and all of its parameters, use the man command `man write_ml_timing_graph`.
`-noedge`	Specifies that edge data should not be dumped. This option can be used to save time. *Data_type*: int, optional
`-prefix string`	Specifies the prefix for the output files. *Data_type*: string, required
`-register_only`	Specifies that only nodes for register should be dumped. *Data_type*: bool, optional
`-views view_list`	Dumps the data for the specified analysis view(s). *Data_type*: tcl_obj, optional

Example

- The following command writes the timing-related data for JedAI to csv files with the specified prefix:

```
write_ml_timing_graph -prefix out/
```

Related Information

- `init_ml`
- `write_ml_design`
- `write_ml_library`
- `write_ml_timing_path`

write_ml_timing_path

```
write_ml_timing_path
[-help]
[-anchor_file string]
[-each_endpoint]
[-gen_anchor]
[-hpin]
[-io_only]
[-max_paths int]
[-max_slack float]
[-nworst int]
[-path_group string]
[-per_partition]
-prefix string
[-retime {aocv ssta path_slew_propagation aocv_path_slew_propagation}]
[-start_pathid int]
[-verbose]
[-views view_list]
```

Writes timing-related data for JedAI to csv files. It includes data for individual timing paths. Timing path data can be computed in either graph-based analysis (GBA) or path-based analysis (PBA) fashion using the `-retime` option.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_ml_timing_path` parameter. For a detailed description of the command and all of its parameters, use the man command `man write_ml_timing_path`.
`-anchor_file` *string*	Specifies the name of the anchor file to be used as input. *Data_type*: string, optional
`-each_endpoint`	Specifies whether to dump at least one path for each end point. *Data_type*: bool, optional

`-gen_anchor`	Generates the anchor file. *Data_type*: bool, optional
`-hpin`	Dumps hpin in timing points. *Data_type*: bool, optional
`-io_only`	Specifies that only the io path should be dumped. *Data_type*: bool, optional
`-max_paths` *int*	Specifies the max_paths for `report_timing`. *Data_type*: int, optional
`-max_slack` *float*	Specifies the max_slack for `report_timing`. *Data_type*: float, optional
`-nworst` *int*	Specifies the nworst for `report_timing`. *Default*: `100` *Data_type*: int, optional
`-path_group` *string*	Specifies the path_group for `report_timing`. *Data_type*: string, optional
`-per_partition`	Specifies that only paths through top level partitions should be dumped. *Data_type*: bool, optional
`-prefix` *string*	Specifies the prefix for the output files. *Data_type*: string, required
`-retime {aocv ssta path_slew_propagation aocv_path_slew_propagation}`	
	Specifies the method to be used for reanalysis of specified set of paths with `report_timing`. *Data_type*: enum, optional
`-start_pathid` *int*	Specifies the starting path id. *Default*: `1` *Data_type*: int, optional

`-verbose`	Displays a more detailed message. *Data_type*: bool, optional
`-views` *view_list*	Dumps the timing path for the specified analysis view(s). *Data_type*: tcl_obj, optional

Example

- The following command writes out the attributes of timing paths to csv files with the specified prefix:

```
write_ml_timing_path -prefix out/ -max_paths 10000 -nworst 1
```

add_metal_fill

```
add_metal_fill
[-help]
[-area x1 y1 x2 y2 ]
[-extra_critical_nets net_name_list ]
[-exclude_vias via_list ]
[-ignore_lef_density]
[-iteration_names { list_of_iteration_names } ]
[-keep_square_floating]
[-layers layerName | { list_of_layer_names } ]
[-on_cell [-std]]
[-pg_fill]
[-remove_floating_fill]
[-slack_threshold slack ]
[-snap]
[-square_shape] | [-nets { net_name_list } [-generated_via_only] [-mesh | -mesh_only]]
[-stagger {on | off | diag}]
[-timing_aware {on | off | sta}]
[-use_non_default_spacing]
```

Inserts inactive metal into a placed and routed design to achieve the metal density within the range required by a specific manufacturing process. Avoids inserting metal on top of macros if it can achieve the preferred metal density without doing so. Use this command to insert metal fill after timing analysis and post route is complete.

`add_metal_fill` provides complete support for Through Silicon Via (TSV) designs. You can insert tied-off metal fill in back side metal layers and add metal fill in iterations to back side layers.

During timing-driven metal fill, the software assigns costs to signal and clock nets so it can avoid placing metal fill near timing-critical nets.

- It is recommended that you add metal fill after adding via fill. Alternatively, the via fill can also be added between floating metal fill.
- If you use the `-timing_aware sta` parameter, you must run timing analysis before adding metal fill.

This command uses the values specified by the `set_metal_fill` command.

Some technologies use triangular shapes for Corner Stress Relief patterns. However, metal fill does not support triangular route blockages currently.

Adding Metal Fill in Multi-Threading Mode

You can add metal fill in multi-threading mode by using the `set_multi_cpu_usage` command before adding the metal fill.

Metal Fill supports the new `set_multi_cpu_usage` command use model. For more information, see the following documents:

- Multiple-CPU Processing Commands chapter of the *Innovus Text Command Reference*.
- Accelerating the Design Process By Using Multiple-CPU Processing chapter of the *Innovus User Guide*.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `add_metal_fill` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man add_metal_fill`

`-area` *x1 y1 x2 y2*	Specifies a set of coordinates within which to add metal fill. This command reduces the fill area by half of the maximum design rule spacing defined in the LEF file. For example, if you specify `-area 0 0 100 100`, and the maximum spacing rule in the LEF file is 2.5 µ, `add_metal_fill` adds fill in the following area: `1.25 1.25 98.75 98.75`. *Default:* If you do not specify this parameter, adds metal fill to the entire design area (taking the maximum spacing rule into account). ***Behavior of add_metal_fill -area with external metal density*** When metal fill is added to a block design the external metal density provides a density assumption to `add_metal_fill`. The external density is used only for density calculation purposes and no fill shapes are added outside of the design area. When the `-area` parameter is not specified, the external density value is not used. In this case, the `add_metal_fill` window is pushed back if it extends outside the design area, as shown in the figure below.  If the `-area` parameter is specified and is larger than the design size then `add_metal_fill` windows extend outside the block area and use the external density value (see `set_metal_fill` for external density value specification) for that area. If external density is less than the specified preferred density, it is more likely that shapes will be added to the area. If external density is greater than the preferred density it is less likely that shapes will be added (shapes are only added within the design boundary). **Note:** Windows outside the design boundary are ignored. *Data_type*: rect, optional

`-exclude_vias` *via_list*	Specifies vias or via rules to exclude from use by metal fill. Use this parameter to prevent the software from using the same vias inside MACROs and for metal fill insertion.
	
	Separate the arguments with spaces. You can specify both via names and via rules.
	• The following example shows how to specify a list of via names:
	`-exclude_vias {VIA12 VIA23}`
	• The following example shows how to specify a list of via rules:
	`-exclude_vias {via1Array via2Array}`
	• The following example shows how to specify both via names and via rules:
	`-exclude_vias { VIA12 VIA23 via1Array via2Array}`
	
	Data_type: string, optional

`-extra_critical_nets` *net_name_list*	Specifies a list of extra critical nets for adding metal fill in the timing-aware mode. If you are using a third-party tool for sign-off static timing analysis (STA), your list of timing critical nets may be different from that generated by `report_timing` in Innovus/Tempus. In such a case, you can use `-extra_critical_nets` in one of the following ways: • In the `-timing_aware sta` mode: The tool adds the extra nets you specify to the Innovus list of critical nets determined via the `-slack_threshold` method. If the list you specify is exactly the same as the Innovus list of critical nets, the tool works in the same way as it would without `-extra_critical_nets`. • In the `-timing_aware on` mode: In this mode, the tool will consider the specified critical net list as medium cost. Use `-extra_critical_nets` in this mode if you want to avoid the runtime hit associated with performing timing analysis using the `-timing_aware sta` option. **Note:** If you use the `-extra_critical_nets` option in the `-timing_aware off` mode, the tool waives the option and issues a warning message. *Data_type*: string, optional
`-generated_via_only`	Specifies that only generated vias are used for metal fill connections. **Note:** This parameter is enabled only when the `-nets` parameter is specified. *Data_type*: bool, optional
`-ignore_lef_density`	Ignores the MACRO `DENSITY` table in the LEF file and instead uses the default macro density calculation method. For more information on the default macro density calculation method, refer to the "*Estimating Density of Blockage*" section in the Optimizing Metal Density chapter of the *Innovus User Guide*. **Note:** If you do not specify this parameter, `add_metal_fill` uses the LEF MACRO density table for density calculations. *Data_type*: bool, optional

`-iteration_names` {*list_of_iteration_names*}	Specifies a list of iterations (the names are specified by the `set_metal_fill -iteration_names` parameter) for adding metal fill. Processes the iterations in the order listed, and stops when the preferred density is reached in any iteration.
	Running `add_metal_fill` without the `-iteration_names` parameter is the same as running the following command:
	`add_metal_fill -iteration_names default`
	If `add_metal_fill` is looking for `default`, that is, if `-iteration_names default` is specified or if you do not specify the `-iteration_names` parameter, and the default settings are not defined by `set_metal_fill`, the `add_metal_fill` command uses it own internal default values, which are not derived from any `set_metal_fill -iteration_names` name.
	When you run `add_metal_fill` in iteration mode, it runs several times with just one invocation of the command, and uses the ending density from an iteration as the starting density of the next iteration. For that one invocation, the window size and step for a specific layer must be the same for all iterations.
	Because `add_metal_fill` uses preferred density to estimate the macro density, a different preferred density setting in `iteration_name_list will` cause the different density estimation. The same preferred density setting in `iteration_name_list` is recommended.
	In the following example, `add_metal_fill` fails because the specified values for `-window_size` and `-window_step` in `step1`, `step2`, and `step3` are different:
	`set_metal_fill -iteration_names step1 -layers ... \`
	`  -window_size 100 100 -window_step 50 50`
	`set_metal_fill -iteration_name step2 -layers ... \`
	`  -window_size 100 100 -window_step 50 50`
	`set_metal_fill -iteration_names step3 -layers ... \`
	`  -window_size 50 50 -window_step 25 25`
	`add_metal_fill -iteration_names {step1 step2 step3} ...`
	If you run `add_metal_fill` two times, and separate `step3`, (because its values are different from those of `step1` and `step2`) the commands will succeed:
	`add_metal_fill -iteration_names {step1 step2} ...`
	`add_metal_fill -iteration_names step3 ...`
	Data_type: string, optional

`-keep_square_floating`	Specifies that unconnected (floating) metal fill must be square. *Default:* If you do not specify this parameter, the software can create rectangular and square metal fill that is unconnected. *Data_type*: bool, optional

`-layers layerName | {list_of_layer_names}`	Specifies the layers, including back side metal layers, on which the metal fill shapes will be created. If you specify more than one layer, separate each layer with a space and enclose the list in braces or double quotation marks. For example, to specify metal layers 1, 2, and 3, type one of the following commands:
	`add_metal_fill -layers "METAL1 METAL2 METAL3"`
	`add_metal_fill -layers {METAL1 METAL2 METAL3}`
	Default: If you do not specify the `-layers` parameter, Innovus adds metal fill to all layers.
	Data_type: string, optional

`-mesh`	Connects metal fill shapes to the power mesh, allowing it to carry current as part of the power and ground structure. With mesh connections the software uses the maximum number of cuts in vias, based on the intersection area between layers, instead of the following the minimum-cut rule used with tree connections. Increasing the number of cuts helps to reduce IR drop. **Note:** This parameter is enabled only when the `-nets` parameter is specified. The default values for the metal fill commands are optimized for timing, not power. For recommendations for values that are optimized for power, see "Recommendations for Power Strapping Mode" in the Optimizing Metal Density chapter of the *Innovus User Guide*. *Data_type*: bool, optional
`-mesh_only`	Adds only multi-connection PG fill in the design. To improve IR drop, you may want to use tied-off metal fill to connect to power/ground (PG) nets. However, single-connection PG fill does not help in controlling IR drop. `add_metal_fill -mesh_only` enables you to add only mesh or multi-connection fill and removes any single-connection PG fill. As a result, you can improve IR drop and reduce timing impact in the design. With `-mesh_only`, the following PG fills are removed:  The following PG fills are retained with `-mesh_only`:  *Data_type*: bool, optional
`-nets {net_name_list}`	Specifies a list of special nets to which to connect metal fill. The nets must be listed in the `SPECIALNETS` section of the DEF file. PG nets that overlap with the fillwire are sorted by width and length. `add_metal_fill` gives higher priority to the PG nets with greater dimensions (wider width and longer length), irrespective of their sequence in the `net_name_list`. *Default:* If you do not specify this parameter, metal fill is not connected to special nets (it is floating). To specify nets VDD and VSS for connection, type the following command: `add_metal_fill -nets {VDD VSS}` **Note:** Do not specify this parameter if you also specify `-square_shape` as `-nets` only applies rectangular shapes. *Data_type*: string, optional

`-on_cell [-std]`	Allows the software to add metal fill to `CLASS BLOCK` and `CLASS PAD` macro cells. Before adding the metal fill, make sure that the cells are at the preferred density, because adding metal fill shapes inside the cells might lead to timing problems inside the cells. If there are PIN/OBS in a cell, metal fill should be added on cells in layers with `-on_cell` option. The density of macro will be estimated according to OBS/PIN area. If there are no PIN/OBS in a cell, metal fill should be added on cells in layers without `-on_cell` option. **Note:** The software can always add metal fill to `CLASS CORE SPACER` cells, but can add it to `CLASS BLOCK` and `CLASS PAD` cells only when the `-std` parameter is specified. Specify the `-std` parameter as well if you want to add metal fill only to standard cells. *Data_type*: bool, optional
`-pg_fill`	Enables the use of power/ground fill flow. *Data_type*: bool, optional
`-remove_floating_fill`	Removes unconnected metal fill from the design. When the software adds metal fill, it creates both connected and unconnected fill. When you specify `-remove_floating_fill`, it removes all the unconnected fill and leaves only metal fill that is connected. *Default:* If you do not specify this parameter, the software leaves floating metal fill in the design. *Data_type*: bool, optional
`-slack_threshold` *slack*	Specifies a slack threshold, in nanoseconds, for critical nets during timing-driven metal fill when you specify `-timing_aware sta`. All nets with slack less than the `-slack_threshold` are considered critical. For most designs, Cadence recommends you specify a small positive value for the slack threshold, such as 100 picoseconds, which gives you a small safety margin, as in the following command: `add_metal_fill -slack_threshold 0.1` *Default:* `0.0` *Data_type*: float, optional
`-snap`	Snaps edges of metal fill shapes and centers of cuts to a user- defined snap grid that is a multiple of the manufacturing grid. When the shapes are snapped to this grid, the edges of the shapes lie on the manufacturing grid. If the shapes are enclosed by on-Mgrid shapes, the shapes will ignore manufacturing grid check. Other Innovus features share the grid, including verify, power planning and routing, and wire editing. Define the grid using the `set_snap_grid` command. If `set_snap_grid` is not specified, the software snaps the shapes to the manufacturing grid. For more information, see `set_snap_grid`. **Note:** When you specify this parameter, the software assumes that vias from the LEF file meet the snap grid requirements. *Data_type*: bool, optional
`-square_shape`	Specifies that only square-shaped metal fill is added. *Default:* If you do not specify this parameter, both rectangular and square metal fill can be added. **Note:** Do not specify this parameter if you use the `-nets` parameter as `-nets` applies only to rectangular shapes. *Data_type*: bool, optional

`-stagger {on | off | diag}`	Specifies the pattern for adding metal fill.
	Default: `on`
	Specify one of the following parameters:
	• `on`: Adds metal fill shapes in a staggered pattern in the preferred routing direction and in an aligned pattern in the non-preferred direction.
	• `off`: Adds metal fill shapes that line up in both the preferred and non-preferred routing directions, so that metal fill is not staggered.
	• `diag`: Adds metal fill shapes in a staggered pattern in both the preferred and non-preferred directions. Specify the offset for staggering with the following command:
	`set_metal_fill -diag_offset x y`
	For example:
	`set_metal_fill -diag_offset 0.05 0.05`
	add_metal_fill -stagger parameters
	 	
	Data_type: enum, optional

`-std`	Adds metal fill to standard cells only. **Note:** The `-std` parameter can be used only when the `-on_cell` parameter is used. *Data_type*: bool, optional

`-timing_aware {on | off | sta}`	Specifies whether the software considers the timing impact of adding metal fill.
	Default: `on`
	
	Specify one of the following parameters:
	• `off`: Does not consider timing.
	• `on`: Assigns timing costs to nets and adds metal fill to nets with the lowest timing cost first. Adds less metal fill near clock and signal routing.
	Divides nets into categories based on timing cost. The categories are:
	  ◦ Clock nets (highest cost)
	  ◦ Signal nets (moderate cost)
	  ◦ Power and ground nets--netss marked + USE POWER or + USE GROUND in the DEF file (0 cost)
	• sta: Runs in timing-aware mode using the Innovus common timing engine (CTE) for static timing analysis (STA). To benefit from using the sta parameter, you must have run timing analysis with the report_timing command prior to adding metal fill. If there are no timing structures in memory, the sta parameter behaves like the on parameter.
	
	The `sta` parameter also divides nets into categories, but it uses the timing analysis results for assigning timing costs to nets. It adjusts the costs as a function of the slack (the worst slack has the highest cost) and uses the slackThreshold to separate critical and noncritical signal nets. Critical nets are signal nets with slack less than the threshold, and therefore have a higher cost than noncritical nets.
	
	The categories are:
	  ◦ Clock nets (highest cost)
	  ◦ Critical signal nets (moderate cost)
	  ◦ Non-critical signal nets (small cost)
	  ◦ Power and ground nets--marked `+ USE POWER` or `+ USE GROUND` in the DEF file (0 cost)
	
	ⓘ Specify a value for `-slack_threshold` if you specify `sta`.
	
	Data_type: enum, optional

`-use_non_default_spacing`	Uses nondefault spacing for adding metal fill. Some critical nets use a nondefault rule (NDR) for routing as they may need to have wider wires or wider spacing than other nets. Use the `-use_non_default_spacing` option to extend NDR control to `add_metal_fill`. *Data_type*: bool, optional

Example

- The following command adds connected metal fill to the specified area on *METAL1*, *METAL2*, and *METAL3*, using the values set by the `set_metal_fill` command:

  ```
  add_metal_fill -layers {METAL1 METAL2 METAL3} -area 100 200 300 400 -netss {VDD GND}
  ```

  Here's a sample output from the software:

  ```
  add_metal_fill -q .metalfill_27257.conf
  ************************
  Timing Aware on
  P/G Nets: 321
  Signal Nets: 8784
  Clock Nets: 0
  ************************
  Density calculation ...... Slot : 1 of 1
  Density calculation ...... Slot : 1 of 1
  End of Density Calculation : cpu: 0:00:00, real: 0:00:01, peak: 566.00 megs
  process data during iteration 1 in region 1 of 4.
  process data during iteration 1 in region 2 of 4.
  process data during iteration 1 in region 3 of 4.
  process data during iteration 1 in region 4 of 4.
  process data during iteration 2 in region 1 of 4.
  process data during iteration 2 in region 2 of 4.
  process data during iteration 2 in region 3 of 4.
  process data during iteration 2 in region 4 of 4.
  End metal filling: cpu: 0:00:01.2, real: 0:00:02.0, mem 361.10 megs.
  ```

- The following set of commands:
  - Creates a nondefault rule `testndr` that sets the spacing of all layers to `0.8` micrometers.
  - Sets the nondefault rule `testndr` for the `clk` net.
  - Specifies that the router should strictly honor nondefault spacing.
  - Adds metal fill using nondefault spacing
  - Checks the nondefault rule spacing values for every route of the net `clk`.

  ```
  initNdr

  setNdrSpacing 0.8

  createNdr testndr

  setAttribute -nets clk -non_default_rule testndr

  set_db route_strict_honor_non_default_rule 1

  add_metal_fill -use_non_default_spacing

  verifyGeometry -use_non_default_spacing
  ```

- The following command inserts PG fill in back side layers `B1` and `B2`:

  ```
  add_metal_fill -nets {VDD VSS} -layers {B1 B2}
  ```

- The following command saves run time by adding metal fill in iterations to back side layers `B1` and `B2`.

  ```
  add_metal_fill -iteration_names {iter1 iter2} -layers {B1 B2}
  ```

- The following set of commands inserts metal fill in three iterations`-step1`, `step2`, and `stepopc`-to layers metal`1` to metal`8` in timing-aware mode:

  ```
  read_db

  time_design -post_route -report_dir prefill
  ```

```
set_metal_fill -layers {1 2 3 4 5 6 7 8} -iteration_name step1 /
             -gap_spacing 0.140 -min_width 1 -decrement 0.050 /
             -min_length 2 -max_width 5 -max_length 20 -active_spacing 0.8 /
             -window_size 50 50 -window_step 25 25 -min_density 15 /
             -max_density 80 -preferred_density 35 -diagonal_offset 1 1

set_metal_fill -layers {1 2 3 4 5 6 7 8} -iteration_name step2 /
             -gap_spacing 0.140 -min_width 0.140 -decrement 0.010 /
             -min_length 0.14 -max_width 1 -max_length 10 -active_spacing 0.2 /
             -window_size 50 50 -window_step 25 25 -min_density 15 /
             -max_density 80 -preferred_density 25 -diagonal_offset 0.2 0.2

set_metal_fill -layers {1 2 3 4 5 6 7 8} -iteration_name stepopc -opc /
             -gap_spacing 0.07 -min_width 0.07 -decrement 0.010 /
             -min_length 0.07 -max_width 1 -max_length 10 -active_spacing 0.07 /
             -opcactive_spacing 0.1 -window_size 50 50 -window_step 25 25 /
             -min_density 15 -max_density 80 -preferred_density 25

Runs the signoff metal fill flow as per specified primary and sub options.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `add_metal_fill_signoff` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man add_metal_fill_signoff`
`-and_area_size` *`size_value`*	Specifies a value for sizing up the changed area to use shapes within this area. This parameter helps in calculating the density and creating areas to be filled, if they fall below the minimum density. The default value of this parameter is 10. A value lesser than the default value may be used to improve the flow performance, if no accuracy issues occur. A value greater than the default value can be used to fix the accuracy issues. The minimum value of this parameter is `0.001` and maximum value is `1000`.
`-area {x1 y1 x2 y2}`	Specifies a set of coordinates within metal fill can be trimmed.
`-attach_instance_name` *`attr_num`*	Specifies the instance name to attach.
`-attach_net_name` *`attr_num`*	Specifies the net name to attach.
`-attach_net_prop {{`*`prop_name`* `attr_num} ...}`	
	Specifies the net property to attach.
`-auto_load_fills`	Updates the FILL data automatically in the software after when the `add_metal_fill_signoff` command modifies the HMF database. In case the HMF database is not modified, the FILL data will be hidden in the software's design.
`-background_mode`	Runs metal fill in the background mode without locking up the software license. **Note:** All the metal fill options running in the background must be used with the `-background_mode` parameter.
`-clock`	Specifies whether to trim metal fill around all clock nets.

`-common_blockage {`*`layer_num1 layer_datatype1`* `...}`	Specifies common blockage fill layers. This allows you to specify the blockage layer only once, instead of multiple individual blockages for the metal fill layers. The parameter value format is `{`*`layer_number layer_datatype`*`}`. You can also specify multiple layers, and each blockage layer should specify a set of two values. The *`layer_number`* must be an integer. Following are the examples of the usage of this parameter:
	`add_metal_fill_signoff -common_blockage {150 28}`
	`add_metal_fill_signoff -common_blockage {150 28 120 55}`

`-control` *`file_name`*	Specifies the control file, which is created automatically when a job is submitted from the PVS GUI. This parameter can be used, if you have run a directory submitted from the GUI. Use this parameter to rerun the PVS job from the command line and get the results, which are exactly the same as the GUI submission. The control file is placed in the run directory with the `pvsdrcctl` name and has only the command entries for certain fields in the GUI. You must not modify the file by adding commands or parameters that are not available in the GUI. If you do that, the commands can be ignored by the PVS rule compiler or the results can be indeterminate.
`-delete_area {{`*`layer_list1`*`} {`*`x1 y1 x2 y2`*`} ...}`	Specifies the x and y coordinates of the area where metal fill is deleted. Following is the usage example of this parameter: `add_metal_fill_signoff -delete_area {{M1 M2 M6} {0 0 50 50}}`
`-delete_fill`	Deletes metal fills in the specified window or coordinates.
`-delete_flatten_fills`	Deletes flattened metal fills without updating the HMF database.
`-delete_point {{`*`layer_list1`*`}{`*`x1 y1`*`}...}`	Specifies the x and y coordinates of the point where metal fill is deleted. Following is the usage example of this parameter: `add_metal_fill_signoff -delete_point {{M2} {134.7 14.21}}`
`-die_area_as_boundary`	Specifies the die area as boundary.

`-distributed n`	Specifies the number of local cores to use. The default value is fetched from the EDI settings.
`-distributed_timeout value`	Specifies the time to wait for the slave processes to start.
`-excluded_area_size size_value`	Specifies the area to be created around the metal fill area to check for the existing metal fill shapes and to avoid creation of metal fill shapes too close to the existing metal fill shapes. The default value of this parameter is `1.6`. A value lesser than the default value may be used to improve the flow performance, if no accuracy issues occur. A value greater than the default value can be used to fix the accuracy issues. The minimum value of this parameter is `0.001` and maximum value is `1000`. The following picture shows the usage of `-and_area_size` and `-excluded_area_size` parameters: `-fill`	Runs the signoff metal fill flow to generate hierarchical metal fills database.
`-fill_cell cell_name`	Specifies metal fill cell name.
`-fill_layer {layers_list}`	Fills only a set of specified metal and/or via metal layers. Following is the usage example of this parameter: `add_metal_fill_signoff -fill_layer {M1 VIA12 M2}`
`-fill_output_mode {gdsii | oasis}`	Generates metal fill database in the `gdsii` or `oasis` format. The default format is `gdsii`.
`-flatten`	Flattens metal fills database and loads into the software.
`-incremental`	Runs incremental metal fill post ECO.
`-layer_map_file streamOut_map_file`	Specifies the `streamOut` metal layer map file.
`-license_timeout`	Specifies the time (in seconds) to wait if the software license is not immediately available while initiating the run. The default value of this parameter is 300 seconds.
`-license_distributed_continue`	Initiates the software run using fewer available CPUs based on the number of licenses obtained. Use this parameter in case PVS cannot obtain the required number of licenses in the multiprocessing mode.
`-lib_name library_name`	Specifies the library name.

`-lsf`	Distributes the processing of the software run to different CPUs using LSF. While using this parameter, the `DP_LSF_RESOURCE` environment variable must be set to specify the LSF resource string, as shown below: `setenv DP_LSF_RESOURCE 'resource string for slave processes'` Additionally, the `-tmp_working_dir` *`work_dir`* should be used to specify local working directory for the LSF run.
`-master_lsf`	Submits the master PVS process on LSF. While using this parameter, the `MASTER_LSF_RESOURCE` environment variable should be set to specify LSF resource string, as shown below: `setenv MASTER_LSF_RESOURCE 'resource string for master process'`
`-merge` *`list_of_external_stream_files`*	
	Merges the external stream files.
`-merge_fill_edits`	Updates metal fill database with the metal fill edits executed in the software.
`-min_density percent1` *`layer_list1`*	Specifies percentage value of the minimum metal density. The default value of this parameter is `0` for each metal layer. This parameter trims metal fill below when the specified window density percentage could cause any metal density violations. This parameter is controlled by the `-window_size` and `-window_step` values, as shown in the below example: `add_metal_fill_signoff -min_density {20 {M1 M2} 35 M3}`
`-net net_names`	Specifies a list of critical net names or pointers, which are surrounded by the metal fill area.
`-no_structure_name`	Merges the GDSII file without loading the design.
`-no_via_fills`	Specifies not to generate metal via fills.
`-offset {`*`x y`*`}`	Defines the offset displacement to be applied.
`-output_macros`	Displays the LEF abstract information about macros, such as LEF pin geometries and obstructions.
`-report_file`	Displays the cell name, which is changed to file.
`-rule_file` *`rule_file_name`*	Specifies metal fill rule file name.
`-skip_map_check`	Ignores the cross-referencing of the `-layer_map_file` parameter and the Innovus layer names.
`-slack_threshold` *`float`*	Trims any critical net(s) in the timing aware flow with the slack lesser than the specified value (in nanoseconds). Following is the usage example of this parameter: `add_metal_fill_signoff -slack_threshold 0.1`
`-spacing` *`float`*	Trims metal fill on the specified metal layer around critical net routes. **Note:** The `-spacing` and `-trim_effort` parameters are mutually exclusive.
`-spacing_above` *`float`*	Trims metal fill on above the specified metal layer around critical net routes.
`-spacing_below` *`float`*	Trims metal fill on below the specified metal layer around critical net routes.
`-stripes` *`number`*	Specifies the number of stripes that divide the design. The default is value of this parameter is `1`.
`-structure_name` *`structureName`*	Specifies the superstructure that consists of all the geometries that the map file writes out.
`-tech_lib` *`string`*	Specifies the PVS technology library for `-fill` and `-incremental`.
`-tech_set` *`string`*	Specifies the PVS technology set for `-fill` and `-incremental`.

`-tech` *`string`*	Specifies the PVS technology to use for identifying the sign-off rules file. **Note:** You can use this parameter with either the `-rule_file` or `-tech` parameter.
`-tmp_working_dir` *`work_dir`*	Specifies the working directory for the background or LSF run.
`-trim`	Trims metal fills in the metal fills database for timing. This parameter is density-related.
`-trim_effort {high | med | low}`	Trims metal fill area with the high, medium, or low effort around the critical net routes. This parameter also helps in determining the blockage size for trimming metal fill. Following are the parameter values: • `high`: Presents area of two times of the layer pitch value. • `med`: : Presents area of 1.5 times of the layer pitch value. • `low`: : Presents the same area of the layer pitch value. Following is the usage example of this parameter: `add_metal_fill_signoff -trim_effort med` Here, if the M2 layer pitch is `0.8 um`, M2 fills will be trimmed around selected nets within the distance of `1.2 um`. **Note:** The `-trim_effort` and `-spacing` parameters are mutually exclusive.
`-trim_layer {`*`layers_list`*`}`	Trims only the set of specified layers. Following is the usage example of this parameter: `add_metal_fill_signoff -trim_layer {M1 M2}`

`-trim_metal_fill` *spacing_file*	Specifies the spacing file containing information related to trim metal fill in the incremental run. Spacing file contains spacing values between the routed metal, non-OPC and OPC metal fill layers. Metal fills are trimmed around ECO changes according to the specified spacing values, post which incremental run generates fill data in the trimmed area. Following is the format of the spacing file:
	`#layer f-a o-a`
	`M1 0.60 0.16`
	`M2 0.60 0.16`
	`M3 0.60 0.16`
	`M4 0.60 0.16`
	`M5 0.60 0.16`
	`M6 0.60 NA`
	Here:
	• `Mx`: Specifies the LEF layer name.
	• `f-a`: Specifies the metal fill active spacing.
	• `o-a`: Specifies the is OPC fill active spacing.
	• `NA`: Refers to no trimming.
	The following picture shows the usage of `-trim_metal_fill` parameter:
	 	
	The spacing file for the above example has the following settings for the M2 layer:
	`M2 1.5 0.6`
	In this example, the non-OPC metal fills, which are 1.5 um or closer to the modified wire, are trimmed. Additionally, the metal fill data is regenerated in the trimmed area.

`-union_density {`*percent1 layer_list1* `[{`*percent2 layer_list2*`}]...}`	
	Specifies percentage value of the union metal density. The default value of this parameter is `0` for each metal layer. Union density for a layer is the sum of metal density of the current layer, layer below, and layer above the specified windows. Metal fills are trimmed not to violate the `-union_density` settings for the current metal. Following is the usage example of this parameter: `add_metal_fill_signoff -union_density {20 M1}`
`-uniquify_cell_names`	Creates unique cell names, if there are name collisions while using the `-merge` parameter.
`-units {100 | 200 | 400 | 800 | 1000 | 2000 | 4000 | 8000 | 10000 | 20000}`	
	Specifies the resolution of the input/output file. The default value of this parameter is obtained from software database.
`-view_fills`	Loads the existing HMF database into the software to view the metal fills.

`-window_size float`	Specifies the size of the window, which the metal trim uses to examine the metal density. The default value of this parameter is `100`. Following is the usage example of this parameter: `add_metal_fill_signoff -window_size 50`
`-window_step float`	Specifies the stepping distance between two successive positions of the window for a stepped-window trim density check. The default value of this parameter is `50`. Following is the usage example of this parameter: `add_metal_fill_signoff -window_step 25`

Examples

- The following command runs the background LSF job by setting the resource master and slave LSF resource string before launching the software:
  ```
  setenv MASTER_LSF_RESOURCE'-q lnx64 -W "40:00" -n 4 -P "PVS15.23:PE:test"'
  setenv DP_LSF_RESOURCE'-q lnx64 -W "15:00" -P "PVS15.23:PE:test"'
  ```
- The following commands launch a background LSF job in both the master and slave on LSF:
  ```
  Puts "Launching background lsf job; both master and slave on lsf"
  set Bgdir "./LSF_RUN"
  add_metal_fill_signoff -fill -background_mode -master_lsf -lsf -tmp_working_dir $Bgdir
  ```
  It starts HMF generation in the working directory. Post that, you can choose to continue working in the software or exit from the session. The software license is released, as shown below:

  ```
  ################################################################################
  ###### Running add_metal_fill_signoff
  ################################################################################
  ###### Mode '-fill background mode' on cell 'tdsp'
  ################################################################################

  ######  FILL DB Preparing design data
  Ending "FILL DB Preparing design data" (total cpu=0:00:00.2, real=0:00:00.0, peak res=550.0M, current mem=550.0M)

  ######  FILL DB Submitting -fill background run on LSF
  Job <724739> is submitted to queue <lnx64>.
  Ending "FILL DB Submitting -fill background run on LSF" (total cpu=0:00:00.0, real=0:00:01.0, peak res=550.0M, current mem=532.5M)
  Working directory: "/lan/dfm/pvsqa_test01/PVS/HMF_TESTING/FILL_RUN"

  ################################################################################
  Ending "FILL DB add_metal_fill_signoff" (total cpu=0:00:00.3, real=0:00:01.0, peak res=550.0M, current mem=532.5M)
  ```
- The following command checks the status of the background job:
  ```
  add_metal_fill_signoff -check_background_run $Bgdir
  ```
  Following is the output of the above command:

Run is in progress:

```
#################################################################################
###### Running add_metal_fill_signoff
#################################################################################
BG run information:
 fill_cell:       'tdsp'
 fill_layer:      {M1 M2 M3 M4 M5 M6}
 output_format:   'gdsii'
 LSF job queue:   'lnx64'
 LSF job id:      '724739'

Checking status of BG run:
 run status:      IN PROGRESS
 operation group: 194/1815
 output files:    NOT READY
```

Run completed:

```
#################################################################################
###### Running add_metal_fill_signoff
#################################################################################
BG run information:
 fill_cell:       'tdsp'
 fill_layer:      {M1 M2 M3 M4 M5 M6}
 output_format:   'gdsii'
 LSF job queue:   'lnx64'
 LSF job id:      '724739'

Checking status of BG run:
 run status:      COMPLETED
 operation group: 1815/1815
 output files:    READY
#################################################################################
Ending "FILL DB add_metal_fill_signoff" (total cpu=0:00:00.0, real=0:00:01.0, peak res=533.3M, current mem=533.2M)
```

- The following command restores initial software database link and generates HMF:

```
add_metal_fill_signoff -load_fill_db $Bgdir
```

- The following command kills the background run that is in progress:

```
add_metal_fill_signoff -kill_bg_run $Bgdir
```

  Following is the output of the above command:

```
#################################################################################
###### Running add_metal_fill_signoff
#################################################################################
Job <724739> is being terminated
#################################################################################
Ending "FILL DB add_metal_fill_signoff" (total cpu=0:00:00.0, real=0:00:01.0, peak res=533.6M, current mem=533.6M)
```

- The following command presents an LSF example where master is not on LSF:

```
setenv MASTER_LSF_RESOURCE '-q lnx64 -W "40:00" -n 4 -P "PVS:15.23:PE:test"'
setenv DP_LSF_RESOURCE '-q lnx64 -W "15:00" -P "PVS:15.23:PE:test"'
add_metal_fill_signoff -fill -background_mode -lsf -tmp_working_dir LSF_RUN1
```

  Following is the output of the above command:

```

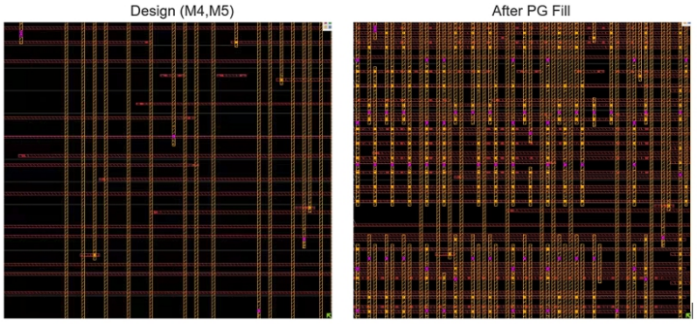
Runs Pegasus PG Fill with default settings and any specified options. This command adds only the floating Track-based Fill (TBF).

Pegasus PG Fill

Pegasus PG Fill is an in-design software used to insert fills connected to Power and/or Ground. PG Fill is generally used for power integrity. These fills are available on the design routing tracks and follow the same DRC rules as design. Pegasus PG Fill:

- Improves IR drop in worst scenarios
- Ensures no negative slack after PG Fill insertion
- Keeps power increase under control

The following example design of the M4 and M5 layers in which fills are inserted post Pegasus PG Fill processing:



Parameters

`-help`	Outputs a brief description that includes the type and default information for each `add_pg_fill` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man add_pg_fill`
`-attach_instance_name` *attr_num*	Specifies the instance name to be attached. *Data_type*: int, optional
`-attach_net_name` *attr_num*	Specifies the net name to be attached. *Data_type*: int, optional
`-attach_net_prop {{`*prop_name attr_num*`} ... }`	Specifies the net property to be attached. *Data_type*: string, optional
`-bsub` *resource_string*	Runs the fill process through BSUB with the specified resource string. *Data_type*: string, optional
`-core_license` *license_combination*	Sets an exact combination of licenses to be used. *Data_type*: string, optional
`-die_area_as_boundary`	Writes the die area as a polygon or a boundary. When this parameter is not specified, the `write_stream` command writes the die area as a rectangle or a box. *Data_type*: bool, optional
`-distributed` *n*	Runs Pegasus in a multi-processor mode. The *n* variable specified with this parameter presents the number of processors. By default, this value is taken from the Innovus multi-CPU usage. *Data_type*: int, optional
`-distributed_timeout` *seconds*	Specifies the wait time for the DP processes to start. *Data_type*: int, optional
`-extra_options` *options*	Specifies the additional run options. *Data_type*: string, optional
`-fix_post_process_drc`	Runs the fill clean-up utility to resolve the DRC issues, which appear post the fill steps. *Data_type*: bool, optional
`-format {stream oasis}`	Specifies the format of the flow. *Data_type*: enum, optional
`-incremental`	Runs Pegasus incremental PG fill. **Note**: This parameter is used with the `-initial_working_dir` and `-working_dir` parameters. *Data_type*: bool, optional
`-initial_working_dir` *string* `-initial_working_dir` *string*	Specifies the working directory with taking information from the previous run. *Data_type*: string, optional
`-layer_map_file` *streamOut_map_file*	Specifies the name of the `write_stream` layer map file. *Data_type*: string, optional
`-lib_name` *library_name*	Specifies the library name. *Data_type*: string, optional
`-license_distributed_continue`	Specifies that if the required number of licenses cannot be obtained in the DP processes, the software continues with fewer CPUs based on the number of licenses obtained. *Data_type*: bool, optional
`-license_timeout` *seconds*	Specifies the wait time (in seconds) to run the software, if a license is not immediately available. *Default*: `300` *Data_type*: int, optional

`-merge` *list_of_external_stream_files*	Specifies the list of external stream files. *Data_type*: string, optional
`-nc` *resource_string*	Runs the fill process through NC with the specified resource string. *Data_type*: string, optional
`-no_structure_name`	Merges the GDSII file without loading the software database. **Note:** This parameter is used with the `-merge` parameter. *Data_type*: bool, optional
`-offset {`*x y*`}`	Specifies the location (in microns) of the design in the GDSII output file. *Data_type*: point, optional
`-output_macros`	Displays the LEF abstract information, such as LEF pin geometries and obstructions for macros. *Data_type*: bool, optional
`-pg_fill_config_file` *file_name*	Specifies the configuration file for the PG fill flow. Any overrides to the default behavior are written in this file. *Data_type*: string, optional
`-pg_hookup_flow {ALL | PG_ONLY | FLOAT_ONLY}`	Specifies the type of fills to be generated. *Default*: `PG_ONLY` *Data_type*: enum, optional
`-qsub` *resource_string*	Runs the fill process through QSUB with the specified resource string. *Data_type*: string, optional
`-report_file`	Specifies the cell name to be changed to the file. *Data_type*: bool, optional
`-stripes` *number*	Specifies the number of stripes that divide the design. *Default*: 1 *Data_type*: int, optional
`-structure_name` *structureName*	Specifies the superstructure that consists of all the geometries that the map file writes out. *Data_type*: string, optional
`-turbo` *jobs_num*	Speeds up the fill process by running the specified number of parallel fill jobs. *Data_type*: int, optional
`-uniquify_cell_names`	Creates unique cell names if there are name collisions, when the software merges files. *Data_type*: bool, optional
`-units {100 | 200 | 400 | 800 | 1000 | 2000 | 4000 | 8000 | 10000 | 20000}`	
	Specifies the resolution for values in the GDSII/OASIS file. *Data_type*: enum, optional
`-working_dir` *working_directory*	Specifies the working directory. *Data_type*: string, optional
`-xor_via_layers`	Switches on comparison of via during incremental fill. **Note:** Via-XOR consumes more time on large databases. *Data_type*: bool, optional

```

Adds the Track-Based Fill (TBF) flow to the metal fill layers. Pegasus TBF flow is designed to reuse empty tracks for metal filling. It provides a better fill rate than the signoff fill, because the TBF fills are more homogeneous to the design. The TBF solution is timing aware and DRC-neutral. The flow can be run at any stage of the design and does not require any manual input, since all the required information is fetched from the Innovus database.

The TBF flow also allows altering the default TBF behavior through the various configuration parameters. It supports incremental mode to update TBF fills during the ECO cycles. For better performance and scalability, the TBF flow supports partitioning through the `-turbo` parameter, and job distribution through the `-bsub`, `-qsub`, and `-nc` parameters.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `add_tra` For a detailed description of the command and all its parameters, use the `man` command: `man add_track_fill`
`-attach_instance_name attr_num`	Specifies the instance name to be attached. *Data_type*: int, optional
`-attach_net_name attr_num`	Specifies the net name to be attached. *Data_type*: int, optional
`-attach_net_prop {{prop_name attr_num} ... }`	Specifies the net property to be attached. *Data_type*: string, optional
`-bsub resource_string`	Runs the fill process through BSUB with the specified resource string. *Data_type*: string, optional
`-core_license license_combination`	Sets an exact combination of licenses to be used. *Data_type*: string, optional

`-die_area_as_boundary`	Writes the die area as a polygon or a boundary. When this parameter is not specified, the *Data_type*: bool, optional
`-distributed n`	Runs Pegasus in a multi-processor mode. The `n` variable specified with this parameter pr Innovus multi-CPU usage. *Data_type*: int, optional
`-distributed_timeout seconds`	Specifies the wait time for the DP processes to start. *Data_type*: int, optional
`-extra_options options`	Specifies the additional run options. *Data_type*: string, optional
`-fix_post_process_drc`	Runs the fill clean-up utility to resolve the DRC issues, which appear post the fill steps. *Data_type*: bool, optional
`-format {stream oasis}`	Specifies the format of the flow. *Data_type*: enum, optional
`-incremental`	Runs Pegasus incremental track fill. **Note**: This parameter is used with the `-initial_working_dir` and `-working_dir` paramete *Data_type*: bool, optional
`-initial_working_dir string-initial_working_dir string`	Specifies the working directory with taking information from the previous run. *Data_type*: string, optional
`-layer_map_file streamOut_map_file`	Specifies the name of the `write_stream` layer map file. *Data_type*: string, optional
`-lib_name library_name`	Specifies the library name. *Data_type*: string, optional
`-license_distributed_continue`	Specifies that if the required number of licenses cannot be obtained in the DP processes, licenses obtained. *Data_type*: bool, optional
`-license_timeout seconds`	Specifies the wait time (in seconds) to run the software, if a license is not immediately ava *Default*: `300` *Data_type*: int, optional
`-merge list_of_external_stream_files`	Specifies the list of external stream files. *Data_type*: string, optional
`-nc resource_string`	Runs the fill process through NC with the specified resource string. *Data_type*: string, optional
`-no_structure_name`	Merges the GDSII file without loading the software database. **Note:** This parameter is used with the `-merge` parameter. *Data_type*: bool, optional
`-offset {x y}`	Specifies the location (in microns) of the design in the GDSII output file. *Data_type*: point, optional
`-output_macros`	Displays the LEF abstract information, such as LEF pin geometries and obstructions for m *Data_type*: bool, optional
`-qsub resource_string`	Runs the fill process through QSUB with the specified resource string. *Data_type*: string, optional

`-report_file`	Specifies the cell name to be changed to the file. *Data_type*: bool, optional
`-stripes` *number*	Specifies the number of stripes that divide the design. *Default*: 1 *Data_type*: int, optional
`-structure_name` *structureName*	Specifies the superstructure that consists of all the geometries that the map file writes out. *Data_type*: string, optional
`-track_fill_config_file` *file_name*	Specifies the configuration file for track fill flow.
`-turbo` *jobs_num*	Speeds up the fill process by running the specified number of parallel fill jobs. *Data_type*: int, optional
`-uniquify_cell_names`	Creates unique cell names if there are name collisions, when the software merges files. *Data_type*: bool, optional
`-units {100 | 200 | 400 | 800 | 1000 | 2000 | 4000 | 8000 | 10000 | 20000}`	
	Specifies the resolution for values in the GDSII/OASIS file. *Data_type*: enum, optional
`-working_dir` *working_directory*	Specifies the working directory. *Data_type*: string, optional

add_via_fill

```
add_via_fill
[-help]
[-area x1 y1 x2 y2]
[-layers [cut_layer_number | {list_of_cut_layer_numbers}]]
[-include_vias vias]
[-modes {all | floatingOnly | connectedOnly | {floating connectToPG connectBetweenFill}}]
[-snap]
```

Uses the values specified by the `set_metal_fill` command to determine sizes of vias to create. Via fill is inserted to get uniform cut density. Only vias that meet Minimum Area Rule requirements are used. `add_via_fill` also uses values from `set_via_fill` for the window size, step, and density values.

For information, see `set_metal_fill` and `set_via_fill`.

Note: Default values from `set_metal_fill` for `min_width` and `min_length` are biased towards the needs of `add_metal_fill` use and should be overridden with values that are more useful for via generation.

Add via fill in the following areas immediately before adding metal fill:

- Where metal fill shapes would intersect with power or ground nets on consecutive layers if no via fill was added.
- Where metal fill shapes on consecutive layers would intersect if no via fill was added.

To reduce the need for via fill, insert multiple-cut vias with the NanoRoute router. For information, see route Category Attributes.

Adding Via Fill in Multi-Threading Mode

You can add via fill in multi-threading mode by using the `set_multi_cpu_usage` command before adding the via fill.

Via Fill supports the new `set_multi_cpu_usage` command use model. For more information, see the following documents:

- Multiple-CPU Processing Commands chapter of the *Innovus Text Command Reference*.
- Accelerating the Design Process By Using Multiple-CPU Processing chapter of the *Innovus User Guide*.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `add_via_fill` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man add_via_fill`
`-area x1 y1 x2 y2`	Specifies a set of coordinates within which to add via fill. For example, specify `-area 0 0 100 100`. *Default:* If you do not specify this parameter, adds via fill to the entire design area. *Data_type*: rect, optional

`-include_vias vias`	Specifies a list of vias (VIA in LEF) to be included or via rules (VIARULE GENERATE in LEF) to be used or a combination of the two. Separate the arguments with spaces. You can specify both via names and via rules.
	• The following example shows how to specify a list of via names:
	`-include_vias {VIA12 VIA23}`
	• The following example shows how to specify a list of via rules:
	`-include_vias {via1Array via2Array}`
	• The following example shows how to specify both via names and via rules:
	`-include_vias {VIA12 VIA23 via1Array via2Array}`
	Note: Non-default rule (NDR) vias can also be specified with `-include_vias`.
	Data_type: string, optional

`-layers {`*`cut_layer_number`*` | {`*`list_of_cut_layer_numbers`*`}}`	Specifies the cut layers for adding via fill. If you specify more than one layer, separate each layer with a space and enclose the list in braces or double quotation marks. To specify *cut12*, *cut23*, and *cut34*, type one of the following commands:
	`add_via_fill -layers "VIA12 VIA23 VIA34"`
	`add_via_fill -layers {VIA12 VIA23 VIA34}`
	Default: If you do not specify this parameter, adds via fill to all cut layers.
	Data_type: string, optional

`-modes {all | floatingOnly | connectedOnly | {floating connectToPG connectBetweenFill}}`	
	Specifies the connection mode for via fill. Via fill can be connected to power or ground nets (tied off), or connected between floating metal fill, or unconnected to metal fill (floating). Via fill cannot be connected to signal nets. Specify one or more of the following parameters, as required: • `all`: Enables addition of unconnected and connectToPG via fill. • `floatingOnly`: Adds unconnected via fill only. The option will be made obsolete in a future release. • `floating`: Adds unconnected via fill. It is equivalent to `-modes floatingOnly`, which will be made obsolete in a future release. • `connectToPG`: Adds connected via fill to PG. It is equivalent to `-modes connectOnly`, which will be made obsolete in a future release. • `connectBetweenFill`: Adds connected via fill between floating metal fill. • `connectedOnly`: Adds connected via fill to PG only. The option will be made obsolete in a future release. *Default:* `all` *Data_type*: string, optional
`-snap`	Snaps edges of via fill shapes and centers of cuts to a user-defined snap grid that is a multiple of the manufacturing grid. When via shapes are snapped to this grid, the edges and centers of the via shapes lie on the grid. If a grid is not specified, the software snaps the shapes to the manufacturing grid. You can define a grid using the `set_snap_grid` command. For more information, see `set_snap_grid`. *Data_type*: bool, optional

Example

The following set of command inserts unconnected via fill and connected via fill between floating metal fill in layers `VIA1` to `VIA8` and `RV` based on existing `set_metal_fill` and `set_via_fill` settings:

```
set_via_fill -layers {VIA1 VIA2 VIA3 VIA4 VIA5 VIA6 VIA7} /
           -window_size 100 100 -window_step 50 50 -min_density 0.01 /
           -max_density 30 -preferred_density 1

set_via_fill -layers {VIA8 RV} -window_size 100 100 -window_step 50 50 /
           -min_density 0.25 -max_density 30 -preferred_density 10

add_via_fill -layers {VIA1 VIA2 VIA3 VIA4 VIA5 VIA6 VIA7 VIA8 RV} /
           -modes {floating connectBetweenFill}
```

Related Information

The following sections in the Optimizing Metal Density chapter of the *Innovus User Guide*:

- Overview
- Adding Via Fill

delete_metal_fill

```
delete_metal_fill
[-help]
[-area {x1 y1 x2 y2}]
[-layers {layer_number | {list_of_layer_numbers} } ]
[-modes {all | connected_only | floating_only} ]
[-shapes {[FILLWIRE] [FILLWIREOPC}] ]
```

Removes metal and via fill in order to start over with the metal fill process. If you run this command without specifying parameters, it deletes all the metal and via fill in the design.

Note: Deleting via fill with this command might create open violations.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `delete_metal_fill` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man delete_metal_fill`
`-area {x1 y1 x2 y2}`	Specifies a set of coordinates within which to delete metal and via fill. For example, specify `-area {0 0 100 100}`. *Default:* If you do not specify this parameter, deletes fill from the entire design area. *Data_type*: string, optional

`-layers {layer_number | {list_of_layer_numbers}}`	Specifies the layers from which to remove metal and via fill. If you specify more than one layer, separate each layer with a space and enclose the list in braces or double quotation marks. This parameter accepts metal layers, cut layers, or a combination.
	• If you specify a cut layer, the command removes vias that contain that cut layer only. For example:
	`delete_metal_fill -layers {VIA2 VIA3}`
	• If you specify a metal layer, metal fill shapes on that layer and vias that contain that layer are removed. For example:
	`delete_metal_fill -layers {metal2 metal3}`
	Default: If you do not specify this parameter, removes metal and via fill from all layers.
	Data_type: string, optional

`-modes {all | connected_only | floating_only}`	Specifies whether the command removes only connected fill, only floating fill, or all fill.
	Default: `all`
	Removes connected and floating metal and via fill.
	`connected_only`
	Removes only connected metal and via fill.
	`floating_only`
	Removes only floating metal and via fill.
	Data_type: enum, optional

`-shapes {[FILLWIRE] [FILLWIREOPC]}`	Specifies whether the software removes `FILLWIRE` or `FILLWIREOPC` shapes or both kinds of shapes. *Default:* `FILLWIRE FILLWIREOPC` *Data_type*: string, optional

Example

- The following command removes via fill from cut layers `VIA12`, `VIA23`, `VIA34`, `VIA45`, `VIA56`:
  ```
  delete_metal_fill -layers {VIA12 VIA23 VIA34 VIA45 VIA56}
  ```
- The following command removes only floating `FILLWIREOPC` via fill from layer metal2 and vias containing that layer:
  ```
  delete_metal_fill -area {0 0 100 100} -layers metal2 -modes floating_only /
  -shapes FILLWIREOPC
  ```

Related Information

The Optimizing Metal Density chapter of the *Innovus User Guide*:

fix_open_fill

```
fix_open_fill
[-help]
[-nets list_of_net_names]
[-area x1 y1 x2 y2]
[-remove]
```

Fixes any isolated power/ground (PG) fills. Isolated PG fills are FILL shapes attached to a power-ground (PG) net that are not connected to at least one non-FILL shape.

In designs with floating fill, the `trim_metal_fill` command is used after routing signal nets to trim fill that causes DRC violations. In designs with tied fill, i.e. metal or via fill connected to special nets, `trim_metal_fill` causes isolated fills to appear. In such cases, use the `fix_open_fill` command after `trim_metal_fill` to either change the isolated fills to floating fills or to remove them from the design.

If you choose to remove the isolated fills with `fix_open_fill -remove`, you can then run incremental `add_metal_fill` to see if any of those islands can be tied, either to the same or to another PG rail.

If you run the `fix_open_fill` command without specifying any parameters, it changes all isolated fills in the design to floating.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `fix_open_fill` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man fix_open_fill`
`-area x1 y1 x2 y2`	Specifies a set of coordinates within which to fix open fill issues. *Default:* If you do not specify this parameter, fixes open fills in the entire design area. *Data_type*: rect, optional
`-nets list_of_net_names`	Specifies a list of special net names to fix. *Data_type*: string, optional
`-remove`	Specifies whether to remove the open fills. If this option is not specified, `fix_open_fill` changes isolated PG fills to floating fills. *Data_type*: bool, optional

Example

The following command removes all isolated PG fills from the design:

```
fix_open_fill -remove
```

- Trimming Metal Fill

get_metal_fill_spacing_table

```
get_metal_fill_spacing_table
[-help]
[-layers layer_name_list]
[-fill_to_active]
[-fill_to_fill]
[-fill_to_opc]
[-opc_to_active]
[-opc_to_opc]
```

Prints the spacing table for specified or for all layers. If no option is specified, prints all spacing tables for all layers.

To specify spacing table based on existing metal fill width, use the `set_metal_fill_spacing_table` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `get_metal_fill_spacing_table` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man get_metal_fill_spacing_table`
`-fill_to_active`	Prints the fill to active spacing table for specified or all layers. *Data_type*: bool, optional
`-fill_to_fill`	Prints the fill to fill spacing table for specified or all layers. *Data_type*: bool, optional
`-fill_to_opc`	Prints the fill to OPC spacing table for specified or all layers. *Data_type*: bool, optional
`-layers` *layer_name_list*	Prints spacing table for specified layers. *Default*: Prints spacing table for all layers *Data_type*: string, optional
`-opc_to_active`	Prints the OPC to active spacing table for specified or all layers. *Data_type*: bool, optional
`-opc_to_opc`	Prints the OPC to OPC spacing table for specified or all layers. *Data_type*: bool, optional

Example

- The following command prints the fill to active spacing table for layer `METAL2`:

  ```
  get_metal_fill_spacing_table -layers 2 -fill_to_active
  ```

  The output is as follows:

  ```
  Layer 2,
  fill_to_active {0.08 0.27}{0.14 0.36}{0.32 0.63}
  ```

- The following command prints all spacing tables for all layers:

  ```
  get_metal_fill_spacing_table
  ```

  The output is as follows:

  ```
  Layer metal2,
  fill_to_active {0.08 0.27}{0.14 0.36}{0.32 0.63}
  Layer metal3,
  fill_to_fill {0.08 0.2}{0.14 0.3}{0.32 0.6}
  Layer metal3,
  opc_to_active {0.05 0.08}{0.08 0.1}{0.1 0.12}
  ```

get_pg_fill_config

```
get_pg_fill_config
[-help]
[-attach_instance_name]
[-attach_net_name]
[-attach_net_prop]
[-core_license]
[-die_area_as_boundary]
[-distributed]
[-distributed_dir]
[-distributed_timeout]
[-extra_options]
[-format]
[-layer_map_file]
[-license_distributed_continue]
[-license_timeout]
[-merge]
[-no_structure_name]
[-offset]
[-output_macros]
[-pg_fill_config_file]
[-pg_hookup_flow]
[-report_file]
[-stripes]
[-structure_name]
[-uniquify_cell_names]
[-units]
[-working_dir]
```

Prints the parameters of the `add_pg_fill` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `get_pg_fill_config` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man get_pg_fill_config`
`-attach_instance_name`	Prints the instance name to be attached. *Data_type*: bool, optional
`-attach_net_name`	Prints the net name to be attached. *Data_type*: bool, optional
`-attach_net_prop`	Prints the net property to be attached. *Data_type*: bool, optional
`-core_license`	Prints an exact combination of licenses to be used. *Data_type*: bool, optional
`-die_area_as_boundary`	Prints the die area as a polygon or a boundary. *Data_type*: bool, optional
`-distributed`	Runs Pegasus in a multi-processor mode. The *n* variable specified with this parameter presents the number of processors. By default, this value is taken from the Innovus multi-CPU usage. *Data_type*: bool, optional
`-distributed_dir`	Prints the name of the distributed directory. *Data_type*: bool, optional

`-distributed_timeout`	Prints the wait time for the distributed processes to start. *Data_type*: bool, optional
`-extra_options`	Prints the additional run options. *Data_type*: bool, optional
`-format`	Prints the format of the flow. *Data_type*: bool, optional
`-layer_map_file`	Prints the name of the `write_stream` layer map file. *Data_type*: bool, optional
`-lib_name`	Prints the library name. *Data_type*: bool, optional
`-license_distributed_continue`	Specifies that if the required number of licenses cannot be obtained in the distributed processes, the software continues with fewer CPUs based on the number of licenses obtained. *Data_type*: bool, optional
`-license_timeout`	Prints the wait time (in seconds) to run the software, if a license is not immediately available. *Default*: `300` *Data_type*: bool, optional
`-merge`	Prints the list of external stream files. *Data_type*: bool, optional
`-no_structure_name`	Merges the GDSII file without loading the software database. **Note:** This parameter is used with the `-merge` parameter. *Data_type*: bool, optional
`-offset`	Prints the location (in microns) of the design in the GDSII output file. *Data_type*: bool, optional
`-output_macros`	Prints the LEF abstract information, such as LEF pin geometries and obstructions for macros. *Data_type*: bool, optional
`-pg_fill_config_file`	Prints the configuration file for the PG fill flow. Any overrides to the default behavior are written in this file. *Data_type*: bool, optional
`-pg_hookup_flow`	Prints the type of fills to be generated. *Default*: `PG_ONLY` *Data_type*: bool, optional
`-report_file`	Prints the cell name to be changed to the file. *Data_type*: bool, optional
`-stripes`	Prints the number of stripes that divide the design. *Default*: 1 *Data_type*: bool, optional
`-structure_name`	Prints the superstructure that consists of all the geometries that the map file writes out. *Data_type*: bool, optional
`-uniquify_cell_names`	Creates unique cell names if there are name collisions, when the software merges files. *Data_type*: bool, optional
`-units`	Prints the resolution for values in the GDSII/OASIS file. *Data_type*: bool, optional

`-working_dir` *working_directory*	Prints the working directory. *Data_type*: bool, optional

get_track_fill_config

```
get_track_fill_config
[-help]
[-attach_instance_name]
[-attach_net_name]
[-attach_net_prop]
[-core_license]
[-die_area_as_boundary]
[-distributed]
[-distributed_dir]
[-distributed_timeout]
[-extra_options]
[-format]
[-layer_map_file]
[-license_distributed_continue]
[-license_timeout]
[-merge]
[-no_structure_name]
[-offset]
[-output_macros]
[-report_file]
[-stripes]
[-structure_name]
[-track_fill_config_file]
[-uniquify_cell_names]
[-units]
[-working_dir]
```

Prints the parameters of the `add_track_fill` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `get_track_fill_config` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man get_track_fill_config`
`-attach_instance_name`	Prints the instance name to be attached. *Data_type*: bool, optional
`-attach_net_name`	Prints the net name to be attached. *Data_type*: bool, optional
`-attach_net_prop`	Prints the net property to be attached. *Data_type*: bool, optional
`-core_license`	Prints an exact combination of licenses to be used. *Data_type*: bool, optional
`-die_area_as_boundary`	Prints the die area as a polygon or a boundary. *Data_type*: bool, optional
`-distributed`	Runs Pegasus in a multi-processor mode. The *n* variable specified with this parameter presents the number of processors. By default, this value is taken from the Innovus multi-CPU usage. *Data_type*: bool, optional
`-distributed_dir`	Prints the name of the distributed directory. *Data_type*: bool, optional
`-distributed_timeout`	Prints the wait time for the distributed processes to start. *Data_type*: bool, optional

`-extra_options`	Prints the additional run options. *Data_type*: bool, optional
`-format`	Prints the format of the flow. *Data_type*: bool, optional
`-layer_map_file`	Prints the name of the `write_stream` layer map file. *Data_type*: bool, optional
`-lib_name`	Prints the library name. *Data_type*: bool, optional
`-license_distributed_continue`	Specifies that if the required number of licenses cannot be obtained in the distributed processes, the software continues with fewer CPUs based on the number of licenses obtained. *Data_type*: bool, optional
`-license_timeout`	Prints the wait time (in seconds) to run the software, if a license is not immediately available. *Default*: `300` *Data_type*: bool, optional
`-merge`	Prints the list of external stream files. *Data_type*: bool, optional
`-no_structure_name`	Merges the GDSII file without loading the software database. **Note:** This parameter is used with the `-merge` parameter. *Data_type*: bool, optional
`-offset`	Prints the location (in microns) of the design in the GDSII output file. *Data_type*: bool, optional
`-output_macros`	Prints the LEF abstract information, such as LEF pin geometries and obstructions for macros. *Data_type*: bool, optional
`-report_file`	Prints the cell name to be changed to the file. *Data_type*: bool, optional
`-stripes`	Prints the number of stripes that divide the design. *Default*: 1 *Data_type*: bool, optional
`-structure_name`	Prints the superstructure that consists of all the geometries that the map file writes out. *Data_type*: bool, optional
`-track_fill_config_file` *file_name*	Specifies the configuration file for track fill flow. *Data_type*: bool, optional
`-uniquify_cell_names`	Creates unique cell names if there are name collisions, when the software merges files. *Data_type*: bool, optional
`-units`	Prints the resolution for values in the GDSII/OASIS file. *Data_type*: bool, optional
`-working_dir` *working_directory*	Prints the working directory. *Data_type*: bool, optional

report_metal_fill

```
report_metal_fill
[-help]
[-out_file file_name]
[-fill_area]
[-fill_length]
[-mesh]
```

Generates a report on metal fill to summarize the number and area of fill shapes on a per-net and per-layer basis. Use the generated report to tune the `add_metal_fill` flow parameters to achieve the desired distribution across multiple nets and layers as well as to minimize floating fill.

Before generating a metal fill report, you should have:

- Imported the design
- Completed detailed routing
- Added metal fill

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `report_metal_fill` parameter. For a detailed description of the command and all its parameters, use: `man report_metal_fill`
`-fill_area`	Reports area information for metal fill for each layer. *Data_type*: bool, optional
`-fill_length`	Reports length information for metal fill for each layer. *Data_type*: bool, optional
`-mesh`	Reports mesh information for metal fill. *Data_type*: bool, optional
`-out_file file_name`	Writes the report to a file with the specified name. *Default*: *top_cell_name*`_metal_fill_report.rpt` *Data_type*: string, optional

Example

- The following command writes a metal fill report to the dtmf_metal_fill.rpt file.

```
report_metal_fill -out_file dtmf_metal_fill.rpt
```

The output is as follows:

```

set_metal_fill

```
set_metal_fill
[-help]
[-layer {layerNumber} | {list_of_layer_numbers}]
[-active_spacing spacing]
[-opc_active_spacing spacing]
[-border_spacing spacing]
[-decrement value]
[-diagonal_offset x y]
[-external_density percent]
[-gap_spacing spacing]
[-honor_lef_value]
[-iteration_name name]
[-max_density percent]
[-max_length length]
[-max_union_density_to_above_layer float]
[-max_width width]
[-min_density percent]
[-min_length length]
[-min_union_density_to_above_layer float]
[-min_width width]
[-opc | -regular]
[-preferred_density percent]
[-window_size xSize ySize]
[-window_step xStep yStep]
```

Specifies values for parameters that the `add_metal_fill`, `trim_metal_fill`, and `check_metal_density` commands use for metal fill size, spacing, verification, and metal density. You can also specify some of these parameters in the Layer (Routing) section of the LEF file - they are identified in the "Parameters" section below.

If you want your metal fill settings to be saved in the .init file when saving the design, you must set the write_db_include_metal_fill_rules global to `1` before saving the design. You can easily reload your settings by restoring the saved design

Note: Check the chip manufacturer's DRC manual specifications for metal fill (sometimes called dummy fill) for the correct values if they are not specified in the LEF file.

- For more information on LEF, see the LEF Syntax chapter in the *LEF/DEF Language Reference*.
- For more information on the metal fill commands, see the `add_metal_fill`, `trim_metal_fill`, and `check_metal_density` commands.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `set_metal_fill` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man set_metal_fill`
`-active_spacing spacing`	Specifies the minimum distance in microns between a metal fill shape and any other type of object in the design. For example, `set_metal_fill -active_spacing 0.6`. **Note:** The `set_metal_fill -active_spacing` settings are used for creating regular `FILLWIRE` shapes. For `FILLWIREOPC` shapes, design rules are used. LEF equivalent: `FILLACTIVESPACING` *Default:* `FILLACTIVESPACING` in the LEF file; if not specified, `0.6` for thin layers (less than 0.24), `0.8` for thick layers *Data_type*: float, optional

`-border_spacing` *spacing*	Specifies the space in microns along the design border that needs to be kept free of metal fill. This parameter is useful if you want open space next to the place and route border. If you have set border spacing, the `add_metal_fill` and `check_metal_density` commands consider the density in the specified border space area as 0.  *Data_type*: float, optional
`-decrement` *value*	Specifies the number of microns the software decreases the size of each successively smaller piece of metal fill or via fill until it reaches the size specified by the `-min_width` parameter. The software uses the maximum fill size specified unless it is impossible to fit a piece of fill into a particular area. The software then attempts to use successively smaller pieces of fill until the minimum length value is reached. This parameter allows you to control how many different sizes of metal fill or via fill can appear within the design. For example, if the value of `-max_width` is `8`, the value of `-min_width` is `4`, and the value of `-decrement` is `2`, the software can add fill shapes with widths of `8`, `6`, and `4` microns. The software tries to add fill shapes with the width specified by `-max_width`. If a shape of that width does not fit in the available space without creating a violation, the software decreases the width by the amount specified by the `-decrement` parameter. It continues to decrease the width until it reaches the width specified by the `-min_width` parameter. To increase flexibility in adding metal or via fill, decrease the value of this parameter. For example, if the value of `-decrement` is `1`, metal fill with widths of `8`, `7`, `6`, `5`, and `4` microns can be added. *Default:* `WIDTH` value specified in the `Layer` (Routing) statement of the LEF file *Data_type*: float, optional
`-diagonal_offset` *x y*	Specifies the offset for staggering metal fill. To enable this parameter, `add_metal_fill -stagger diag` must be specified. *x* Specifies the horizontal offset. *y* Specifies the vertical offset. **set_metal_fill diagonal_offset *x y***  *Data_type*: point, optional

`-external_density` *percent*	Specifies a percentage value for the external metal density for a layer when `add_metal_fill` windows lie partially outside of the die area. For each layer, a different external density value can be specified. Metal fill uses the external density value in the estimation of layer density outside of the blocks being developed. *Data_type*: float, optional
`-gap_spacing` *spacing*	Specifies the minimum distance in microns between one metal fill shape and another metal fill shape. For example, `set_metal_fill -gap_spacing 0.4`. *Default:* `0.4` for thin layers (less than 0.24 width/minWidth), `0.8` for thick layers *Data_type*: float, optional
`-honor_lef_value`	Specifies that the LEF values `MINIMUMDENSITY, MAXIMUMDENSITY, DENSITYCHECKWINDOW,` and`DENSITYCHECKSTEP` should be used to overwrite the `min_density, max_density, window_size` and `window_step` parameters of `set_metal_fill` if the values specified for these parameters are not valid. If the `-layer` option is used with `set_metal_fill`, only the specified layers are changed to the LEF values. **Note:** If one of the keywords`-MINIMUMDENSITY, MAXIMUMDENSITY, DENSITYCHECKWINDOW,` or`DENSITYCHECKSTEP-` is not defined in the LEF, an error message like the following is displayed: `ERROR: DENSITYCHECKWINDOW of MetalX is not defined in the LEF.` *Data_type*: bool, optional

`-iteration_name` *name*	Specifies a name for a set of values for `set_metal_fill` parameters that the software stores and uses during a later `add_metal_fill` run. Use `add_metal_fill -iteration_name_list` to add the metal fill using the stored set of parameters.
	The window size and step must be the same for all iterations of a specific layer. For example, the following specifications are not allowed because the values are not consistent:
	`set_metal_fill -iteration_name step1 -layer 1 \`
	`  -min_density 20 -window_size 100 100 -window_step 50 50`
	`set_metal_fill -iteration_name step1 -layer 1 \`
	`  -min_density 25 -window_size 50 50 -window_step 25 25`
	Important Specifying `set_metal_fill -iteration_name default` is the same as running `set_metal_fill` without specifying the `-iteration_name` parameter.
	`set_metal_fill -iteration_name default` is expected before `verify_metal_denstiy`. `verify_metal_denstiy` honors only `default iteration_name`. If `default iteration_name` is not set, `default` value will be used in `verify_metal_denstiy`.
	Default: "`default`"
	Data_type: string, optional

`-layer {`*layerNumber*`|`
`{`*list_of_layer_numbers*`}`
	Specifies the layers to which the parameters of the `set_metal_fill` command apply. If you specify more than one layer, separate each layer with a space and enclose the list in braces or double quotation marks.
	To specify metal layers Metal1, Metal2, and Metal3, type one of the following commands:
	`set_metal_fill -layer "METAL1 METAL2 METAL3"`
	`set_metal_fill -layer {METAL1 METAL2 METAL3}`
	Data_type: string, optional

`-max_density` *percent*	Specifies a percentage value for the maximum metal density allowed. LEF equivalent: `MAXIMUMDENSITY` *Default:* `MAXIMUMDENSITY`. If this value is not defined, the default is `80`. **Note:** This parameter only overrides a value in the LEF file if it is more restrictive than the LEF value. For example, if the value specified in the LEF file is 80, and you specify `-max_density 70`, metal fill uses 70 percent as the maximum density. *Data_type*: float, optional

`-max_length` *length*	Specifies the maximum length of the metal fill shapes, in microns. Metal fill stops at the chip boundary if the specified maximum length would cause it to extend outside the boundary. *Default:* `10.0` *Data_type*: float, optional
`-max_union_density_to_above_layer` *float*	Specifies the maximum allowed sum union density of the current layer and its top layer window. This avoids the union density violations found while verifying density results of trim metal fill flow using PVS or Pegasus. *Default:* `0` *Data_type*: float, optional
`-max_width` *width*	Specifies the maximum width of metal fill shapes, in microns. Metal fill stops at the chip boundary if the specified maximum length would cause it to extend outside the boundary. *Default:* Maximum routing width defined in the LEF file; if not specified, `2.0` LEF equivalent: `MAXWIDTH` **Note:** This parameter only overrides a value in the LEF file if it is more restrictive than the LEF value. *Data_type*: float, optional
`-min_density` *percent*	Specifies a percentage value for the minimum metal density allowed in the design. LEF equivalent: `MINIMUMDENSITY` *Default:* `MINIMUMDENSITY`. If this value is not defined, the default is `20`. **Note:** This parameter only overrides a value in the LEF file if it is more restrictive than the LEF value. For example, if the value specified in the LEF file is 20, and you specify `-min_density 25`, metal fill uses 25 percent as the minimum density. *Data_type*: float, optional
`-min_length` *length*	Specifies the minimum length of metal fill shapes, in microns. *Default:* `1.0` *Data_type*: float, optional
`-min_union_density_to_above_layer` *float*	Specifies the minimum allowed sum union density of the current layer and its top layer window. This avoids the union density violations found while verifying density results of trim metal fill flow using PVS or Pegasus. *Default:* `200` *Data_type*: float, optional
`-min_width` *width*	Specifies the minimum width of metal fill shapes, in microns. *Default:* `0.4` for thin layers (less than 0.24) and `0.8` for thick layers. **Note:** This parameter only overrides a value in the LEF file if it is more restrictive than the LEF value. *Data_type*: float, optional
`-opc`	Specifies metal fill that will go through the optical proximity correction (OPC) process. This fill can be smaller than non-OPC metal fill and is governed by the same design rules as regular wires, instead of the rules that govern non-OPC metal fill. • OPC metal fill that is floating (unconnected) is included in the Fills statement of DEF 5.7. • OPC metal fill that is tied off (connected) is included in the Special Wiring statement of DEF 5.7. • The GDSII Stream/OASIS map file identifies the following object names for OPC and non-OPC metal fill: `FILL`, `FILLOPC`, `VIA`, `VIAFILL`. **Note:** `-opc` and `-regular` cannot be specified at the same time. *Data_type*: bool, optional
`-opc_active_spacing` *spacing*	Specifies the minimum distance in microns between the OPC metal fill shapes (FILLWIREOPC) and main patterns. **Note:** If this parameter is not specified, the minimum DRC spacing is used by default. *Data_type*: float, optional

`-preferred_density` *percent*	Specifies a percentage value for the preferred metal density for the layer. When the metal density in a window is less than the minimum metal fill density value, adds metal fill to achieve a density slightly above the preferred density if possible. In addition, metal fill uses the preferred density value in the estimation of `MACRO` density for layers that have most of the `MACRO` covered by `OBS` shapes and for DEF `BLOCKAGES` without both `+ FILLS` and `+ PUSHDOWN`. Metal fill uses the following scheme for the treatment of DEF blockages with `+ FILLS` or `+ PUSHDOWN`: • DEF `BLOCKAGES` with `+ PUSHDOWN` = 100 percent density (the same as real metal segments) • DEF `BLOCKAGES` with `+ FILLS` = 0 percent density Cadence recommends modelling LEF `MACRO`s by using the `DENSITY` statement, with density windows that are smaller than the metal fill windows. For example, if the metal fill windows are 100 x 100, use 25 x 25 or smaller values for the density rectangles. For more information, see the "Adding Metal Fill Over Macros" section in the Optimizing Metal Density chapter of the *Innovus User Guide.* *Default:* `35` *Data_type*: float, optional

`-regular`	Specifies that regular metal fill shape is to be used. Use this option to switch to inserting regular metal fill without restarting the session after you have been adding OPC metal fill.
	`set_metal_fill -opc`
	`add_metal_fill`
	`#Inserts opc metal fill`
	`set_metal_fill -regular`
	`add_metal_fill`
	`#Inserts regular metal fill`
	Data_type: bool, optional

`-window_size` *xSize ySize*	Specifies the x and y dimensions in microns of the area `set_metal_fill` uses to examine the metal density. The software assesses the metal density in each window, moving the window iteratively through the design. For example, `set_metal_fill -window_size 100 100`. LEF equivalent: `DENSITYCHECKWINDOW` *Default:* `DENSITYCHECKWINDOW`. If this value is not defined, the default is 100 microns in each dimension. *Data_type*: point, optional
`-window_step` *xStep yStep*	Specifies the x and y step distance in microns the window moves for each iteration of metal density analysis. For example, `set_metal_fill -window_step 50 50`. LEF equivalent: `DENSITYCHECKSTEP` *Default:* `DENSITYCHECKSTEP`. If this value is not defined, the default is 50 microns in each dimension. *Data_type*: point, optional

Example

- The following command sets window size and step settings for layer `METAL1`:

  ```
  set_metal_fill -layer METAL1 -window_size 200 200 -window_step 100 100
  ```

  These parameters are applied when you use the `add_metal_fill` command.

- The following command specifies an iteration `step1` with various settings for inserting metal fill:

  ```
  set_metal_fill -layer {1 2 3 4 5 6 7 8} -iteration_name step1 /
                 -gap_spacing 0.140 -min_width 1 -decrement 0.050 /
                 -min_length 2 -max_width 5 -max_length 20 -active_spacing 0.8 /
                 -window_size 50 50 -window_step 25 25 -min_density 15 /
                 -max_density 80 -preferred_density 35 -diagonal_offset 1 1
  ```

set_metal_fill_spacing_table

```
set_metal_fill_spacing_table
[-help]
[-layer layer_name_list]
[-fill_to_active {{width1 spacing1}{width2 spacing2}...}]
[-fill_to_fill {{width1 spacing1}{width2 spacing2}...}]
[-fill_to_opc {{width1 spacing1}{width2 spacing2}...}]
[-opc_to_active {{width1 spacing1}{width2 spacing2}...}]
[-opc_to_opc {{width1 spacing1}{width2 spacing2}...}]
[-reset]
```

Specifies the spacing table used by `trim_metal_fill` based on existing metal fill width. The spacing table includes the following spacing values:

- Fill to active spacing
- Fill to fill spacing
- Fill to OPC spacing
- OPC to OPC spacing
- OPC to active spacing

As `trim_metal_fill` honors the spacing table, you can then run `trim_metal_fill` to trim metal fill and get expected spacing. When required, you can use the `get_metal_fill_spacing_table` command to print the spacing table.

Note: If no spacing table is specified, `trim_metal_fill` honors the `set_metal_fill` settings for `-active_spacing` and `-gap_spacing`. If `set_metal_fill` values are also not specified, `trim_metal_fill` uses the default settings.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `set_metal_fill_spacing_table` parameter. For a detailed description of the command and all its parameters, use the `man` command: `man set_metal_fill_spacing_table`
`-layer` *layer_name_list*	Specifies the metal layers for the setting. Metal layers can be specified as numbers (`2`) or in the LEF format (`METAL2`) or as metal`2`. *Data_type*: string, optional
`-fill_to_active {{`*width1 spacing1*`}{`*width2 spacing2*`}...}`	Specifies a spacing table for fill to active spacing for trimming metal fill. *Data_type*: string, optional
`-fill_to_fill {{`*width1 spacing1*`}{`*width2 spacing2*`}...}`	Specifies a spacing table for fill to fill spacing for trimming metal fill. *Data_type*: string, optional
`-fill_to_opc {{`*width1 spacing1*`}{`*width2 spacing2*`}...}`	Specifies a spacing table for fill to OPC spacing for trimming metal fill. *Data_type*: string, optional
`-opc_to_active {{`*width1 spacing1*`}{`*width2 spacing2*`}...}`	Specifies a spacing table for OPC to active spacing for trimming metal fill. *Data_type*: string, optional
`-opc_to_opc {{`*width1 spacing1*`}{`*width2 spacing2*`}...}`	Specifies a spacing table for OPC to OPC spacing for trimming metal fill. *Data_type*: string, optional
`-reset`	Resets the spacing tables. *Data_type*: bool, optional

Example

The following set of commands specify the spacing table for fill to active spacing as given below and trim metal fill accordingly:

Layer	min_width (=>) max_width (<=) active_spacing (>=)
2	0.32 ∞ 0.63
2	0.14 0.32-1MFG 0.36
2	0.08 0.14-1MFG 0.27

```
set_metal_fill_spacing_table -layer {2} -fill_to_active {{0.08 0.27}{0.14 0.36}{0.32 0.63}}
trim_metal_fill -layer 2
```

The software checks the existing metal fill with the specified spacing table. If no violations are detected, existing metal fill is retained. If the existing metal fills have `active_spacing` violations with other features, `trim_metal_fill` uses the `fill_to_active` spacing table to trim metal fill.

Sample output is as follows:

```
*** START TRIM METALFILL *** (CPU Time: 0:00:00.0 MEM: 558.359M)
 Number of metal fills with spacing or/and short violations:4920
 Total number of deleted metal fills: 4920
 Total number of added metal fills: 4779
 (CPU Time: 0:00:01.2 MEM: 558.359M)
 *** END OF TRIM METALFILL ***
```

[-working_dir working_directory]
```

Sets the parameters of the `add_pg_fill` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `set_pg_fill_` For a detailed description of the command and all its parameters, use the `man` command: `man set_pg_fill_config`
`-attach_instance_name attr_num`	Specifies the instance name to be attached. *Data_type*: int, optional
`-attach_net_name attr_num`	Specifies the net name to be attached. *Data_type*: int, optional
`-attach_net_prop {{prop_name attr_num} ... }`	Specifies the net property to be attached. *Data_type*: string, optional
`-core_license license_combination`	Sets an exact combination of licenses to be used. *Data_type*: string, optional
`-die_area_as_boundary`	Writes the die area as a polygon or a boundary. When this parameter is not specified, the `write` *Data_type*: bool, optional
`-distributed n`	Runs Pegasus in a multi-processor mode. The `n` variable specified with this parameter presents Innovus multi-CPU usage. *Data_type*: int, optional
`-distributed_timeout seconds`	Specifies the wait time for the DP processes to start. *Data_type*: int, optional

`-extra_options` *options*	Specifies the additional run options. *Data_type*: string, optional
`-format {stream oasis}`	Specifies the format of the flow. *Data_type*: enum, optional
`-layer_map_file` *streamOut_map_file*	Specifies the name of the `write_stream` layer map file. *Data_type*: string, optional
`-lib_name` *library_name*	Specifies the library name. *Data_type*: string, optional
`-license_distributed_continue`	Specifies that if the required number of licenses cannot be obtained in the DP processes, the so licenses obtained. *Data_type*: bool, optional
`-license_timeout` *seconds*	Specifies the wait time (in seconds) to run the software, if a license is not immediately available *Default*: `300` *Data_type*: int, optional
`-merge` *list_of_external_stream_files*	Specifies the list of external stream files. *Data_type*: string, optional
`-no_structure_name`	Merges the GDSII file without loading the software database. **Note:** This parameter is used with the `-merge` parameter. *Data_type*: bool, optional
`-offset {`*x y*`}`	Specifies the location (in microns) of the design in the GDSII output file. *Data_type*: point, optional
`-output_macros`	Displays the LEF abstract information, such as LEF pin geometries and obstructions for macros *Data_type*: bool, optional
`-pg_fill_config_file` *file_name*	Specifies the configuration file for the PG fill flow. Any overrides to the default behavior are writt *Data_type*: string, optional
`-pg_hookup_flow {ALL | PG_ONLY | FLOAT_ONLY}`	Specifies the type of fills to be generated. *Default*: `PG_ONLY` *Data_type*: enum, optional
`-report_file`	Specifies the cell name to be changed to the file. *Data_type*: bool, optional
`-reset {`*parameter_name* `|` *all*`}`	Resets a specified parameter or all parameters to the default value.
`-stripes` *number*	Specifies the number of stripes that divide the design. *Default*: 1 *Data_type*: int, optional
`-structure_name` *structureName*	Specifies the superstructure that consists of all the geometries that the map file writes out. *Data_type*: string, optional
`-uniquify_cell_names`	Creates unique cell names if there are name collisions, when the software merges files. *Data_type*: bool, optional
`-units {100 | 200 | 400 | 800 | 1000 | 2000 | 4000 | 8000 | 10000 | 20000}`	
	Specifies the resolution for values in the GDSII/OASIS file. *Data_type*: enum, optional

`-working_dir working_directory`	Specifies the working directory. *Data_type*: string, optional

set_track_fill_config

```
set_track_fill_config
[-help]
[-attach_instance_name attr_num]
[-attach_net_name attr_num]
[-attach_net_prop {{prop_name attr_num} ... }]
[-core_license license_combination]
[-die_area_as_boundary]
[-distributed n]
[-distributed_timeout seconds]
[-extra_options options]
[-format {stream oasis}]
[-layer_map_file streamOut_map_file]
[-lib_name library_name]
[-license_distributed_continue]
[-license_timeout seconds]
[-merge list_of_external_stream_files]
[-no_structure_name]
[-offset {x y}]
[-output_macros]
[-report_file]
[-reset {parameter_name | all}]
[-stripes number]
[-structure_name structureName]
[-track_fill_config_file file_name]
[-uniquify_cell_names]
[-units {100 | 200 | 400 | 800 | 1000 | 2000 | 4000 | 8000 | 10000 | 20000}]
[-working_dir working_directory]
```

Sets the parameters of the `add_track_fill` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `set_track_fi` For a detailed description of the command and all its parameters, use the `man` command: `man set_track_fill_config`
`-attach_instance_name attr_num`	Specifies the instance name to be attached. *Data_type*: int, optional
`-attach_net_name attr_num`	Specifies the net name to be attached. *Data_type*: int, optional
`-attach_net_prop {{prop_name attr_num} ... }`	Specifies the net property to be attached. *Data_type*: string, optional
`-core_license license_combination`	Sets an exact combination of licenses to be used. *Data_type*: string, optional
`-die_area_as_boundary`	Writes the die area as a polygon or a boundary. When this parameter is not specified, the `write` *Data_type*: bool, optional
`-distributed n`	Runs Pegasus in a multi-processor mode. The `n` variable specified with this parameter presents Innovus multi-CPU usage. *Data_type*: int, optional
`-distributed_timeout seconds`	Specifies the wait time for the DP processes to start. *Data_type*: int, optional
`-extra_options options`	Specifies the additional run options. *Data_type*: string, optional

`-format {stream oasis}`	Specifies the format of the flow. *Data_type*: enum, optional
`-layer_map_file` *streamOut_map_file*	Specifies the name of the `write_stream` layer map file. *Data_type*: string, optional
`-lib_name` *library_name*	Specifies the library name. *Data_type*: string, optional
`-license_distributed_continue`	Specifies that if the required number of licenses cannot be obtained in the DP processes, the s licenses obtained. *Data_type*: bool, optional
`-license_timeout` *seconds*	Specifies the wait time (in seconds) to run the software, if a license is not immediately available *Default*: `300` *Data_type*: int, optional
`-merge` *list_of_external_stream_files*	Specifies the list of external stream files. *Data_type*: string, optional
`-no_structure_name`	Merges the GDSII file without loading the software database. **Note:** This parameter is used with the `-merge` parameter. *Data_type*: bool, optional
`-offset {`*x y*`}`	Specifies the location (in microns) of the design in the GDSII output file. *Data_type*: point, optional
`-output_macros`	Displays the LEF abstract information, such as LEF pin geometries and obstructions for macros *Data_type*: bool, optional
`-report_file`	Specifies the cell name to be changed to the file. *Data_type*: bool, optional
`-reset {`*parameter_name* `|` *all*`}`	Resets a specified parameter or all parameters to the default value.
`-stripes` *number*	Specifies the number of stripes that divide the design. *Default*: 1 *Data_type*: int, optional
`-structure_name` *structureName*	Specifies the superstructure that consists of all the geometries that the map file writes out. *Data_type*: string, optional
`-track_fill_config_file` *file_name*	Specifies the configuration file for track fill flow. *Data_type*: string, optional
`-uniquify_cell_names`	Creates unique cell names if there are name collisions, when the software merges files. *Data_type*: bool, optional
`-units {100 | 200 | 400 | 800 | 1000 | 2000 | 4000 | 8000 | 10000 | 20000}`	
	Specifies the resolution for values in the GDSII/OASIS file. *Data_type*: enum, optional
`-working_dir` *working_directory*	Specifies the working directory. *Data_type*: string, optional

set_via_fill

```
set_via_fill
[-help]
[-layer {layer_number | {list_of_layer_numbers}}]
[-window_size xSize ySize]
[-window_step xStep yStep]
[-min_density percent]
[-max_density percent]
[-preferred_density percent]
```

Specifies window and density values for inserting via fill. Use this command before running `add_via_fill`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_via_fill` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man set_via_fill`.

`-layer layer_number | {list_of_layer_numbers}`	Specifies the cut layers to which the parameters of the `set_via_fill` command apply. If you specify more than one layer, separate each layer with a space and enclose the list in braces or double quotation marks. To specify *cut12*, *cut23*, and *cut34*, type one of the following commands:
	`add_via_fill -layer "Via12 Via23 Via34"`
	`add_via_fill -layer {Via12 Via23 Via34}`
	Data_type: string, optional

`-max_density percent`	Specifies a percentage value for the maximum cut density. For example, `set_via_fill -max_density 30`. *Default:* `30` *Data_type*: float, optional
`-min_density percent`	Specifies a percentage value for the minimum cut density. For example, `set_via_fill -min_density 0.01`. *Default:* area of two cuts divided by 100 square microns *Data_type*: float, optional
`-preferred_density percent`	Specifies a percentage value for the preferred cut density. When the cut density in a window is less than the minimum cut density value, this parameter adds via fill to achieve a density as close as possible to the preferred value. To disable the preferred density feature, specify `0`. For example, `set_via_fill -preferred_density 0.02`. *Default:* area of two cuts in the cut layer *Data_type*: float, optional
`-window_size xSize ySize`	Specifies the x and y dimensions in microns of the area `set_via_fill` uses to examine the cut density. The software assesses the cut density in each window, moving the window in iterative manner through the design. For example, `set_via_fill window_size 100 100`. *Default:* 10 microns in each dimension *Data_type*: point, optional
`-window_step xStep yStep`	Specifies the x and y step distance in microns the window moves for each iteration of cut density analysis. For example, `set_via_fill -window_step 50 50`. *Default:* 5 microns in each dimension *Data_type*: point, optional

Example

The following command sets window and density values for inserting via fill in cut layers `VIA1` to `VIA7`:

```
set_via_fill -layer {VIA1 VIA2 VIA3 VIA4 VIA5 VIA6 VIA7} -window_size 100 100 /
          -window_step 50 50 -min_density 0.01 -max_density 30 /
          -preferred_density 1
```

Related Information

The following sections in the Optimizing Metal Density chapter of the *Innovus User Guide* document:

- Overview
- Adding Via Fill

trim_metal_fill

```
trim_metal_fill
[-help]
[-allow_polygon]
[-area x1 y1 x2 y2]
[-delete_violation]
[-ignore_special_net]
[-layer {layer_num_list | layer_name_list}]
[-use_non_default_spacing]
```

Trims metal fill and via fill (FILLWIRE and FILLWIREOPC shapes) that causes DRC violations. This command uses the values set by the set_metal_fill command. Therefore, you must ensure that you have correct set_metal_fill settings before running trim_metal_fill to avoid false violations.

Note: Use set_metal_fill without -iteration_name or with -iteration_name default to set the DRC rules used by trim_metal_fill. set_metal_fill -iteration_name *name*, where *name* is other than default, is used to set construction rules used by add_metal_fill with the -iteration_names option.

Use this command to trim metal fill if the design has floating metal or via fill. By trimming the fill, you reduce the chance of introducing timing problems caused by cross-coupling.

If the design has metal or via fill that is connected to special nets, use fix_open_fill after using trim_metal_fill.

Use the trim_metal_fill command after routing signal nets. For more information, see Route Commands and Attributes.

Parameters

-help	Prints a brief description that includes the type and default information for each trim_metal_fill parameter. For a detailed description of the command and all its parameters, use: man trim_metal_fill
-allow_polygon	Allows rectilinear shapes after trimming metal fill (FILLWIRE and FILLWIREOPC shapes). By default, the Innovus software supports rectangular shapes only. *Data_type*: bool, optional
-area *x1 y1 x2 y2*	Specifies a set of coordinates within which metal fill needs to be trimmed. By limiting the area in which metal fill is trimmed, you can speed up the trimming process. **Note:** This option is recommended for use with only floating metal fill. If you use trim_metal_fill -area on tied-off fill shapes, the command returns a warning message that some of the shapes may become isolated from the Power/Ground network. *Data_type*: rect, optional
-delete_violation	Deletes metal fill shapes that cause DRC violations or shorts, instead of trimming sections of the shapes. After running the trim_metal_fill command with this parameter specified, the remaining shapes are still rectangles. If using this parameter causes metal density to drop below the target density, re-run the add_metal_fill command. Always specify this parameter in the following two cases: • If the design has minimum step rules, specify this parameter to avoid creating minimum step violations. • If you ran add_metal_fill -snap, specify this parameter to delete entire shapes, instead of trimming sections of the shapes, otherwise the trimmed shapes will not be on-grid. *Data_type*: bool, optional
-ignore_special_net	Ignores special nets while checking for DRC violations. *Data_type*: bool, optional
-layer {*layer_num_list* | *layer_name_list*}	Specifies the metal layers in which metal fill needs to be trimmed. **Note:** This option is recommended for use with only floating metal fill. If you use trim_metal_fill -layer on tied-off fill shapes, the command returns a warning message that some of the shapes may become isolated from the Power/Ground network. *Data_type*: string, optional
-use_non_default_spacing	Uses non-default spacing for trimming metal fill. Some critical nets use a non-default rule (NDR) for routing as they may need to have wider wires or wider spacing than other nets. Use -use_non_default_spacing to extend NDR control to trim_metal_fill. *Data_type*: bool, optional

Example

The following command trims metal fill and allows rectilinear shapes:

```
trim_metal_fill -allow_polygon
```

Related Information

- The following sections in the Optimizing Metal Density chapter of the *Innovus User Guide* document:
  - Overview
  - Connected and Floating Metal Fill
  - Trimming Metal Fill
- The 'Shape' section in the DEF Syntax chapter of the *LEF/DEF Language Reference* document

trim_metal_fill_near_net

```
trim_metal_fill_near_net
[-help]
[-area {x1 y1 x2 y2}]
[-clock]
[-create_fill_blockage blockage_name]
[-layers layer_name_list]
[-min_trim_density {percent1 layer_list1 [{percent2 layer_list2}]}]
[-min_trim_union_density_to_above_layer {percent1 layer_list1 [{percent2 layer_list2}]..}]
[-nets {net_name_list | net_object_pointer_list}]
[-recompute_density]
[-remove]
[-slack_threshold slack_in_ns]
[-spacing dist_in_um]
[-spacing_above dist_in_um]
[-spacing_below dist_in_um]
```

Trims any metal fill around critical nets. This command enables you to reduce the timing impact on critical nets due to metal fill on the layer above, below and the same layer for the routing of any critical net. Using this command, you can specify the critical net list, desired spacing around critical nets, and metal fill density limit.

The intended usage model is to run timing analysis before metal fill, add metal fill, then run timing analysis after metal fill, then trim the metal fill that caused timing to get worse. See the examples below.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `trim_metal_fill_near_net` parameter. For a detailed description of the command and all its parameters, use: `man trim_metal_fill_near_net`
`-area {x1 y1 x2 y2}`	Specifies a set of coordinates within which to trim metal fill. If this parameter is not specified, metal fill is trimmed around critical nets in the entire design area. *Data_type*: rect, optional
`-clock`	Specifies whether metal fill is to be trimmed around all clock. *Data_type*: bool, optional
`-create_fill_blockage blockage_name`	Creates a fill blockage so that any subsequent fill steps do not refill the trimmed area. If you specify a name, the tool uses that name as the fill blockage name. If you do not specify a name, the tool uses the default name *netName_layerName_** for the fill blockage. *Data_type*: string, optional
`-layers layer_name_list`	Trims metal fill only on the specified layers. If this parameter is not specified, metal fill is trimmed on all layers. *Data_type*: string, optional
`-nets {net_name_list | net_object_pointer_list}`	Specifies a list of critical net names or pointers which are surrounded by metal fill. *Data_type*: string, optional
`-min_trim_density {percent1layer_list1 [{percent2layer_list2}]}`	Trims metal fill only until the specified window density percentage is reached to avoid causing any metal density violations. The window sizes are controlled by `set_metal_fill. check_metal_density` is used to compute the metal-density using the same set_metal_fill settings. You can specify different window density percentages for different layers. For example, {{20 metal1 metal2} {30 metal3}} would set the min-density for metal1, metal2 windows to 20%, and for metal3 to 30%. *Data_type*: string, optional
`-min_trim_union_density_to_above_layer {percent1 layer_list1 [{percent2 layer_list2}]..}`	Trims metal fill only till meeting the specified percent window density. *Default:* `0` *Data_type*: string, optional

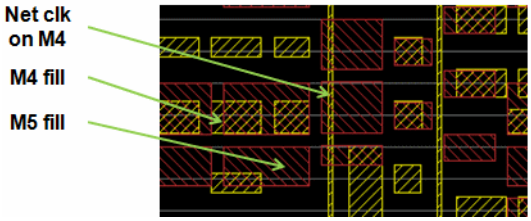
`-recompute_density`	By default, if metal density values are required for `-min_trim_density`, and they are available in the database from a previous call to `check_metal_density`, the existing database values are used. This option forces a call to `check_metal_density` to recompute window densities instead of using the stored values. *Data_type*: bool, optional
`-remove`	Specifies that the metal fill shapes overlapping the critical-nets halo area should be removed entirely instead of being trimmed to the halo edge created with different `-spacing*` options. This avoids the possibility of smaller metal fill shapes that might be left over after trimming. *Data_type*: bool, optional
`-slack_threshold` *slack_in_ns*	Trims metal fill around nets with slack less than the specified value. The value specified should be in nanoseconds. *Data_type*: float, optional
`-spacing` *dist_in_um*	Trims fill on the same layer by specified distance around critical net routes. The distance specified should be in micrometers (`um`). The default is 0 so no trimming is done. *Data_type*: float, optional
`-spacing_above` *dist_in_um*	Trims fill on the layer above the current layer by specified distance around critical net routes. The distance specified should be in micrometers (`um`). The default is 0 so no trimming is done. *Data_type*: float, optional
`-spacing_below` *dist_in_um*	Trims fill on the layer below the current layer by specified distance around critical net routes. The distance specified should be in micrometers (`um`). The default is 0 so no trimming is done. *Data_type*: float, optional

Examples

- The most common usage model is to run timing anlaysis before metal fill, add metal fill, run timing analysis after metal fill, and then trim the metal fill that causes timing to get worse. Suppose the WNS before metal fill was -0.2ns, and after metal fill the WNS is -0.4ns. This means the metal fill caused a 0.2ns degradation. One strategy is to trim any net that got pushed about beyond the original WNS of -0.2ns aggressively with a larger trim spacing value because the extra WNS is directly caused by metal-fill, and then trim any negative slack nets above 0.0ns to improve timing margins. The spacing values depend on the technology node and timing criticality. A reasonable starting point would be to choose between 5x to 10x min-spacing for the aggressive trim value. So you might use these commands:

```
#Trim by 1.0um the layer above/below/same for any net with worse slack than the pre-metal fill WNS of -0.2
#Do not trim if the metal density will fall below 20% for metal1, metal2, or 30% for metal3 using the set_metal_fill window settings
trim_metal_fill_near_net -slack_threshold -0.2 -spacing 1.0 -spacing_above 1.0 -spacing_below 1.0 -min_trim_density {{20 metal1 metal2} {30 metal3}}
#Trim less aggressively using 0.4um spacing for any net with WNS above 0.0 to improve timing margins
trim_metal_fill_near_net -slack_threshold 0.0 -spacing 0.4 -spacing_above 0.4 -spacing_below 0.4 -min_trim_density {{20 metal1 metal2} {30 metal3}}
```

- In the following example, there is a critical net overlap with the metal fill on the upper layer, metal5:



The following command trims metal fill on the upper layer, metal5, and creates a fill blockage around the `clk` net.

```
trim_metal_fill_near_net -nets clk -layers {metal4 metal5} -create_fill_blockage -spacing_above 0.2
```

Mixed Signal Commands

- delete_integration_route_constraints
- get_integration_route_constraint
- pull_block_constraints
- run_vsr
- set_integration_route_constraint
- write_integration_route_constraints

delete_integration_route_constraints

```
delete_integration_route_constraints
[-help]
[-net net1 net2 ... | -name constraint_name | -custom_constraints  | -all ]
```

Deletes routing constraints in the database.

Note: Integration constraints are used to convey the design intent in a mixed signal design. These constraints are fully interoperable between the digital and custom environments.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `delete_integration_route_constraints` parameter. For a detailed description of the command and all of its parameters, use the man command `man delete_integration_route_constraints`.
`-all`	Deletes all integration constraints, including constraints that are understood by NanoRoute and used to route nets with simple shield or NDR constraints. *Data_type*: bool, optional
`-custom_constraints`	
	Deletes all diffPair, matchLength, complex shield, and complex netClass constraints. *Data_type*: bool, optional
`-name` *constraint_name*	Allows the deletion of a specific constraint by name. You can specify multiple constraint names, enclosed in braces. Use the `get_integration_route_constraint` command to get the name of any constraint in the design. *Data_type*: string, required
`-net` *net1 net2 ...*	Indicates the nets for which the constraints will be deleted. If the net is part of a netClass, the netClass will be deleted as well. *Data_type*: string, required

Examples

- The following command deletes all diffPair, matchLength, complex shield, and complex netClass constraints.

  ```
  delete_integration_route_constraints -custom_constraints
  ```

- The following command deletes the constraints with the specified names:

  ```
  delete_integration_route_constraints -name {Constr_2__analogNW__DTMF_INST/analogNW_INST
  Constr_1__analogNW__DTMF_INST/analogNW_INST}
  ```

- The following command deletes all Integration constraints in the design.

  ```
  delete_integration_route_constraints -all
  ```

  The tool displays the following warning before deleting the constraints:

  ```
  **WARN: (ENCMSC-270): You are attempting to delete all routing constraints in this design.
  These include many constraints that are intended for use by NR for routing nets with simple
  shield, or NDR constraints.
  ```

Related Information

get_integration_route_constraint

```
get_integration_route_constraint
[-help]
[-net net_name | -name constraint_name]
```

Displays settings needed for the `set_integration_route_constraint` command.

If mixed-signal constraints have not yet been defined, the `get_integration_route_constraint` command does not return anything.

If you run the `get_integration_route_constraint` command without any option, all nets with all constraint names are displayed on the console window.

Note: The output is displayed only on the console window and is not written to the log file. You cannot use `>` to write to a file. The only way to send the output to a file is to run the following:

```
redirect {puts [get_integration_route_constraint xxxx]} > filename
```

Alternatively, use the command `write_integration_route_constraints`.

Note: Integration constraints are used to convey the design intent in a mixed-signal design. These constraints are fully interoperable between the digital and custom environments.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `get_integration_route_constraint` parameter. For a detailed description of the command and all of its parameters, use the man command `man get_integration_route_constraint`.
`-name constraint_name`	Returns a specific constraint by name. You can specify multiple constraint names, enclosed in braces. *Data_type*: string, optional
`-net net_name`	Specifies the net for which the constraints will be returned. If the net is part of a net_class, the constraints for the net_class is returned. You can specify multiple net names, enclosed in braces. *Data_type*: string, optional

Example

- The following command returns the constraint(s) defined for the net `scan_out_1`:

```
get_integration_route_constraint -net scan_out_1
```

The output of the command is:

```
{-type shield  -shield_net { VSS } -shield_type side -shield_tolerance 30.0 -net {
scan_out_1 }
}
```

- The following command returns details of the constraint named `Constr_13__analogSW__DTMF_INST/analogSW_INST`:

```
get_integration_route_constraint -name Constr_13__analogSW__DTMF_INST/analogSW_INST
```

The output of the command is:

```
{-type net_class -name Constr_13__analogSW__DTMF_INST/analogSW_INST -shield_net VSS -
shield_type side -connect_supply anypoint -rule NDR8 -net {analogW4I}
}
```

- The following command returns the constraints on the specified nets:

```
get_integration_route_constraint -net {DTMF_INST/cntrlxo[3] DTMF_INST/cntrlxo[0]}
```

The output of the command is:

```
{-type diff_pair -name Constr_2__analogNW__DTMF_INST/analogNW_INST -tolerance 20 -rule
default -net {DTMF_INST/cntrlxo[3] DTMF_INST/cntrlxo[2]}
} {-type diff_pair -name Constr_1__analogNW__DTMF_INST/analogNW_INST -tolerance 5 -rule
default -net {DTMF_INST/cntrlxo[0] DTMF_INST/cntrlxo[1]}
}
```

- The following command returns all the constraints on all the nets in the design:

```
get_integration_route_constraint
```

A sample output of the command is displayed below:

```
{-type diff_pair -name Constr_2__analogNW__DTMF_INST/analogNW_INST -tolerance 20 -rule
default -net {DTMF_INST/cntrlxo[3] DTMF_INST/cntrlxo[2]}
} {-type diff_pair -name Constr_1__analogNW__DTMF_INST/analogNW_INST -tolerance 5 -rule
default -net {DTMF_INST/cntrlxo[0] DTMF_INST/cntrlxo[1]}
} {-type diff_pair -name Constr_2__analogNL__DTMF_INST/analogNL_INST -tolerance 20 -rule
default -net {DTMF_INST/digsynca DTMF_INST/digsyncb}
} {-type diff_pair -name Constr_3__analogNL__DTMF_INST/analogNL_INST -tolerance 20 -rule
default -net {DTMF_INST/digsyncc DTMF_INST/digsyncd}
} {-type match_length -name Constr_5__analogNL__DTMF_INST/analogNL_INST -tolerance 20 -

pull_block_constraints

```
pull_block_constraints
[-help]
[-override]
[-report_file report_file_name]
{-all_blocks | -block list_of_blocks | -inst list_of_instances | -cell_view
{list_of_libName_cellName_viewName}}
```

Pulls the routing constraints stored on the interface nets of blocks in a design, to their corresponding top-level nets. The `pull_block_constraints` command uses a two-pass approach to handle conflicting constraints on the same net. In this approach, the `pull_block_constraints` command detects block-level and top-level conflicts and reports a warning.

If the `-override` parameter is not specified (non-override mode) and a block-level conflict is detected, no constraints are pulled.

If the `-override` parameter is specified (override mode), `pull_block_constraints` reports the conflicts but pulls the constraints such that the lower-level net constraints override any constraints that might exist on the top-level nets..

Parameters

`-help`	Prints a brief description that includes the type and default information for each `pull_block_constraints` parameter. For a detailed description of the command and all of its parameters, use the man command `man pull_block_constraints`
`-all_blocks`	Specifies that constraints with hierarchical scope will be pulled from all blocks in the design. *Data_type*: bool, required
`-block` *list_of_blocks*	Defines the list of block names of the instances in the design for which the constraints with hierarchical scope will be pulled. *Data_type*: string, required
`-cell_view {`*list_of_libName_cellName_viewName*`}`	
	Specifies the list of library, cell, and view names from which the constraints need to be pulled. *Data_type*: string, required

`-inst` *`list_of_instances`*	Defines the instances in the design for which the constraints with hierarchical scope will be pulled. *Data_type*: string, required
`-override`	When specified, the lower-level net constraints will override any constraints that might exist on the top-level nets. *Default*: `off` *Data_type*: bool, optional
`-report_file` *`report_file_name`*	Specifies the report file name. Given that the standard out report is in the abbreviated format, more details are written out in this mode indicating: • The lower, and upper level net names, the type of constraints pulled. • All the associated parameters. • Any conflicts that need to be resolved. • Which constraint were written to a particular net. *Default*: `dumpPullInfo.log` *Data_type*: string, optional

Examples

- Using the following command, the constraints on the pins in the cellview binded to the block macro of all the instantiations of the block list `pll_clock` and `pwr_monitor` will be pulled up to the top-level nets connected to the instance pins.
  ```
  pull_block_constraints -block {pll_clock pwr_monitor}
  ```
- Using the following command, the constraints on the pins in the cellview binded to the macro instance `I1/I2` will be pulled up to the nets connected to the pins of the instance.
  ```
  pull_block_constraints -inst {I1/I2}
  ```

run_vsr

```
run_vsr
[-help]
[-log_file fileName]
[-no_taper_to_pin_width]
[-post_script scriptname]
[-pre_script scriptname]
[-remove_existing_routes]
[-route_type_order {bus diffpair match nets shield}]
[-run_vsr_script scriptname]
[-share_shields]
[-nets list_of_selected_nets | -include_net_types {bus diffpair match nets shield} | -nets_file
fileName]
```

Launches the Virtuoso Space-based Router (VSR) from Innovus. It works on OpenAccess design as well as restored non-OpenAccess designs. It routes the nets specified with the `-nets`, `-nets_file`, or `-include_net_types` option. If the `-include_net_types` option is used, the nets are routed in the following order: `diffpair`, `match`, `bus`, `nets`, and `shield`. To invoke this wrapper, make sure Virtuoso is available in your path.

Before running the `run_vsr` command, set the following:

```
set_db oa_new_lib_compress_level 1
```

Notes

- Integration constraints are used to convey the design intent in a mixed-signal design. These constraints are fully interoperable between the digital and custom environments.
- If you run `run_vsr` on an abstract inferred from layout, you may see the following WARNING message:

  ```
  "The current database uses quick abstract inference and should be used only for
  floorplanning and not for routing purposes."
  ```

For more information on using `run_vsr`, see the Routing Constraint Interoperability chapter in the *Mixed Signal Interoperability Guide*.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `run_vsr` parameter. For a detailed description of the command and all of its parameters, use the man command `man run_vsr`
`-include_net_types {bus diffpair match nets shield}`	

	Specifies the list of valid net types for VSR to route. **Note:** The `-nets`, `-nets_file`, and `-include_net_types` parameters are mutually exclusive. Do not specify these parameters at the same time. *Data_type*: (enum)+, optional
`-log_file` *fileName*	Specifies the file name for writing the routing report. *Data_type*: string, optional
`-nets` *list_of_selected_nets*	Specifies the list of nets that have to be routed. *Data_type*: string, optional
`-nets_file` *fileName*	Specifies the name of the file listing the nets to be routed. **Note:** The `-nets`, `-nets_file`, and `-include_net_types` parameters are mutually exclusive. Do not specify these parameters at the same time. *Data_type*: string, optional
`-no_taper_to_pin_width`	Does not perform tapering based on the pin width. For instance, if the rule applied on a mixed signal net is NDR1 whose width exceeds the pin width for a particular layer, then VSR automatically tapers the wire to match the pin width. If this option is specified, then tapering is not done. *Data_type*: bool, optional
`-post_script` *scriptname*	Specifies the name of the script to be executed by VSR after loading the design. *Data_type*: string, optional
`-pre_script` *scriptname*	Specifies the name of the script to be executed by VSR before loading the design. *Data_type*: string, optional
`-remove_existing_routes`	Deletes the nets (fixed, normal), including shield, and excluding power nets, which are specified by the -nets parameter before routing. *Data_type*: bool, optional
`-route_type_order {bus diffpair match nets shield}`	
	Specifies the list of valid constraint types in the preferred routing order. *Data_type*: (enum)+, optional

`-run_vsr_script` *scriptname*	Specifies a user-defined script to be run by VSR for custom routing. If this option is specified, the router skips all presetting from VSR and routes the design by sourcing the complete custom script as provided. *Data_type*: string, optional
`-share_shields`	Shares the shielded nets. Using this parameter, you can selectively specify the list of shared shielded nets. *Data_type*: bool, optional

Using Scripts and Environmental Variables with run_vsr

The `run_vsr` command in Innovus supports a limited set of options to route the analog/mixed-signal nets. To have more control of the VSR engine, you can set additional settings through the `.cdsenv` file.

Settings through .cdsenv

Here are two examples of how you can use `.cdsenv` settings to control VSR:

- To force VSR to route on-grid:
  ```
  layout routeUseGrid cyclic "Routing"
  ```
- To force VSR to use the rules from the specified route spec:
  ```
  layout wireConstraintGroup string "LEFDefaultRouteSpec"
  ```

If you set the above settings in the `.cdsenv` file before running the `run_vsr` command, Virtuoso initializes them before calling the VSR engine.

In addition to the settings through `.cdsenv` file, the `run_vsr` command is enhanced to pass additional variables or scripts through `-pre_script` and `-post_script`.

Preloadscript

Usage of settings through `-pre_script` is only for expert VSR users and generally not recommended.

Postloadscript

Example:

- To enable VSR to use the custom vias and not generated or derived vias:
  ```
  setvar db.enable_create_derived_vias false
  ```
- To enable VSR to connect the wires to the center of the pin
  ```
  setvar droute.snap_to_pin_center true
  ```

You can set the above environmental variables in a script and enable them through the following command:

```
run_vsr -nets { neta …..} -post_script scriptname…
```

For more information on the environmental variables which can be set, refer to the following documentation:

- "Environment Variables" chapter in the *Cadence Space-based Router and Chip Optimizer Command Reference*

Note: Consult Cadence for the best use of these variables to obtain the desired results.

Examples

- The following command routes the bus nets using VSR:
  ```
  run_vsr -nets {DATA[0] DATA[1] DATA[2] DATA[3] DATA[4] DATA[5] DATA[6] DATA[7]}
  ```
- The following command routes the given net `lbk_bstart` using mixed-signal constraint, if any constraint has been applied to this net which will be taken from OpenAccess database:
  ```
  run_vsr -nets lbk_bstart
  ```
- The following command routes all the nets which have `diffpair`, `matchpair` and then `net` class in the following order of constraint types:
  ```
  run_vsr -include_net_types {diffpair match nets}
  ```

```

`-type {bus diff_pair match_length ndr net_class shield simple_net}`

Applies specialty routing constraints in the database for nets in the designs. It allows creation of differential pair, match pair, shield nets, and nets with non-default rules.

If required, all routing constraints set by this command can be deleted from the database using the `delete_integration_route_constraints` command.

Also see, `get_integration_route_constraint`.

Notes

- Integration constraints are used to convey the design intent in a mixed signal design. These constraints are fully interoperable between the digital and custom environments.
- If the design has a complex `net_class` constraint that has net members with different constraints, `set_integration_route_constraint` will throw the an error. If you still wish to change the integration constraints in the design, check whether the `net_class` constraints under the *Complex NetClass* tab in the Integration Constraint Editor can be removed. If yes, use the `delete_integration_route_constraints` or the GUI to first delete such constraints, and then repeat the `set_integration_route_constraint` command.
- The rule name `DefaultRule` is obsolete. It still works in this release and is automatically converted to the correct name `default`. Update your scripts to use `default` so that it work correctly in future releases.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `set_integration_route_constraint` parameter. For a detailed description of the command and all of its parameters, use the man command `man set_integration_route_constraint`.
`-access_style {none straight clustered}`	
	Specifies the preferred style for routing the bus after connecting to the bus pins. This parameter is applicable only for`-type bus`. *Default:* `clustered` *Data_type*: enum, optional
`-bottom_layer` *layerNum*	Specifies the bottom routing layer that is to be used. *Data_type*: string, optional
`-bus_group_width` *integer*	

	Specifies the width for the bus groups into which the router splits a bus. The width is specified as an integer value. For example, if a bus is 16 bits, you can specify `-bus_group_width 4` to indicate that the router can route the bus as four bus groups of 4 bits each. *Default*: `1` *Data_type*: int, optional
`-bus_sink_groups` *bus_sink_group_name_list*	
	Specifies the list of names of the busSinkGroups. It sets high-frequency/mixed signal constraints for the nets of the busSinkGroup sinks. It supports all constraints of type BUS. These constraints are honored by the NanoRoute high-frequency router. *Data_type*: string, optional
`-connect_supply {`*float* `anypoint}`	
	Indicates how the shield wires will be connected to the supply line. The default option, `anypoint`, tells the router to connect the wire to supply, anywhere along the length of the shield wire. *Default:* `anypoint` *Data_type*: enum, optional
`-corner_style {none crossover river}`	
	Specifies the type of corner style that the differential pair route or bus should follow when changing directions. This parameter is applicable only for `-type bus` and `-type diff_pair`. *Default:* `crossover` *Data_type*: enum, optional
`-crosstie_shield_interval` *string*	

	Specifies the number of tracks between the cross-tie wires for opportunistic coaxial shielding. The *string* value should have the following format: `{integer | {layer interval1 layer2[:layerN] interval2 ...}}` The integer value specifies the interval in the form of the number of tracks between cross-ties created on a given layer. For example, a value of `0` means that there are no tracks between cross-ties, which means there is a cross-tie on every track. Similarly, a value of 1 means that there is one track between cross-tie wires, which results in a cross tie on every other track. A value of `2` means two tracks between the cross-tie wires and so on. **Note**: This parameter is applicable only if `-shieldType` is specified as `crosstie`. *Default:* `0` *Data_type*: string, optional
`-crosstie_shield_layer_limit` *string*	
	Specifies the layer range that can be used to create cross-tie shields. Use the `-crosstie_shield_layer_limit` parameter if you want to use only specific layers to create cross-ties and keep the remaining layers free for other purposes. The *string* value should have the following format: `{layer_number:layer_number}` For example, if the layer range specified is `{METAL2:METAL7}`, cross-tie shields can be created on `METAL2`, `METAL3`, `METAL4`, `METAL5`, `METAL6`, and `METAL7` but not on `METAL8` or the layers above it. **Note**: This parameter is applicable only if `-shieldType` is specified as `crosstie`. *Data_type*: string, optional
`-crosstie_shielded_layers` *string*	
	Specifies the layer range that will be shield with cross-ties from above and below. Use the `-crosstie_shielded_layers` parameter if you want to minimize congestion by shielding only specific routing layers with cross-ties. The *string* value should have the following format: `{layer:layer}` For example, if the layer range specified is `{METAL3:METAL6}`, cross-tie shields will be built for routes on the net on `METAL3`, `METAL4`, `METAL5`, and `METAL6`. **Note**: This parameter is applicable only if `-shieldType` is specified as `crosstie`. *Data_type*: string, optional

`-group_to_outside_spacing` *layer1 spacing1 layer2*`[:`*layerN*`]` *spacing2*`...`	
	Indicates the spacing per layer (in microns) between the nets in this net group, and the other nets in the design. *Data_type*: string, optional
`-hard`	Indicates that the top or bottom layer routing constraint created should be of hard type. By default, Innovus places the top/bottom routing layer constraints as soft routing constraints in the resulting OpenAccess database. *Data_type*: bool, optional
`-hierarchical_scope {local local_above local_below local_above_below}`	
	Specifies whether the particular constraint is local, and/or can be pulled (above) or pushed (below) across the hierarchy. Setting this option to all possible values enables pull and push. If set to local, it is not saved to the database. *Data_type*: enum, optional
`-inter_group_gap {`*layer1 spacing1 layer2*`[:`*layerN*`]` *spacing2*`...}`	
	Specifies the gap to be kept between the split bus groups when `-bus_group_width` is specified. Default is min spacing. *Data_type*: string, optional
`-layer_gap {`*layer1 gap1 layer2*`[:`*layerN*`]` *gap2*`...}`	
	Indicates the layer names and the gap-spacing values for the nets routed as `diff_pair`. For any layer not listed, the minimum legal spacing for that layer is used. For example: `-layer_gap {`*layer_1 gap_1 layer_2 gap_2*`...}` *Data_type*: string, optional
`-layer_match`	Specifies that each separate layer should be matched for `match_length` nets. By default, only the total length is matched. *Data_type*: bool, optional
`-match_gap {`*layer1 gap1 layer2*`[:`*layerN*`]` *gap2*`...}`	
	Indicates the spacing between two rises of the accordion. This setting is applicable only when `-type` is `match_length` and `-match_style` is `accordion`. You may want to control the spacing between two rises of the accordion if routing resources are restricted. *Data_type*: string, optional

`-match_style {accordion | trombone | coil}`	
	Indicates the routing topology to be used for matching the nets routed as `match_length`. It can be `accordion`, `trombone`, or `coil`. In `accordion`, pulse structures are used to match length while in `trombone`, loops are used. **Matching in accordion style**  **Matching in trombone style**  *Default:* `accordion` *Data_type*: enum, optional
`-max_length` *value*	Indicates the maximum length the router should route a net. The maximum length is specified as a float value. This parameter is applicable only for `-type match_length` and `-type simple_net`. *Data_type*: float, optional
`-max_res` *value*	Indicates the maximum resistance to be used by the Virtuoso Space-based Router (VSR) for the specific net being routed, or for the nets with a match_length constraint if `-type` is `match_length`. The maximum resistance is specified as a float value. This parameter is applicable only for `-type match_length`. *Data_type*: float, optional

`-min_bus_bit` *integer*	
	Indicates the minimum bits allowed for the router to split a bus. As channels get narrower, it becomes challenging to accommodate all the bus bits in the same channel. By default, `-min_bus_bit` value is undefined, not `0`. If you specify an integer value for `-min_bus_bit`, the router splits a bundle with a minimum of this value. For example, if you set `-min_bus_bit` to `4`, the router splits the bus such that each part has at least `4` bits. *Data_type*: int, optional
`-min_length` *value*	Indicates the the minimum length the router should route a net. The minimum length is specified as a float value. This parameter is applicable only for `-type match_length` and `-type simple_net`. *Data_type*: float, optional
`-min_res` *value*	Indicates the minimum resistance to be used by VSR for the specific net being routed, or for the nets with a `match_length` constraint if `-type` is `match_length`. The minimum resistance is specified as a float value. This parameter is applicable only for `-type match_length`. *Data_type*: float, optional
`-name` *string*	Specifies the name of the constraint group being created, changing the default name given to the constraint by Innovus. *Data_type*: string, optional
`-net {`*net1 net2*`}`	Specifies the list of net names to be routed. *Data_type*: string, optional
`-no_share_shield`	Specifies that there should be individual shields, instead of a common shield, between the bus nets. This option is applicable only for constraints of type `bus`.
`-rule` *NDR_name*	Specifies the name of the routing rule that is used for routing a particular type of net(s). *Default:* `"default"` *Data_type*: string, optional
`-shield_gap {`*layer1 gap1 layer2*`[:`*layerN*`] gap2 ...}`	
	Specifies the spacing between the shielded wire and the shield net. For any layer not listed, the minimum legal spacing for that layer is used. *Data_type*: string, optional

`-shield_net {net1 net2}`	Indicates that the net group should be shielded by the specified nets. Valid net names that you can use with `-shield_net` are all power and ground net names in the design. You can specify different shield nets for different sides of a wire. The routers then determine which shield net should be used on which side of the wire. **Note:** You can specify a maximum of two net names with this parameter. In addition, you can specify two shield net names only for the following shield types: • `side` • `top_side` • `bottom_side` • `coaxial` • `tandem_split` For the `top`, `bottom`, or `top_bottom` shield types, you can specify only one shield net. *Default*: The first ground net name in the list of ground nets. *Data_type*: string, optional
`-shield_tolerance {net1 value1 net2 value2 ...}`	

Indicates the percentage of length of the net that can remain unshielded. You can set the same tolerance value or different tolerance values on a group of nets.

The examples below depict different use models:

- In the following example, the same constraint shield tolerance is put on every member of the shield constraint group:

```
set_integration_route_constraint -type shield -shield_net {VSS} -
shield_type side -shield_tolerance 25.0 -connect_supply anypoint -net
{scan_in_2, abc, xyz}
```

- In the example below, different groups of nets get different shield_tolerance values:

```
set_integration_route_constraint -type shield -shield_net {VSS} -
shield_type side -shield_tolerance 25.0 -connect_supply anypoint -net
{scan_in_2, abc, xyz} -shield_tolerance {net1 30 net2 30 net3 30}
```

- In the following example, the nets `scan_in_2`, `abc` and `xyz` are already nets with the shield constraint, but without tolerance values. The command below adds the tolerance value to the existing shielding constraint of the nets. Note that adding shield tolerance changes the net to a complex shield as opposed to a simple shield:

```
set_integration_route_constraint -type shield -shield_tolerance 25 -net
{scan_in_2 abc xyz}
```

Note:

- The shield tolerance value can be set only on nets that are not intended to be routed by NanoRoute. This means that setting the shield tolerance on any net will make that net a complex shield.
- If you use the `set_integration_route_constraint` command to set the shield tolerance on a net or a group of nets, those nets automatically get the MS bit in the DB and show up in the GUI as a complex shield.
- Percentage tolerance is considered by VSR as a soft constraint.
- PVS-cv is the only tool in the flow that checks the percentage tolerance against the geometries created by VSR, and flags any such violations.

Default: `20.0`

Data_type: string, optional

`-shield_type {unspecified side bottom bottom_side top top_side top_bottom coaxial tandem_split interleaved crosstie tandem_split_full tandem_split_nearby tandem_split_special}`

	Specifies the shielding type for the net(s) being routed. For complex coaxial shields, shield type can be specified as explained below: • `tandem_split_nearby` - Specifies that shielding should be added only where required. • `tandem_split_full` - Specifies that one-layer tandem shielding with overhang should be added. The overhang can be specified using the new `-tandem_overhang` and `-tandem_side_overhang` parameters. • `tandem_split_special` - Specifies that two-layer tandem shielding should be added for complete shielding from other nets. Use the new `-tandem_cap_width` parameter to specify the width of the tandem cap shield (second layer shield).  *Default:* `unspecified` for `diff_pair`, `match_length`, and `bus`; `side` for `NDR`, `simple_net`, and `net_class` *Data_type*: enum, optional
`-shield_width {`*`layer1 width1 layer2`*`[:`*`layerN`*`] `*`width2...`*`}`	
	Indicates the width of the shield wire in microns per layer. This only applies to side shields. *Data_type*: string, optional
`-tandem_aggressor_adjacent_layer_separation` *`layer separation`*	

	Specifies the minimum distance between the given signal layer and the above/below layers containing the aggressors. *Data_type*: string, optional
`-tandem_aggressor_same_layer_track_distance {`*`layer1 n1 layer2`*`[:`*`layerN`*`] `*`n2`*`...}`	
	Specifies the minimum pitch tracks (distance) between the given signal net and any aggressors on the same layer. *Data_type*: string, optional
`-tandem_cap_width {`*`layer1 width1 layer2`*`[:`*`layerN`*`] `*`width2`*`...}`	
	Specifies the wire width (in microns) of the tandem cap shield beyond the edge of the route being shielded. For any layer not listed, the minimum legal width for that layer is used. This parameter is needed only for the `tandem_split_special` shield type. *Data_type*: string, optional
`-tandem_nearby_non_aggressor_except_by_name {`*`nameString`*`}`	
	Specifies that only the nets mentioned by name are aggressors; the rest are not considered as aggressors for shielding. *Data_type*: string, optional
`-tandem_nearby_non_aggressor_nets {`*`nameString`*`}`	
	Specifies the net names that are not considered as aggressors for shielding. *Data_type*: string, optional
`-tandem_nearby_non_aggressor_type {`*`typeNameString`*`}`	
	Specifies those signal types that are not considered as signal types of aggressors. Even if they exist within a certain range, the signal net does not need to be protected by shielding. *Data_type*: string, optional
`-tandem_overhang {`*`layer1 width1 layer2`*`[:`*`layerN`*`] `*`width2`*`...}`	
	Specifies the overhang value (in microns) for the tandem shield. *Data_type*: string, optional
`-tandem_side_overhang {`*`layer1 width1 layer2`*`[:`*`layerN`*`] `*`width2`*`...}`	
	Specifies the overhang value (in microns) for the tandem side shield. *Data_type*: string, optional

`-tandem_width {`*`layer1 width1 layer2`*`[:`*`layerN`*`] `*`width2...`*`}`	
	Specifies the overhang value for the shields on the top and bottom layers so as to extend them to overlap the side shields. *Data_type*: string, optional
`-tolerance` *tolerance*	Indicates the percentage difference in length that is allowed when routing nets as `match_length` and `diff_pair`. *Default:* 20.0, *Min*: 0, *Max*: 100 *Data_type*: float, optional
`-top_layer` *layerNum*	Specifies the top routing layer that is to be used for routing. *Data_type*: string, optional
`-type {bus diff_pair match_length ndr net_class shield simple_net}`	
	Specifies the type of routing constraints to be created: • `bus` - Specifies constraints for bus nets. • `diff_pair` - Specifies constraints for differential pair nets. • `match_length` - Specifies constraints for matched nets. • `ndr` - Specifies constraints for a net with a non-default rule. • `net_class` - Specifies constraints for shielding a group of nets. It can also be used for a group of nets that have the same NDR. • `shield` - Specifies constraints for shielding a single net. • `simple_net` - Specifies constraints for a simple net. *Data_type*: enum, required

Examples

- The following command sets the layer 1 gap as 0.4, layer 2 gap as 0.39, layer 3 gap as 0.38:
  ```
  set_integration_route_constraint -type diff_pair -net {n_7862 n_7875} -layer_gap {1 0.4 2 0.39 3 0.38}
  ```
- The following command specifies a shield constraint for the `analogS41` net:
  ```
  set_integration_route_constraint -type shield -shield_net VSS -shield_type side -connect_supply anypoint -rule NDR4 -net analogS4I
  ```
- The following command specifies a shield constraint for the net group comprising nets `analogW1I`, `analogW2I`, `analogW3I`, and `analogW4I`:
  ```
  set_integration_route_constraint -type net_class -shield_net VSS -shield_type side -connect_supply anypoint -net {analogW1I analogW2I analogW3I analogW4I}
  ```
- The following command specifies minimum and maximum length constraints for the `xyz` net:
  ```
  set_integration_route_constraint -type simple_net -net xyz -min_length 2.0 -max_length 3.0
  ```
- The following command specifies that individual shields should be used between the nets in the bus constraint:
  ```
  set_integration_route_constraint -type bus -net {nets_1 nets_2 ...} -shield_net VSS -no_share_shield ...
  ```

Related Information

- `delete_integration_route_constraints`
- `get_integration_route_constraint`
- `write_integration_route_constraints`
- Routing Constraint Interoperability chapter in the *Mixed Signal Interoperability Guide*
- Tools Menu chapter in the *Menu Reference*
  - Mixed Signal -> Integration Constraint Editor

write_integration_route_constraints

```
write_integration_route_constraints
[-help]
out_file
[-net net_name | -name string]
```

Writes the constraints in an output file in the following order: `diff_pair`, `match_length`, `bus`, `net_class`, `ndr`, and `shield`.

Notes

- Integration constraints are used to convey the design intent in a mixed-signal design. These constraints are fully interoperable between the digital and custom environments.
- If the design contains one or more complex netclass constraints with net members that have different constraints, `write_integration_route_constraints` reports the following warning:

  ```
  **WARN: (IMPOAX-2124): This design contains unknown complex constraint on complexNetClass
  'contraint_name'. This is not an interoperable routing constraint for Innovus. When
  sourcing the resulting file from this command in Innovus, these complex constraints will be
  lost. You can see the complex constraints in the design in the integration constraint form.
  ```

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_integration_route_constraints` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_integration_route_constraints`
`out_file`	Specifies the output file name that is to be written out. *Data_type*: string, required
`-name` *`string`*	Writes information for specified constraint by name. Use the `get_integration_route_constraint` command to get the name of any constraint in the design. You can specify multiple constraint names, enclosed in braces. *Data_type*: string, optional
`-net` *`net_name`*	Writes the constraint defined on specified net. If the net is part of a netclass, writes constraints for the netclass. You can specify multiple net names, enclosed in braces. *Data_type*: string, optional

Examples

- The following command writes the constraints in the output file called `myfile.rpt`:
  `write_integration_route_constraints myfile.rpt`
  The file `myfile.rpt` could have the following sample constraints that are written out:
  - For `diff_pair` constraint

    ```
    set_integration_route_constraint -type diff_pair -name
    Constr_3__analogNL__DTMF_INST/analogNL_INST -tolerance 20 \
    -rule default \
    -net { \
    DTMF_INST/digsyncc \
    DTMF_INST/digsyncd \
    }
    ```

  - For `match_length` constraint

    ```
    set_integration_route_constraint -type match_length -name
    Constr_4__analogNL__DTMF_INST/analogNL_INST -tolerance 20
    -match_style accordion \
    -rule default \
    -net { \
    DTMF_INST/digsync3 \
    DTMF_INST/digsync4 \
    }
    ```

  - For `net_class` constraint

    ```
    set_integration_route_constraint -type net_class -name
    Constr_11__analogSW__DTMF_INST/analogSW_INST \
    -shield_net VSS -shield_type side -connect_supply anypoint \
    -rule NDR8 \
    -net { \
    analogW2I \
    }
    ```

  - For `shield` constraint

    ```
    set_integration_route_constraint -type shield -shield_net {VSS} -shield_type side \
    -shield_tolerance 30 -net {tdigit[0] tdigit[1] tdigit[2] tdigit[3] tdigit[4] tdigit[5]
    \
    tdigit[6]tdigit[7]}
    ```

- The following command outputs a constraint file called `test.const` for the constraint named `Constr_2__analogNW__DTMF_INST/analogNW_INST`:
  `write_integration_route_constraints test.const -name`

```
Constr_2__analogNW__DTMF_INST/analogNW_INST
```

The output is as follows:

```
set_integration_route_constraint -type diff_pair -name
Constr_2__analogNW__DTMF_INST/analogNW_INST -tolerance 20 \
-rule default \
-net { \
DTMF_INST/cntrlxo[3] \
DTMF_INST/cntrlxo[2] \
}
```

- The following command outputs a constraint file with name `temp.const` for the constraint defined on net `analogW1I`:

  ```
  write_integration_route_constraints temp.const -net analogW1I
  ```

  The output is as follows:

  ```
  set_integration_route_constraint -type net_class -name
  Constr_10__analogSW__DTMF_INST/analogSW_INST \
  -shield_net VSS -shield_type side -connect_supply anypoint \
  -rule NDR8 \
  -net { \
  analogW1I \
  }
  ```

- The following command writes a constraint file named `test1.const` for the specified constraint names:

  ```
  write_integration_route_constraints -name {Constr_2__analogNW__DTMF_INST/analogNW_INST
  Constr_1__analogNW__DTMF_INST/analogNW_INST} -file test1.const
  ```

  The output is as follows:

  ```
  #Integration constraints ascii out for { ADTMF4 dtmf_chip NoConst_10_18 }

  set_integration_route_constraint -type diff_pair -name
  Constr_2__analogNW__DTMF_INST/analogNW_INST -tolerance 20 \
  -rule default \
  -net { \
  DTMF_INST/cntrlxo[3] \
  DTMF_INST/cntrlxo[2] \
  }
  set_integration_route_constraint -type diff_pair -name
  Constr_1__analogNW__DTMF_INST/analogNW_INST -tolerance 5 \
  -rule default \
  -net { \
  DTMF_INST/cntrlxo[0] \
  DTMF_INST/cntrlxo[1] \
  }
  ```

- The following command writes a constraint file named `test2.const` for the specified net names:

  ```
  write_integration_route_constraints -net {DTMF_INST/cntrlxo[3] DTMF_INST/cntrlxo[0]} -file
  test2.const
  ```

The output is as follows:

```
#Integration constraints ascii out for { ADTMF4 dtmf_chip NoConst_10_18 }

set_integration_route_constraint -type diff_pair -name
Constr_2__analogNW__DTMF_INST/analogNW_INST -tolerance 20 \
-rule default \
-net { \
DTMF_INST/cntrlxo[3] \
DTMF_INST/cntrlxo[2] \
}
set_integration_route_constraint -type diff_pair -name
Constr_1__analogNW__DTMF_INST/analogNW_INST -tolerance 5 \
-rule default \
-net { \
DTMF_INST/cntrlxo[0] \
DTMF_INST/cntrlxo[1] \
}
```

Multiple-CPU Processing Commands

- check_multi_cpu_usage
- get_distributed_hosts
- get_multi_cpu_usage
- monitor_distributed_hosts
- report_resource
- set_distributed_hosts
- set_multi_cpu_usage

check_multi_cpu_usage

```
check_multi_cpu_usage
[-help]
```

Checks if distributed processing can work in the software environment. This command also ensures that the working directory is accessible from the master machine as well as the client machines. The `check_multi_cpu_usage` command is specified after configuring the multi-CPU settings (`set_distributed_hosts` and `set_multi_cpu_usage`) to check if all the specified CPUs can be accessed. This command should be invoked before running any commands that use multiple CPUs.

Parameters

`-help`	Outputs the command usage and a brief description about the command.

Examples

Here are some examples.

- The following example command script checks the distributed computing environment when `set_distributed_hosts -local` is specified:

```
> check_multi_cpu_usage

get_distributed_hosts

```
get_distributed_hosts
{-mode | -hosts | -queue | -resource | -custom_script | -env_script | -args | -
single_cpu_lsf_args | -timeout | -shell_timeout | -report_lsf_info file | -
wait_for_lsf_info value}
[-help]
```

Displays settings for the `set_distributed_hosts` command.

Parameters

`-args`	Displays the additional arguments when the software is running in the Sun Grid Engine (SGE) or Load Sharing Facility (LSF) mode.
`-custom_script`	Displays the name of the custom script when the software is running in `custom` mode.
`-env_script`	Displays the user-defined shell environment script that is run for each of the slave hosts.
`-hosts`	Displays the list of host names when the software is running in `rsh` mode.
`-help`	Outputs the command usage and a brief description about the command parameters.
`-mode`	Displays the distributed processing mode. The possible values are `local`, `sge`, `rsh` , `ssh` , `lsf` and `custom`. *Default*: `local`
`-queue`	Displays the queue name when the software is running in `sge` or `lsf` mode.

`-report_lsf_info` *file*	Specifies to restore the LSF information to the specified file. This parameter can only be used when `set_distribute_host -report_lsf_info` is specified in the current session. You must specify the `get_distributed_hosts -report_lsf_info` only after the LSF tasks exit to obtain the task CPU time. If you specify this command before the task exits, the command gives a warning message.
`-resource`	Displays the resource string when the software is running in `sge` or `lsf` mode.
`-shell_timeout`	Displays the number of seconds the host machine waits for `rsh/ssh` machines to become available for multiple-CPU processing.
`-single_cpu_lsf_args`	Displays the lsf arguments when the software is running in `lsf` mode for a single CPU application.
`-timeout`	Displays the default timeout for a submitted job that will never start.
`-wait_for_lsf_info` *value*	Specifies the timeout period required to wait for task exit and generate the LSF information.

Examples

- The following command displays the current setting for the `-mode` parameter:

  ```
  get_distributed_hosts -mode
  local
  ```

- The following command saves the LSF information to the `lsf.log` file:

  ```
  get_distributed_hosts -report_lsf_info lsf.log
  ```

Related Information

get_multi_cpu_usage

```
get_multi_cpu_usage
[-help]
[-auto_page_fault_monitor]
[-cpu_per_remote_host]
[-keep_license]
[-local_cpu]
[-remote_host]
[-thread_info]
[-verbose]
```

Displays the requested number of threads or hosts.

To request threads or hosts, use `set_multi_cpu_usage`.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`-auto_page_fault_monitor`	Displays the warning rank set for performance issues caused by major page faults
`-cpu_per_remote_host`	Displays the number of CPUs available on every remote host for super-threading.
`-keep_license`	Displays the current setting for the `set_multi_cpu_usage -keep_license` parameter.
`-local_cpu`	Displays the number of available local CPUs for multi-threading.
`-remote_host`	Displays the number of available remote hosts for distributed processing or Superthreading.
`-thread_info`	Displays the level of informational messages for each thread.
`-verbose`	Displays a message with the current multiple-CPU setting.

Examples

- The following command displays the requested number of threads for multi-threading:

  ```
  get_multi_cpu_usage -local_cpu
  ```

- The following command displays the requested number of remote hosts for Superthreading or distributed processing:

  ```
  get_multi_cpu_usage -remote_host
  ```

- The following command displays the requested number of CPUs per remote hosts for Superthreading:

  ```
  get_multi_cpu_usage -cpu_per_remote_host
  ```

Related Commands

- set_multi_cpu_usage

monitor_distributed_hosts

```
monitor_distributed_hosts
[-help]
[-log string]
[-overwrite]
[-period integer]
```

Monitors hosts and periodically dumps memory or CPU usage information for each host to a file. This command automatically determines the hosts to be monitored. By default, after every 60 seconds hosts are monitored and the disk information is written to a log file. This command is not required for DMMMC because it also performs client monitoring.

The `monitor_distributed_hosts` command is also supported in DSTA mode.

Parameters

`-help`	Prints out the command usage. For a detailed description of the command and all of its parameters, use the `man` command: `man monitor_distributed_hosts`.
`-log string`	Specifies the log file name. *Default*: host-monitor.log
`-overwrite`	Overwrites the log file, if it already exists.
`-period integer`	Specifies the sampling period after which hosts will be monitored. *Default*: 60

Examples

- A sample monitor log file is shown below:

```
Status keys: E excellent, G good, B bad, T terrible.
Memory values:
total = Real memory of host
progs = Real memory used by processes, including swappable cache
used = Real memory used by processes, excluding swappable cache
Started at: 17/04/25 04:24:22

Related Commands

- set_multi_cpu_usage

report_resource

```
report_resource
[-help]
[-check_memory_cpu {true | false} [-period integer]]
[-peak]
[-start string | [-end string [-session_cpu] [-diff_memory]]]
[-verbose]
```

Displays the peak memory used during a software session. This command is used to measure the peak memory at any given point in the flow and and make the script better for automation flows.

⚠ The `report_resource` command is only supported in the 64-bit version of the software and Linux port.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`-check_memory_cpu {true|false}`	Checks the machine's physical memory and CPU resources. When specified, the software enables memory/CPU checking and reports a warning if the free memory is below 5 percent of the total memory or if the average CPU load is larger than 1.35.
`-diff_memory`	Outputs different peak memory and current memory between the step start and step end.
`-peak`	Reports current peak memory till a given point in a flow. This parameter also works with the `-start` and `-end` parameters of the `report_resource` command so that peak memory observed by an individual command can be reported.
`-period integer`	Specifies the period for checking the physical memory and CPU usage. *Default*: 1800s *Min*: 1 *Max*: INT_MAX
`-session_cpu`	Reports the current CPU and real-time after the reports' last step status.

`-start` *`startpoint`*	Specifies the start point to measure the peak memory attained during a specific command. **Note:** The `-start` and `-end` parameters support any user-specified string, such as fullFlow, `time_design`, and TD_PR. You must specify the same string for both the `-start` and `-end` parameters to measure the peak memory attained during a specific command.
`-end` *`endpoint`*	Specifies the end point to measure the peak memory attained during a specific command.
`-verbose`	Gives detailed memory usage information. It displays how much memory is being used at any time and of what form (physical vs. virtual). When specified, the following information is displayed: • `Cpu(s)` is the number of available processors in the machine. • `Load` average is the system load averages for the last 1 minute, 5 minutes, and 15 minutes. • `Mem` and `Swap` are the current memory information of the machine. • `Data Resident Set (DRS)` is the amount of physical memory devoted to other than executable code. "`current mem`" shows this value (Total current DRS) . • `Private Dirty (DRT)` is the memory which must be written to disk before the corresponding physical memory location can be used for some other virtual page. "`peak res`" shows this value (Total peak DRT). This is the minimum number that you must reserve to run the program. • `Virtual Size (VIRT)` is the total amount of virtual memory used by the task. • `Resident Size (RES)` is the non-swapped physical memory a task has used. The number of "Total Peak RES" is the recommended physical memory to reserve.

Examples

- The following command script specifies to display the peak memory attained during the `opt_design` command:

  ```
  report_resource -start "optD"
  opt_design
  report_resource -end "optD"
  ```

  The following message is displayed:

  ```
  Ending "optD" (total cpu=0:15:00, real=0:15:09, peak res=468.8M, current
  mem=396.3M)
  ```

- The following command script specifies to display the peak memory attained during the `time_design` command:

  ```
  report_resource -start fullFlow
  report_resource -start TD_PR
  time_design -post_route
  report_resource -end TD_PR
  report_resource -start OD_PR
  opt_design -post_route
  report_resource -end OD_PR
  report_resource -end fullFlow
  ```

  The following message is displayed:

  ```
  Ending TD_PR (total cpu=0:15:00, real=0:15:09, peak res=468.8M, current
  mem=396.3M)
  Ending OD_PR (total cpu=0:15:00, real=0:15:09, peak res=968.8M, current
  mem=796.3M)
  Ending fullFlow (total cpu=0:35:03, real=0:40:09, peak res=968.8M, current
  mem=796.3M)
  ```

- The following command script specifies to display the peak memory attained during the `opt_design` command:

  ```
  report_resource -peak -start optD1
  report_resource -start optD
  opt_design -post_route
  ```

```
report_resource -end optD
`Ending "optD" (total cpu=0:00:12.9, real=0:00:48.0, peak res=358.8M, current
mem=300.2M)'
report_resource -peak -end optD1
`Ending "optD1" peak res=358.8M'
```

- The following command specifies to display detailed memory information:

  ```
  report_resource -verbose
  ```

  The following output is displayed:

  ```
  Current (total cpu=0:00:23.5, real=0:10:24, peak res=567.8M, current mem=567.8M)

  Cpu(s) 40, load average (past 1 minute): 7.41, load average (past 5 minutes):
  7.46, load average (past 15 minutes): 7.52
  Mem: 527321900k total, 317217944k used, 210103956k free, 3752k buffers
  Swap: 134217724k total, 0k used, 134217724k free, 183952200k cached

  Memory Detailed Usage :
                   Data Resident Set(DRS)  Private Dirty(DRT)  Virtual Size(VIRT)
  Resident Size(RES)
  Total current :   642.3M                 155.6M              1743.3M
   567.8M
  peak :            642.3M                 155.6M              1743.3M
   567.8M
  ```

Related Information

- report_timing

set_distributed_hosts

```
set_distributed_hosts
[-help]
[out_file]
[-add string]
[-args string]
[-custom]
[-custom_script string]
[-custom_script_list string]
[-local]
[-lsf]
[-nc]
[-queue string]
[-remove string]
[-resource string]
[-rsh]
[-shell_timeout integer]
[-single_cpu_lsf_args string]
[-ssh]
[-time_out integer]
[-env_script string]
```

Specifies the multiple-CPU processing configuration for distributed processing or Superthreading. The software finds hosts from the last `set_distributed_hosts` command specified before a distributed processing or Superthreading command starts.

Use `get_distributed_hosts` to display the current settings for the `set_distributed_hosts` command.

ⓘ This command is required for distributed processing and Superthreading.

Parameters

`-help`	Prints out the command usage

out_file	Specifies to report LSF information in a single report. This parameter allows you to collect the system statistics on the status of the distributed jobs. It has the following information: • Host name for master and LSF tasks • Number of CPUs on each machine that are being used by a process • Job ID/PID for each task process • Total memory used on each machine • Total virtual memory used on each machine • Total CPU time used on each machine You must specify this parameter with the `-lsf` parameter. To get the LSF information, specify the `get_distribute_host out_file` command parameter. You must specify the `get_distribute_host out_file` only after the LSF tasks exit to obtain the task CPU time. If you specify this command before the task exits, the command gives a warning message.

`-add` *string*	Adds the specified hosts to the `rsh/ssh` configuration. If you specify more than one host, separate each host name with a space.
	Each time you specify a host, the software uses it to run one client process. To run more than one client process on a host, specify it more than once. For example, if you have two machines that each has two CPUs and you want to use both CPUs in both machines, type a command like the following:
	`set_distributed_hosts -rsh -add {machine1 machine2 \`
	`machine1 machine2}`

`-args` *string*	Specifies any additional arguments you need to provide to the Sun Grid Engine (SGE) or Load Sharing Facility (LSF) job submission command.
`-custom`	Specifies to use the custom job submission script for distributed processing.

`-custom_script` *`string`*	Specifies a custom script to run distributed processing. This includes custom job submission script and arguments for "custom" distributed processing mode. You can use this parameter with `-custom` only.
`-custom_script_list` *`string`*	Specifies custom job submission script list and arguments for "custom" distributed processing mode. for example, `{{{stringCommand1} count1} {{stringCommand2} count2} ... {{stringCommandN} countN}}`. Specifies to customize the launch of multiple jobs, based on resources required for these jobs. This parameter allows you to specify multiple launch strings in order of priority with a maximum allowed job count for each string. If you request for N number of jobs, the command starts submitting jobs starting from *`string1`*, until the corresponding count is reached, at which point it starts submitting the next string in the list. Therefore, the command submits the first "*`count1`*" jobs with *`string1`*, the next "*`count2`*" jobs with *`string2`* and so on. It stops when the total submitted jobs has reached the requested number (N). **Note**: This parameter can only be specified with the `-custom` parameter.
`-env_script` *`string`*	Specifies a user-defined shell environment script that is run for each of the slave hosts. The parameter allows you to pass these environment settings to the slave hosts by including them in the shell environment script. The license variables used by the software are also automatically passed to the slave hosts to avoid license errors.
`-local`	Run distributed processing job on the local machine.
`-lsf`	Specifies a Load Sharing Facility configuration. If you do not specify any parameters for `-lsf`, the software uses default settings. **Note:** To use this parameter, LSF must already be set up (typically by specifying the LSF_ENVDIR and LSF_SERVERDIR environment variables) and bsub must be in your search path. Contact your LSF administrator for details.
`-nc`	Allows you to use NC (Network Computer from RTDA) commands for distributed processing.

`-queue` *string*	Specifies the queue for the LSF or SGE configuration.
`-remove` *string*	Removes the specified hosts or all hosts from the `rsh/ssh` configuration. If you specify more than one host, separate each host name with a space.
`-resource` *string*	Specifies a resource string for the SGE or LSF queue. **Note:** The correct resource string is specific to your installation. Contact your LSF administrator for the appropriate parameters and values.
`-rsh`	Specifies a remote shell configuration. For information, see the `rsh` documentation.
`-shell_timeout` *integer*	Specifies the number of seconds the host machine waits for `rsh/ssh` machines to become available for multiple-CPU processing. *Default:* `5`
`-single_cpu_lsf_args` *string*	Specifies the `bsub` options. For information, see the LSF documentation. **Note:** You must use this parameter to adjust the LSF argument for a single CPU application. Alternatively, use the `-args` parameter to adjust the LSF argument for an application that runs in the Superthreading mode.
`-ssh`	Specifies a secure shell configuration.

`-time_out` *integer*	Specifies the default timeout for a submitted job that will never start. This functionality prevents the master machine from hanging when the clients do not come up for some reason. After timeout, a warning message appears informing you that the distributed CPUs did not come online within the expected time. The master will continue waiting for the clients and it is up to you to continue waiting or kill the run if there are problems with the Distributed Resource Management (DRM) system. A sample warning message is given below: Task id 2 did not come up within the specified timeout period (300 seconds). Use `set_distributed_hosts -timeout` to change the value. This may be a real error due to incorrect or incomplete platform/machine specification provided via set_distributed_hosts to your distributed resource management system (LSF/Sun Grid Engine etc.). If running locally (`set_distributed_hosts -local`), the current machine may be overloaded with too many jobs and swapping (check free memory and CPUs with top). For local runs, consider reducing the number of CPUs you are using via the `set_multi_cpu_usage` command or free up some memory by killing other memory intensive processes. *Default:* 3600 for all the modes (LSF, NC, SGE, RSH, SSH, local and custom **Note**: When the `set_distribute_host` command is not specified, the software sets the default mode as local and the EDP timeout is `3600` seconds.

Examples

rsh

The following command creates an `rsh` configuration and adds hosts `host10`, `host11`, and `host12`:

```
set_distributed_hosts -rsh -add {host10 host11 host12}
```

The following commands create an `rsh` configuration with `host1` and `host2` as remote hosts and then adds `host3` and `host4` to the configuration:

```
set_distributed_hosts -rsh -add {host1 host2}
```

```
set_distributed_hosts -rsh -add {host3 host4}
```

LSF

The following command uses an existing LSF environment, and relies on the general LSF set up by the system administrator. In this example, the name of the queue implies that all the machines have 4 Gb of memory.

```
set_distributed_hosts -lsf -queue mem4G
```

The following command schedules a LSF job named `bigQueue` to run on a Linux machine for a maximum of 30 minutes. No other jobs can run on the machine while `bigQueue` is running.

```
set_distributed_hosts -lsf -queue bigQueue -args {-x -W 30} \
   -resource {OSNAME==Linux}
```

The following command schedules a LSF job named `smallQueue` to run on Linux machines with minimum speed of 2000 MHz.

```
set_distributed_hosts -lsf -queue smallQueue -args {-W 20} \
    -resource {OSNAME==Linux && SPEED>2000}
```

Note: Check with your LSF administrator for the correct values for the resource string, as the parameters and their values differ in each installation. For example, the parameter name for the speed of the machine might be `MHZ` instead of `SPEED` (as in the preceding example), and the units might be specified in gigahertz instead of megahertz.

The following command specifies to report LSF information:

```
set_distributed_hosts -lsf -args "-q lnx64" out_file
get_distribute_host out_file lsf.log
```

Note: Use the above two commands together to save the LSF information in the specified file.

SGE

The following command schedules an SGE job named `all.q` to run on Solaris machines with minimum speed of 2000 MHz.

```
set_distributed_hosts -sge -queue all.q \
-resource {OSNAME==Solaris && SPEED>2000} -args {-A [account name] -N [name]}
```

Local

The following command runs all distributed processing jobs on the machine on which you are running the master version of the software:

```
set_distributed_hosts -local
```

Custom

The following command runs distributed processing with a custom script:

```
set_distributed_hosts -custom -custom_script {bsub -q bigQueue -x -R "OS==Linux && memory>20000"}
```

The following command runs distributed processing with a custom script list:

```
set_distributed_hosts -custom -custom_script_list {{{bsub -P ICD -W 2 -q admin -R "OSNAME==Linux && OSREL==EE50"}1} {{rsh hpc1 -e} 1}}
```

Examples

- The following command allows the client to source the `my_env_file` before start up on the same machine:

  ```
  set_distributed_hosts -local -env_script my_env_file
  ```

  This command allows the master to pass on the user-defined environment settings.

- The following command allows the client to run using the LSF:

  ```
  set_distributed_hosts -lsf -noWaitTaskComeUp
  ```

  When the `-noWaitTaskComeUp` parameter is specified, the software will not wait for all the clients to come up when parts of the clients are launching timeout.

Related Commands

- `get_distributed_hosts`

set_multi_cpu_usage

```
set_multi_cpu_usage
[-help]
[-acquire_license integer]
[-auto_page_fault_monitor {0 | 1 | 2 | 3}]
[-cpu_per_remote_host integer]
[-keep_license {true | false}]
[-license_list string]
[-local_cpu string]
[-release_license]
[-remote_host integer]
[-reset]
[-thread_info {0 | 1 | 2}]
[-verbose]
```

Specifies the number of threads to use for multi-threading, or the maximum number of computers to use for distributed processing, or the maximum number of computers and the number of threads to use for Superthreading. Optionally, reports usage information.

ⓘ This command is required for multi-threading, distributed processing, and Superthreading.

The `set_multi_cpu_usage` command enables multi-threaded timing reporting under the following conditions:

- `timing_report_group_based_mode` attribute is set to `true`. If there are multiple paths with the same slack then the selection can change on multiple runs. This may result in some changes in the `report_timing` output.
- `report_analysis_coverage` command is in non-verbose mode.
- `check_timing -include clock_crossing` parameter is specified.
- `-set_table_style -no_frame_fix_width` parameter is specified.

Parameters

`-help`	Prints out the command usage.

`-acquire_license` *integer*	Acquires licenses to enable the specified number of CPUs. For example, if you specify -acquire_license 5, the software checks out enough licenses to enable 5 CPUs. When specified, the tool displays the number of available CPUs.
	`[DEV]Innovus 1> set_multi_cpu_usage -acquirelicense 5`
	`Total CPU(s) requested: 5`
	`Total CPU(s) enabled with current License(s): 2`
	`Current free CPU(s): 2`
	`Additional license(s) checked out: 1`
	`Encounter_CPU_accelerator_GXL license(s) for 4 CPU(s)`
	`Total CPU(s) now enabled: 6`
	After the licenses are checked out, they can be used for multi-threading, distributed processing, or superthreading.

`-auto_page_fault_monitor {0 | 1 | 2 | 3}`	Specifies to set a warning rank for performance issues caused by major page faults. The parameter supports the following values: • `0` - specifies to disable the reporting of major page faults. • `1` - specifies to set the warning rank as 1. This means `PF/total PF` > 0.8, `b` > 10, and `wa` > 85% • `2` - specifies to set the warning rank as 2. This means `PF/total PF` > 0.5, `b` > 5, and `wa` > 65% • `3` - specifies to set the warning rank as 3. This means `PF/total PF` > 0.2, `b` > 1, and `wa` > 40% where `PF` is the number of major page faults from the software, `total PF` is the total number of major page faults in the machine, `b` is the number of blocked processors, and `wa` is CPU waiting time.
`-cpu_per_remote_host` *integer*	Specifies the number of CPUs on each of the remote machines. This parameter is required for Superthreading. ⓘ For Superthreading, you must use this parameter in conjunction with the -remote_host parameter. *Default:* `1`

`-keep_license {true | false}`	Specifies whether to keep the acquired multiple CPU-licenses until the current session ends. Specify this parameter before running any commands that require multiple-CPU applications. To release all multiple-CPU licenses immediately, use the releaseLicense option. *Default:* `true`
`-license_list` *string*	Specifies the list or order of licenses the software should use for checking out licenses during multiple-cpu processing. The parameter does not support an empty license list {}. You must specify at least one license from the following list: enccpu, nru, edsl, and edsxl.

`-local_cpu` *string*	Specifies the number of CPUs on a local machine. When the `-localcpu` parameter is set to `1` (default), the multi-threaded timing propagation mode is enabled. Also, both CPU multi-threading and distributed process are enabled. The `set_multi_cpu_usage -localCpu` command automatically controls the total number of threads used up to the specified number. The number of specified threads cannot be more than the number of CPUs available in the local computer. Consider a computer having 8 CPUs, then the following command will issue a warning that the number of specified local CPUs is greater than the actual number of CPUs available: `set_multi_cpu_usage -localCpu 10` The local CPU count can be the maximum value that is shown as “processors” on the system under “/proc/cpuinfo”. This value can be obtained by running the “checkSysConf” utility in the "tools/bin" folder. `$> tools/bin/checkSysConf` `============== checkSysConf: Version 3.53 ====================` `OS Version .............: Red Hat Enterprise Linux Workstation release 7.6 (Maipo)` `Kernel Version .........: 3.10.0-957.5.1.el7.x86_64` `Hardware Type ..........: x86_64` `Memory .................: 2063415 Megabyte` `CPU model ..............: Intel(R) Xeon(R) Gold 6254 CPU @ 3.10GHz` **`No. of CPUs ............: 72`** `Total Swap Space........: 131072 Megabyte` `==================================` `$> cat /proc/cpuinfo	grep` **`"processor"`** `| tail -1	awk -F ":" '{print $2 + 1}'` `72` *Default*: 1

`-release_license`	Releases all multiple-CPU license(s) immediately. By default, the software holds multiple-CPU licenses until the end of the current session. To specify that the software release multiple-CPU licenses after every multiple-CPU command runs, use -keep_license.
`-remote_host` *integer*	Specifies the number of remote machines. This parameter is required for distributed processing and Superthreading. *Default:* `0`
`-reset`	Resets the specified parameters back to default values.
`-thread_info {0 | 1 | 2}`	Reports usage information. This parameter works for multi-threading only. *Default:* `0` Specify one of the following values:
	0: Does not write messages to the log file.
	1: Writes the final message to the log file. For example, All threaded jobs finished (10 elapsed sec: 0 processor sec (parent), 0 system sec (parent), 0 processor sec (threads), 0 system sec (threads)).

	2: Writes additional starting/ending information for each thread.
	For example,
	`Starting threaded job 1...`
	`Starting threaded job 2...`
	`Starting threaded job 3...`
	`Ending threaded job 2 (1 elapsed sec, 0 processor sec, 0 system sec, 1.160M).`
	`Ending threaded job 3 (2 elapsed sec, 0 processor sec, 0 system sec, 0.895M).`
	`Ending threaded job 1 (10 elapsed sec, 0 processor sec, 0 system sec, 1.172M).`
	`All threaded jobs finished (10 elapsed sec: 0 processor sec (parent), 0 system sec (parent), 0 processor sec (threads), 0 system sec (threads)).`
	Note: This parameter works in multi-threading mode only.

`-verbose`	Displays messages when changing the multiple-CPU settings.

Examples

To run attribute placement with four threads, specify the following commands:

```
set_multi_cpu_usage -local_cpu 4
place_design
```

To run attribute placement with the maximum number of available threads, specify the following commands:

```
set_multi_cpu_usage -local_cpu max
place_design
```

To run detailed routing with the NanoRoute router in Superthreading mode with two machines and six threads, using an LSF queue, specify the following commands:

```
set_distribute_host -lsf -queue myLSFqueue
set_multi_cpu_usage -remote_host 2 -cpu_per_remote_host 6
route_detail
```

Related Information

- check_multi_cpu_usage

OpenAccess Commands and Attributes

- compare_oa_cellview
- create_oa_lib
- create_oa_lib_property
- get_oa_default_rule_lib
- get_oa_design_data
- oa_read_write Category Attributes
- read_oa
- register_trigger
- report_oa_lib
- set_oa_cell_binding
- unlock_oa_design
- update_oa_lib
- write_lef_library
- write_oa
- write_oa_abstract
- write_oa_black_boxes
- write_oa_techfile

compare_oa_cellview

```
compare_oa_cellview
[-help]
[-ignore {pin_purpose}]
[-out_file report_file_name]
{ {{-source {from_lib from_cell from_view} -compare {to_lib to_cell to_view}} | {-lib lib -cell cell -view
{sourceView compareView}}} }
```

Compares specified cell views. Use this command to compare two OpenAccess databases. For instance, you can use this command to compare the lib/cell/view specified using `-source` to the lib/cell/view specified with `-compare`. Boundary and terminals (name, direction, pin location and size) are compared. This command can be used without design import.

Parameters

`-help`	Prints a brief description that includes type and default information for each `compare_oa_cellview` parameter. For a detailed description of the command and all of its parameters, use the man command: `man compare_oa_cellview`.
`-cell cell`	Specifies the cell for comparing two views. *Data_type*: string, optional
`-compare {`*`to_lib to_cell to_view`*`}`	Specifies the library/cell/view that is to be compared. *Data_type*: string, optional
`-ignore {pin_purpose}`	Specifies the list of attributes to be excluded from the cell comparison. As of now, the only attribute that can be ignored is the purpose, which is specified using the value `pin_purpose` with `-ignore`. *Data_type*: (enum)+, optional
`-lib` *`lib`*	Specifies the library for comparing two views. *Data_type*: string, optional
`-out_file` *`report_file_name`*	Specifies the report file in which all the comparison detail is to be written. *Data_type*: string, optional
`-source {`*`from_lib from_cell from_view`*`}`	Specifies the source library, cell, and view. *Data_type*: string, optional
`-view {`*`sourceView compareView`*`}`	Specifies different views of the same library/cell. *Data_type*: string, optional

Examples

- The following command compares two views of the same cell that are present in the same library `zambezi45` and writes the report to the `test1a` file:

  ```
  compare_cellview -source {zambezi45 pll_vcodiv layout} -compare {zambezi45 pll_vcodiv abstract} -out_file
  test1a
  ```

  A sample output is displayed below:

  ```
  ################################################
  # #
  # Compare_cellview comparison #
  # #
  ################################################

  Source Design : 'zambezi45/pll_vcodiv/layout' is identified as layout design
  Compare Design : 'zambezi45/pll_vcodiv/abstract' is identified as abstract design

  Source Design seems to have been modified after the Compare Design has been created

  Compare Celltype

  Source Design has celltype 'none' & Compare Design has Celltype 'block'

  Compare Cell Boundary

  Source Design has different PRBoundary than Compare Design

  Compare Terminals

  Source Design has Pin 'en' which has Port with shape (36.215 0 36.355 0.14) on layer 'Metal5' and purpose
  'pin' is not present in Compare Design
  Compare Design has Pin 'en' which has a Port with shape (36.215 0 36.36 0.14) on layer 'Metal5' and purpose
  'net' is not present in Source Design
  ...

  Antenna Information

  Antenna Information is defined for Pin 'en' in Compare but not defined in Source Design
  Antenna Information is defined for Pin 'vcocalen' in Compare but not defined in Source Design
  ...

  Source Design is not equivalent to Compare Design
  ```

- The following command compares the views `fplan1` and `fplan2` of the library `DesignLib` and the cell `myAlu`:

  ```
  compare_oa_cellview -source {DesignLib myAlu fplan1} -compare {DesignLib myAlu fplan2}
  ```

create_oa_lib

```
create_oa_lib
[-help]
oa_lib
[-out_dir path]
[-no_compress]
{-oa_attach_tech_lib techlib |
-oa_copy_tech_lib techlib |
-oa_reference_tech_libs techliblist}
```

Copies or attaches a technology database to a library. If the library exists, this command does not update the library.

Note: The parameters must appear in the order specified by the syntax.

The `create_oa_lib` command is part of the OpenAccess design flow. Use this command to create an OpenAccess library at the specified path. `create_oa_lib` needs to be called only once before the design is saved. Subsequent `write_db` calls to the same library will automatically find out the library path that gets stored in `cds.lib`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `create_oa_lib` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man create_oa_lib`.
`oa_lib`	Specifies the name of a library to be created. The software creates the library and adds its name to the `cds.lib` file. *Data_type*: string, required
`-no_compress`	Creates a new library without any compression irrespective of the compression settings provided by the `oa_new_lib_compress_level` attribute. *Data_type*: bool, optional
`-oa_attach_tech_lib` *`techlib`*	Attaches the technology database specified by the technology library to the library that is to be created. *Data_type*: string, required
`-oa_copy_tech_lib` *`techlib`*	Copies the technology database specified by *`techLib`* to the library specified by *`oa_lib`*, and saves the library to the current working directory. *Data_type*: string, required
`-oa_reference_tech_libs` *`techliblist`*	Creates a local technology database in the design library that can be modified incrementally. *Data_type*: string, required
`-out_dir` *`path`*	Specifies the name of a directory in which to save the library. The path you specify must include the directory that will become the library itself. *Default:* *`./oa_lib`* (Saves the library to the current working directory) *Data_type*: string, optional

Examples

- The following command creates the library `myLib` in the current directory, and attaches the technology database in `myRefLib` to `myLib`:
  ```
  create_oa_lib myLib -oa_attach_tech_lib myRefLib
  ```
  Note: Note: If `myRefLib` is read-only, the `write_db -oa_lib_cell_view` command generates an error if it needs to update the technology database.
- The following command creates the library `TEST_LIB` at the specified path, and attaches the technology database in `TEST_REF_LIB` to TEST_LIB:
  ```
  create_oa_lib TEST_LIB -out_dir ./outputs/TEST_LIB -oa_attach_tech_lib TEST_REF_LIB
  ```
- The following command generates an error because only one reference library can be specified:
  ```
  create_oa_lib myLib -oa_attach_tech_lib {myRefLib1 myRefLib2}
  ```
- The following command creates the library `myLib`, and copies the technology database from `myRefLib` to `myLib`. If `myRefLib` is modified, the two technology databases will become out of sync. Additionally, any future write operations from the `write_db -oa_lib_cell_view` command will modify the technology database copy in `myLib` and also cause the databases to be out of sync.
  ```
  create_oa_lib myLib -oa_copy_tech_lib myRefLib
  ```
- The following command creates a new library which references existing technology databases (`refLib1` and `refLib2`), but allows local technology updates if required (typically to add new custom vias to the local technology database).
  ```
  create_oa_lib myLib -oa_reference_tech_libs {refLib1 refLib2}
  ```

Related Information

- `create_oa_lib_property`
- `oa_read_write` Category Attributes
  - `oa_new_lib_compress_level`
- `write_db`

create_oa_lib_property

```
  create_oa_lib_property
[-help]
-name prop_name
-oa_lib libName
-type {boolean integer float string}
-value propValue
```

Adds a new property to the specified OpenAccess library. This command cannot be used to change the value of an existing property.

Note: You cannot use the name `techLibName` for the property you are adding because this name is used by the OpenAccess infrastructure to store the property attached to the library.

Parameters

`-help`	Prints a brief description that includes type and default information for each `create_oa_lib_property` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_oa_lib_property`.
`-name` *`prop_name`*	Specifies the name of the property being created. *Data_type*: string, required
`-oa_lib` *`libName`*	Specifies the name of the OpenAccess library to which the property has to be added. *Data_type*: string, required
`-type {boolean integer float string}`	
	Specifies the type of the property being created. *Data_type*: enum, required
`-value` *`propValue`*	Specifies the value to be set for property being created. The value is interpreted from the input string and converted to the specified type. *Data_type*: string, required

Example

In Innovus, the following set of commands creates a library named *`myLib`*, adds the *`prop1`* property to it, and saves the design before exiting:

```
create_oa_lib myLib -oa_attach_tech_lib adiTech

create_oa_lib_property -oa_lib myLib -name prop1 -type string -value value1

write_db -oa_lib_cell_view {myLib block1 layout}

exit
```

You can now add more properties to the library in Virtuoso. When you restore the design in Innovus, all properties previously added to the library, whether in Innovus or Virtuoso, reflect correctly.

Related Information

- create_oa_lib

get_oa_default_rule_lib

```
get_oa_default_rule_lib
[-help]
[-rule rule_name]
[-libs lib_list]
[-verbose]
```

Searches through a specified library (or libraries) to check whether a specified LDRS exists or not. You can run this check before reading a library.

Parameters

`-help`	Prints a brief description that includes type and default information for each `get_oa_default_rule_lib` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man get_oa_default_rule_lib`
`-libs lib_list`	Specifies the list of library names to search through. If not specified, all libraries are searched. *Data_type*: string, optional

`-rule rule_name`	Specifies the name of the rule to find.
	If not specified, the `init_oa_default_rule` attribute is used. If the attribute has an empty string value, the standard lookup (`LEFDefaultRouteSpec` by type, then by name) is used.
	If the specified *rule_name* does not exist, the command displays an error such as:
	`Rule '<rule_name>' was not found in specified libraries.`
	If the specified *rule_name* is found, the command returns the name of the library where the specified *rule_name* was found. This could be from the `-libs lib_list` or any ITDB that one of those libraries refers to.
	If the specified *rule_name* is found but is not a legal LDRS type as determined by the OAX reader code, the command displays an error such as:
	`Constraint group '<rule_name>' was found in library '<lib_name>', but is not a legal LEFDefaultRouteSpec`
	Data_type: string, optional

`-verbose`	Echoes details of library name where the rule was found (including descending through technology references from libraries specified in the *lib_list*. *Data_type*: bool, optional

Examples

- The following example shows how `get_oa_default_rule_lib` can be used to search for a specific library and the graph of techs that it references:

```
set_db init_oa_ref_libs "tech_lib macro_lib"
set_db init_oa_default_rule LDRS_65nm_6lm
set tech_lib [lindex $init_oa_ref_libs 0]
set lib_found [get_oa_default_rule_lib -libs $tech_lib] # use the init_oa_default_rule to look up the library
if {$lib_found != ""} {
Puts "$init_oa_default_rule was found in $lib_found or in the graph of libraries that $tech_lib references"
} else {
Puts "$init_oa_default_rule was not found in $tech_lib nor in the graph of libraries that $tech_lib
references"
}
```

- The following command shows how the `-verbose` option can be used:

```
get_oa_default_rule_lib -verbose
INFO: Default rule 'LEFDefaultRouteSpec' was found in library 'FEOAreflib8'.
FEOAreflib8
```

Related Information

- `init` Category Attributes
  - `init_oa_default_rule`
  - `init_oa_ref_libs`

get_oa_design_data

```
get_oa_design_data
[-help]
{{-all_oa_libs} | {{-design_data dd_objHandle | -oa_lib libName | -oa_cell {lib cell} | -oa_cellview {lib cell
view}}
[-children | -file | -path | -type |-name]}}
```

Returns OpenAccess library information.

Parameters

`-all_oa_libs`	Returns a list of design data (`dd`) object handles for the list of libraries present in the library definition file (`cds.lib`). *Data_type*: bool, required
`-children`	Returns the `dd` object handles of the children of the specified `dd` object handle. Children of libraries are cells. Children of cells are views. *Data_type*: bool, optional
`-design_data dd_objHandle`	Specifies the `dd` object to be processed. *Data_type*: string, required
`-file`	Returns the `dd` object handles of all the files in the specified `dd` object handle. *Data_type*: bool, optional
`-name`	Returns the name of the specified `dd` object handle. *Data_type*: bool, optional
`-oa_cell {lib cell}`	Specifies the names of the library and cell to be processed. *Data_type*: string, required
`-oa_cellview {lib cell view}`	Specifies the names of the library, cell, and view to be processed. *Data_type*: string, required
`-oa_lib libName`	Specifies the name of the library to be processed. *Data_type*: string, required
`-path`	Returns the absolute path name (`dd` path) of the specified `dd` object handle. *Data_type*: bool, optional
`-type`	Returns the type of the specified `dd` object handle. *Data_type*: bool, optional

Examples

- The following command returns the path of the specified library/cell/view as shown below:

  ```
  get_oa_design_data -cellview {pdkLib cell1 abstract} -path
  ```

  returns:

  ```
  /libs/pkdLib/cell1/abstract
  ```

  This command is equivalent to the following SKILL function:

  ```
  ddGetObjReadPath(ddGetObj("pdkLib" "cell1" "abstract"))
  ```

- The following proc traverses the cds.lib structure (expanding #INCLUDE as required) to get the complete list of OpenAccess libraries and their full paths.

  ```
  # expand #INCLUDE as needed and print all libraries and their full paths
  proc print_all_lib_paths {} {
     puts [format "%16s -> %s" "Library Name" "Library Path"]
     puts "------------------------------------------------------------------"
     foreach oa_lib [get_oa_design_data -all_oa_libs] {
         puts [format "%16s -> %s" [get_oa_design_data -design_data $oa_lib -name] [get_oa_design_data -
  design_data $oa_lib -path]]
     }
  }
  ```

oa_read_write Category Attributes

The root attributes in the `oa_read_write` category are:

- oa_allow_analysis_only
- oa_allow_bit_connection
- oa_allow_tech_update
- oa_bindkey_file
- oa_cell_view_dir
- oa_convert_diagonal_path_to
- oa_cut_rows
- oa_display_resource_file
- oa_display_resource_file_in_library
- oa_drc_fill_purpose
- oa_enclose_quick_abstract_pins
- oa_full_layer_list
- oa_full_path
- oa_inst_placed_if_none
- oa_lib_create_mode
- oa_lock
- oa_logic_only_import
- oa_merge_trim
- oa_new_lib_compress_level
- oa_pin_purpose
- oa_push_pin_constraint
- oa_quick_abstract_for_custom_cells
- oa_read_system_reserved_layers
- oa_silently_ignore_unsupported_vias
- oa_text_purpose
- oa_tie_net
- oa_update_mode
- oa_use_virtuoso_bindkey
- oa_use_virtuoso_color
- oa_view_sub_type
- oa_write_cds_fixed_vias
- oa_write_mask_data_locked
- oa_write_net_voltage

- oa_write_relative_path

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `oa_read_write` category, use the following command:

```
get_db -category oa_read_write
```

oa_allow_analysis_only

`oa_allow_analysis_only {true | false}`

Default: `false`

Data_type: bool, read/write

Allows analysis only flow.

`assemble_design` is not allowed when `oa_allow_analysis_only` is set to `false` and `oa_update_mode` is set to `true`, thereby locking the OpenAccess databse. To allow `assemble_design` to proceed, you must change `oa_allow_analysis_only` to `true`. If you set `oa_allow_analysis_only` to `true` and the Innovus session is in `oa_update_mode` = `true` mode (whether set explicitly or internally on the fly), the `oa_update_mode` setting is ignored.

Note that there may be loss of some semantic information, such as MPPs, while saving the design when `oa_allow_analysis_only` is set to `true`. However, the saved design would be geometrically correct.

oa_allow_bit_connection

`oa_allow_bit_connection {true | false}`

Default: `false`

Data_type: bool, read/write

Creates databases for instances that only have bit-based terminals, without requiring the corresponding bus terminals.

When set to `true`, it saves the connectivity information by bits if the bus connections are not available.

When set to `false`, an error will be issued if the abstract view is missing expected bus terminal information.

oa_allow_tech_update

`oa_allow_tech_update {true | false}`

Default: `true`

Data_type: bool, read/write

Allows the technology database to be updated. The common reason that a technology database would need to be updated is that new vias have been added to the design that are not in a parameterized form. Via masters that are a simple list of rectangles require that a "custom via" be created in the technology database, If the design library had been created with an attached technology, the value should be set to `false` allowing a reference library technology that is shared by multiple designs to have design specific vias to be added to it. For design libraries that have been created in reference mode, allowing the technology database to be updated is typically fine but normally it is best to always use paramaterized vias for OpenAccess-based flows.

Using `set_db generate_special_via_symmetrical_via_only true` before any power planning or routing will typically prevent the creation of non-parameterized vias in the flow.

When `oa_allow_tech_update` is set to `false`, the creation of the OpenAccess database will fail if any custom vias would need to be created within the design library.

Related Commands and Attributes

`generate_special_via_symmetrical_via_only`

oa_bindkey_file

`oa_bindkey_file` *`fileName`*

Default: `""`

Data_type: string, read/write

Maps into Innovus equivalent bindkeys. If the bindkey file is not specified, the Virtuoso default bindkey information is used.

For more information, see the "SKILL to TCL Mapping" section in the Importing and Exporting Designs Design Import and Export in Stylus chapter of the *User Guide*.

Related Commands and Attributes

`oa_use_virtuoso_bindkey`

oa_cell_view_dir

`oa_cell_view_dir` *`string`*

Default: ""

Data_type: string, read/write

Specifies the path name to the physical location of the lib/cell/view that was restored using `read_db -oa_lib_cell_view`. `oa_cell_view_dir` is a system-defined, transient (non-persistent) attribute used in the OpenAccess flow. This should be treated as a *read-only* attribute.

Related Commands

`read_db`

oa_convert_diagonal_path_to

`oa_convert_diagonal_path_to {polygon | default_style}`

Default: `polygon`

Data_type: enum, read/write

Enables interoperability of the end style of geometries of type path segment between Virtuoso and Innovus.

This attribute applies to the diagonal path segments only.

- If the end-style of a diagonal path segment is `custom`, then the end style is retained as is.

- If the end style of a diagonal path segment is not `custom`, then if you set the value to `polygon`, Innovus converts the path segment into a geometrically equivalent polygon.
- If the value specified is `default_style`, then the end style of the path segment is set to `default_style`. In this case, Innovus retains the semantics of the object to be a path segment.

Important: To ensure that there is no loss of semantic or geometric information, the path segments in Virtuoso -XL and Virtuoso-GXL should use the `custom` end-style on diagonal path segments which can be created using *Create-Shape-Geometric Wire*.

oa_cut_rows

```
oa_cut_rows {true | false}
```

Default: `false`

Data_type: bool, read/write

Cuts rows against placement obstructions, block halos, or power domain fence minimum gaps.

The following command cuts rows against placement obstructions, block halos, or power domain fence minimum gaps:

```
set_db oa_cut_rows true
```

oa_display_resource_file

```
oa_display_resource_file pathName
```

Default: `""`

Data_type: string, read/write

Allows you to specify a specific `display.drf` file that is to be used. It overrides all the searching options and the specified file is used.

The following command searches for the `mydisplay.drf` file irrespective of the value of the `oa_display_resource_file_in_library` attribute:

```
set_db oa_display_resource_file /servers/oastore/mydisplay.drf
```

oa_display_resource_file_in_library

```
oa_display_resource_file_in_library {true | false}
```

Default: `false`

Data_type: bool, read/write

Allows the tool to search for the `display.drf` file in the technology library (or complete technology graph in case of ITDB) when set to `true`. If not found, it looks for the file in the current working directory followed by the home directory.

When set to `false`, the tool searches for the `display.drf` file first in the current working directory followed by the home directory.

oa_drc_fill_purpose

```
oa_drc_fill_purpose {gap_fill | drawing}
```

Default: `gap_fill`

Data_type: enum, read/write

Specifies whether to save DRCFILL shapes to the `gap_fill` or `drawing` purpose. By default, DEF routes with + SHAPE DRCFILL are mapped to the `gapFill` purpose in OpenAccess. However, some OpenAccess tech files do not have this purpose defined so any shapes mapped to the `gapFill` purpose would not be visible in Virtuoso and would not be written out in GDS or OASIS. In such cases, set the `oa_drc_fill_purpose` attribute to `drawing` to save these shapes to the `drawing` purpose. When you do so, these shapes get an additional internal attribute so they can round-trip back to DRCFILL shapes properly.

oa_enclose_quick_abstract_pins

`oa_enclose_quick_abstract_pins {true | false}`

Default: `true`

Data_type: bool, read/write

Specifies that shapes enclosing the layout pin shapes should be included as part of the pins during Quick Abstract Inference (QAI) pin modeling. Check the Quick Abstract Inference chapter in the *Mixed Signal (MS) Interoperability Guide* for details.

oa_full_layer_list

`oa_full_layer_list {true | false}`

Default: `true`

Data_type: bool, read/write

Imports the complete list of OpenAccess layers, when importing an OpenAccess design.

If you specify `false`, only OpenAccess layers defined with `oacMaterial` and type are imported.

oa_full_path

`oa_full_path {true | false}`

Default: `false`

Data_type: bool, read/write

Creates the `DEFINE` statements in the `lib.def` files using full paths. If you specify `-oa_full_path false`, the software creates the statements using relative paths.

The following command instructs the Innovus software to create the `DEFINE` statements using full paths:

```
set_db oa_full_path true
```

oa_inst_placed_if_none

`oa_inst_placed_if_none {true | false}`

Default: `true`

Data_type: bool, read/write

Maps the placement status of instances in the OpenAccess database to the placement status in the Innovus software. When set to `true`, the instances in the OpenAccess database that have an unknown placement status are treated as "placed" in the Innovus software. When set to `false`, instances with an unknown placement status are treated as "unplaced."

oa_lib_create_mode

```
oa_lib_create_mode {none | attach | copy | reference}
```

Default: `reference`

Data_type: enum, read/write

Specifies the mode in which `write_db -oa_lib_cell_view` creates a library.

- `none`: Turns off the ability to have `write_db` create a library if it does not already exist.
- `attach`: Attaches the technology database specified by the technology library to the library that is to be created.
- `copy`: Copies the technology database specified by `techLib` to the library specified by `libName`, and saves the library to the current working directory.
- `reference`: Creates a local technology database in the design library that can be modified incrementally. This is the recommended setting to handle the case where the design may have "custom vias" added at some point by power planning/routing.

Related Commands

- `write_db`

oa_lock

```
oa_lock {true | false | error_if_locked}
```

Default: `false`

Data_type: enum, read/write

Specifies whether or not the OpenAccess database will be locked when the design is restored in Innovus. You can specify one of the following options:

- `false`: This is the default option. When set to `false`, the tool does not check whether the design cell view is locked before restoring the design. The OpenAccess database can continue to be edited by other processes even while the design is restored in Innovus.
  Note: If the `oa_update_mode` attribute is set to `true`, the software automatically locks the database, even if the `oa_lock` attribute is set to `false`.
- `true`: When set to `true`, Innovus locks the design cell view during `read_db`, provided that it is not already locked by some other tool. With this setting, other tools cannot edit the OpenAccess database as long as it is locked for the Innovus session but they can still access the database in the read-only mode. To remove the lock, specify the `reset_design` command or exit the Innovus software.
  Note: If the design cell view is already locked by some other tool before `read_db`, Innovus issues a warning but continues to read in the cell view.
- `error_if_locked`: If you want the tool to be more restrictive, set the `oa_lock` attribute to `error_if_locked`. With this option, if the design is already locked while importing or restoring a design, the tool aborts and reports the following error:

  ```
  **ERROR: (IMPOAX-7995): updateMode/locking is on. Design is already locked by another tool. You are
  recommended to close this design from another application before proceeding.
  ```

Default: `false`

ⓘ The value of `-locking` cannot be changed while a design is in memory.

Notes

- If you set the `oa_update_mode` attribute to `true`, the software automatically locks the database, even if the `oa_lock` attribute is set to `false`.
- The value of `oa_lock` cannot be changed while a design is in memory.

Related Commands

- `unlock_oa_design`

oa_logic_only_import

```
oa_logic_only_import {true  | false}
```

Default: `false`

Data_type: bool, read/write

Controls what information the software reads when importing an OpenAccess maskLayout database.

When set to `true`, the software reads only the logical (Verilog netlist equivalent) connectivity during the `init_design` process. When set to `false` (the default value), the software automatically reads physical information, such as floorplan, placement, and routing, from the database, and updates physical net connectivity for power and ground connections.

Note: The `oa_logic_only_import` attribute applies only to OpenAccess maskLayout databases. For other types of OpenAccess databases, the software always reads only the logical connectivity.

Related Commands

- `init_design`

oa_merge_trim

```
oa_merge_trim {true  | false}
```

Default: `true`

Data_type: bool, read/write

Merges the trim metal shapes during save when the trim metal gap is less than or equal to the max_gap settings defined with the `design_merge_trim_shapes` attribute. Refer to the `design` category attribute, `design_merge_trim_shapes`, for detailed merging options.

Related Commands

- `design`
- `write_oa`

oa_new_lib_compress_level

`oa_new_lib_compress_level` *`value`*

Default: `1`

Data_type: int, read/write

Sets the compression level of a library during the library creation process. Cellviews written to a library will follow the compression level of the library and not the current `oa_new_lib_compress_level` setting.

Valid values range between 0 to 9. A value of 0 indicates that compression is turned off.

Related Commands

- `create_oa_lib`

oa_pin_purpose

`oa_pin_purpose {true | false}`

Default: `false`

Data_type: bool, read/write

Writes out pin shapes with the purpose `pin`. When set to `false`, writes out pin shapes with the purpose `drawing`.

oa_push_pin_constraint

`oa_push_pin_constraint {true | false}`

Default: `false`

Data_type: bool, read/write

Specifies whether or not `write_db` or `write_oa_black_boxes` should push an interoperable pin constraint into its corresponding blackbox abstract cellview.

Note: Interoperable pin constraints refer to pin constraints that are understood by Innovus, Virtuoso, and PVS.

Related Commands

`write_db`

`write_oa_black_boxes`

oa_quick_abstract_for_custom_cells

`oa_quick_abstract_for_custom_cells {pcells stdcells all off}`

Default: `all`

Data_type: enum, read/write

Trims design shapes of custom cells. By default, this capability is turned on for all types of custom cells. The following settings are allowed for this attribute:

- `pcells` - Trims design shapes of only custom parameterized cells (PCells).

- `stdcells` - Trims design shapes of only custom standard cells.
- `all` - Trims design shapes of all custom cells.
- `off` - Does not trim design shapes of any custom cell.

Note: This feature needs the INVS30 (Innovus Mixed Signal Option) license. If this license is not available, the abstract that gets generated for custom cells will not work properly in Innovus.

oa_read_system_reserved_layers

```
oa_read_system_reserved_layers  {all | text | off}
```

Default: `all`

Data_type: enum, read/write

Reads the system-reserved layers from the PDK. The following settings are supported:

- `all` - All system-reserved layers are read.
- `text` - Only text layer is read.
- `off` - No system-reserved layer is read.

oa_silently_ignore_unsupported_vias

```
oa_silently_ignore_unsupported_vias  {true | false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether `read_db` should issue messages about vias that are not supported in Innovus when a Virtuoso design is read in.

oa_text_purpose

```
oa_text_purpose purpose_name
```

Default: `drawing`

Data_type: string, read/write

Specifies the purpose name that will be used when text labels are written.

By default, any text label created in Innovus (typically via the `create_text` command) is automatically mapped to the `drawing` purpose. Use the `oa_text_purpose` attribute to map the text labels to a user-defined purpose.

Note: `oa_text_purpose purpose_name` overrides the default `drawing` purpose on output.

oa_tie_net

```
oa_tie_net {tieHighNetName tieLowNetName}
```

Default: `""`

Data_type: string, read/write

Specifies the global tie high and tie low net names to be created in the OpenAccess database. The nets are used to represent the Verilog `1'b1/1'b0` connections to the instance ports. Typically, `tie1` and `tie0` are used as tie high and tie low net names,

respectively. If these names exist in the design locally in any module, then the global names should be changed.

oa_update_mode

`oa_update_mode {true | false | auto}`

Default: `false`

Data_type: enum, read/write

Specifies whether or not to save or restore an OpenAccess design in update mode. If `oa_update_mode` is set to `true`, `read_db -oa_lib_cell_view` processes parameterized cells (PCells) and other custom objects correctly in the Innovus database. For information about generating/regenerating the PCell cache, refer to the "Preparing the IP Library" section in the Technology Data Preparation chapter of the *Mixed Signal (MS) Interoperability Guide*. Setting

`oa_update_mode` to `true` also ensures that `write_db -oa_lib_cell_view` updates the Innovus-modified portion of an OpenAccess database without making changes to PCells or other custom objects.

⚠ In the `oa_update_mode true` mode, the tool locks the source cellview for the duration of the Innovus session.

The `oa_update_mode` attribute provides the ability to import OpenAccess database created from Virtuoso that contains objects which are not understood by Innovus. Complete the digital part in Innovus and update only the objects modified by Innovus in the original OpenAccess database. If your design has any of the following objects, they would only be visible (not editable) in Innovus:

- PCells
- Modgen cells
- Fig-groups
- PCell vias
- RODs (Example, Multi-Part Paths, and so on)
- User defined properties on design objects such as nets, shapes (`lxStickyNet`), instances, abstract views, intermediate hierarchical instances, and so on.

You won't be allowed to edit or modify these objects.

On using the `oa_update_mode` attribute, the property on shapes (for example, `lxStickyNet`) and nets created in VLS-XL / GXL would be kept as-is.

In case of designs where parameterized vias are used, Innovus understands these attributes and evaluates them on-the-fly to create an exact shape and orientation of the cuts.

If the `oa_update_mode` attribute is set to `auto` and the cellview contains objects that are not supported in Innovus, the software internally enables update mode with a message such as follows:

```
INFO: Objects have been found in the cellview requiring updateMode to be enabled so that there is no loss of semantic information when the cellview is saved.
```

Note that enabling update mode can affect `write_db` performance.

Notes

- The value of the `oa_update_mode` attribute cannot be changed while a design is in memory. If this attribute has been set to `true` before importing an OpenAccess design into Innovus, you cannot convert the `oa_update_mode` attribute to `false` in any new Innovus session.
- The on-disk OpenAccess cellview is locked between the restore and save steps when the `oa_update_mode` attribute is set to `true`.

- In `oa_update_mode auto`, the lock is applied at the time that `read_oa` or `read_db -oa_lib_cell_view` starts and released at the end of the command if no objects were encountered that required updateMode to be enabled.

oa_use_virtuoso_bindkey

`oa_use_virtuoso_bindkey {true | false}`

Default: `false`

Data_type: bool, read/write

Allows you to use Virtuoso bindkeys.

oa_use_virtuoso_color

`oa_use_virtuoso_color {true | false}`

Default: `false`

Data_type: bool, read/write

Allows you to display colors and stipples for the design layers (including full custom layers). Using this attribute, Innovus utilizes the same colors and stipples that you would see if you open the design in Virtuoso.

oa_view_sub_type

`oa_view_sub_type {vce | vxl | none}`

Default: `vxl`

Data_type: enum, read/write

Indicates which Virtuoso application should be used for viewing the layout cellviews in the saved OpenAccess database.

- When set to `vce`, cellviews are opened in Virtuoso Chip Editor.
- When set to `vxl`, cellviews are opened in Virtuoso XL.
- When set to `none`, it indicates that the OpenAccess database can be edited by any editor within Virtuoso platform based on its license availability.

oa_write_cds_fixed_vias

`oa_write_cds_fixed_vias {new_vias_only | off}`

Default: `off`

Data_type: enum, read/write

Controls how fixed/custom vias are created in OpenAccess library when saving a design from Innovus to OpenAccess:

- `off` - No cdsFixedVias are created. All fixed/custom vias in the design are saved as oaCustomVia.
- `new_vias_only` - Any newly created custom via is saved as a fixed via while any pre-existing custom via in the Incremental Technology Database (ITDB) is reused when saving the design.
  Note: This feature needs the INVS30 (Innovus Mixed Signal Option) license. If this license is not available, the default `off` value will be used and no fixed vias will be created.

oa_write_mask_data_locked

```
oa_write_mask_data_locked {true | false}
```

Default: `false`

Data_type: bool, read/write

Sets the shapes with mask coloring (mask values other than 0) to locked in the saved cellview, when set to `true`.

By default, `write_oa` and `write_db` write out shapes with their mask coloring information in an unlocked state. Some tools treat the unlocked color information as the recommended color. However, for some foundry processes, shapes with unlocked mask coloring information are written to GDSII/Stream as gray (uncolored). In such cases, set the `oa_write_mask_data_locked` parameter to `true` to lock the mask coloring of shapes explicitly.

Note: This option affects only the saving of shapes with non-zero mask coloring values. Review the map file that will be used to create GDSII/Stream output from the OpenAccess cellview to determine if the map file requires shapes to be locked for them to be written out as colored.

Related Commands

- `write_db`
- `write_oa`

oa_write_net_voltage

```
oa_write_net_voltage {true | false}
```

Default: `false`

Data_type: bool, read/write

Saves the minimum and maximum net voltage across all loaded timing views to every net. When this attribute is set to `true`, `write_db` writes voltage information to the voltage attribute of oaBitNet. This is useful for Virtuoso, and other tools that may read the cellview, to understand the minimum and maximum net voltage without needing to interpret the CPF or .lib file to get that information. The round-trip of the information into Innovus is not dependent on this setting.

oa_write_relative_path

```
oa_write_relative_path {true | false}
```

Default: `true`

Data_type: bool, read/write

Specifies whether or not to save the relative path in the configuration file. Defines the current working directory (`$cwd`) in the configuration file as ". ". When set to `true`, a design can be restored, even if the directory path of the design file is changed.

read_oa

```
read_oa
[-help]
oa_lib
oa_cell
oa_view
[-filter {block_insts blockages boundary fixed_core_insts floorplan pad_insts pin_shapes regions regular_routing
special_routing bump_insts}]
[-nets { netnames }]
```

Restores floorplan, placement, and routing data using the OpenAccess format. This command only reads physical information from the OpenAccess database. For information on restoring an OpenAccess database, see read_db.

You can use the `read_oa` command after importing the design.

Note: Innovus supports only the following begin/end extension values for DEF `NETS` style wiring segments: 0, width/2 or LEF `LAYER WIREEXTENSION`. If any of the wire extensions has unsupported extension value, then Innovus converts it to a special wire (DEF `SPECIALNETS`). While writing back OpenAccess (`write_oa` or `write_db -oa_lib_cell_view`), these special wires will again be converted back to DEF `NETS` style wiring.

Parameters

`-help`	Outputs a brief description that includes type and default information for each parameter of the `read_oa` command. For a detailed description of the command and all of its parameters, use the `man` command: `man read_oa`.
oa_lib	Specifies the OpenAccess library name. *Data_type*: string, required
oa_cell	Specifies the name of the top cell to import. *Data_type*: string, required
oa_view	Specifies cellview name to import. *Data_type*: string, required
`-filter {block_insts blockages boundary fixed_core_insts floorplan pad_insts pin_shapes regions regular_routing special_routing bump_insts}`	

	Lists the OpenAccess cellview information data to be read. When not specified, all information is read from the OpenAccess cellview. When `-filter` is specified, only the object types that are chosen will be read. Additionally, when reading pin_shapes or instances, information in the cellview that refers to terminals or instances that do not exist in memory will be ignored. The legal `-filter` options are: • `block_insts` - Indicates that any CLASS BLOCK instances should be updated. Physical-only block instances may be added to the database if the placement status is `fixed` or `cover`. • `blockages` - Indicates that blockages should be processed. If a blockage is attached to an instance that does not exist in the in-memory database, then it is ignored. • `boundary` - Indicates that the design boundary information, including rows and tracks, should be updated. When `boundary` is specified, the design boundary, rows and tracks are created from the new boundary. • `fixed_core_insts` - Indicates that any CLASS CORE instances that have placement status `fixed` or `cover` should be updated. Physical-only core instances may be added to the database if the placement status is `fixed` or `cover`. • `floorplan` - Is equivalent to specifying "`block_insts blockages boundary fixed_core_insts pad_insts pin_shapes regions special_routing`" • `pad_insts` - Indicates that any CLASS PAD instances should be updated. Physical-only pad instances may be added to the database if the placement status is `fixed` or `cover`. • `pin_shapes` - Indicates that pin shapes should be read. When `pin_shapes` is specified, the existing pins are replaced by the ones being read from the cellview. • `regions` - Indicates regions should be updated. • `regular_routing` - Indicates that nets should be processed and regular routing (and associated shield net wiring) and net constraints updated. • `special_routing` - Indicates that nets should be processed and special routing (except shield nets wiring) should be read. • `bump_insts` - Indicates that bump instances from the cell view need to be read. Use `read_oa -filter` to read floorplanning information from a cellview whose connectivity does not match the current Innovus in-memory connectivity. The `-filter` option allows you to load some data selectively, while not loading others. When `-filter` is used, error checking for database consistency (nets, instances, terminals, etc.) is disabled. While similar to Virtuoso Load Physical View (LPV), the `-filter` option is only a subset and not intended to be a complete replacement. *Data_type*: (enum)+, optional
`-nets {`*netnames*`}`	
	Specifies the list of nets whose routing (routing and special) and constraints have to be read with the `-filter` option. Shielding wiring/vias are also read in if they are used to shield any of the specified nets. If this option is used, typically `regular_routing` is not specified as part of the `-filter` objects. *Data_type*: string, optional

Example

- The following command restores data using OpenAccess:
  ```
  read_oa design amba_usb layout
  ```

register_trigger

```
register_trigger
[-help]
[{-pre | -post}
command_name
proc_name]
```

Registers the `-pre` or `-post` callback procedures with the specified commands.

The procedure registered with `-pre` parameter runs before the *`command_name`* parameter is used while the procedure registered with `-post` parameter runs after the *`command_name`* parameter is used.

Note: The arguments passed to *`command_name`* are passed to *`proc_name`*. If the procedure registered with the `-pre` parameter returns a `TCL_ERROR`, then *`command_name`* is not run.

You can use the `register_trigger` command after starting the Innovus software.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `register_trigger` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man register_trigger`.
`command_name`	Specifies the command name. The supported command names are `read_db`, `write_db`, `read_oa`, and `write_oa`. *Data_type*: string, required
`proc_name`	Specifies the procedure name that is to be registered as callback. *Data_type*: string, required
`-post`	Specifies the procedure to be called after the command. *Data_type*: bool, required
`-pre`	Specifies the procedure to be called before the command. *Data_type*: bool, required

report_oa_lib

```
report_oa_lib
[-help]
lib_name
[-header]
[-filter {cdsinfo | compression | constraint_groups | property | tech_graph}]
```

Reports information about OpenAccess libraries from within Innovus. You can use this command to query for attributes that are controlled by some of the oa_read_write Category Attributes and the `update_oa_lib` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `report_oa_lib` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_oa_lib`.
`lib_name`	Specifies the name of the OpenAccess library to be queried. *Data_type*: string, required
`-filter {cdsinfo | compression | constraint_groups | property | tech_graph}`	
	Specifies the list of information to be included in the report. You can choose from the following filter options: • `cdsinfo` - Reports whether the `cdsinfo.tag` exists in the specified library. • `compression` - Reports the compression level (0 = uncompressed) of the library. • `constraint_groups` - Reports the constraint groups defined in the libraries in the technology graph. Constraint groups that are compatible with the default rule and `NONDEFAULTRULE` requirements will be indicated. • `property` - Reports the property information that was added to the library. The `add_oa_library_property` command is one source of library properties. • `tech_graph` - Reports information about the technology graph from the specified library. If you do not specify a filter option, all the above information is included in the report. *Data_type*: (enum)+, optional
`-header`	Indicates that header information should be displayed. This option is useful if the report is being redirected to a file. *Data_type*: bool, optional

Example

The following command reports information about the `zambezi45` OpenAccess library along with the header:

```
innovus 18> report_oa_lib zambezi45 -header

;*******************************
; Header Info
;*******************************
; Generated by: Cadence Innovus 18.10-a025_1
; OS: Linux x86_64(Host ID donut)
; Generated on: Mon Feb 12 15:53:07 2018
```

```
; Command: report_oa_lib zambezi45

set_oa_cell_binding

```
set_oa_cell_binding
[-help]
[-abstract ]
[-oa_lib list_of_libs]
{-base_cell list_of_cell_patterns -oa_view list_of_views}
```

Changes the layout binding for a cell. This also affects the layout viewing and automatic remastering. When specified with `-abstract` parameter, this instead of affecting the abstract binding replaces the in-memory cell information with the matched cells.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_oa_cell_binding` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man set_oa_cell_binding`.
`-abstract`	Replaces in-memory cell information for the matched cells. *Data_type*: bool, optional
`-base_cell list_of_cell_patterns`	Specifies one or more cell name patterns that are to be replaced. *Data_type*: string, required
`-oa_lib list_of_libs`	Specifies the OpenAccess library that is to be used to look for cell abstracts. *Data_type*: string, required
`-oa_view list_of_views`	Specifies the cellview name. *Data_type*: string, required

Examples

- The following command looks for the cells in Innovus database that match the cell pattern and replaces their binding with the specified view found in the library list.

```
set lib_list1 {lib1 lib2}
set_oa_cell_binding -oa_lib $lib_list1 -base_cell {cell1 cell2 cell3} -oa_view {abc}
```

Related Information

- `write_oa`

unlock_oa_design

```
unlock_oa_design
[-help]
oa_lib
oa_cell
oa_view
```

Unlocks the specified OpenAccess design.

A design cannot be opened if `set_db oa_lock` is set to `1`, and the design is currently locked. You can use the `unlock_oa_design` command to free the lock so that other tools can access and edit the database. You also can use the command to override the lock, if the design is incorrectly locked.

You can use the `unlock_oa_design` command at any time.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `unlock_oa_design` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man unlock_oa_design`.
`oa_lib`	Specifies the name of the OpenAccess oa_library in which the design was saved. *Data_type*: string, required
`oa_cell`	Specifies the name of the top oa_cell to unlock. *Data_type*: string, required
`oa_view`	Specifies the name of the oa_cell oa_view to unlock. *Data_type*: string, required

Example

- The following command unlocks the oa_view `layout` in the oa_cell `dtmf_chip` in the oa_library `designLib`:
  ```
  unlock_oa_design designLib dtmf_chip layout
  ```

Related Information

- oa_read_write Category Attributes
  - `oa_lock`

update_oa_lib

```
update_oa_lib
[-help]
lib_name
[-compress_level value]
[-create_cdsinfo_tag]
[-tech_attach_to_reference]
```

Updates the specified OpenAccess library from within Innovus. You can use this command to:

- Converts the specified library to use a tech reference from the attached tech so that the non-parameterized or custom vias can be written to it. If an OpenAccess design has non-parameterized vias, you should run `update_oa_lib` before invoking `write_db`. The tool is then able to save the design and does not throw an error because it can now write non-parameterized vias to the converted library.
- Add a cdsinifo.tag to legacy libraries created by earlier versions of Innovus.
- Modify the compression level for the library.

If you run the `update_oa_lib` command on a library that is not in attached mode, a warning is displayed. However, the script continues to run. This is useful if you want to make sure that libraries are writable for new vias and the `write_db` command does not fail.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `update_oa_lib` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man update_oa_lib`.
`-compress_level` *value*	Sets the compression level of the specified library. Cellviews written to the library follow the specified compression level. However, existing cellviews in the library are not modified. Use the oazip utility to modify the existing cellviews in the library. Valid compression level values range from 0 to 9. A value of 0 indicates that compression is turned off. *Data_type*: int, optional
`-create_cdsinfo_tag`	Adds a `cdsinfo.tag` file to the specified library. *Data_type*: bool, optional
lib_name	Specifies the name of the library to be updated. *Data_type*: string, required
`-tech_attach_to_reference`	Converts the specified library to use a tech reference from the attached tech so that new custom via definitions can be added to the library. *Data_type*: bool, optional

Examples

- The following command sets the compression level of the `lib1` library to 9. However, it does not change the compression of the existing cellviews in the library:
  ```
  update_oa_lib lib1 -compress_level 9
  ```
  The tool displays warning such as the following:
  ```
  Changed library compressLevel from '0 (uncompressed)' to '9'. Cellviews within the library are not affected by changing the library's compressLevel. To update the cellviews, use the oazip utility.
  ```
- The following command decompresses the `my_lib` library, which previously is at compression level `1`:
  ```
  update_oa_lib my_lib -compress_level 0
  ```

Related Information

- `oa_read_write` Category Attributes
- *Mixed Signal (MS) Interoperability Guide*
  - Static Timing Analysis for Mixed Signal Designs chapter

write_lef_library

```
write_lef_library
[-help]
[lef_file]
[-all_auto_generated_via | -macro_only]
[-macro_only [-no_property]]
[-tech_only | -macro_only]
[-tech_only | -macro_list string]
```

Writes the LEF library data (composed of technology data and macros) that is present in the Innovus database.

The `write_lef_library` command facilitates comparisons between LEF-based input and OpenAccess-based input. LEF allows cases where `VIARULE GENERATE` has `WIDTH` specified for either the top or bottom layer. However, such cases are not supported by the OpenAccess tech. To make the comparison between LEF-based and OpenAccess-based input easier, `write_lef_library` dumps `"WIDTH 0 TO 1000 ;"` for any `VIARULE GENERATE` that does not have WIDTH specified in the original LEF.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `write_lef_library` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_lef_library`.
`lef_file`	Specifies the output LEF file name. *Data_type*: string, optional
`-all_auto_generated_via`	
	Includes all auto-generated vias from the `add_route_via_defs` command. *Data_type*: bool, optional
`-macro_list` *`string`*	
	Writes the macros specified in the macro list. *Data_type*: string, optional
`-macro_only`	Writes only the macro data to the LEF file. *Data_type*: bool, optional
`-no_property`	Writes data in the LEF file without any properties. This option can be used only with the `-macro_only` option. *Data_type*: bool, optional
`-tech_only`	Writes only the technology data to the LEF file. *Data_type*: bool, optional

Examples

- The following command writes the technology data into the `tech.lef` file:
  ```
  write_lef_library tech.lef -tech_only
  ```
- You can set the LEF version to 5.7 or 5.8 using `write_def_lef_out_version`:
  ```
  set_db write_def_lef_out_version 5.8
  ```

write_oa

```
write_oa
[-help]
oa_lib
oa_cell
oa_view
[-auto_remaster]
[-cut_rows]
[-early_global_route]
[-no_overwrite_abstract]
[-oa_leaf_views { lefView1 lefView2 ... }]
[-oa_ref_libs { refLib1 refLib2 ... }]
[-no_connectivity [-no_std_cells]]
```

Saves floorplan, placement, and routing data in the OpenAccess format.

You can use the `write_oa` command after importing the design.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `write_oa` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_oa`.
oa_lib	Specifies the target OpenAccess library name. *Data_type*: string, required
oa_cell	Specifies the target cell name. *Data_type*: string, required
oa_view	Specifies the target view name. *Data_type*: string, required
`-auto_remaster`	Overrides the reference libraries and leaf view names specified binding, and utilizes the cell layout viewing binding stored on the library cell master for each leaf cell (stored in the library cell's layout library and layout view attributes). The binding can be specified using the `set_oa_cell_binding` command. *Data_type*: bool, optional
`-cut_rows`	Specifies that rows are cut against placement obstructions and block halos, similar to the behavior of the `write_def` command. *Default:* Does not cut rows. *Data_type*: bool, optional
`-early_global_route`	Writes out a design containing Early Global Route data. *Data_type*: bool, optional

`-no_connectivity`	Writes out a design that contains instances and physical shapes. When specified, the software creates an OpenAccess module domain using the instance hierarchy, but does not attempt to create any nets, pins, or instance pins. This behavior is similar to writing a DEF file without the NETS section. **Note** - Designs written out using the `-no_connectivity` parameter cannot be reloaded into the Innovus software. *Data_type*: bool, optional
`-no_overwrite_abstract`	Prevents the software from overwriting abstracts of partitions and blackboxes. *Default:* Innovus overwrites abstracts of partitions and blackboxes. Innovus never overwrites abstracts of library data. *Data_type*: bool, optional
`-no_std_cells`	Does not save instances of core cells to the OpenAccess database. However, if an instance is either fixed or covered, it is saved to the database. Use this parameter if you just need the preliminary design for DRC checks of the floorplan. In such cases, leaving out the standard cell information makes the file smaller and reduces the DRC run time. **Note** - The `-no_std_cells` parameter must be used with the `-no_connectivity` parameter. *Data_type*: bool, optional
`-oa_leaf_views {lefView1 lefView2 ...}`	
	Specifies a list of view names to be searched during leaf cell instance binding. *Data_type*: string, optional
`-oa_ref_libs {refLib1 refLib2 ...}`	
	Specifies the names of the external libraries that will contain the leaf cell masters, LEF abstract, and technology file. This parameter only accepts library names, not paths. The mapping between the external library name and its path is defined in the `cds.lib` file. Innovus references technology information only from the first library in the list of libraries. *Data_type*: string, optional

Example

- The following command shows the usage of ITDB style libraries:

```
create_oa_lib myDesignLib -oa_reference_tech_libs {techLib}
write_oa -auto_remaster myDesignLib myTopCell layout
```

write_oa_abstract

```
write_oa_abstract
[-help]
[-cut_obs]
[-cut_obs_min_spacing]
[-extract_block_obs]
[-extract_block_pg_pin_layers layerNameList]
[-oa_lib lib]
[-oa_view view]
[-pg_pin_layers layerNameList]
[-stripe_pin {top all none}]
[-top_layer topLayerName]
```

Generates hierarchical design abstract information for the current block-level design. By default, if `write_oa_abstract` creates power and ground pins on the design and creates a single obstruction shape for each routing layer. The output abstract contains the antenna information, if you run antenna verification.

In a bottom-up flow (where the block was not created using the `create_partition` or `commit_partitions` command, you normally create a simple OpenAccess abstract that contains:

- one obstruction (`OBS`) shape per routing layer
- signal pins located along the block boundary
- power pins for the top metal layer

You can use the `write_oa_abstract` command after loading a block-level design.

Parameters

`-help`	Prints a brief description that includes the type and default information for each `write_oa_abstract` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_oa_abstract`.
`-cut_obs`	Creates cut-outs (obstructions) in the blockages for signal pins, power and ground pins, vias, and power and ground stripes. *Default*: Creates a single obstruction shape for each routing layer. *Data_type*: bool, optional
`-cut_obs_min_spacing`	Creates cut-outs (obstructions) in the blockages around pins using the minimum width to calculate the spacing. *Data_type*: bool, optional
`-extract_block_obs`	Extracts all obstruction (`OBS`) information from the instantiated `CLASS BLOCK` or `RING` macros and writes out the obstructions to the output OpenAccess file. `OBS` information is extracted for layers that are not already being completely covered under the normal routing layer range and for cut layers between routing layers that are completely covered. *Data_type*: bool, optional
`-extract_block_pg_pin_layers layerNameList`	

	Extracts the power and ground pin information from any CLASS BLOCK and CLASS RING macros with pins on layers in the specified layer list and writes out the pin information to the OpenAccess file. You can use metal layer numbers (for example, specify `4` for `metal4)`. Specify a list of layer numbers by leaving a space between each number. For example, to create a list with layers `metal3`, `metal4`, and `metal5`, specify `-extract_block_pg_pin_layers 3 4 5`. *Default*: Does not extract the pin information from any macros. *Data_type*: string, optional
`-oa_lib` *lib*	Specifies the target library name. *Default*: The abstract is written into the library from which the current data was loaded. *Data_type*: string, optional
`-oa_view` *view*	Specifies the target view name. *Default*: `abstract` *Data_type*: string, optional
`-pg_pin_layers` *layerNameList*	
	Specifies the list of layers. *Data_type*: string, optional
`-stripe_pin {top all none}`	Writes out power and ground stripes on the top metal layer as power and ground pins. You can use this parameter in a bottom-up methodology, when you create abstracts for blocks that you will use at the next higher level of a hierarchical design. *Data_type*: enum, optional
`-top_layer` *topLayerName*	Writes out obstruction information only for layers up to the specified layer. You can use the metal layer number (for example, specify `4` for `metal4`). *Default:* Top routing layer (therefore, writes out obstruction information for all layers) *Data_type*: string, optional

write_oa_black_boxes

```
write_oa_black_boxes
[-help]
-base_cells list_of_cells
-oa_lib libName
[-oa_view viewName]
```

Saves the specified blackbox abstracts, using the OpenAccess database format. You can use the `write_oa_black_boxes` command at any time after importing the design.

Note that when the design is saved using the `write_db` command, the tool automatically saves abstracts for any blackboxes in the design. However, if you are performing pin optimization or manipulating the blockages on a particular macro in the design, you may wish to save the abstract for only that particular macro. The `write_oa_black_boxes` command is useful in such situations.

Parameters

`-help`	Prints a brief description that includes type and default information for each `write_oa_black_boxes` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_oa_black_boxes`
`-base_cells` *`list_of_cells`*	Specifies one or more blackboxes to save. If you specify more than one blackbox, you must enclose them in either double quotation marks or curly braces, and separate them with an empty space. *Data_type*: string, required
`-oa_lib` *`libName`*	Specifies the OpenAccess library to use to save the blackbox abstracts. If an OpenAccess library with the same name already exists, the software creates a cell view in that library. If the library does not exist, the software creates the library in the working directory, with the library name and the path name being the same. If a new library is created, the technology file is copied from the technology library to the new library. *Data_type*: string, required
`-oa_view` *`viewName`*	Specifies the cell view to save. *Default:* Uses the view name `abstract` *Data_type*: string, optional

Examples

- The following command saves the blackbox `myBlackbox` in view `abstract`:
  ```
  write_oa_black_boxes -oa_lib myLib -base_cells myBlackbox -oa_view abstract
  ```
- The following command saves the blackboxes `myBlackbox1` and `myBlackbox2` in view `abstract`:
  ```
  write_oa_black_boxes -oa_lib myLib -base_cells "myBlackbox1 myBlackbox2" -oa_view abstract
  ```
- The following command also saves the blackboxes `myBlackbox1` and `myBlackbox2` in view `abstract`:
  ```
  write_oa_black_boxes -oa_lib myLib -base_cells {myBlackbox1 myBlackbox2} -oa_view abstract
  ```

Related Information

- write_db

write_oa_techfile

```
write_oa_techfile
[-help]
[out_file]
[-include_rules]
[-process_node coord]
```

Writes out a DFII style ASCII technology file that can be given to the `techLoadDump` executable to create an equivalent OpenAccess technology database.

This command is used to create and verify OpenAccess technology files that match LEF technology files. By default, `write_oa_techfile` writes out only DRC information and no LDRS or VIA information.

The expected flow for new processes is as follows:

1. Read a LEF file into Innovus with `init_design`.
2. Use `write_oa_techfile` to write out the tech (`.tf`) file.
3. Run `techLoadDump` using the `.tf` file.
4. Use `lef2oa -pnrLibDataOnly` to create the LDRS and vias.

For more information, refer to the chapter "Technology File Layer Attributes" of the *Virtuoso Technology Data ASCII Files Reference*.

Parameter

`-help`	Outputs a brief description that includes type and default information for each `write_oa_techfile` parameter. For a detailed description of the command and all of its parameters, use the man command: man `write_oa_techfile`.
out_file	Specifies the output ASCII file name. *Data_type*: string, optional
`-include_rules`	Includes LDRS and VIA information in the output tech file. This option should be used only if the LEF default and NDRs do not utilize fixed vias. *Data_type*: bool, optional
`-process_node` *coord*	Specifies a process node value in nm. When specified, `write_oa_techfile` creates a processNode entry in the techfile for processes using the MASK construct. For example, if you specify `-process_node 20` to indicate a 20nm process, the following entry is included in the control() section of the techfile: `processNode(0.020)` If `-process_node` is not specified and the `write_oa_techfile` command detects MASK constructs on any layer, it returns an error. *Data_type*: int, optional

Examples

- The following set of commands updates an OpenAccess technology file with any missing information from a LEF technology file:

```
#Initialize a design using LEF files
write_lef_library -tech_only lef.lef  #A LEF file in canonical
                                      #sorted order for easy
                                      #comparison with diff
write_oa_techfile lef.tf              #A DFII ASCII tech file
                                      #that can be given to
                                      #techLoadDump executable
#Edit existing OA tech file to add any missing information in
#the lef.tf file
#Initialize a design using the new OA tech. Then:
write_lef_library -tech_only oa.lef #A LEF file in canonical
                                    #order derived from OA tech
#Compare the two LEF files. Any differences need to be fixed
#or explained.
diff lef.lef oa.lef
```

add_connection_to_neighbor_partition

```
add_connection_to_neighbor_partition
[-help]
```

Adds a partition pin on the abutted edge of unique abutting partitions to create a 2-partition pin scenario for target pins. This helps to avoid floating pins on abutted edges. The `add_connection_to_neighbor_partition` command targets the following pins:

- Input partition pins with have tie definition and a GNC/UPF to resolve the tie net to a supply
- Floating output partition pins

Note: The target pins may or may not have any load/driver inside the partition.

This command should be used after the pins have been assigned for the target partition and tie cells have been specified using the `add_tieoffs_cells` attribute.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `add_connection_to_neighbor_partition` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man add_connection_to_neighbor_partition`

Example

- The following command adds partition pins on abutting partitions and reports the number of new partition pins and tie cells in a table.

```
add_connection_to_neighbor_partition
-------------------------------------------------------------------------------------
|    Type     | Total Pins | Pins placed in abutted edge | New partition pins added |
-------------------------------------------------------------------------------------
|   Tie-low   |          4 |                           4 |                        4 |
|   Tie-hi    |          4 |                           4 |                        4 |
| Floating(I) |         16 |                          16 |                        - |
| Floating(O) |         16 |                          16 |                       16 |
-------------------------------------------------------------------------------------
```

add_partition_feedthrus

```
add_partition_feedthrus
[-help]
[-all_lower_case]
[-blockage_file file_name]
[-blocked_edges_file file_name]
[-inst_prefix instance_prefix]
[-net_prefix net_prefix]
[-reuse_buffer {true false 0 1}]
[-symmetrical_repeat_abutted_floorplan]
[-use_short_name]
[-verbose]
[-write_topological_file topology_file_name]
[[[-include_nets_file file_name | -selected_nets | -auto_select_nets_by_congestion | -auto_select_nets_by_slack |
[ [-exclude_nets_file file_name] ]] ] | -use_topological_file topology_file_name ]
[ -use_topological_file topology_file_name | -route_based | -route_based_strict |
[-exclude_partitions {partition_name | partition_name_list} ] ] [ -use_topological_file topology_file_name | -route_based | -
route_based_strict ]
[ -route_based [-auto_select_nets_by_slack ] [-auto_select_nets_by_congestion ]]
[-no_buffer | [[-buffer_cell {cell_name | cell_name_list}] [-double_buffer ]]]
[[-check_only ] | [[-eco_file file_name] [-net_mapping file_name]] ] [-use_topological_file topology_file_name ] [-no_buffer ]
```

Inserts feedthrough buffers into the partitions, changing the original netlist, to avoid routing a net over a block area. ECO placement runs automatically with this command. The buffer supplied during design import is taken as default. For Alternately, you can specify a buffer with the `-buffer_cell` parameter or specify the `-no_buffer` parameter to generate an ASSIGN statement in the netlist. You can use this command after the floorplanning steps for a partitioned design.

The `add_partition_feedthrus` command can detect if the design has power domains. This way, appropriate buffers which are inserted into power domains will automatically be derived based on power domain library binding. An error message is reported if no regular buffer is found for an *Always On* power domain in the feedthrough path. Both placement and route based feedthrough insertions can support *Always On* and switchable power domains.

You can save the feedthrough buffer topology tree information in a file by using the `-write_topological_file` parameter. You can later use the `-use_topological_file` parameter to replicate feedthrough buffer insertions for an ECO netlist by specifying the file that has the topology tree information. You can also manually create a topology file to guide feedthrough insertion for specific nets.

Notes:

- The `add_partition_feedthrus` command by default derives the feedthrough topology using a shortest-path algorithm, which is based on the placement results.
- The `add_partition_feedthrus` command by default considers a design to be channel-less, having no channel available for routing. Therefore all nets are candidates for feedthrough insertion.
  The default behavior assumes a true channel-less design - that is, the possibility of routing through channels is considered minimal. It does not consider routing congestion, routing blockages, route guides, pin guides, and bus guides. If these considerations are required, use the `-route_based` parameter to derive the feedthrough topology based on the routing results.
- Feedthroughs are inserted in nets that connect to floating ports. Floating ports are hierarchical ports that are not connected to any logic inside the module.
- The `add_partition_feedthrus` command removes nets that are inserted with feedthrough buffers from any net groups to which they belong. After running this command you should, therefore, update the net groups that contain feedthrough nets.
- If a pin guide exists for a net for which feedthrough buffers are inserted, the pin guide information is updated.
- The `add_partition_feedthrus` command will handle designs with master/clone partitions automatically. However, it may create infeasible pin solution for channel-less designs with fully abutted partitions.
- The `add_partition_feedthrus` command supports nested partitions. For inserting feedthrough buffers into nested partitions, the `add_partition_feedthrus` command, first, automatically deletes the parent partitions and keeps only the bottom-most partition. It then does a single-level feedthrough insertion and then automatically restores the parent partitions and brings the nested partition definition back as it is. In nested designs, the `add_partition_feedthrus` command only puts buffers and ports in the bottom most level of partitions.
- The `add_partition_feedthrus` command prints a summary of all messages issued for nets in the log file.
- A feedthrough always uses a low power compatible buffer/AO-buffer. If it cannot use a low power complaint cell, then the default buffer (specified with the `-buffer_cell` parameter) is used, and the buffer name is prefixed with “MSV_INVALID”.

Parameters

`-all_lower_case`	Specifies all lowercase characters for the inserted feedthrough buffer and feedthrough net names. *Data_type*: bool, optional
`-auto_select_nets_by_congestion`	Specifies that the critical nets in congested channels will be identified automatically. These critical nets are routed flat so that later they can be feedthrough over partition(s) to reduce congestion, while other remaining nets are routed by honoring fences. Once the routing is done, feedthroughs are inserted based on the routing result. *Data_type*: bool, optional
`-auto_select_nets_by_slack`	Specifies that the critical nets in the design will be identified automatically. These critical nets are routed flat so that later on they can be feedthrough over partition(s) to improve timing while other remaining nets are routed by honoring fences. Once the routing is done, feedthroughs are inserted based on the routing result. *Data_type*: bool, optional
`-blockage_file` *file_name*	Specifies a file that contains the coordinates of line segments that are considered as blockages for placement based feedthrough insertion. The following is the format of the blockage file: *x1 y1 x2 y2* *x1 y1 x2 y2* *...* *xn yn xm ym* The blockage lines are specified as coordinates of a box, however, the boxes should be of zero width or height. *Data_type*: string, optional
`-blocked_edges_file` *file_name*	Specifies a file that contains the names of the partitions followed by the edge numbers for the partition which are considered as blocked for the purpose of `add_partition_feedthrus` command. *Data_type*: string, optional
`-buffer_cell {`*cell_name* `|` *cell_namel_list*`}`	
	Specifies the name of the feedthrough buffer cell type. **Note:** You can specify multiple buffer cells with MSV designs. The first buffer will be used for the default power domain. *Data_type*: string, optional
`-check_only`	Specifies that the feedthrough buffers are *not* inserted. This parameter is useful when you want to know how the `add_partition_feedthrus` command will affect the design. A summary information will be printed. You can specify this parameter along with the `-write_topological_file` parameter. This will save the feedthrough topology information. *Data_type*: bool, optional
`-double_buffer`	Adds a buffer close to the feedthrough input pin and adds a buffer close to the feedthrough output pin. *Data_type*: bool, optional
`-eco_file` *file_name*	Specifies the file for logging ECO directives. This parameter cannot be used with the `-check_only` parameter. *Data_type*: string, optional
`-exclude_nets_file` *file_name*	
	Specifies a file that contains net names to be excluded from being a feedthrough net for a partition. *Data_type*: string, optional
`-exclude_partitions {`*partition_name* `|` *partition_list*`}`	
	Specifies that feedthrough buffers should not be added to the specified partitions. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `add_partition_feedthrus` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man add_partition_feedthrus`
`-include_nets_file` *file_name*	Specifies a file that contains net names to be feedthrough nets for a partition and inserted feedthrough buffers. *Data_type*: string, optional

`-inst_prefix` *instance_prefix*	Specifies a prefix for the newly created instances. The prefix that you specify will be used instead of the default prefix. *Data_type*: string, optional
`-net_mapping` *file_name*	Generates a file that maps the original net name to the new net name created for the feedthrough buffers. **Note:** You must specify this parameter if you later want to run the `gui_highlight_feedthru_nets` command to highlight the feedthrough paths of the nets. *Data_type*: string, optional
`-net_prefix` *net_prefix*	Specifies a prefix for the newly created nets. The prefix that you specify will be used instead of the default prefix. *Data_type*: string, optional
`-no_buffer`	Generates an `ASSIGN` statement in the netlist instead of inserting a buffer. *Data_type*: bool, optional
`-reuse_buffer {true | false | 0 | 1}`	
	Reuses inserted buffers across multiple instantiation of a module within one run. This option should only be used for designs that have master and clone partitions. *Default*: `true` *Data_type*: enum, optional
`-route_based`	Derives the feedthrough topology based on the routing results. *Data_type*: bool, optional
`-route_based_strict`	Derives the feedthrough topology based on the routing results and follows each criss-cross. In comparison to the `-route_based` parameter, the `-route_based_strict` option inserts more number of buffers depending on the routing cross-overs and also supports special routes. It can insert buffers on intra-partition net, if the routing crosses outside the boundary. However, such a net needs to be handled via selected feedthrough insertion and not default selection. The `-route_based_strict` parameter places the pins at each of the routing cross-point. **Note:** You can use the `gui_show_partition_wire_cross_over` command to get `[design_name].nets_not_crossing_mc.txt` for a selection of nets on which to use this option. *Data_type*: bool, optional
`-selected_nets`	Specifies that feedthrough buffers should be inserted on the nets that are currently selected in the GUI. *Data_type*: bool, optional
`-symmetrical_repeat_abutted_floorplan`	
	This option is relevant to master clone designs. It is to be used for the floorplans which have repeated components arranged in a symmetric fashion with a data flow going from the top to each component independently. If the design has nested partitions, it will delete all the partitions which are parents. It will hold more partitions within them, perform its operation and restore the parent partitions once finished. *Data_type*: bool, optional
`-write_topological_file` *file_name*	
	Saves a file with feedthrough buffer topology tree information from an existing floorplan. *Data_type*: string, optional
`-use_topological_file` *topology_file_name*	

	Specifies the file that has the topology tree information. This information is used to create feedthrough buffers for the netlist. If you use the `-use_topological_file` parameter, only those nets that are specified in the topology file are considered for feedthrough buffer insertion. If a net does not exist in the design, it should not be in the topology file. For example, if ECO changes remove a net, that net should be removed from the topology file. **Note:** Hierarchical bus names are not supported in the Innovus software. Therefore, you cannot use hierarchical bus names in the topology file. **Note:** The names of the feedthrough nets, buffers, and ports created might change in the different runs of the command. Only the feedthrough path (the partitions through which the net will pass) will always remain the same across the different runs of the command. *Data_type*: string, optional
`-use_short_name`	Specifies the abbreviation of inserted feedthrough net names so that the net names do not extend too long for multiple runs. *Data_type*: bool, optional
`-verbose`	Specifies that net-specific information is included in the logs. *Default:* Only the summary information is included in the logs. *Data_type*: bool, optional

Examples

- The following command generates a file, `K_ABC.topo`, with the feedthrough buffer topology tree information:
  ```
  add_partition_feedthrus -write_topological_file K_ABC.topo -net_mapping abcfile
  ```
  The following is the generated topology file:
  ```
  ############################################################
  #  Generated by: Cadence Innovus
  #  OS:           Linux x86_64(Host ID nofcnl040)
  #  Generated on: Mon Jan 21 12:34:59 2015
  #  Design:       test
  #  Command:      add_partition_feedthrus -write_topological_file K_ABC.topo
  ############################################################
  version 1.0;
  net K_ABC_NET
  hinst-hinst p4 p8;
  hinst-hinst p4 p7;
  end net
  ```
- The following command specifies that topology tree information from the `topology_info` file should be used to generate feedthrough buffer insertions:
  ```
  add_partition_feedthrus -use_topological_file topology_info
  ```

align_partition_clones

```
align_partition_clones
[-help]
[partition]
[-out_file filename]
[-check_only | -snap_all_corners ]
[ [[-pg_horizontal_grid ] [-pg_vertical_grid ] [-pg_layers {layeridList}] [-update_user_grid ] [-snap_all_corners ] [-skip_finfet_grid ]] |
[[-symmetry_pattern_reference string [-symmetry_pattern_target string
 [[-target_orientation {r0 r90 r180 r270 mx mx90 my my90}][-target_origin {x y}] ]]] | [-symmetric_orientation ]]
 [-pg_layers {layeridList} [-pg_net pgNetName | -pg_center_line float]] [-pg_pitch float [-pg_center_line float]]
```

Aligns partition clones with the master partition on a power mesh and with routing tracks. You can use this command after specifying a master partition and clone partition(s). This will avoid off-track pins in clones and avoid potential DRC violations due to misalignment of power meshes inside clone.

Note: The power mesh must be regular for `align_partition_clones` to work correctly.

The `align_partition_clones` command detects and highlights any gap or overlap of fence created in an abutted floorplan.

Parameters

`-check_only`	Specifies that the design should not be modified. When enabled, it only reports messages. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `align_partition_clones` param man `align_partition_clones`
`-out_file filename`	Specifies the name of the output file in which to save the master and clone alignment report with details. **Note:** The `align_partition_clones` command supports tracks with multiple definitions. The `-out_file` paramete *Data_type*: string, optional
`-pg_center_line float`	Specifies the centerline of the first virtual symmetric pg stripe (in microns). This option can be repeated. *Data_type*: float, optional
`-pg_layers {layeridList}`	Specifies layer(s) for the pg stripe. This option can be repeated. *Data_type*: string, optional
`-pg_horizontal_grid`	Provide information about horizontal PG grid. *Data_type*: bool, optional
`-pg_net pgNetName`	Specifies name of the pg stripe net name. This option can be repeated. *Data_type*: string, optional
`-pg_pitch float`	Specifies pitch of the pg stripe net (in microns). This option can be repeated. *Data_type*: float, optional
`-pg_vertical_grid`	Provide information about vertical PG grid. *Data_type*: bool, optional
partition	Specifies name of the partition. **Note:** If the partition name is not specified, the command is run on all partitions. *Data_type*: string, optional
`-skip_finfet_grid`	Disables alignment with the FinFet grid. *Data_type*: bool, optional
`-snap_all_corners`	Snaps all corners of master and its clone partition to the user grid. **Note:** The `-snap_all_corners` parameter fixes partition overlaps. *Data_type*: bool, optional

`-symmetric_orientation`	Checks the orientation between each pair of partitions and fixes the symmetry by finding the optimum symmetric c **Note:** If Innovus suggests changing the orientation of a partition, it indicates it as (diff) in the report for quick identi **Note:** The `-symmetric_orientation` parameter can find orientations based upon the floorplan. Even if the `align_p` orientations. It supports nested designs. *Data_type*: bool, optional
`-symmetry_pattern_reference` *string*	Specifies the names of the partitions that are used as a reference set to maintain a symmetrical pattern for the oth **Note:** The first partition in the list is considered as the seed partition from which all the relative locations and orier *Data_type*: string, optional
`-symmetry_pattern_target` *string*	Specifies the names of the partitions that are used as a target set to maintain a symmetrical pattern relative to the **Notes:** • The number of partitions and their order must be the same as that specified with the `-symmetry_pattern_refer` • The current location and orientation of the seed partition is used to relatively move the other partitions in the lis locations and orientations are calculated for the rest of the partitions in the list. • You can specify master partitions in the target partitions set list. However, master partitions can only have r0 or *Data_type*: string, optional
`-target_orientation {r0 r90 r180 r270 mx mx90 my my90}`	
	Specifies the new orientation of the seed partition of the target partition set (`-symmetry_pattern_target`). The spec to maintain the relative orientation of the different pairs of clones. **Notes:** • The seed partition is the first partition specified with the `-symmetry_pattern_target` parameter from which all th • The orientation of the master partitions cannot be changed. *Data_type*: enum, optional
`-target_origin {x y}`	Specifies the new origin of the seed partition of the target partition set (`-symmetry_pattern_target`). The specified  **Notes:** • It does not let the target seed partition go outside the core boundary. • The seed partition is the first partition specified with the `-symmetry_pattern_target` parameter from which all th *Data_type*: point, optional
`-update_user_grid`	Updates the user grid with the new values. *Data_type*: bool, optional

Example

- The following command aligns the partition clones with the master partition and displays a report:
  ```
  align_partition_clones
  ```

  ```
  ================================================================================
                  align_partition_clones Summary
  ================================================================================
  Partition                    | Orientation |   Status   | Moved-by(X) | Moved-by(Y)
  ================================================================================
  MASTER_CLONE(I_MC_1)         |             |    Aligned |             |             |
  +I_MC_0                      |     MY      |    Aligned |             |             |
  MC(I_A/A_MC)                 |             |    Aligned |             |             |

align_pins

```
align_pins
[-help]
[-ignore_pin_shapes]
[-mark_fixed]
[-move_fixed_pin]
[-keep_layer | -new_layer layer]
[-legalize]
[-no_snap]
[-pins pin_list]
[-reference ref_obj_name]
[-reference_type {partition_pin hinst}]
[-target ptn_name]
[-verbose]
```

Aligns pins between blocks on their facing edges. By default, this command snaps pins to the routing grid. You can use this command after partitioning floorplanning.

Notes:

- Specified pins will not be aligned if they do not have the reference connections on the reference block, or if the reference pins are not assigned prior to running this command.
- If this command is run on a blackbox that has one or more pins with a single LEF port but with multiple shapes within the LEF port, the command will remove these multiple shapes and create a single shape. If this command is run on a blackbox that has one or more pins with multiple LEF ports, the first LEF port will be processed as per the command and the remaining LEF ports will remain unchanged.
- This command supports Multi Level Hierarchical Flow.

The pin alignment priority is as follows:

- If you specify the `-reference` and the `-target` parameters but not the `-pins` parameter, the `align_pins` command aligns *all* pins of specified instances that are connected to the referenced object.
- If you specify the `-reference` parameter but not the `-target` and the `-pins` parameter, the `align_pins` command aligns *all* pins of all partitions that are connected to the referenced object.
- If you specify the `-reference`, `-target`, and the `-pins` parameters, the `align_pins` command tries to align *all* possible pins that can be aligned.
- If you do not specify the `-reference` parameter, the following order of priority will be used for aligning partition pins that have multiple connections:
  - Hard macro pins
  - I/O pads or pins
  - Partition pins
  - Standard cell pins

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `align_pins` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man align_pins`
`-ignore_pin_shapes`	Specifies that the aligned pin will ignore matching of shape with the reference pin. *Data_type*: bool, optional
`-keep_layer`	Specifies whether to keep the current pin layer. *Default*: If you do not specify this option, the new pin layer will be the same as the referenced layer to reduce wire routing. *Data_type*: bool, optional
`-legalize`	Specifies that the `legalize_pins` command should run automatically after the `align_pins` command.
`-mark_fixed`	Specifies that the pins that are moved by this command will have a *Fixed* status. *Default*: By default, the pins moved by this command have a *Placed* status. *Data_type*: bool, optional
`-move_fixed_pin`	Specifies that the pins with a *Fixed* status can also be moved. *Data_type*: bool, optional
`-new_layer` *layer*	Specifies a new pin layer. **Note:** Layers can be specified using the LEF layer names or layer ID numbers. *Data_type*: string, optional
`-no_snap`	Disables pins from being snapped to the routing grid. *Data_type*: bool, optional
`-pins` *pin_list*	Specifies the pin(s) to be aligned between the facing edges of the target block and reference block. You can use wildcards (`*?`) with this parameter. If you specify more than one pin, you must enclose them in curly braces. *Data_type*: string, optional
`-target` *ptn_name*	Specifies the target instance where its pins will be aligned to the pins of the specified instance. *Data_type*: string, optional
`-reference` *ref_object_name*	Specifies the reference object where the specified pins of the target block will be aligned to the pins of the reference object. The reference object can be a standard cell, an I/O pin, an I/O pad, a macro, or all I/O pins in the design by specifying the top cell as the reference object. Now the `align_pins` command can also take uncommitted ptn as the reference object. **Note:** You can also use wildcard (* or ?) for specifying the reference object names. *Data_type*: string, optional
`-reference_type {partition_pin hinst}`	Specifies the type of reference objects to consider. You can specify partition pins or hinsts. *Data_type*: enum, optional
`-verbose`	Generates intermediate messages. *Data_type*: bool, optional

Examples

- The following command aligns `A0` and `A1` pins of `p1` to the reference pins of `blockA`:

```
align_pins -reference blockA -target p1 -pins {A0 A1}
```

- Assume the following netlist:

```
module testcase (in1, in2, in3);
input in1, in2, in3;
wire net;
a i_a(.in1(in1), .in2(in2), .in3(in3), .out1(net));
```

```
BUFX1 i0(.A(net));
endmodule

module a(in1, in2, in3, out1);
input in1, in2, in3;
output out1;
endmodule
```

The following command aligns pins `in1`, `in2`, and `in3` on partition `i_a`:

```
align_pins -reference testcase -target i_a
```

```
  Moving pin [in1] of partition [a] connected to pin [in1] of top cell [testcase] to ALIGNED location ( 0.000 21.000 Metal3).
  Moving pin [in2] of partition [a] connected to pin [in2] of top cell [testcase] to ALIGNED location ( 0.000 38.920 Metal5).
  Moving pin [in3] of partition [a] connected to pin [in3] of top cell [testcase] to ALIGNED location ( 0.000 57.960 Metal3).
  Aligned 3 pin(s) of the partition [a] successfully.
```

Note: Only 3 of the 4 partition pins are moved because pin `out1` is connected to a nearby instance rather than a top-level IO pin.

assemble_design

```
assemble_design
[-help]
[-keep_pg_pin_geometry]
[-out_file fileName]
[-keep_block_halo]
[-skip_cells] [-skip_components] [-skip_nets] [-skip_special_nets]
{{[-top_dir dirname [-mmmc_file mmmcFile] [-cpf_file cpfFile] ]
  {[-block_dir dirname [[-encounter_format ]| [-floorplan_only ]]][-block_data {defFileName netListFileName} |
   {-floorplan_only | -encounter_format } ] [-no_def_merge ]}}|
   {[-top_design {topLib topCell topView} [-mmmc_file mmmcFile] [-cpf_file cpfFile] ] {[-oa_block {blockLib blockCell blockView} | -
block_cell blockCell ]
  [-all_timing_blocks [-ignore_timing_blocks {list_of_blocks}] [-report_only ]]}} }
[-encounter_format | -floorplan_only | -no_def_merge ]
[-keep_pin_geometry ]
```

Brings back specified block data to the top-level design for chip assembly. You should run this command from the directory with the full chip-level floorplan for the top-down hierarchical flow. You can run this command for designs that use the FE database as well as for designs that use the OpenAccess database. The `assemble_design` command supports mixed-origin design. That is, all partitions can have a design origin at the center, lower-left, any location inside the design boundary, or any location outside the design boundary. You can use this command after implementing blocks and top-level designs.

There are two main modes of operation - full and incremental.

- Full mode: When operating in full mode, a session is initiated with the assemble_design command which first loads the top-level design with blocks represented as hard macros then each block is merged within the full-chip context.
- Incremental mode: When operating in incremental mode, a top-level design is loaded prior to calling `assemble_design` which then merges the contents of one or more blocks.

Notes:

- The `assemble_design` command supports designs saved in the Innovus database format as well as OpenAccess designs.
- The `assemble_design` command supports the incremental capability which handles master/clones partitions at different levels of hierarchy and supports nested partitions. The incremental `assemble_design` capability enables partitions to be brought back in one session, thus, avoiding the need to run multiple sessions for bringing back all the data of a design. You can call the incremental `assemble_design` for a block multiple times in the same session without having to partition it.
- The `assemble_design` command supports mixed-origin design. That is, all partitions can have a design origin at the center, lower-left, any location inside the design boundary, or any location outside the design boundary. You can use this command after implementing blocks and top-level designs.
- The `assemble_design` command preserves Interface Logic Model (ILM) information by automatically bringing back ILMs from block level design to full-chip level design. For DEF data, ILMs can only be brought back if the `-block_dir` option is specified.
- The `assemble_design` command supports mixed data types. While specifying partition blocks, you can have different types of data for different partition blocks.
- The `assemble_design` command supports partitions with flexmodels. It re-assembles partition blocks with flexmodels back to the top-level design.
- The `assemble_design` command can read design information from the global init_* variables saved in the *.global file.
- The `assemble_design` command internally calls the `commit_global_net_rules` command that applies or restores the global net connectivity rules to the design and creates the necessary connections between instances and global nets. Consequently, the `assemble_design` command automatically generates a database where the global nets are already connected. This helps to ensure that all instance are correctly tied to PG nets.
- The `assemble_design` command internally checks color issues and uses the shift-mask functionality to assign correct colors to objects. As a result, at the end of `assemble_design`, the objects are already given the mask numbers (colorized) and the design has less color violations.
- The `assemble_design` command compares the properties of each block and top and uses a specific resolution for each property.
- The `assemble_design` command (DEF based) supports multi-threading. It honors the settings of the `set_multi_cpu_usage -local_cpu` parameter that is used to specify the number of CPUs on the local machine and is required for multi-threading.

  Note: This capability is not supported by the `-encounter_format` based `assemble_design`.

During `assemble_design` all rows are cut at the top and only the rows from inside the block are brought at the time of assembly. The `check_place` command does not report any false placement violations. Only in cases where partitions are rotated R90 (like vertical rows) are the cells marked as fixed.

A summary report is generated at the end of each `assemble_design` run which helps in debugging issues. The generated report includes information like the run-time for `assemble_design`, number of partitions and their instance count.This report is useful in identifying potential issues in the flow.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `assemble_design` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man assemble_design`
`-all_timing_blocks`	Enables automatic detection and assembly of blocks with digital content. The `-block_cell` option can be used to manually force blocks to be assembled, and `-except_blocks` option can be used to exclude cells from being assembled as it overrides to the default list of blocks to be assembled. *Data_type*: bool, optional
`-block_cell` *blockCell*	Specifies the cell name for the block cell. *Data_type*: string, optional
`-block_data` *defNamenetlistName*	
	Specifies the DEF file name and the Verilog netlist file name. Use this parameter if the Verilog netlist file name or the DEF file name is different from the cell or module name. You must provide the full path (absolute or relative) with the file names. **Note:** If you specify more than one block-level design, specify the `-block_data` option separately for each block-level DEF file and Verilog netlist file. For example: `-block_data defFile_1 VerilogFile_1 -block_data defFile_2 VerilogFile_2` *Data_type*: string, optional
`-block_dir` *dirname*	Specifies the path to the block-level design(s). **Note**: If you specify more than one block-level design, specify the -block_dir option separately for each block-level directory. For example: `-block_dir ptnDir1 -block_dir ptnDir2` *Data_type*: string, optional
`-cpf_file` *cpfFile*	Specifies the name of the (Chip Level) CPF file that contains the power intent and timing information. *Data_type*: string, optional
`-encounter_format`	Specifies that the Innovus place-and-route data should be used for `-block_dir` option. **Note**: The `-encounter_format` parameter cannot be used with the `-block_data` parameter because the `-encounter_format` parameter points to data from the Innovus database format whereas the `-block_data` parameter points to data from Verilog netlist and DEF name. *Default*: By default, data from DEF files is used. *Data_type*: bool, optional
`-floorplan_only`	Specifies that only floorplan data should be assembled. When specified it brings back the floorplan changes from a partition block to full-chip level design. It supports un-committed partition(s) and replaces the top level uncommitted partition(s) with updated block floorplan data. **Note:** After `assemble_design -floorplan_only` command, any signal net at top-level design may be overlapped with other floorplan objects. You may need to reroute or ECO route the design. Additionally, PG net of CHIP, place, and route data may not be brought back.
`-ignore_timing_blocks {`*list_of_blocks*`}`	
	Specifies the list of block names to be excluded from being assembled even if they contain digital content. This option only applies to the case where `-all_timing_blocks` is used. If not specified, there is no restriction on the detection and assembly that is automatically determined. *Default*: `""` *Data_type*: string, optional
`-keep_block_halo`	When specified, the `assemble_design` command preserves the block place and route halo. *Data_type*: bool, optional
`-keep_pg_pin_geometry`	Retains the partition PG pin geometry. *Data_type*: bool, optional

`-keep_pin_geometry`	Specifies that for every partition pin, a DRCFILL metal of the type special route is placed on top of the partition pins. *Data_type*: bool, optional
`-mmmc_file mmmcFile`	Specifies the name of the (Chip Level) MMMC file that is used to supply the MMMC information. Normally, it is a chip level file named *viewDefination.tcl*. *Data_type:* string, optional
`-no_def_merge`	Specifies that the DEF merge capability will be disabled and normal `assemble_design` will be used. *Data_type*: bool, optional
`-oa_block blockLib blockCell blockView`	
	Specifies the block-level library, cell, and view names respectively for a design that was saved into an OpenAccess database. This parameter is used when bringing back block data for the partition from an OpenAccess database. **Note:** If you specify more than one block-level design, specify the `-oa_block` option separately for each block. For example: `-oa_block libForOA TDSP_CORE ptnView1 -block libForOA TDSP_ARB ptnView1` *Data_type*: string, optional
`-out_file fileName`	Specifies name of the output file. *Default*: `./<design>.assembleDesign.rpt` *Data_type*: string, optional
`-report_only`	When enabled, the `assemble_design` command only reports the list of blocks that would be assembled and does not perform actual assembling. **Note:** The `-report_only` parameter can only be used in the `assemble_design` command along with the `-all_timing_blocks` option, to get a list of (and not actually assemble) blocks that would be assembled by a subsequent `assemble_design -all_timing_blocks` command invocation without the `-report_only` option. This list of blocks can be used to include or exclude blocks to be assembled via the `-block_cell` or `-ignore_timing_blocks` options. *Data_type*: bool, optional
`-skip_cells`	Skips merging standard cells. It does not load the standard cells section from DEF. *Data_type*: bool, optional
`-skip_components`	Skips merging all components.It does not load the COMPONENT section from DEF. *Data_type*: bool, optional
`-skip_nets`	Skips merging signal routes. It does not load the NETS section from DEF. *Data_type*: bool, optional
`-skip_special_nets`	Skips merging special routes. It does not load the SPECIALNETS section from DEF. *Data_type*: bool, optional
`-top_design topLib topCell topView`	
	Specifies the top-level library, cell, and view names respectively for a design that was saved into an OpenAccess database. This parameter is used when bringing back top-level data from an OpenAccess database. *Data_type*: string, optional
`-top_dir dirname`	Specifies the path to the top-level design. This design directory should contain the Verilog netlist and DEF files. *Data_type*: string, optional

Examples

- The following command assembles the design after bringing back information from the top-level cell and two block-level cells. The top-level design data is in the `dirTop` directory and the block-level data is in the `dirBlock1` and `dirBlock2` directories.

  ```
  assemble_design -top_dir dirTop -block_dir dirBlock1 -block_dir dirBlock2
  ```

- The following command assembles a design with the following block-level information:
  - the DEF file with the name `def_file`

    - the verilog netlist v_netlist.v

      ```
      assemble_design -top_dir dirTop -block_data def_file v_netlist.v
      ```

- The following command assembles a design that was saved in an OpenAccess database. The design contains two blocks.
    - The library, cell, and view names for the top-level are `libForOA`, `DTMF`, and `ptnView1` respectively.
    - The library, cell, and view names for the first block are `libForOA`, `TDSP_CORE`, and `ptnView1` respectively.
    - The library, cell, and view names for the second block are libForOA, TDSP_ARB, and ptnView1 respectively.

      ```
      assemble_design -top_design {libForOA DTMF ptnView1} -oa_block {libForOA TDSP_CORE ptnView1} -oa_block {libForOA TDSP_ARB ptnView1}
      ```

- The following command is an example of incremental assemble design capability that can restore master and clones at different levels of hierarchy. Along with assembling nested partitions:
    - Block1 and Block2 are partitions at top level
    - Block1 contains Block3 and Block4
    - Block4 is a clone of Block2

      ```
      read_db topDesign.enc.dat
      assemble_design -block_dir Block1.enc.dat -block_dir Block2.enc.dat -block_dir Block3.enc.dat
      ```

- `-mmmc_file` and `-cpfFile` do not work with incremental `assemble_design`, however in the following command they will work:

  ```
  assemble_design -top_dir dirTop -block_dir dirBlock1 -mmmcFile  viewDefination.tcl. -cpf_file cpfFile
  ```

assign_io_pins

```
assign_io_pins
[-help]
[-align]
[-debug_pin_all]
[-debug_pin_file fileName]
[-improve_si]
[{-pins { pin_name_list } | -pin_file  filename  | -exclude_pin_file  filename } [-move_fixed_pin ] [ -ignore_group_pins ]]
[-auto_bus_group ]
```

Assigns the top I/O pin locations for a block-level design. Set the maximum or minimum pin layers with `assign_pins_max_layer or assign_pins_min_layer` attributes. By default, the `assign_io_pins` command sets the depth of all partition pins equal to: MINAREA/pin width. This ensures that the minimum area rule is met. However, if any pin-size-related constraints are specified on these pins, the user-specified pin size will have a higher precedence.

Notes:

- The MINAREA/pin width means that the default pin width will be met MAR (minimum area rule) if an area rule of this layer is defined in the technology LEF. An I/O pin width value is based on the following order:
  1. User-specified pin width constraint.
  2. Minimum area rule of the layer if it is available in the technology file.
  3. Default layer width
- When assigning pins, the `assign_io_pins` command does not check for violations between placed pins and shapes of objects (such as macros, standard cells, etc) just inside the partition fence (design boundary). This may result in DRV violations if the fence (design boundary) to core distance is zero.
- The `assign_io_pins` command honors preferred routing layer attributes as soft constraints during pin assignment and reports the nets that have these attributes. It also honors the *keep out spacing* constraints on pin groups and net groups.
- In bottom-up flow, the `assign_io_pins` command promotes both signal and P/G pins from the list of pins promoted by the `set_promoted_macro_pin` command.
- **Note**: The `assign_io_pins` command honors net/pin groups that have all nets from multiple buffer chains added in the same group. Such groups can be generated through bus guide flow, feedthrough insertion flow, or can be user created. It places the pins of such nets in order to achieve better pin alignment and improve the QoR.

You can use this command after running placement and early global routing to legalize the I/O pins. However, placement is not a mandatory step for pin assignment. Placement is recommended for better QOR.

Parameters

`-align`	If you specify this option, each top I/O pin will be aligned with one of the instance pins to which it is connected. The instance pin with which the I/O pin is aligned is the one whose distance from its nearest edge is shortest among all the instance pins connected to the top I/O pin. *Default*: If you do not specify this option, the location of the top pin is based on the average of the distance of all instance pins (that are connected to the top I/O pin) from their respective nearest edges. *Data_type*: bool, optional
`-auto_bus_group`	Specifies that the buses will be grouped automatically. **Note:** Internally the `create_pin_group` command is applied on buses. It is removed automatically after the command execution. *Data_type*: bool, optional

`-debug_pin_all`	Specifies that all pins will be debugged. **Note:** The `-debug_pin_all` and `-debug_pin_file` parameters can be used to write the following information in the log file: • Pin assign mode information • Connectivity information of each partition pin, including pinGroup/netGroup name and NDR name • Available pin slot information on each edge for each layer and pin slot density • PinGuide box and virtual pinGuide box information, master-clone series, feedthru chain and so on. • Reason for failure on the first failed location • For pins with location constraints, if the pin is not placed at the location constraint then the reason is provided in a tabular form. • For placed partition pins, the pin location, layer, edge, spacing and so on are provided. *Data_type*: bool, optional
`-debug_pin_file` *filename*	Specifies the file containing the pin-list for partition or the net that is to be used for debugging. *Data_type*: string, optional
`-exclude_pin_file` *filename*	Specifies pin-list to be excluded for partition in a file. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `assign_io_pins` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man assign_io_pins`
`-ignore_group_pins`	Avoid placing the whole group of pins. With this parameter enabled, the `pin_group` and `net_group` pins are ignored during selected pin assignment. *Data_type*: bool, optional
`-improve_si`	Avoid signal integrity issues by blocking tracks while placing pins to avoid overlap of wires. With this parameter specified, the `assign_io_pins` command does not allow pins to be placed on the tracks in an area which spans a layer higher or lower (on the preferred routing direction) and also on the tracks on the left and right of the placed pin. *Data_type*: bool, optional
`-move_fixed_pin`	If you use this parameter, the specified pins with a *`Fixed`* status can also be moved. However, this parameter must be used with the -pins parameter to specify the list of fixed pins to move while assigning io-pins. **Note:** Pins that are not specified but have a *`Fixed`* status are not moved. *`Default`* : If you do not specify this parameter, the specified pins with a *`Fixed`* status are *not* moved. *Data_type*: bool, optional
`-pins` *pin_name_list*	Specifies that only the specified pins should be assigned. **Note:** To move fixed pins while assigning io pins, you must specify the `-move_fixed_pin` parameter. *`Default`* : If you do not specify this parameter, all pins are assigned. *Data_type*: string, optional

`-pin_file` *`filename`*	Specifies the pin list for a partition in a file.
	In the pin file, the pins and nets are specified in the following format:
	`Partition:` *`PtnName/BlockName`*
	`Pin1`
	`Pin2`
	`..`
	`PinN`
	`Partition:` *`PtnName/BlockName`*
	`Pin1`
	`Pin2`
	`..`
	`PinN`
	`Nets:`
	`netA`
	`netB`
	`..`
	`netN`
	Note: While specifying the pin list in the pin_file, it is necessary to give the “Partition” keyword followed by the name of the partition or block. If this is not specified, no operations are performed. You can specify multiple partitions in the same pin_file.
	The pin_file does not support buses or wild cards for pin names. If a pin specified in the list or a partition is not present in the design, a warning is displayed.
	Data_type: string, optional

Example

- The following command assigns all io pins and can also move pins with fixed-status.

  ```
  assign_io_pins -move_fixed_pin -pins *
  ```

- The following command accept a file *`pinLst.txt`* that contains the list of pins and assigns io pins.

  ```
  assign_partition_pins -pin_file pinLst.txt
  ```

  Where *`pinLst.txt`* contains:

  ```
  Partition: top
  out1
  out2
  out3
  Partition: A
  in1
  in2
  in3
  Partition: B
  pina
  pinb
  pinc
  ```

  The `assign_io_pins` command selects all Io pins under the section `Partition:top`.

assign_partition_pins

```
  assign_partition_pins
[-help]
[-based_on_master_only]
[-blackbox]
[-debug_pin_all]
[-debug_pin_file filename]
[-write_virtual_pin_guide]
[-ignore_abutted_check]
[-improve_pin_order]
[-improve_si]
[-layer_priority {layeridList}]
[-mark_fixed] [-pin_movement_statistics]
[-skip_auto_bus_bit_order]
[-skip_place_external_unconnected_pin]
[-unplaced_only]
[ {{{-partitions partition_name  {-pins {pin_name list}}} |
 {-pin_file filename [-exclude_partitions ptn_name]} |
 -exclude_pin_file filename}
[-move_fixed_pins ] [ -ignore_group_pins ]}]
[-align_feedthru_pins_opt_with_master_clone ]
[-enforce_route | -enforce_route_legal | -enforce_flightline ]
[-auto_bus_group ]
```

Assigns partition pins before the partitions are committed. By default, the assigned pins will be in a Placed status after running this command. You can specify a Fixed status by running this command with the `-mark_fixed` option. The `assign_partition_pins` command does not align pins in the local context thus avoiding mis-aligning in other scenarios. minimizing maximum mis-alignment effects across farsighted net pairs (2-pins nets). For example, in master/clone pin assignment, since the clone pin follows the master's position, the position of the pin on master partition is determined such that pin on clone also gets aligned on clone.

Running the `write_floorplan` command saves the pin assignment in the floorplan to a separate file named `fpFileName.fp.ptnpin`, which is included in main `fpFileName.fp` floorplan file.

By default, the `assign_partition_pins` command sets the depth of all partition pins equal to: MINAREA/pin width. This ensures that the minimum area rule is met. However, if any pin-size-related constraints are specified on these pins, the user-specified pin size will have a higher precedence. The `assign_partition_pins` command internally calls the `report_unaligned_nets` command to generate the summary report at the command line. When assigning pins, the `assign_partition_pins` command does not check for violations between placed pins and shapes of objects (such as macros, standard cells, etc) just inside the partition fence (design boundary). This may result in DRV violations if the fence (design boundary) to core distance is zero. You can use this command after specifying the partitions, placing the design, and after running or loaded routing information. If no routing information is available, the Innovus software uses the projected pin assignment. However, placement is not a mandatory step for pin assignment. Placement is recommended for better QOR.

Notes:

- The `assign_partition_pins` command honors preferred routing layer attributes as soft constraint during pin assignment and reports the nets that have some attributes assigned to them. It also honors the keep out spacing constraint for a pin group or net group.
- This command only assigns signal pins. Power and ground pins are created during partition. However, this pin optimization honors power stripes and follow pins.
- This command assigns pins for blackboxes as well as regular partitions. If this command is run on a blackbox that has one or more pins with a single LEF port but with multiple shapes within the LEF port, the command will remove these multiple shapes and create a single shape. If this command is run on a blackbox that has one or more pins with multiple LEF ports, the first LEF port will be processed as per the command and the remaining LEF ports will remain unchanged.
- The `assign_partition_pins` command performs automatic pin assignment of partitions inside other partitions. It places pins of nested partitions similar to single level partitions.
- The `assign_partition_pins` command honors net/pin groups that have all nets from multiple buffer chains added in the same group. Such groups can be generated through bus guide flow, feedthrough insertion flow, or can be user created. It places the pins of such nets in order to achieve better pin alignment and improve the QoR.
- The `assign_partition_pins` command can place the pins on the partitions that are connected to PG supplies defined in the netlist.

Parameters

`-align_feedthru_pins_opt_with_master_clone`	Specifies that the pins should be placed such that they are aligned on different partitions across buffers on master/clone partitions.
	• In symmetric designs, since there is no conflict with master/clone so it aligns the pins of all the path.
	• In non-symmetric designs, it will try to place pins such that master-clone alignment count should not degrade.
	  ◦ It only assigns a feedthru path if there is common alignment zone available between master-clone alignment and feedthru chain alignment.
	  ◦ It assigns pins in common alignment zone for first pins in feedthrough path.
	Data_type: bool, optional

`-auto_bus_group`	Specifies that the buses will be grouped automatically. **Note:** Internally the `create_pin_group` command is applied on buses. It is removed automatically after the command execution. *Data_type*: bool, optional
`-based_on_master_only`	Specifies that for designs that have partition clones, the command should consider only the partition master and use the master assignment for all the clones. *Default*: For designs that have partition clones, this command by default also considers partition clones while assigning pins. *Data_type*: bool, optional
`-blackbox`	Assigns pins of blackboxes. *Data_type*: bool, optional
`-debug_pin_all`	Specifies that all pins will be debugged. **Note:** The `-debug_pin_all` and `-debug_pin_file` parameters can be used to write the following information in the log file: • Pin assign mode information • Connectivity information of each partition pin, including pinGroup/netGroup name and NDR name • Available pin slot information on each edge for each layer and pin slot density • PinGuide box and virtual pinGuide box information, master-clone series, feedthru chain and so on. • Reason for failure on the first failed location • For pins with location constraints, if the pin is not placed at the location constraint then the reason is provided in a tabular form. • For placed partition pins, the pin location, layer, edge, spacing and so on are provided. *Data_type*: bool, optional
`-debug_pin_file` *filename*	Specifies the file containing the pin-list for partition or the net that is to be used for debugging. *Data_type*: string, optional
`-enforce_flightline`	Specifies that the pin assignment completely follows fly lines, without taking into consideration any pin constraints. *Data_type*: bool, optional
`-enforce_route`	Specifies that the pin assignment completely follows the routing results generated by Early Global Route, without taking into consideration any pin constraints. For example, the following constraints are not considered when the `-enforce_route` parameter is used: • Constraints related to pin spacing, layer, width, depth, and side • Pin Guide constraints and Pin Group constraints The `-enforce_route` parameter can be useful when, for example, you want to compare pin locations based purely on Early Global Route results with pin locations that honor the specified pin constraints. *Data_type*: bool, optional

`-enforce_route_legal`	Specifies that during pin assignment, the pins are placed close to the routing cross points but at legal locations only. consequently all the pins are legally placed. The `-enforce_route_legal` parameter ignores the pin_group, net_group, and pin_guide constraints. *Data_type*: bool, optional
`-exclude_partitions` *ptn_name*	Specifies pin-list to be excluded for a partition in a file. In the pin file, the pins and nets are specified in the following format: `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Nets:` *netA* *netB* .. *netN* *Data_type*: string, optional
`-exclude_pin_file` *filename*	Specifies pin-list to be excluded for partition in a file. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `assign_partition_pins` parameter. For a detailed description of the command and all of its parameters, use the man command: `man assign_partition_pins`.
`-ignore_abutted_check`	When enabled, the abutted check is ignored during pin assignment. This results in faster pin assignment on abutted designs. *Data_type*: bool, optional
`-ignore_group_pins`	Avoid placing the whole group of pins. With this parameter enabled, the `pin_group` and `net_group` pins are ignored during selected pin assignment. **Note:** If all the pins in a group have been individually selected for pin assignment and `-ignore_group_pins` is applied then the pin assignment takes precedence and `-ignore_group_pins` parameter is not honored for this group. Rest of the groups whose pins appear in the selection list continue to be ignored. *Data_type*: bool, optional
`-improve_pin_order`	Reduces flightline crossing during pin alignment. The partition and the blackbox pins are rearranged to be aligned with external connections: • Guided pins are reordered within the pin guide box. • Pins are rearranged at (or close to) their original locations. • Pin ordering is performed independently for each partition edge. The locations of fixed pins, aligned pins or multi-location pins is not changed. Master-clone pins are not reordered. **Note:** `-improve_pin_order` is a post processing step during pin assignment so it can override the pin assignment that is complying with `-max_pin_movement_for_align`. This option should not be used with `-max_pin_movement_for_align`, if you strictly want to control the maximum pin movement for alignment. *Data_type*: bool, optional
`-improve_si`	Avoid signal integrity issues by blocking tracks while placing pins to avoid overlap of wires. With this parameter specified, the `assign_partition_pins` command does not allow pins to be placed on the tracks in an area which spans a layer higher or lower (on the preferred routing direction) and also on the tracks on the left and right of the placed pin. *Data_type*: bool, optional

`-layer_priority {layeridList}`	Specifies the metal layer(s) that should be used with priority during pin assignment such that there is an increase in alignment in the prioritized layers. With this parameter specified, there is no degradation in the total unaligned nets of the partition/design. There is an increase in the unaligned number in the prioritized layers and a decrease in the over all pin count in the non-prioritized layers. **Note**: The list of layers to be given priority must be a sunset of the layers selected with `assign_pins_max_layer` and `assign_pins_min_layer` attributes. **Note**: In case of conflict in the layer priority between the `assign_partition_pins` command and the `create_pin_guide` command on some edges, the `create_pin_guide` command priority takes precedence. For example, in the following command: `assign_partition_pins -layer_priority {7 6 2 3}` • Most aligned pins are in layers 7 and 3 or 6 and 2 (horizontal / vertical) • Most unaligned pins are also in 7,6,2,3 • Maximum pins are in these layers *Data_type*: string, optional
`-mark_fixed`	Specifies that all pins will have a *Fixed* status. *Data_type*: bool, optional
`-move_fixed_pins`	If you use this parameter, the specified pins with a *Fixed* status can also be moved. **Note:** Pins that are not specified but have a *Fixed* status are not moved. *Default*: The specified pins with a *Fixed* status are not moved. *Data_type*: bool, optional
`-partitions partition_name`	Specifies the partition names for pin assignment. *Default*: Pins are assigned for all partitions. **Note:** Pin assignment for a selected partition by specifying the `partitionName` is obsolete and will be removed in the next major release of the software. The obsolete parameter still works in this release, but to avoid warnings, and to ensure compatibility with future releases, update your scripts to use `-partitions partition_name -pins pin_list ...` *Data_type*: string, optional

`-pin_file filename`	Specifies the pin list for a partition in a file.
	In the pin file, the pins and nets are specified in the following format:
	`Partition: PtnName/BlockName`
	`Pin1`
	`Pin2`
	`..`
	`PinN`
	`Partition: PtnName/BlockName`
	`Pin1`
	`Pin2`
	`..`
	`PinN`
	`Nets:`
	`netA`
	`netB`
	`..`
	`netN`
	Note: While specifying the pin list in the pin_file, it is necessary to give the “Partition” keyword followed by the name of the partition or block. If this is not specified, no operations are performed. You can specify multiple partitions in the same pin_file.
	The pin_file does not support buses or wild cards for pin names. If a pin specified in the list or a partition is not present in the design, a warning is displayed.
	Data_type: string, optional

`-pins {pin_name list}`	Specifies the list of pins to be assigned in the respective partitions. *Default*: Pins are assigned for all partitions. *Data_type*: string, optional

`-pin_movement_statistics`	Prints a summary of the deviation (in micrometers) of the final pin locations from the point of intersection of the net and the partition edge.
	The report on the screen contains the following statistics:
	• Maximum displacement on the X axis. This is the difference in the x-coordinates of the point of intersection of the net and the partition edge, and the point at which the pin is finally assigned.
	• Maximum displacement on the Y axis.
	• Maximum X+Y displacement. The X+Y displacement of a pin is the sum of the displacement of a pin on the X axis and the displacement of the pin in the Y axis. For example, if a pin has moved 10 micrometers on the X axis and 5 micrometers on the Y axis, the X+Y displacement for that pin is 15. Thus, if there are three pins and their X+Y displacements are 5, 23, and 30 respectively, the maximum X+Y displacement is reported as 30.
	• Mean of the X+Y displacement.
	The report appended to the Innovus log file contains the following additional details:
	• Names of the pins that have moved the maximum distances.
	• The coordinates of the point of intersection of the net and the partition edge, and the point at which the pin is finally assigned.
	Here is a sample report displayed on screen.
	`Partition: [tdsp_core]`
	`maximum X = 120.1200 um (Pin: t_data_out[6])`
	`maximum Y = 58.8000 um (Pin: rom_data_in[4])`
	`maximum X+Y = 154.5600 um (Pin: t_data_out[6])`
	`moved from (706.2000, 1025.0800) -> (586.0800, 990.6400)`
	`mean X+Y = 12.5600 um`
	`total pins = 114`
	`pins moved = 75`
	The log file has additional information such as:
	`Pin: int: X Movement: 3.3000 um ; Y Movement: 0.0000. From (701.2500, 1247.6800) -> (697.9500, 1247.6800)`
	Data_type: bool, optional

`-skip_auto_bus_bit_order`	Skips automatically placing the bus pins together. *Data_type*: bool, optional
`-skip_place_external_unconnected_pin`	Skips placing partition pins that are not connected outside the partition. *Data_type*: bool, optional
`-unplaced_only`	Assigns only unplaced pins. *Data_type*: bool, optional
`-write_virtual_pin_guide`	Writes the virtual pin_guide for net_group and pin_group. *Data_type*: bool, optional

Example

- The following command assigns partition pins of all partitions
  `assign_partition_pins`
- The following command assign partition pins, including those which have fixed status of all partitions and mark them as fixed after assigning them
  `assign_partition_pins -mark_fixed -move_fixed_pins`
- The following command accept a file *`pinLst.txt`* that contains the list of pins to be placed.

```
assign_partition_pins -pin_file pinLst.txt
```

Where *pinLst.txt* contains:

```
Partition: top
out1
out2
out3
Partition: A
in1
in2
in3
Partition: B
pina
pinb
pinc
```

The `assign_partition_pins` command, considers all pins of all partitions in the file, except the pins under the section Partition:top.

- The following command ignores the `partition B` mentioned in the pin file pin.list.
  ```
  assign_partition_pins -pin_file pinLst.txt -exclude_ptn {B}
  ```

assign_pins Category Attributes

The root attributes in the assign_pins category are:

- assign_pins_advanced_node_rule_support
- assign_pins_allow_non_ndr_net_pins_on_ndr_tracks
- assign_pins_allow_unconnected_in_abutted_edge
- assign_pins_blocked_boundary_macro_distance
- assign_pins_edit_in_batch
- assign_pins_force_abutment_with_fixed
- assign_pins_max_channel_width_as_abutted
- assign_pins_max_distance_pair
- assign_pins_off_stripe
- assign_pins_pin_to_stripe_distance
- assign_pins_pin_to_via_distance_non_preferred_direction
- assign_pins_pin_to_via_distance_preferred_direction
- assign_pins_promoted_macro_bottom_layer
- assign_pins_promoted_macro_top_layer
- assign_pins_restricted_boundary_macro_distance
- assign_pins_strict_abutment

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `assign_pins` category, use the following command:

```
get_db -category assign_pins
```

assign_pins_advanced_node_rule_support

```
assign_pins_advanced_node_rule_support {true | false}
```

Default: `true`

Data_type: bool, read/write

A `true` value specifies that 20nm (and below) as well as DPT LEF rules will be respected (if present in LEF technology file) for determining and resolving any DRC violations, during all pin assignment related commands.

Related Commands

- `assign_io_pins`
- `assign_partition_pins`
- `align_pins`
- `edit_pin`

assign_pins_allow_non_ndr_net_pins_on_ndr_tracks

```
assign_pins_allow_non_ndr_net_pins_on_ndr_tracks {true | false}
```

Default: `true`

Data_type: bool, read/write

A `true` value allows general pins to be placed on NDR tracks (if available). Alternatively, if the value is set to false, the NDR-track rule is followed strictly and the net pins are placed on matching NDR tracks only.

Related Commands

- `assign_io_pins`
- `assign_partition_pins`
- `align_pins`
- `edit_pin`

assign_pins_allow_unconnected_in_abutted_edge

`assign_pins_allow_unconnected_in_abutted_edge {true | false}`

Default: `true`

Data_type: bool, read/write

A `true` value specifies that unconnected partition pins can be placed in abutted edges.

Related Commands

- `assign_io_pins`
- `assign_partition_pins`
- `align_pins`
- `edit_pin`

assign_pins_blocked_boundary_macro_distance

`assign_pins_blocked_boundary_macro_distance` *`distance`*

Default: 3

Minimum: 0

Maximum: 100

Data_type: float, read/write

Blocks automatic pin assignment from putting pins, on the part of the partition boundary facing the block, where the channel width between the partition boundary and the block is less than the value specified.
For channel width below the specified value, it blocks pins on the boundary facing this channel.

Related Commands

- `assign_io_pins`
- `assign_partition_pins`
- `align_pins`
- `edit_pin`

assign_pins_edit_in_batch

`assign_pins_edit_in_batch {true | false}`

Default: `false`

Data_type: bool, read/write

Enables pin-editing in batch mode.

Note: Once the interactive pin assignment is complete, it is important to set the mode to false. This can be done using the `set_db assign_pins_edit_in_batch false` command.

Note: The `assign_pins_edit_in_batch` attribute does not support the internal pins.

Related Commands

- `assign_io_pins`
- `assign_partition_pins`
- `align_pins`
- `edit_pin`

assign_pins_force_abutment_with_fixed

`assign_pins_force_abutment_with_fixed {true | false}`

Default: `true`

Data_type: bool, read/write

Specifies that for the connected pin of fixed abutted pins, ignore soft constraints check.

Some partitions in abutted design have preassigned pins with 1-track spacing and marked as fixed. As the design is abutted, there is no other legal location for such pins. Also, the automatic pin assignment has default spacing of two tracks. As a result, all pins connecting to these reference pins with one spacing are not assigned and lot of pins are left unassigned. When enabled, track spacing violations are ignored. As a result, assigns the corresponding pins opposite to the prefixed pins while maintaining abutment of pins.

Related Commands

- `assign_io_pins`
- `assign_partition_pins`
- `align_pins`
- `edit_pin`

assign_pins_max_channel_width_as_abutted

`assign_pins_max_channel_width_as_abutted` *`channel_width_in_microns`*

Default: 3

Minimum: 0

Maximum: 400

Data_type: double, read/write

Specifies that all channels with width less than or equal to the specified width will be considered as abutted and abutment rules will be applied on them.

Notes:

- The `assign_partition_pins`, assign_io_pins, and the `legalize_pins` commands do not place non-neighbor pins in the thin channels considered abutted.
- The check_pin_assignment command reports an abutment violation in case a non-neighboring pin is placed in the thin channel (abutted). The `-pre_check` option of the `check_pin_assignment` command that checks for the feasibility of pin assignment, also treats these thin channels as abutted.

Related Commands

- `assign_partition_pins`
- `align_pins`
- `check_pin_assignment`
- `edit_pin`

assign_pins_max_distance_pair

`assign_pins_max_distance_pair` *`distance`*

Default: 50

Minimum: 0

Maximum: 10000

Data_type: double, read/write

Ignores moving corresponding connected pins of 2-pin-connection nets where distance (in microns) between the pins is equal or greater than distance specified. You can avoid moving the corresponding pin for any channel width (routing bends are acceptable in channels) by using the distance value for the `-max_distance_paring` parameter as 0.

Related Commands

- `assign_io_pins`
- `assign_partition_pins`
- `align_pins`
- `edit_pin`

assign_pins_off_stripe

`assign_pins_off_stripe {below | all | none}`

Default: `none`

Data_type: enums {below all none}, read/write

Prevents the generation of pins on metal layers with respect to the power and ground stripe.

- `below`: Prevents the generation of pins on metal layers below the power and ground stripes.
- `all`: Prevents the generation of pins on all metal layers, above and below the power and ground stripes.
- `none`: Allows the generation of overlapping pins on all metal layers.

Related Commands

- `assign_io_pins`
- `assign_partition_pins`
- `align_pins`
- `check_pin_assignment`
- `edit_pin`

assign_pins_pin_to_stripe_distance

`assign_pins_pin_to_stripe_distance {`*`listOfLayerDistanceValuePair`*`}`

Default: `{}`

Data_type: string, read/write

Specifies the distance (in microns) from pin to stripe. It is layer specific.

Related Commands

- assign_io_pins
- assign_partition_pins
- align_pins
- check_pin_assignment
- edit_pin

assign_pins_pin_to_via_distance_non_preferred_direction

`assign_pins_pin_to_via_distance_non_preferred_direction {listOfLayerDistanceValuePair}`

Default: {}

Data_type: string, read/write

Specifies the distance (in microns) from pin to via-stack. It is layer specific.

Related Commands

- assign_io_pins
- assign_partition_pins
- align_pins
- check_pin_assignment
- edit_pin

assign_pins_pin_to_via_distance_preferred_direction

`assign_pins_pin_to_via_distance_preferred_direction {listOfLayerDistanceValuePair}`

Default: {}

Data_type: string, read/write

Specifies the distance (in microns) from pin to via-stack from the partition fence boundary. It is layer specific.

Related Commands

- assign_io_pins
- assign_partition_pins
- align_pins
- check_pin_assignment
- edit_pin

assign_pins_promoted_macro_bottom_layer

`assign_pins_promoted_macro_bottom_layer {layername}`

Default: 31

Data_type: string, read/write

Specifies the minimum metal layer name for promoting macro pins.

Related Commands

- assign_io_pins
- assign_partition_pins

assign_pins_promoted_macro_top_layer

`assign_pins_promoted_macro_top_layer {layername}`

Default: `31`

Data_type: string, read/write

Specifies the maximum metal layer name for promoting macro pins.

Related Commands

- assign_io_pins
- assign_partition_pins

assign_pins_restricted_boundary_macro_distance

`assign_pins_restricted_boundary_macro_distance distance`

Default: `30.0`

Minimum: 0

Maximum: 100

Data_type: double, read/write

Blocks automatic pin assignment, from putting pins on the part of the partition boundary facing the block, in the places where the channel width between the partition boundary and the block is less than the specified value.
For the channel width below the specified value, allowed layers and the channel length/width will be considered to allow a suitable number of pins on the boundary facing this channel.

Related Commands

- assign_io_pins
- assign_partition_pins
- align_pins
- check_pin_assignment
- edit_pin

assign_pins_strict_abutment

`assign_pins_strict_abutment {true | false}`

Default: `true`

Data_type: bool, read/write

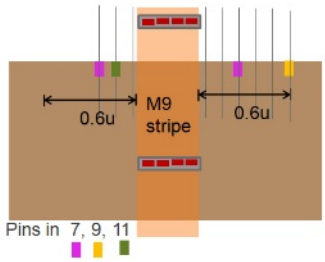
Controls abutted check for non-neighbour 2-pin and multi-partition pins.

Related Commands

- assign_io_pins
- assign_partition_pins
- align_pins
- check_pin_assignment
- edit_pin

Examples

- The following attribute prevents the generation of pins below power and ground strips:
  ```
  assign_pins_off_stripe below
  ```
- The following attribute will leave .6u of space between Metal9 stripe and Metal9 pins, and leave 1u of space between Metal11 stripe and Metal11 signal pin
  ```
  assign_pins_to_stripe_distance {{9 .6} {11 1}}
  ```

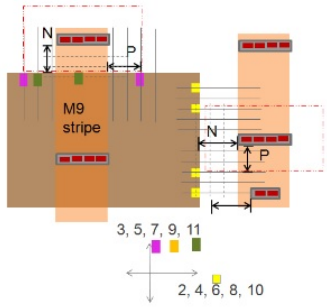


- For preferred direction pins, the following attributes will:
  - Leave .1u of space between Metal2,Metal4,Metal6 stack via to pins in same layer, and leave .3u of space between Metal9 stacked via and corresponding signal pin, on left/right edges
  - Leave .1u of space between Metal3,Metal5,Metal7 stack via to pins in same layer, and leave .3u of space between Metal9 stacked via and corresponding signal pin, on top/bottom edges

  ```
  assign_pins_to_via_distance_preferred_direction {{2 .1} {3 .1} {4 .1} {5 .1} {6 .1} {7 .1} {8 .3} {9 .3}}
  ```
- For any pins in non preferred direction, the following attributes will:
  - Leave .2u of space between Metal2,Metal4,Metal6 stack via to pins in same layer, and leave .4u of space between Metal9 stacked via and corresponding signal pin, on top/bottom edges
  - Leave .2u of space between Metal3,Metal5,Metal7 stack via to pins in same layer, and leave .4u of space between Metal9 stacked via and corresponding signal pin, on left/right edges

  ```
  assign_pins_pin_to_via_distance_non_preferred_direction {{2 .2} {3 .2} {4 .2} {5 .2} {6 .2} {7 .2} {8 .4} {9 .4}}
  ```

  Note: In the following picture, N stands for non-preferred and P stands for preferred.



change_current_design

```
change_current_design
[-help]
[partition_name]
```

Changes the partition view. It helps you to switch between different block cells and get back to the top cell.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `change_current_design` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man change_current_design`
`partition_name`	Specifies name of the partition to set as top cell. **Note:** • If no partition name is specified, then you are taken to the parent cell of the current top cell. • In nested partition designs, you can only switch to the next level partition. *Data_type*: string, optional

Examples

- The following commands changes sets `tdsp_top` as the top cell.
  `change_current_design tdsp_top`

- Change Partition View chapter in the *Innovus Common UI Menu Reference*
- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

check_bus_guides

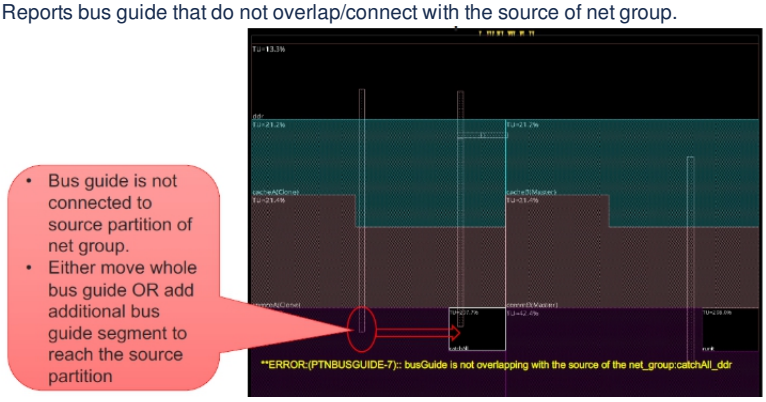
```
check_bus_guides
[-help]
```

Checks bus guides for violations during master-clone-aware bus guide operations. It checks for the consistency of net groups and bus guides by performing the following:

- Bus-guide physical checks:
  - Reports over-drawn bus guides.

  - Reports under-drawn bus guides (bus guide does not reach the sink of net group).

  - Reports bus guide that do not overlap/connect with the source of net group.



- Checks the net-group consistency and reports non-homogeneous nets in a net group.

Note: The `check_bus_guides` command does not support nested designs yet.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `check_bus_guides` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man check_bus_guides`

Example

- The following command checks the bus guides for violations.
  ```
  check_bus_guides
  ```

Related Information

- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

check_hier_route

```
check_hier_route
[-help]
[-partition {ptnName | ptnList}]
[-out_file outputFileName]
```

Checks and reports hierarchy violations for nets in the specified partitions.

The following conditions for hierarchy violations are checked:

- Intra-partition nets: All routes of this net should be within the partition boundary.
- Pure-Top nets: All routes of this net should be outside the partition boundary or touch the partition boundary from *outside*.
- Inter-partition nets: At least one route of this net must cross the partition boundary at partition pin. No route should cross the partition boundary at any other point.

Note: You can use this command to check for hierarchy violations before you push down the signal routes with the `commit_partitions -push_route` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `check_hier_route` parameter. For a detailed description of the command and all of its parameters, use the man command: `man check_hier_route`.
`-partition {ptnName | ptnList}`	Report the nets that violate the hierarchy with respect to the specified partition(s). *Default:* The command checks the hierarchy violations for nets on all partitions. *Data_type*: string, optional
`-out_file outputFileName`	Prints the details of net-wise violations in the specified file. *Default:* By default, the name of the file is `hier.rpt`. *Data_type*: string, optional

Examples of hierarchy violation conditions:

The following are examples of hierarchy violation conditions:

- If wires of a inter-partition net, are crossing the partition boundary at a place other than the corresponding pin shape.
- If wires of a inter-partition net, are crossing the partition boundary at multiple places.
- If wires of a pure top net, are crossing over a partition.
- If wires of a intra partition net are going outside the boundary of its partition.

Example

The following command checks the violations for nets on all the partitions in the design. A report of the violations is printed in the `hier.rpt` file.

```
check_hier_route
```

The output of this command on the display terminal is as follows:

```
------------------------------------------------------------
Summary of hierarchy violating nets with respect to each partition:
Partition: p1: 3 nets (0 intra, 2 inter, 1 top, 0 global)
Partition: p2: 1 nets (0 intra, 1 inter, 0 top, 0 global)
Partition: p3: 2 nets (1 intra, 0 inter, 1 top, 0 global)
Details of hierarchy violating nets reported in: hier.rpt
------------------------------------------------------------
```

The report printed in the `hier.rpt` file is as follows:

```
------------------------------------------------------------

Added the new header as follows:
############################################################
```

```
# Generated by: Cadence Innovus

check_pin_assignment

```
check_pin_assignment
[-help] [-out_file file_name]
[-report_same_net_pin_as_overlap]
[-partitions partition_name list]
[-partitions partition_name list | {-pins_file file_name [-exclude_partitions ptn_name]} | -exclude_pin_file file_name]
[-report_violating_pin ]
[-ignore {bus_guide net_group pin_abutment pin_depth pin_group pin_guide pin_layer pin_min_area pin_on_fence pin_on_track pin_spacing
pin_width clones logical_pin pin_color unplaced} ]
[[-pre_check [-skip_check {overlap layer spacing_constraint fixed_io_pins multi_term_net master_clone net_group connection orient_relation
grid_track_alignment symmetry_offset master_clone_size align_zone}] [-exclude_net_file file_name] ] |
{ [-partitions partition_name list] [-pins {pin_name list}] [-pins_file file_name] [-exclude_pin_file file_name]
[-ignore {bus_guide net_group pin_abutment pin_depth pin_group pin_guide pin_layer pin_min_area pin_on_fence pin_on_track pin_spacing
pin_width clones logical_pin pin_color unplaced}]
[-report_violating_pin ]
[-exclude_partitions ptn_name]}]
```

Checks the generated partition pins and I/O pins for the following:

- Pins are assigned to the proper metal layer depending on the side of the partition
- Pins are assigned within the range of layers reserved for the partition
- Any particular location on a routing layer has only one pin assigned
- Pins are assigned on the routing track
- Pins have a valid spacing from:
  - routing blockages
  - power pins and ground pins
- Pins have the correct size, status, and type
- Pin assignment follows the minimum area rule
- If the `-minArea` parameter is specified, the command checks for and reports the pins that are:
  - floating from inside (that is, the pins that are connected only to the top level)
  - floating from both inside the partition and at the top level.
- Pins follow the *`keep out spacing`* constraints for a pin group or net group and reports any violations in pin spacing.
- Checks and reports pin violations on clones in a master clone design.

The summary report generated by the command also includes information about feedthrough pins. These reports also provide a summary for all pins of the partition, blackbox, and the top module. However, summary report for pins is only displayed when there are multiple objects. It does not provide such a summed up pin summary report when we use the `check_pin_assignment` command for individual objects. For example, when you use the `-partitions` option, the summary report for all pins is not displayed.

Notes:

- The `check_pin_assignment` command honors preferred routing layer attributes as soft constraint during pin assignment and reports violations in pin layers as an error.
- You can use this command after running early global routing and then partitioning with pin assignment.
- If this command is run on a blackbox that has one or more pins with a single LEF port but with multiple shapes within the LEF port, the command will check violations only with respect to the first shape and will ignore all other shapes. If this command is run on a blackbox that has one or more pins with multiple LEF ports, the command will check violations only with respect to the first LEF port and will ignore all other LEF ports.
- The `check_pin_assignment` command supports nested partitions and reports the pin status for pins of nested partitions.
- Each time the `check_pin_assignment` command is run, it automatically refreshes the violations as properties of pins. It clears all violation properties on all pins and populates fresh violation properties on each pin based on the latest `check_pin_assignment` results. These properties are persistent in save/restore DB. You can query results of the pin violations report generated by the `check_pin_assignment` command to automate the flow. For example:
  - To query for all partition pins with depth violation, you can use the following query:
    ```
    get_db [get_db partitions .master -if {.obj_type == hinst}] .local_hpins -if {.vio_depth == 1}
    ```
  - To query for all pins (partition pins, bbox pins and IO pins) with depth violation, you can use the following query:
    ```
    puts [concat \
    [get_db ports -if {.vio_depth == 1}] \
    ```

```
[get_db [get_db partitions .master -if {.obj_type == inst}] .pins -if {.vio_depth == 1}] \
[get_db [get_db partitions .master -if {.obj_type == hinst}] .local_hpins -if {.vio_depth == 1}] \
]
```

- To query for all pins in a master partition having pin depth violations, you can use the following query:
  ```
  get_db [get_db partitions .master -if {.obj_type == hinst && .name == "S"}] .local_hpins -if {.vio_depth == 1}
  ```

Parameters

`-help`	Outputs a brief description that includes type and default information for each `check_pin_assignment` parameter. For a detailed description of the command and all of its parameters, use the man command: `man check_pin_assignment`
`-exclude_partitions` *`ptn_name`*	Specifies the list of excluded partition for pin file. *Data_type*: string, optional
`-exclude_pin_file` *`file_name`*	Specifies pin-list to be excluded for partition in a file. *Data_type*: string, optional
`-exclude_net_file` *`file_name`*	Specifies the file containing the list of nets that are excluded while checking the pin assignment. *Data_type*: string, optional

`-ignore`	Ignores the mentioned list of categories from checking and reporting.
	• `bus_guide`: When specified the command ignores the violations of bus guide constraints.
	• `net_group`: When specified the command ignores the ordering and exclusion checks on nets.
	• `pin_abutment`:When specified the command ignores pin positions for abutted partitions.
	• `pin_depth`: When specified the command ignores violations of pin depth constraints.
	• `pin_group`: When specified the command ignores ordering and exclusion checks on pins.
	• `pin_guide`: When specified the command ignores violations of pin guide constraints.
	• `pin_layer`: When specified the command ignores violations of pin layer constraints.
	• `pin_min_area`:When specified the command ignores the pins that are:
	  ◦ floating from inside the partition
	  ◦ floating from both inside the partition and at the top level
	• `pin_on_fence`: When specified, the command ignores whether the pins are on fence or not.
	• `pin_on_track`: When specified the command ignores pins that are placed on layer tracks.
	• `pin_spacing`: When specified the command ignores violations of pin spacing constraints.
	• `pin_width`: When specified the command ignores violations of pin width constraints.
	• `clones`: When specified the command violations relating to clone pins.
	• `logical_pin`: When specified the command ignores violations of the logical pin.
	• `pin_color`: When specified the command ignores violations of pin color.
	• `unplaced`: When specified, the command ignores violations relating to unplaced pins.
	Data_type: (enum)+, optional

`-out_file` *`file_name`*	Specifies that in addition to displaying the report on screen, the command should also print the output in the specified file. *Default*: `<design_name>.checkPin.rpt` *Data_type*: string, optional

`-partitions` *partition_name list*	Specifies the partition for which the pins will be checked. This parameter is required if the partition is not the top-level module. *Data_type*: string, optional
`-pins {`*pin_name* `|` *pin_name_list*`}`	Specifies that the command should be run on the specified pin(s) only. *Data_type*: string, optional
`-pins_file` *file_name*	Specifies the pin list for a partition in a file. In the pin file, the pins and nets are specified in the following format: `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Nets:` *netA* *netB* .. *netN* **Note:** While specifying the pin list in the pin_file, it is necessary to give the “Partition” keyword followed by the name of the partition or block. If this is not specified, no operations are performed. You can specify multiple partitions in the same pin_file. The pin_file does not support buses or wild cards for pin names. If a pin specified in the list or a partition is not present in the design, a warning is displayed. *Data_type*: string, optional
`-pre_check`	Checks for the feasibility of pin assignment mainly to catch the reason for unplaced pins in fully abutted design. **Note**: No other `check_pin_assignment` command parameter can be used if `-pre_check` is being used. *Data_type*: bool, optional
`-report_same_net_pin_as_overlap`	Reports the pins (connected to same net) placed at the same location and the same layer as overlap violation. *Data_type*: bool, optional
`-report_violating_pin`	Reports all the pins with violations. *Data_type*: bool, optional
`-skip_check {overlap layer spacing_constraint fixed_io_pins multi_term_net master_clone net_group connection orient_relation grid_track_alignment symmetry_offset master_clone_size align_zone}`	

	Skips checking the category from the list of type of checks. This parameter is used with the `-pre_check` parameter. • `overlap`: When specified, the command skips checking for any partition fences which are overlapping. • `layer`: When specified, the command skips checking for allowed layers on abutted edges of partition. • `spacing_constraint`: When specified, the command skips checking for spacing on abutted edges. • `fixed_io_pins`: When specified, the command skips checking if the block pin is placed on an abutted edge with its connected partition. • `multi_term_net`: When specified, the command skips checking for multi partition pin nets in abutted design. • `master_clone`: When specified, the command skips checking for master and clone partitions. • `net_group`: When specified, the command skips checking the net group ordering check in master and clone. • `connection`: When specified, the command skips checking if symmetric abutted designs have each master-clone pair connected to same pin. • `orient_relation`: When specified, the command skips checking the clone inside clone orientation. The clone inside a clone should have a relative orientation with its parent which is checked with master/clone inside master. • `grid_track_alignment`: When specified, the command skips checking for routing track offset in Master-Clone design to avoid off grid pins. • `symmetry_offset`: When specified, the command skips checking if the clone to clone offset (relativedistance on abutted edges) is same as in the master to master/clone connection pair. This is required so that the pins in each clone-clone and master-master/clone pair is the same. • `master_clone_size`: When specified, the command skips checking the master-clone size. This is required to check the number of poly edges of clones with master and check each edge size for any mismatch. • `align_zone`: When specified, the command skips checking for the common alignment zone between master-clone and their connected partitions. *Data_type*: (enum)+, optional

Example

- The following command checks violations on pins of partition `tdsp_core` and reports them to file `reportViolation.txt` :

  ```
  check_pin_assignment -partitions tdsp_core -out_file reportViolation.txt
  ```

  The output will look like:

  ```
  Start Checking pins of partition: [tdsp_core]
  Summary report for partition: [tdsp_core]
  Total Pins : 134
  Legally Assigned Pins : 110
  Illegally Assigned Pins : 0
  Unplaced Pins : 0
  Constant/Spl Net Pins : 24
  Internal Pins : 0
  Legally Assigned Feedthru Pins : 0
  Illegally Assigned Feedthru Pins : 0
  End of Summary report
  End Checking pins of partition: [tdsp_core]
  ```

- The following command accepts a file that contains the list of pins for partition A and partition B and checks any violations in pin assignment.

  ```
  check_pin_assignment -partitions {A B} -pins_file pinLst.txt
  ```

Related Information

clone_partition_obj

```
clone_partition_obj
[-help]
[-check_only]
[-objs {all place_blockage route_blockage pin_blockage macros fences bus_guides}]
[-redo]
[-ref_hinsts list_of_hinst_names]
[-sync]
[-target_hinsts list_of_hinst_names]
[-undo]
```

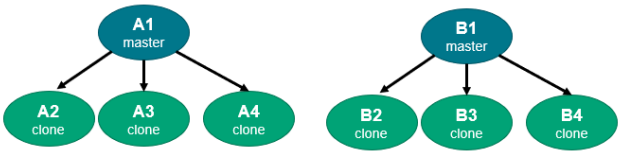
Syncs up the changes made to the specified objects in the master or clone partitions in the design with other hierarchical instances (master and clones) of the same module.

Parameters

`-check_only`	When specified, the tool check if the master and clone partitions are out of sync or not. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `clone_partition_obj` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man clone_partition_obj`
`-objs {all place_blockage route_blockage pin_blockage macros fences bus_guides}`	When specified, the tool does the sync-up of the specified objects. The objects that can be synced up include place_blockage, route_blockage, pin_blockage, macros, fences, and bus_guides. *Data_type*: enum, optional
`-redo`	When specified, the changes made to the object are done again . The master and clone partitions are brought to the next committed sync state. **Note**: Currently this parameter only supports the `bus_guides` object type (-objs). **Note**: This parameter is exclusive with the `-ref_hinsts` and –`target_hinsts` parameter options. *Data_type*: bool, optional
`-ref_hinsts list_of_hinst_names`	Specifies the name of the master or clone hierarchical instance *from which* the obj data is to be copied. *Default*: All master partitions in the design. *Data_type*: string, optional
`-sync`	When specified, the objects in all master and clone partitions are synced up by looking at the changes in shape in any hierarchical instance of the master and clone partitions. **Note**: Currently this parameter only supports the `bus_guides` object type (-objs). **Note**: This parameter is exclusive with the `-ref_hinsts` and –`target_hinsts` parameter options. *Data_type*: bool, optional

`-target_hinsts` *list_of_hinst_names*	Specifies the name of the master or clone hierarchical instance *to which* the obj data is to be copied. • When a master partition is specified with the `-target_hinsts` parameter, specifying the `-ref_hinsts` becomes mandatory as a user provided hinst is considered to sync up objects. • When clones partitions are specified with the `-target_hinsts` parameter, specifying the `-ref_hinsts` is optional as master hierarchical instances are automatically considered (default) to sync-up objects *Default*: All clone partitions in the design. *Data_type*: string, optional
`-undo`	When specified, the changes made to the object are reverted. The master and clone partitions are brought to the last committed sync state. **Note**: Currently this parameter only supports the `bus_guides` object type (-objs). **Note**: This parameter is exclusive with the `-ref_hinsts` and –`target_hinsts` parameter options. *Data_type*: bool, optional

Example



```
Hinst: A1 (master), A2 (clone), A3(clone), A4 (clone)
Hinst: B1 (master), B2 (clone), B3(clone), B4 (clone)
```

- The following commands syncs all clones to their respective master.
  ```
  clone_partition_obj
  ```
- The following command syncs the hinsts A2 and A3 (clones) to the master of module A (A1).
  ```
  clone_partition_obj -target_hinsts {A2 A3}
  ```
- The following command syncs the hinsts A1 (master) and A3 (clone) to the hinst A2 (clone)
  ```
  clone_partition_obj -target_hinsts {A1 A3} -ref_hinsts {A2}
  ```
- The following command syncs the hinsts A1 (master), A3, B2, B3 (clones) to hinsts A2 (clone) and the master of module B (B1)
  ```
  clone_partition_obj -target_hinsts {A1 A3 B2 B3} -ref_hinsts {A2}
  ```
- The following command checks and reports if the hinsts A1(master) and A3, B2, B3 (clones) are synced to hinst A2 (clone) and the master of module B (B1)
  ```
  clone_partition_obj -target_hinsts {A1 A3 B2 B3} -ref_hinsts {A2} -check_only
  ```
- The following command checks and reports if the hinsts A1 (master) and A3, B2, B3 (clones) are synced to hinst A2 (clone) and the master of module B (B1) for bus guides only.
  ```
  clone_partition_obj -target_hinsts {A1 A3 B2 B3} -ref_hinsts {A2} -check_only -objs {bus_guides}
  ```
- The following command syncs the hinsts A1 (master) and A3, B2, B3 (clones) to hinst A2 (clone) and the master of module B (B1) for bus guides only.
  ```
  clone_partition_obj -target_hinsts {A1 A3 B2 B3} -ref_hinsts {A2} -objs {bus_guides}
  ```

[-skip_route_blockages_outside_partition]
[-tcf]
[-pin_cut_space ]
[-no_inherit_physical ]
```

Converts the specified module fences to be partitions, pushes down the physical cells or power routing information to the partition level design(s), and duplicates strips in the partition that overlap with the partition boundary at their original widths. You can use this command after specifying the partition(s).

Notes:

- While bringing back misaligned rows to top-level design, the `commit_partitions` command automatically detects mis-aligned rows and pushes down the row information as it is to the top-level design.
- To assign signal pins for the partitions, use the `assign_partition_pins` command.
- The `commit_partitions` command should be used in combination with the `assign_partition_pins` command. Cadence recommends not mixing these version 4.2 pin commands with previous (version 4.1 or earlier) pin commands in the design flow.
- While handling metal fills, the `commit_partitions` command removes the metal-fill shapes that cross the partition boundary. It pushes down only those fill-shapes that are inside the partition boundary and are on the metal-layers owned by the partition.
- In top-down flow, the partition command only promotes P/G pins from the list of pins promoted by the `set_promoted_macro_pin` command.
- The `commit_partitions` command supports partitions with flexmodels.
- The `commit_partitions` command pushes down the route blockage layer even when the layer type is master-slice. It creates routing blockages for master-slice layers, in the "OBS" section of LEF (from macro/IP/PADs), that are overlapping partition fences. With this feature:
  - The shape of the routing blockage is the same as the overlapping shape of the layer, in the "OBS" section.
  - The routing blockage is given a “pushdown” property, so that it is not brought back in `assemble_design`.
  - The union of overlapping shapes of layers in “OBS” section is taken for master and clones.
- The `commit_partitions` command automatically saves all the bus guide constraints with associated net groups. This enables bus routing at block level as per chip level constraints.
- The `commit_partitions` command automatically saves all the cell padding information to each partition block data. This information is saved in partitioned block .fp file.
- The `commit_partitions` command inherits all the attributes assigned to a net for block implementation flow. Preserving these attributes allows the Early Global Router and the NanoRoute Router to route the nets following specific requirements.
- The `commit_partitions` command now preserves all the pin shapes of nets.

Parameters

`-add_pin_for_pg_wire_layers_in_distance {{layers} distance}`

	Specifies the layers and distance to consider for creating pins on PG stripes that lie in the specified distance range from **Note:** Some designs shorten the PG stripes to avoid stripes of different net/voltages in different abutted partition abutting create any pins by default since the PG stripes do not touch the partition boundary. However, you can use the `-add_pin` wire shapes that lie in the specified distance range from the partition boundary. The `-add_pin_for_pg_wire_layers_in_` preferred direction of route) of the partition boundary to create pin shapes on them.  For example, the following command creates pins on PG stripes on layers M10-M13 that are within a distance of 5 um fr `commit_partitions -add_pin_for_pg_wire_layers_in_distance {{M10 M11 M12 M13} 5}` *Data_type:* string, optional
`-input_nets_for_wire_distribution` *file_name*	
	Specifies the file containing the net names to use for wire distribution. *Data_type:* string, optional
`-no_inherit_physical`	Specifies that physical only (filler) cells are not pushed down into the partition; they remain at the top level. *Data_type:* bool, optional
`-no_top_pushdown`	Specifies that top-level power routing is not pushed down from top-level design to partition blocks on layers not reserved *Data_type:* bool, optional
`-no_via_cut_space`	Specifies that there are no cuts in the obstructions around vias. You can use this parameter when you want to ensure tha corresponding cover blockages. *Data_type:* bool, optional

`-partition` *partition_name...*	Specifies the partition names to be committed. *Data_type:* string, optional
`-pg_pushdown_honor_1801`	When enabled, the UPF information is pushed down to partitions. *Data_type:* bool, optional
`-pin_cut_space`	Specifies that there are cuts in the obstructions around pins. *Default:* By default, there are no cuts in the obstructions around pins so that the top-level routing can connect the pins wi *Data_type:* bool, optional
`-push_route`	Pushes down signal routes when the design is partitioned. **Note:** All the wires of a hierarchy-violating net are discarded, in case even a single wire of that net has a hierarchy viola *Data_type*: bool, optional
`-pushdown_non_pg_special_net`	Specifies that the non PG special nets should also be pushed down into the partition. *Data_type:* bool, optional
`-pushdown_honor_inside_pin_for_special_net`	
	Preserves wire segments till partition pins at the top level while wire segments beyond partition pins are still pushdown a having a fixed status over the partition and all top- level nets crossing the partition boundary. The pure top level nets alo block data and the actual wire segments are retained at the top level. At the top-level: • All wires till the partition pin (with fixed status) are kept. For pure top nets, all wires are kept. • LEF obstructions are cut out for preserved wires segments. • LEF shape against overlapping top instances are cut out. At the block level: • Routing blockages till the partition pin for wires that were retained at top level are created. • All wires segments after the partition pin are retained. • Placement blockages are created for top instances overlapping partition fence area. **Note:** Before using this option, ensure that partition area pins – of the corresponding net – must be FIXED.  *Data_type:* bool, optional
`-pushdown_selected_pg_bump`	Specifies that only the selected PG bumps should be pushed down into the partition. The bumps which are not selected *Data_type:* bool, optional

`-pushdown_selected_pg_wires_as_route_blockage`	
	Pushes down selected PG routes as route blockages into the partition. This parameter enables you to select the wire se special PG Routes.  *Data_type:* bool, optional
`-pushdown_special_net_as_obs {SNet list}`	
	Specifies a list of special nets, which will be pushed down as routing blockages. It supports all types of special nets incl *Data_type:* string, optional
`-skip_route_blockages_outside_partition`	
	Skips pushing of objects which are close to partition fence. *Data_type:* bool, optional
`-tcf`	Enables tcf writing for the block. **Note:** A TCF file is used to store power related information of the nets in the design by keeping their toggle count relatec data of partition blocks. This data can be later saved using the `write_partitions` command into their respective directo *Data_type:* bool, optional

Example

- The following command converts fences to partition data and pushes down route crossing over fence `EUG` inside the partition boundary:
  ```
  commit_partitions EUG -push_route
  ```
- PG is Metal7, Metal8
  Partition is defined with reserved layer Metal6

  The following command copies PG from top to block for all the PG layers:
  ```
  commit_partitions -partition partitionName
  ```
  The following command cuts PG from top to block for PG layers reserved for partitions. For layers above the reserved layer, PG is not pushed down to ptn.
  ```
  commit_partitions -partition partitionName -no_top_pushdown
  ```
  If reserved layer is Metal7 then Metal7 PG is cut at top and pushed down and Metal8 PG will not be pushed down.

commit_pushdown_eco

```
  commit_pushdown_eco
[-help]
-eco_obj_dir dir_name
-post_eco_dir dir_name
-pre_eco_dir dir_name
[-partition ptn_name_list]
```

Commits ECO for a partition block by applying ECO and generating a database for the block. It applies the previously generated ECO objects, to each partition, in parallel, using EDP (parallel/distributed) framework.

Note: The `commit_pushdown_eco` command also commits the FlexHtree amendment into the partition block. Clock amendments can be restored by using the `create_clock_tree_spec` command.

Parameters

`-eco_obj_dir dir_name`	Specifies the parent directory which contains all partition sub-directories in which ECO object files of partitions are kept. **Note:** The eco object file names are pre-determined to be: *eco_logical.txt* *eco_physical.txt* *eco_net.def.gz* *eco_pin.txt* *Data_type:* string, required
`-help`	Outputs a brief description that includes type and default information for each `commit_pushdown_eco` parameter. For a detailed description of the command and all of its parameters, use the man command: `man commit_pushdown_eco`.
`-partition ptn_name_list`	Specifies the list of partition names for which ECO objects are created. *Data_type:* string, optional
`-post_eco_dir dir_name`	Specifies the parent directory in which, after applying the ECOs, the partition databases are to be saved. *Default: ./post_eco_dir* *Data_type:* string, required
`-pre_eco_dir dir_name`	Specifies the latest version of original design, to which ECO objects need to be applied. It contains sub-directories to represent latest version of each partition database. *Data_type:* string, required

compare_pin_assignment_statistics

```
compare_pin_assignment_statistics
[-help]
[-ignore_min_wire_length min_wire_length]
[-out_file qor_compare_fine_name]
-reference reference_file_name
-target target_file_name
```

Generates a pin QoR comparison file based on a reference and a target pin QoR file.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `compare_pin_assignment_statistics` parameter. For a detailed description of the command and all of its parameters, use the man command: `man compare_pin_assignment_statistics`.
`-ignore_min_wire_length min_wire_length`	Specifies the minimum wire length. If reference wire length at a partition pin is less than the *`min_wire_length`*, then it is not reported in the output file. *Default*: 60 *Data_type*: string, optional
`-out_file qor_compare_fine_name`	Specifies an output file for the pin QoR comparison. *Default*: `./qor_compare.txt` *Data_type*: string, optional
`-reference reference_file_name`	Specifies the reference file generated using the `report_pin_assignment_statistics` command. For example, the following command generates a reference pin QoR file named `pin_qor_reference.txt`. `report_pin_assignment_statistics -outFile pin_qor_reference.txt` *Data_type*: string, required
`-target target_file_name`	Specifies the target file generated using the `report_pin_assignment_statistics` command. For example, the following command generates a target pin QoR file named `pin_qor_target.txt`. `report_pin_assignment_statistics -out_file pin_qor_target.txt` *Data_type*: string, required

Example

The following command generates a pin QoR comparison file, `pin_qor_compare.txt`:

```
report_pin_assignment_statistics -out_file pin_qor_reference.txt
report_pin_assignment_statistics -out_file pin_qor_target.txt
compare_pin_assignment_statistics -reference pin_qor_reference.txt -target pin_qor_target.txt -out_file pin_qor_compare.txt
```

connect_macro_feedthru

```
connect_macro_feedthru
[-help]
[-nets string | -exclude_nets string | -selected_nets]
[-insts string | -exclude_insts string]
[-report_eco string | -check_only]
[-port_map string]
[-verbose]
[-max_search_distance float]
[-search_all_sides]
[-abutment float]
[-report_abutment string]
[-report_floating_ports string]
```

Connects predefined feedthrough pins in custom macros to overlapping nets that have wires crossing over the custom macros, based on the routing information. The feedthrough connectivity details are defined in a mapping file, which is specified through the `-port_map` *`filename`* parameter. You can include or exclude specific nets or instances. This command deletes routing only for the modified nets. You can run this command after placing the design and running Early Global Route.

Parameters

`-abutment` *`float`*	Specifies the distance that pins on the same track and layer must have from one another so as to be considered as abutted. If two or more pins are considered as abutted, any feedthrough path that passes through one of the pins will pass through the other pin(s) as well. *Default:* If this parameter is not specified, the default value is `1` micron. *Data_type*: float, optional
`-check_only`	Specifies that only a report of the messages should be displayed but no changes should be made to the netlist. *Data_type*: bool, optional
`-exclude_insts` *`string`*	Prevents feedthrough buffers from being added for the specified instance. The names of the instances are specified in a file, specified by *`fileName`*. In the file, you can specify wildcards (*) for the instance names to exclude. *Default:* All instances of the cell types specified in the portmap file are considered. *Data_type*: string, optional
`-exclude_nets` *`string`*	Prevents feedthrough buffers from being added to the specified net. The names of the nets are specified in a file, specified by *`fileName`*. In the file, you can specify wildcards (*) for the net names to exclude. *Default:* All nets or bus names are considered. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `connect_macro_feedthru` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man connect_macro_feedthru`
`-insts` *`string`*	Specifies that the feedthrough buffers should be added only for the specified instances. *Data_type*: string, optional
`-max_search_distance` *`float`*	Specifies the distance in microns from the wire crossing till which the command should search to find a connected feedthrough. **Note:** Specifying a large value for this parameter might have an adverse impact on the Quality of Results (QoR). *Data_type*: float, optional
`-nets` *`string`*	Specifies that the feedthrough buffers should be added only to the specified nets. *Data_type*: string, optional

`-port_map` *string*	Specifies the name of the file that contains the feedthrough connectivity definitions.
	Default: If you do not specify a file name, a file with the name `portmap` in the current directory is used.by default.
	Note: A file with the feethrough connectivity definitions must be available.
	The syntax of the file is as follows:
	`MACRO MacroName`
	`Macro definition section`
	`END MACRO`
	The definition of the macro is provided in the *`Macro definition`* section, which can contain one or more feedthrough sections. The name of the feedthrough section is optional.
	The syntax of the Feedthrough section is as follows:
	`Feedthrough [FeedthroughName]`
	`Pin Section`
	`END FEEDTHROUGH`
	Each Feedthrough section contains one section for the INPUT PIN and one section for the output pin.
	Note: Multi-fanout feedthrough sections are not supported.
	The syntax of the pin section is as follows:
	`PIN PinName`
	`DIRECTION {in | out };`
	`SIDE {left | right | top | bottom};`
	`END PIN`
	If the pin direction is not specified, it is read from the LEF file. If you specify a value for pin direction, ensure that it is consistent with the description in the LEF file.
	Note: The pin direction `inout` is not supported.
	Note: All the predefined macro feedthrough pins should be floating pins.
	Here is an example of a mapping file:
	`MACRO RAMXXX`
	`FEEDTHROUGH feedthrough1`
	`PIN feedthrough1_in`
	`END PIN`
	`PIN feedthrough1_out`
	`END PIN`
	`END FEEDTHROUGH`
	`FEEDTHROUGH feedthrough2`
	`PIN feedthrough2_in`
	`END PIN`
	`PIN feedthrough2_out`
	`END PIN`
	`END FEEDTHROUGH`
	`END MACRO`
	Data_type: string, optional

`-report_abutment` *string*	Reports, in the file specified, the list of pins that are considered as abutted. In the file, each feedthrough path is traced from the first input pin to the last input pin. Each path is preceded by the word `Begin` on a new line and followed by the word `End` on a new line.
	Here is the extract from an example file:
	`Begin`
	`Inst [Inst1], Term In [A1] Term Out [X1]`
	`Inst [Inst2], Term In [A2] Term Out [X2]`
	`End`
	In the previous example, the out term `X1` of instance `Inst1` is abutted with the in term `A2` of instance `Inst2`.
	Data_type: string, optional

`-report_eco` *string*	Specifies the name of the ECO file that will contain a report of the changes. You can use this file while performing ECO changes.
	Here is a sample report generated through this parameter:
	`FORMATVERSION 2`
	`ATTACHTERM eco_instance1 inputbuf2[2] testnet`
	`ADDNET FE_FTM_1_testnet`
	`ATTACHTERM eco_instance1 outputbuf2[2] FE_FTM_1_testnet ATTACHTERM i1 A FE_FTM_1_testnet ATTACHTERM eco_instance1 rstb FE_FTM_1_testnet`
	Data_type: string, optional

`-report_floating_ports` *string*	Specifies that the list of unused ports should be saved in the specified file. The file lists the instance name and the pin name for each unused port. After running the `connect_macro_feedthru` command, the unused ports should be manually tied. You can use this parameter to save the list of the unused ports to a file. *Data_type*: string, optional
`-search_all_sides`	Specifies that if the closest available feedthrough pin on the same side cannot be connected, the command should search for the feedthrough pins on other sides as well. When you specify this parameter, it is recommended to limit the distance of the search using the `-max_search_distance` option to get good QoR. *Default*: The command searches for a feedthrough whose in and out pins lie *on the same sides* of the macro on which the wires enter and exit the macro. *Data_type*: bool, optional
`-selected_nets`	Specifies that feedthrough buffers should be added only to the nets that are currently selected. *Default:* All nets.are considered. *Data_type*: bool, optional
`-verbose`	Provides additional messages, for example net-specific messages. *Data_type*: bool, optional

Example

The following command connects predefined feedthrough buffers in custom macros for nets that are listed in the file named `NetsToIncludeFile`. The command searches for a distance of 10 microns. The feedthrough connectivity is described in a file named `portmapFileForNets`.

```
connect_macro_feedthru portMap portmapFileForNets -nets NetsToIncludeFile -max_search_distance 10
```

convert_blackbox_to_fence

```
convert_blackbox_to_fence
[-help]
{-cell cellName | -inst instName}
```

Converts a blackbox to a fence. Once the black box netlist is well defined, use this command to convert the black box back to a regular partition.

Parameters

`-cell cellName`	Specifies the name of a module or submodule that should be converted to a fence. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `convert_blackbox_to_fence` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man convert_blackbox_to_fence`
`-inst instName`	Specifies the name of the blackbox instance that should be converted to a fence. *Data_type*: string, optional

Example

```
convert_blackbox_to_fence -inst hinst5
```

Related Information

- `create_blackbox`
- `convert_fence_to_black_box`
- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

convert_fence_to_black_box

```
convert_fence_to_black_box
[-help]
{-module cellName | -hinst hinstName}
[-size { x y }]
```

Converts a fence to a blackbox. Use this command before committing partition.

Parameters

`-module cellName`	Specifies the name of a module or submodule that should be converted to a black box. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `convert_fence_to_black_box` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man convert_fence_to_black_box`
`-hinst hinstName`	Specifies the name of the hierarchical instance that should be converted to a black box. *Data_type*: string, optional
`-size {x y}`	Specifies the width and height of the blackbox. *Default:* If you do not specify this parameter, the current fence size is taken as the initial size of the blackbox. *Data_type*: point, optional

Example

```
convert_fence_to_black_box -module cp1A -size 12 44
```

Related Information

create_blackbox

```
create_blackbox
[-help]
[-core_spacing {left right top bottom}]
[-min_pitch_left integer]
[-min_pitch_right integer]
[-min_pitch_top integer]
[-min_pitch_bottom integer]
[-pin_layer_left {list_of_layers}]
[-pin_layer_right {list_of_layers}]
[-pin_layer_top {list_of_layers}]
[-pin_layer_bottom {list_of_layers}]
[-reserved_layer {list_of_layers}]
[-place_halo {left right top bottom}]
[-route_halo float]
[-route_halo_top_layer integer]
[-route_halo_bottom_layer integer]
[-skip_build_timing]
[ -cell string| -master_inst string]
{-size {x y}
    | -area float
    | -gate_count string | {-gate_area float [-cell_density float]
[ -include_macro_area {0 | 1}
{-macro_area float | -macro_list {macroName [count]}}]}}
[{-area float | -gate_count string}
[-min_width float | -min_height float | -fixed_width float | -fixed_height float ]]
[-min_width float | -min_height float | -fixed_width float | -fixed_height float |-aspect_ratio_range {min max}]
[-aspect_ratio float |-aspect_ratioRange {min max}]
```

Converts a hard macro into a blackbox. It is also used for specifying an instance to be the master of multiplying instantiated blackboxes. You can use this command after importing the design.

Note: You can convert a hard macro into a blackbox; however, Cadence does not recommend this because it will not update the blockage definitions when you change the blackbox size.

Note: For designs that have backside metal layers, both the backside and frontside layers are accepted. However, the automatic pin assignment flow is not impacted with the support for backside metal layers. It assigns pins on front layers only.

Parameters

`-area float`	Specifies the total area in square micrometers. If you specify the block size area, the default for the created block aspect ratio is 1. *Data_type*: float, optional
`-aspect_ratio float`	Specifies the aspect ratio value. This value combined with the area information determines the width and height. *Data_type*: float, optional
`-aspect_ratio_range {min max}`	Sets the minimum and maximum values for the aspect ratio range. This value combined with the specified related area information enables the blackbox to be reshaped while maintaining the current area. *Data_type*: point, optional
`-cell string`	Specifies the name of the cell. *Data_type*: string, optional
`-cell_density float`	Specifies the cell utilization. This value is used to derive the area of the blackbox, which is calculated using the following formula: `Blackbox area = (standard cell area / cell utilization) + macro area` *Default*: The default value of cell utilization is `1` (100%). *Data_type*: float, optional

`-core_spacing {left right top bottom}`	Specifies the space, in micrometers, between the module boundary and core design area of the module on the left, right, top, and bottom sides respectively. The partition pins will be located at the partition instance boundary and the core area. *Data_type*: string, optional
`-fixed_height float`	Specifies the fixed height of the module. *Data_type*: float, optional
`-fixed_width float`	Specifies the fixed width of the module. *Data_type*: float, optional
`-gate_area float`	Specifies the gate area. If the value of the `-include_macro_area` parameter is `0`, the gate area is equal to the standard cell area. If the value of the `-include_macro_area` parameter is `1`, the gate area also includes the macro area. *Data_type*: float, optional
`-gate_count string`	Specifies a gate count value. The total cell area is equal to the specified gate count multiplied by the specified area per gate. • *count:* Specifies the gate count value. • *areaPerGate:* Specifies an area per gate value in square micrometers. To get the cell area, this value is multiplied by the specified gate count. • *utilizationValue:* Specifies the cell utilization. This value derives the area that is reserved for routing. The final block size is equal to the total cell area plus the routing area. *Default*: The default value is 0.7 (70%) *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `create_blackbox` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_blackbox`
`-include_macro_area {0 | 1}`	A value of `0` specifies that the gate area does not include the macro area specified through the `-macro_area` or the `-macro_list` parameter. A value of `1` specifies that the gate area includes the macro area specified through the `-macro_area` or the `-macro_list` parameters. *Default:* The default value is `0`. *Data_type*: enum, optional

`-macro_area float`	Specifies the total area of the macro(s) in square microns.
	• If the value of the `-include_macro_area` parameter is set to 0:
	`Total blackbox area = (gate area / cell utilization value) + macro area`
	• If the value of the `-include_macro_area` parameter is set to 1:
	`Total blackbox area = ((gate area - macro area) / cell utilization value) + macro area`
	Data_type: float, optional

`-macro_list {macroName [count]}`	Specifies the name of the hard macro whose area will be included while calculating the total gate area. The `macroName` argument specifies the name of the macro, and the `count` argument specifies the number of times the macro is referenced. Thus, by specifying a value for count, you avoid repeating the macro names for macros that are referenced multiple times.
	• If the value of the `-include_macro_area` parameter is set to 0:
	`Total blackbox area = (gate area / cell utilization value) + macro area`
	• If the value of the `-include_macro_area` parameter is set to 1:
	`Total blackbox area = ((gate area - macro area) / cell utilization value) + macro area`
	Default: The default value of `count` is `1`.
	Data_type: string, optional

`-master_inst string`	Specifies the name of the master blackbox. *Data_type*: string, optional
`-min_height float`	Specifies the minimum height of the specified module. *Data_type*: float, optional

`-min_pitch_left integer`	Specifies the pin pitch dimension for the *Left* side of the blackbox. The default is 2, which places one pin for every two metal tracks. The actual pin pitch depends on the pin's metal layer. *Data_type*: int, optional
`-min_pitch_right integer`	Specifies the pin pitch dimension for the *Right* side of the blackbox. The default is 2, which places one pin for every two metal tracks. The actual pin pitch depends on the pin's metal layer. *Data_type*: int, optional
`-min_pitch_top integer`	Specifies the pin pitch dimension for the *Top* side of the blackbox. The default is 2, which places one pin for every two metal tracks. The actual pin pitch depends on the pin's metal layer. *Data_type*: int, optional
`-min_pitch_bottom integer`	Specifies the pin pitch dimension for the *Bottom* side of the blackbox. The default is 2, which places one pin for every two metal tracks. The actual pin pitch depends on the pin's metal layer. *Data_type*: int, optional
`-min_width float`	Specifies the minimum height of the specified module. *Data_type*: float, optional
`-pin_layer_left {list_of_layers} -pin_layer_right {list_of_layers} -pin_layer_top {list_of_layers} -pin_layer_bottom {list_of_layers}`	Specifies the metal layers to use for the blackbox. The metal layers correspond to the sides of the blackbox, where the vertical metal layers (for example, *Metal2, Metal4*, and so on) are for the Top and Bottom sides, and horizontal metal layers (for example, `Metal3, Metal5`, and so on) are for the Left and Right sides of the blackbox. Specify this value in integers, for example `-pin_layer_top {2 4}` *Data_type*: string, optional
`-place_halo {left right top bottom}`	Specifies extra spacing, in micrometers around the sides (left, bottom, right and top respectively) of the blackbox that should not be used for placement. At the top-level design, this information is saved as part of the partition section in a floorplan file. This information is also saved in a partition floorplan file when saving partitions. By default, the value is 0 for all the sides. *Data_type*: string, optional
`-reserved_layer {list_of_layers}`	Specifies the metal layers that are used for routing in the partition and generating partition pins. Any metal layers that are not specified, usually the top-most metal layers, are allowed to route over the partition.A normal six-metal layer specification is Metal1, Metal2, Metal3, Metal4 and Metal5 specified, and Metal6 unspecified. When saving the partition, the LEF generated for this partition will have routing blockages on their layers so that the top-level router is aware of which metal layers are being used in the partition. *Data_type*: string, optional
`-route_halo float`	Specifies routing spacing, in micrometers, around the sides of the blackbox. You can specify a positive or a negative value for the routing halo. A positive value means that the halo will be outside the blackbox. A negative value means that the halo will be applicable during block implementation, inside of the blackbox. The same value is used for all sides of the blackbox. *Data_type*: float, optional
`-route_halo_bottom_layer integer`	Specifies the bottom partition layer for which routing halo will be created. *Default*: By default, the bottom layer reserved for the partition is used. *Data_type*: int, optional
`-route_halo_top_layer integer`	Specifies the top partition layer for which routing halo will be created. *Default*: By default, the top layer reserved for the partition is used. *Data_type*: int, optional
`-size x y`	Specifies fixed width and height of a specified module, in micrometers. *Data_type*: point, optional

`-skip_build_timing`	Skips re-building the time graph and re-initializing the top cell information in order to improve the run time of the blackbox specification for designs with a large number of blackboxes. **Note:** Since the timing graph only needs to build for the last blackbox, you must specify the final `create_blackbox` command without this parameter. For example, if your design has three blackboxes, the first two `create_blackbox` commands should be specified with the `-skip_build_timing` parameter while the last `create_blackbox` command should be specified without this parameter. *Data_type*: bool, optional

Examples

- The following command converts the hard macro `hn246` into a black box. The gate area is specified as 100000 square microns and the specified macro area is 220 square microns. The cell utilization value is not specified, and so the default value of 1 is used. The `-include_macro_area` parameter is not specified and so the default value of 0 is used.
  When the `-include_macro_area` parameter is 0, the blackbox area is calculated using the formula:
  `Total blackbox area = (gate area / cell utilization value) + macro area`
  The total black box area in this case is, therefore, (100000 / 1) + 220 that is 100220 square microns.
  ```
  create_blackbox -cell hn246 -gate_area 100000 -macro_area 220
  ```
- The following command is similar to the command in the previous example, except that the value of `-include_macro_area parameter` is set to 1 and the value of the `-cell_density` parameter is set to `.7`
  When the `-include_macro_area` parameter is set to 1, the blackbox area is calculated using the formula
  `Total blackbox area = ((gate area - macro area)/cell utilization value) + macro area`
  The total blackbox area in this case is, therefore, ((100000 -220) /.7 + 220) that is 142762.86 square microns.
  ```
  create_blackbox -cell hn246 -gate_area 100000 -include_macro_area 1 -macro_area 220 -cell_density 0.7
  ```
- The following command converts the macro `hn246` into a blackbox and specifies that the areas of macros `macro_2A` and `macro_2B` should be added while calculating the blackbox area. The macro named `macro_2A` is included four times and the macro named `macro_2B` is included three times.
  ```
  create_blackbox -cell hn246 -gate_area 100000 -macro_list macro_2A 4 macro_2B 3
  ```

create_net_group

```
  create_net_group
[-help]
[-mixed_signal]
[-spacing minSpaceInTracks]
[ {[-opt_order ]} | -spread_pins | -compact_area ]
[-exclude_pins {all_layer | same_layer | all_layer_in_guided_area}
[-keep_out_spacing integer]]
{ [-name netGroupName [-nets netNameList]] }
```

Creates an empty net group. A net group can contain net names, bus names, or segments of a bus. To add nets into the net group, use the `update_net_group` command. You can use this command after importing the design.

Note: If a net is part of a net group, and you add the same net to another net group, the Innovus software will display a warning, but the net will be added to the second net group too. However, when pin assignment is performed, the net is considered part only of the *first* net group to which it was added – and *not* part of any other net group to which it was subsequently added.

Parameters

`-compact_area`	Specifies that pins in the group are assigned tightly together. By default, pins which are part of a group and associated to a guide can be spread inside the guide based on the area available and alignment to targets. The `compact_area` option, when used, ignores the alignment and available area and forces the pins to the minimum area on guide honoring the minimum spacing constraint and overlooking any alignment to targets.  *Data_type*: bool, optional
`-exclude_pins {all_layer | same_layer | all_layer_in_guided_area}`	
	Specifies that pins in the group exclude foreign pins on all layers, same layer, or on all layers in the guided area. • `all_layer`: Specifies that pins in the group exclude foreign pins between grouped pins on all layers. • `same_layer`: Specifies that pins in the group exclude foreign pins grouped pins on all same layer. • `all_layer_in_guided_area`: Specifies that pins in the group exclude foreign pins in the guide area defined for the group, on all layers. **Note:** If guide is not defined for a group down the flow, `all_layer_in_guided_area` option would be treated like `-exclude_pins {all_layer}` for the group without guides behavior. *Data_type*: enum, optional
`-help`	Outputs a brief description that includes type and default information for each `create_net_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_net_group`.
`-keep_out_spacing integer`	Specifies the minimum spacing between the pins placed outside of the group, in number of tracks or pitch. *Minimum:* 0 *Maximum:* 65535 *Data_type*: int, optional

`-mixed_signal`	Specifies to identify a mixed signal group. *Data_type*: bool, optional
`-nets` *netNameList*	Specifies the name of the net(s). You can use wildcards (`*?`) with this parameter. *Data_type*: string, optional
-name netGroupName	Specifies the name of the created net group name. *Data_type*: string, optional
`-opt_order`	Specifies that pins in the group are reordered to optimize wire length. If this option is not selected, the pin order is exactly as specified in the pin group. *Data_type*: bool, optional
`-spacing` *minSpaceInTracks*	Specifies the minimum spacing between the pins of the net group. *Default:* The default value is two tracks. *Data_type*: int, optional
`-spread_pins`	Specifies that pins in the group must be distributed evenly. *Data_type*: bool, optional

Example

- The following command creates a net group `bundle1`:
  ```
  create_net_group bundle1
  ```
- The following command creates a net group `bundle1` and allows re-ordering of the nets definition inside the group:
  ```
  create_net_group bundle1 -opt_order
  ```

create_partition

```
create_partition
[-help]
[-core_spacing {left right top bottom}]
[-min_pitch_bottom x]
[-min_pitch_left x]
[-min_pitch_right x]
[-min_pitch_top x]
[-pin_layer_left {list_of_layers}]
[-pin_layer_right {list_of_layers}]
[-pin_layer_top {list_of_layers}]
[-pin_layer_bottom {list_of_layers}]
[-place_halo {left right top bottom}]
[-rail_width railWidth]
[-reserved_layer {list_of_layers}]
[-route_halo floatValue]
[-route_halo_bottom_layer integerValue]
[-route_halo_top_layer integerValue]
[-std_cell_height x]
{-hinst hinst_name | -proto_hinsts {master_hinst_name_list} | -cell cell_name}
[-check_clone_alignment]
[-hinst hinst_name  [-copy_from ref_partition_name]] [-cell cell_name [-copy_from ref_partition_name]]
```

Defines a new partition corresponding to a hierarchical instance. The `create_partition` command supports nested partitions and can be used to specify partitions inside a partition. While specifying partitions, you can specify the definition in any order. You can use this command after importing the design.

Note: The `create_partition` command does not check for fence constraint on clones and does not align them to the partition with respect to the master. If the clones do not have fence constraint, `create_partition` makes fences for clone modules.

Note: For designs that have backside metal layers, both the backside and frontside layers are accepted. However, the automatic pin assignment flow is not impacted with the support for backside metal layers. It assigns pins on front layers only.

Parameters

`-cell cell_name`	Specifies the name of the cell for defining a new partition at an instance that has R0 orientation. **Note**: For black-boxes, an instance with non-R0 orientation is chosen if an instance with R0 orientation is not found. *Data_type*: string, optional
`-check_clone_alignment`	Specifies to check only the alignment of the clone partition with the master partition. *Data_type*: bool, optional
`-copy_from ref_partition_name`	Specifies the name of the reference partition from which to copy their properties. While copying the constraints, the shape, orientation, and location are considered: • **Orientation**: The orientation of the partition being defined is copied from the reference partition (*ref_partition_name*). If the reference partition has clones, then the orientation of the master is considered. • **Shape**: The shape of the partition being defined is copied from the reference partition (*ref_partition_name*). • **Location**: The fence location of the partition hinst being defined takes priority. In case the target partition hinst does not have a fence constraint (location), the location information is copied from the reference partition master hinst. This will result in overlapping fences. **Note:** If the `-copy_from` parameter is being used with the -cell parameter that has multiple Hinsts, then the location of the hinst that has a fence (location) constraint is considered as the master of the partition being defined. *Data_type*: string, optional
`-core_spacing {left right top bottom}`	

	Specifies the space, in micrometers, between the module boundary and core design area of the partition module on the left, right, top, and bottom sides respectively. The partition pins will be located at the partition instance boundary and the core area. **Note**: These core-to-edge values are always synchronized between the partition and the corresponding power domain as follows: If the specified instance was also earlier defined as a power domain, these values for the partition, by default, will have the same value as the values for the power domain. If you specify different values for the partition, the values for the power domain are updated so that they are the same as the values defined for the partition. Similarly, if a power domain is created (or an existing power domain modified) on the specified instance after the partition is defined, the values set earlier for the partition are updated so that they are the same as the values defined for the power domain. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `create_partition` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_partition`
`-hinst` *hinst_name*	Specifies the name of the hierarchical instance. **Note**: None of its ancestors or descendants in the netlist tree can be a partition. *Data_type*: string, optional
`-min_pitch_bottom` *x*	Specifies the pin pitch dimension for the bottom partition side. The default is 2, which places one pin for every two metal tracks. The actual pin pitch depends on the pin's metal layer. The Partition Pin Guide floorplan object will supersede this entry and use the Min. Space entry in the object's Attribute Editor. *Data_type*: int, optional
`-min_pitch_left` *x*	Specifies the pin pitch dimension for the left partition side. The default is 2, which places one pin for every two metal tracks. The actual pin pitch depends on the pin's metal layer. The Partition Pin Guide floorplan object will supersede this entry and use the Min. Space entry in the object's Attribute Editor. *Data_type*: int, optional
`-min_pitch_right` *x*	Specifies the pin pitch dimension for the right partition side. The default is 2, which places one pin for every two metal tracks. The actual pin pitch depends on the pin's metal layer. The Partition Pin Guide floorplan object will supersede this entry and use the Min. Space entry in the object's Attribute Editor. *Data_type*: int, optional
`-min_pitch_top` *x*	Specifies the pin pitch dimension for the top partition side. The default is 2, which places one pin for every two metal tracks. The actual pin pitch depends on the pin's metal layer. The Partition Pin Guide floorplan object will supersede this entry and use the Min. Space entry in the object's Attribute Editor. *Data_type*: int, optional
`-pin_layer_bottom {`*list_of_layers*`}`	Specifies the metal layers to use for the partition. The metal layers correspond to the sides of the partition, where the vertical metal layers (for example, Metal2, Metal4, and so on) are for the Top and Bottom sides, and horizontal metal layers (for example, Metal3, Metal5, and so on) are for the Left and Right sides of the partition. Specify this value in integers, for example `-pin_layer_bottom {2 4}` **Note**: Only layers in their preferred routing direction are accepted. **Note**: If these option is not supplied, all allowed layers in preferred routing direction will be assumed for that side. **Note:** For designs that have backside metal layers, both the backside and frontside layers are accepted. *Default*: All allowed layers in preferred direction. *Data_type*: string, optional

`-pin_layer_left {list_of_layers}`	Specifies the metal layers to use for the partition. The metal layers correspond to the sides of the partition, where the vertical metal layers (for example, Metal2, Metal4, and so on) are for the Top and Bottom sides, and horizontal metal layers (for example, Metal3, Metal5, and so on) are for the Left and Right sides of the partition. Specify this value in integers, for example `-pin_layer_left {3 5}` **Note**: Only layers in their preferred routing direction are accepted. **Note**: If these option is not supplied, all allowed layers in preferred routing direction will be assumed for that side. **Note:** For designs that have backside metal layers, both the backside and frontside layers are accepted. *Default*: All allowed layers in preferred direction. *Data_type*: string, optional
`-pin_layer_right {list_of_layers}`	Specifies the metal layers to use for the partition. The metal layers correspond to the sides of the partition, where the vertical metal layers (for example, Metal2, Metal4, and so on) are for the Top and Bottom sides, and horizontal metal layers (for example, Metal3, Metal5, and so on) are for the Left and Right sides of the partition. Specify this value in integers, for example `-pin_layer_right {3 5}` **Note**: Only layers in their preferred routing direction are accepted. **Note**: If these option is not supplied, all allowed layers in preferred routing direction will be assumed for that side. **Note:** For designs that have backside metal layers, both the backside and frontside layers are accepted. *Default*: All allowed layers in preferred direction. *Data_type*: string, optional
`-pin_layer_top {list_of_layers}`	Specifies the metal layers to use for the partition. The metal layers correspond to the sides of the partition, where the vertical metal layers (for example, Metal2, Metal4, and so on) are for the Top and Bottom sides, and horizontal metal layers (for example, Metal3, Metal5, and so on) are for the Left and Right sides of the partition. Specify this value in integers, for example `-pin_layer_top {2 4}` **Note**: Only layers in their preferred routing direction are accepted. **Note**: If these option is not supplied, all allowed layers in preferred routing direction will be assumed for that side. **Note:** For designs that have backside metal layers, both the backside and frontside layers are accepted. *Default*: All allowed layers in preferred direction. *Data_type*: string, optional
`-place_halo {left right top bottom}`	
	Specifies extra spacing, in micrometers (around the left, bottom, right and top sides respectively) of the partition that should not be used for placement. The placement program will not place standard cells in the area for partition placement. This spacing is called placement halo. At the top-level design, this information is saved as part of the partition section in a floorplan file. This information is also saved in a partition floorplan file when saving partitions. By default, the value is 0 for all the sides. If the hierarchical instance was earlier defined as a power domain, then this field corresponds to the minimum gap parameter of the power domain. **Note**: The minimum gap value of the power domain and the placement halo values of the partition are always synchronized as follows: If the specified instance was also earlier defined as a power domain, the placement halo values for the partition, by default, will have the same value as the minimum gap values for the power domain. If you specify a different value for the partition, the value for the power domain is updated so that it is the same as the value defined for the partition. Similarly, if a power domain is created (or an existing power domain modified) on the specified instance after the partition is defined, the value set earlier for the partition is updated so that it is the same as the value defined for the power domain. **Note**: The placement halo created by the `create_partition` command cannot be honored by `place_design` before partitions have not been committed. *Data_type*: string, optional
`-proto_hinsts {master_hinst_name_list}`	
	Specifies the master hierarchical instances list for the prototyping flow. It defines new partitions for the specified hierarchical instances with guide constraints. It is used before `proto_design`, which will convert the physical constraint from guide to fence finally. *Data_type*: string, optional

`-rail_width railWidth`	Specifies the standard cell power rail width, in micrometers. If partition pins are not allowed above power or ground rail width, specify the dimension of the power rail width. If a value of 0.0 is entered (the default), the width from the Technology file will be used. *Data_type*: float, optional
`-reserved_layer {list_of_layers}`	
	Specifies the metal layers that are used for routing in the partition and generating partition pins. Any metal layers that are not specified, usually the top-most metal layers, are allowed to route over the partition. A normal six-metal layer specification is Metal1, Metal2, Metal3, Metal4 and Metal5 specified, and Metal6 unspecified. When saving the partition, the LEF generated for this partition will have routing blockages on their layers so that the top-level router is aware of which metal layers are being used in the partition. **Note:** For designs that have backside metal layers, both the backside and frontside layers are accepted. *Data_type*: string, optional
`-route_halo floatValue`	
	Specifies routing spacing, in micrometers, around the sides of the partition. A routing halo is honored only by the signal router. The signal router treats routing on the specific routing layers in the routing halo area as very high cost routing. However, perpendicular routing or straight connections to pins are acceptable. The special router does not honor routing halos. To block special routing, use routing blockages instead. You can specify a positive or a negative value for the routing halo. A positive value means that the halo will be outside the partition. A negative value means that the halo will be applicable during block implementation, inside of the partition. The same value is used for all sides of the partition. **Note**: For instance blocks - blackboxes, hard macros or block-level designs - specify the routing halo through the *Floorplan - Edit Floorplan - Edit Halos* form in the GUI or through the `create_route_halo` command. Also, for bottom- up hierarchical flow, specify routing halo for a block at the top-level design or at the block-level design through the *Floorplan - Edit Floorplan - Edit Halos* form in the GUI or through the `create_route_halo` command. *Data_type*: float, optional
`-route_halo_top_layer integerValue`	
	Specifies the top partition layer for which routing halo will be created. *Default*: By default, the top layer reserved for the partition is used. *Data_type*: int, optional
`-route_halo_bottom_layer integerValue`	
	Specifies the bottom partition layer for which routing halo will be created. *Default*: By default, the bottom layer reserved for the partition is used. *Data_type*: int, optional
`-std_cell_height x`	Specifies the standard cell height for the partition. *Default*: The default value is derived from the default technology site and row height. *Data_type*: float, optional

Example

```
create_partition -hinst ctr_inst
-core_spacing 0.56 0.56 0.0 0.0
-rail_width 0.0
-min_pitch_left 2
-min_pitch_right 2
-min_pitch_top 2
-min_pitch_bottom 2
-reserved_layer {1 2 3 4}
-pin_layer_top {2 4}
-pin_layer_left {3}
-pin_layer_bottom {2 4}
-pin_layer_right {3}
-place_halo 10.0 0.0 0.0 0.0
-route_halo 10.0
-route_halo_top_layer 7
-route_halo_bottom_layer 1
```

create_partition_feedthru

```
create_partition_feedthru
[-help]
-area x1 y1 x2 y2
[-layer]
[-name string]
```

Creates a partition routing feedthrough object. The object area keeps pins from being created on the specified metal layer. A cdump file with routing obstruction is created for the top level partition (done when saving the partition). You can use this command during partition floorplanning.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `create_partition_feedthru` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man create_partition_feedthru`
`-area x1 y1 x2 y2`	Specifies the coordinates (*x1 y1 x2 y2)* of the feedthrough area. *Data_type*: rect, optional
`-layer`	Specifies the metal layer where pins are not to be created. **Note:** If `-layer` is not specified then by default feed-through is created on all the partition layers. *Data_type*: int, optional
`-name string`	Specifies the name of the routing feedthrough. *Data_type*: string, optional

Example

The following command creates a feedthrough object to block pins being generated on layer *Metal5*:

```
create_partition_feedthru 2353.8000 7123.000 2653.8000 8298.2000 5
```

Related Information

create_partition_wrapper

```
create_partition_wrapper
[-help]
-partitions partition_names
[-pushdown]
[-wrapper_name wrapper_suffix_string]
```

Creates a wrapper partition that embeds the specified partition cell to preserve its verilog module definition in the netlist. The wrapper partition can be used for making netlist changes without changing the netlist of the embedded (wrapped) cell definition. The wrapper partition has the same partition definition attributes as the specified partition. The timing constraints (through SDC) and low power information (through UPF) of the wrapper partition is updated with the correct hierarchical pin information. The pin constraints applied on pins of the original partition are mapped to the new wrapper pins.

Note: After the wrapper partition is created using the `create_partition_wrapper` command:

- the original partition ceases to exist (`delete_partitions`).
- the fence attributes and pin constraints of the original partition are removed.
- the module pins of the original partition as preserved such that they cannot be altered later.

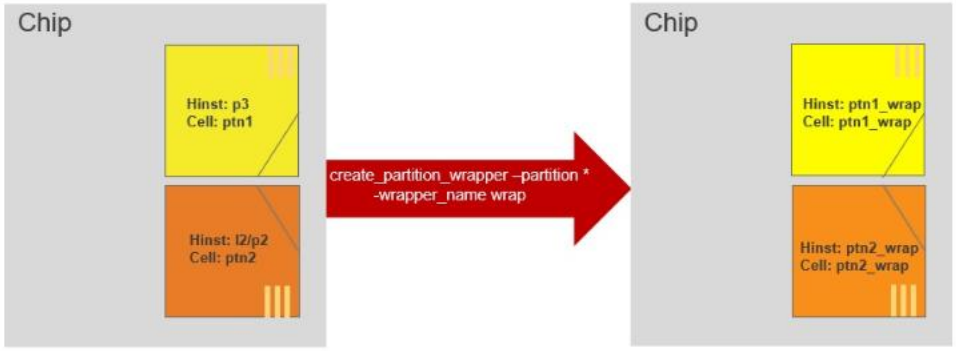
Parameters

`-help`	Outputs a brief description that includes the type and default information for each `create_partition_wrapper` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man create_partition_wrapper`
`-partitions partition_names`	Specifies the name of one or more partitions on which the wrapper is created. **Note:** The partition_wrapper will have the same: • Number, name and locations (If already assigned) of pins • Area, shape, location, orientation *Data_type*: string, optional
`-pushdown`	When enabled, it keeps the partition hinst intact for the wrapper partition. *Data_type*: bool, optional
`-wrapper_name wrapper_suffix_string`	Specifies the suffix that is added to a partition name for creating a partition wrapper. *Default*: <`ptnName>_wrapper` *Data_type*: string, optional

Example

The following command creates a wrapper partition with suffix wrap for all the partitions in the design:

```
create_partition_wrapper -partition * -wrapper_name wrap
```



Related Information

- `delete_partitions`
- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

create_pin_blockage

```
create_pin_blockage
[-help] [-cell cell_name] [-layer {layer_id_list}]
{ -area {x1 y1 x2 y2} | [-edge edge_number [[-offset_start distance] [-offset_end distance]]] |
[-abutted_master_clone_channel_access_only [-feedthru_blockage_file file_name]] }
[ -name blockage_name [ -include_pin_patterns {pin_name_pattern_list} | -exclude_pin_patterns {pin_name_pattern_list} ]]
```

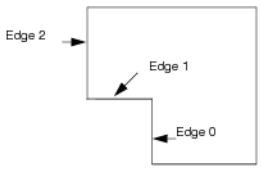
Creates a pin blockage for a module. You can run this command on the top-level module also. You can use this command during partition floorplanning.

Parameters

`-abutted_master_clone_channel_access_only`	Creates pin blockages on abutted edges of master-clones that abut to its parent or other master-clones. *Data_type*: bool, optional
`-area x1 y1 x2 y2`	Specifies the lower left x coordinate, lower left y coordinate, upper right x coordinate, and upper right y coordinate respectively of the blockage area. **Note:** The values of `x1`, `y1`, `x2`, and `y2` are relative to the top-level coordinates. *Data_type*: box, optional
`-cell cell_name`	Specifies the module for which the pin blockage will be created. This parameter is required if the module is not the top-level module. *Data_type*: string, optional
`-edge edge_number`	Specifies the integer value where edge numbering starts from lower-left corner of a partition clock-wise. Edge `0` is the edge that has the smallest y value. *Data_type*: int, optional
`-exclude_pin_patterns {pin_name_pattern_list}`	Specifies the pin-list on which the pin-blockage is not applicable. Pins which are specified in this list can be placed in this area legally. **Note**: The `-exclude_pin_patterns` and `-include_pin_patterns` options are mutually exclusive and cannot be used in a single command. Both these options require the use of the `-name` option to specify the name of the partition pin blockage. *Data_type*: string, optional
`-feedthru_blockage_file file_name`	Outputs a file with coordinates of blocked edges for pin assignment transformed into feedthru blockage_file format. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `create_pin_blockage` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man create_pin_blockage`
`-include_pin_patterns {pin_name_pattern_list}`	Specifies the pin-list on which the pin-blockage is applicable. All other pins can be placed in this area legally. **Note**: The `-exclude_pin_patterns` and `-include_pin_patterns` options are mutually exclusive and cannot be used in a single command. Both these options require the use of the `-name` option to specify the name of the partition pin blockage. *Data_type*: string, optional
`-layer {layer_id_list}`	Specifies the metal layer(s) for which pins are not to be created. **Note:** Layers can be specified using the LEF layer names or layer ID numbers. *Default:* If no layer number is specified, all metal layers are blocked. *Data_type*: string, optional

`-name` *`blockage_name`*	Specifies the name of the partition pin blockage. *Default:* By default, the name is `defPtnPinBlkName`. *Data_type*: string, optional
`-offset_end` *`distance`*	Specifies the distance, in microns, from the ending corner of the edge. *Minimum Value:* 0 *Maximum Value:* 65535 *Data_type*: float, optional
`-offset_start` *`distance`*	Specifies the distance, in microns, from the starting corner of the edge. *Minimum Value:* 0 *Maximum Value:* 65535 *Data_type*: float, optional

Examples

- The following command creates a pin blockage named `pinBlkg1` on the edge `0` of layers `Metal5` and `Metal7` for the module `PtnBlock1`.
  ```
  create_pin_blockage -edge 0 -name pinBlkg1 -cell PtnBlock1 -layer {Metal5 Metal7}
  ```
  


- The following command creates a pin blockage named `pinBlkg2` on layers Metal5 and Metal7 for the module `PtnBlock2`. The blockage area is bounded by the lower-left coordinates `100`, `200` and the upper-right coordinates `300`, `400`.
  ```
  create_pin_blockage -area 100 200 300 400 -name pinBlkg2 -cell PtnBlock2 -layer {Metal5 Metal7}
  ```
- The following command creates a pin blockage named pinBlkg3 that only applies to partition pins that match pattern1 and pattern2. All other partition pins can be placed in this area legally.
  ```
  create_pin_blockage -include_pin_patterns {*pattern1* *pattern2*} -cell PtnBlock3 -area $area -name pinBlkg3
  ```
- The following command creates a pin blockage named pinBlkg4 that only applies to all partition pins except those that match pattern1 and pattern2. Only pins that match pattern1 and pattern2 can be placed at this edge legally.
  ```
  create_pin_blockage -exclude_pin_patterns {*pattern1* *pattern2*} -cell PtnBlock4 -edge 0 -name pinBlkg4
  ```

create_pin_group

```
   create_pin_group
[-help]
[-exclude_pins {all_layer | same_layer | all_layer_in_guided_area}]
[-keep_out_spacing integer]
[-partition string]
[-spacing integer]
[-width width]
[ {[-opt_order ]} | -spread_pins | -compact_area ]
[ {-name pin_group_name [-pins {pin_name_list}]} ]
```

Creates a pin group for a partition or for the top-level. Pin groups in conjunction with pin guides are used to guide pin placement when the `assign_io_pins` or `assign_partition_pins` command is called. A pin group is a first class data object–delete with the `delete_pin_groups` command.

Parameters

`-compact_area`	Specifies that pins in the group are assigned tightly together. By default, pins which are part of a group and associated to a guide can be spread inside the guide based on the area available and alignment to targets. The `compact_area` option, when used, ignores the alignment and available area and forces the pins to the minimum area on guide honoring the minimum spacing constraint and overlooking any alignment to targets.  *Data_type*: bool, optional
`-exclude_pins {all_layer | same_layer | all_layer_in_guided_area }`	
	Specifies that pins in the group exclude foreign pins on all layers, same layer, or on all layers in the guided area. • `all_layer`: Specifies that pins in the group exclude foreign pins between grouped pins on all layers. • `same_layer`: Specifies that pins in the group exclude foreign pins between grouped pins on the same layer. • `all_layer_in_guided_area`: Specifies that pins in the group exclude foreign pins in the guide area defined for the group, on all layers. **Note**: If a guide is not defined for a pin group, `-exclude_pins all_layer_in_guided_area` option is treated like `-exclude_pins all_layer`. *Data_type*: enum, optional
`-help`	Outputs a brief description that includes type and default information for each `create_pin_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_pin_group`
`-keep_out_spacing integer`	Specifies the minimum spacing between the pins named in the pin group and any other pins, in number of tracks. *Minimum*: 0 *Maximum*: 65535 *Data_type*: int, optional
`-name pin_group_name`	Specifies the name of the pin group being created. *Data_type*: string, required

`-opt_order`	Specifies that pins in the group are to be reordered to optimize wire length during pin placement. Otherwise the pin order is exactly as specified in the pin group. *Data_type*: opt, optional
`-partition` *string*	Specifies the name of the module or submodule to which the pin group applies. This parameter is not required if the pin group being created is for the top level. *Data_type*: string, optional
`-pins` *port_name_list*	Specifies the pins to be added to the pin group. Additional pins can be added subsequently with the `update_pin_group` command. *Data_type*: string, optional
`-spacing` *integer*	Specifies the minimum spacing between the pins of the pin group, in number of tracks. *Default*: Two tracks. *Data_type*: int, optional
`-spread_pins`	Specifies that pins in the group are distributed evenly. *Data_type*: bool, optional
`-width` *width*	Specifies the pin width, in microns. *Data_type*: float, optional

Example

- The following command creates a pin group PG_A22 for module SH17 and adds the pins pinA22_1 and pinA22_2 to it.
  ```
  create_pin_group PG_A22 -partition SH17 -pins {pinA22_1 pinA22_2}
  ```
- The following command creates a pin group PG_A for module SH17 and adds the pins pinA22_1 and pinA22_2 to it. No other pins are to be placed between pinA22_1 and pinA22_2 in any layer.
  The pins may be reordered to optimize wire length.
  ```
  create_pin_group PG_A22 -partition SH17 -pins {pinA22_1 pinA22_2} -exclude_pins all_layer -opt_order
  ```
- The following command deletes the pin group named *myPinGroup*:
  ```
  delete_obj [ get_db pin_groups "myPinGroup" ]
  ```

create_pin_guide

```
create_pin_guide
[-help]
{[ -area {x1 y1 x2 y2} | [-edge integer  [[-offset_start float] [-offset_end float]]] ] [ -layers {layeridList} [-layer_priority ]]}
 [-pin string | -pin_group string | -net string | -net_group string | -name string ]
[-edge integer | -net string | -net_group string]
[-partition string | -net string | -net_group string]
```

Creates a pin guide object. The pin guide restricts the pins associated with the pin guide within the specified area. You can run this command on the top-level module also. You can assign the same pin group or net group to multiple pin guides. Pin guides are generated for buses, nets, net groups, pins, and pin groups. For buses and nets that do not physically connect to the partition, pin guides will not be created. You can use this command during partition floorplanning.

Parameters

`-area x1 y1 x2 y2`	Specifies the coordinates of the pin guide area. • x1: Specifies the lower left x coordinate of the pin guide area. • y1: Specifies the lower left y coordinate of the pin guide area. • x2: Specifies the upper right x coordinate of the pin guide area. • y2: Specifies the upper right y coordinate of the pin guide area. *Data_type*: rect, required
`-edge integer`	Specifies the integer value where edge numbering starts from lower-left corner of a partition clockwise. Edge 0 is the edge that has the smallest y value. *Data_type*: int, optional
`-help`	Outputs a brief description that includes type and default information for each `create_pin_guide` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_pin_guide`.
`-layer_priority`	Assign pins based on the order of layers specified by the user. *Data_type*: bool, optional
`-layers {layerIdList}`	Specifies the metal layer(s) for the pin guide. *Default*: You must specify the correct pin layer. If you do not specify the pin layer, Innovus will display an error instead of choosing the preferred layer to assign pins like the old behavior. **Note**: Layers can be specified using the LEF layer names or layer ID numbers. *Data_type*: string, optional
`-name string`	Specifies the name of the partition pin guide object. If you specify this parameter, the command will automatically detect whether the object is a pin, pin group, net, net group, or bus. In case there are different objects with the same name, the command selects the object with the following precedence: • If a cell name is specified, the command selects the object with the following precedence: a. pin b. pin group c. net d. net group or bus • If a cell name is not specified, the command selects the object with the following precedence: a. net b. net group or bus For example, if the value of objectName is P1, and there is a pin group named P1 as well as a bus named P1, the command will select the pin group named P1. *Data_type*: string, optional

`-net string`	For nets, specifies the name of the net. For buses, specifies the name of the bus or the bus radix. *Data_type*: string, optional
`-net_group string`	Specifies the name of the net group. *Data_type*: string, optional
`-offset_end float`	Specifies the distance, in microns, from the ending corner of the edge. *Minimum Value*: 0 *Maximum Value*: 65535 *Data_type*: float, optional
`-offset_start float`	Specifies the distance, in microns, from the starting corner of the edge. *Minimum Value*: 0 *Maximum Value*: 65535 *Data_type*: float, optional
`-partition string`	Specifies the name of the cell. This parameter is not required if you are using the command for a top-level module. *Data_type*: string, optional
`-pin string`	Specifies the name of the pin. *Data_type*: string, optional
`-pin_group string`	Specifies the name of the pin group. *Default*: By default the name is `defRGuideName`. *Data_type*: string, optional

Example

- The following command creates a pin guide object for bus addr:
  ```
  create_pin_guide -area 2353.8000 7123.000 2653.8000 8298.2000 -name addr
  ```

create_pushdown_eco

```
  create_pushdown_eco
[-help]
[-generate_script_only]
[-eco_obj_dir outputDirName]
-original_dir originalDirName
[-partition_net_dir ptnNetDirName]
[-partition ptnNameList]
-pushdown_dir pushdownDirName
```

Creates logical and physical ECO files that are used to push down ECO objects by comparing two partition databases. It generates logical and physical ECO objects for each partition, in parallel, using EDP (parallel/distributed) framework. The regular/special wire ECO is generated for those nets which are specified via `-partition_net_dir`.

Note: A FlexHtree amendment file will also be created besides the logical ECO and DEF file.

Parameters

`-eco_obj_dir` *outputDirName*	Specifies the directory in which eco objects for each partition will be created. The eco objects are saved in sub-directories, one for each partition. *Default*: `./eco_obj_dir` *Data_type*: string, optional
`-generate_script_only`	Generates a TCL command file but does not execute it. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes type and default information for each `create_pushdown_eco` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_pushdown_eco`.
`-original_dir` *originalDirName*	Specifies the directory in which original partition sub-directories are present. *Data_type*: string, optional
`-partition_net_dir` *ptnNetDirName*	Specifies the directory in which net file for each partition is present. The net file contains the nets for which regular/special wire ECO is generated. **Note**: Specifying `-partition_net_dir` iis not mandatory for the `create_pushdown_eco` command. If the `-partition_net_dir` parameter is not specified, then logically modified nets are selected for DEF ECO generation. Otherwise, a union of `-partition_net_dir` and logically-modified-nets is selected for DEF ECO generation. *Data_type*: string, optional
`-partition` *ptnNameList*	Specifies the list of partition names for which ECO objects are to be created. *Data_type*: string, optional
`-pushdown_dir` *pushdownDirName*	Specifies the directory in which pushdown (Example, clock tree constructed) version of partition sub-directories are present. These partitions will be compared with respective original partitions, and ECO objects will be generated for each of them. *Data_type*: string, required

delete_all_partition_cuts

```
delete_all_partition_cuts
[-help]
```

Deletes all the partition cuts in the floorplan. You can use this command after specifying a partition.

Note: Command `delete_all_partition_cuts` is now obsolete and will be removed in the next major release of the software. This command has been replaced by the `delete_partition_cuts` command.

Parameters

`-help`	Outputs a brief description of the `delete_all_partition_cuts` command. For a detailed description of the command, use the `man` command: `man delete_all_partition_cuts`

Related Information

- `delete_partition_cuts`
- `delete_partitions`

delete_all_partition_feedthrus

```
delete_all_partition_feedthrus
[-help]
```

Deletes all the partition feedthrough objects in the floorplan. You can use this command during partition floorplanning.

Parameters

`-help`	Outputs a brief description of the `delete_all_partition_feedthrus` command. For a detailed description of the command, use the `man` command: `man delete_all_partition_feedthrus`

Example

The following command removes all feedthrough objects from the floorplan:

```
delete_all_partition_feedthrus
```

Related Information

delete_black_boxes

```
delete_black_boxes
[-help]
{-cells cellName | -all}
[-keep_partition]
```

Deletes or unspecifies a blackbox and converts it to a module if the blackbox was originally defined as a module, or a block if the blackbox has a cdump or LEF macro definition. You can use this command after importing the design.

Note: You cannot delete a blackbox of an undefined module or cell.

Parameters

`-all`	Selects all blackboxes for deletion. *Data_type*: bool, optional
`-cells cellname`	Selects an individual blackbox for deletion. You can use wildcards (`*?`) with this parameter. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `delete_black_boxes` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_black_boxes`
`-keep_partition`	Preserves the partition information. You should only use this option if the blackbox is placed inside the core area and is defined as a module in the netlist. *Data_type*: bool, optional

Example

The following command deletes all blackboxes that begin with the letter A – some of which are inside the core area, and some which are outside the core area and converts them to either a fence or module.

```
delete_black_boxes -cells A*
```

delete_net_group

```
delete_net_group
[-help]
net_group_name
```

Removes a net group that was created earlier.

Note: When you delete a net group, any bus guide associated with the net group also gets deleted.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `delete_net_group` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_net_group`
`net_group_name`	Specifies the name of the net group. You can use wildcards (`*?`) with this parameter. *Data_type*: string, required

Example

The following command removes netgroup `NG_22`.

```
delete_net_group NG_22
```

Related Information

  - Net Group

delete_nets_from_net_group

```
delete_nets_from_net_group
[-help]
net_group
-delete_nets {netName | netNameList}
```

Removes a net from a net group. You can use this command after importing the design.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `delete_nets_from_net_group` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_nets_from_net_group`
net_group	Specifies the name of the net group. You can use wildcards (`*?`) with this parameter. *Data_type*: string, required
`-delete_nets {`*netName* `|` *netNameList*`}`	Specifies the name of the net(s). You can use wildcards (`*?`) with this parameter. *Data_type*: string, required

Example

The following command removes net `NET1` from net group `NG22`:

```
delete_nets_from_net_group NG22 NET1
```

delete_partition_cuts

```
delete_partition_cuts
[-help]
{-partition {ptnName | ptnNameList} | -all}
```

Deletes all the partition cuts.

Parameters

`-all`	Deletes all the partition cuts. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes type and default information for each `delete_partition_cuts` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_partition_cuts`
`-partition {ptnName | ptnNameList}`	Specifies the name of the partition, or the list of partitions for which partition cuts are deleted. *Data_type*: string, optional

Example

The following command deletes partition cuts for partition `sheet17`:

```
delete_partition_cuts -partition sheet17
```

Related Information

- `delete_all_partition_cuts`
- `delete_partitions`
- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

delete_partitions

```
delete_partitions
[-help]
{ partition_name | -all | -nested | -non_leaf }
[-undo_tcl_file file_name [-non_leaf ]]
```

Deletes the specified partition.

Note: The Hinst retains the fence property.

Parameters

`-all`	Deletes all partitions. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `delete_partitions` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_partitions.`
`-nested`	Deletes all nested partitions in the design. *Data_type*: bool, optional
`-non_leaf`	Deletes all non-leaf partitions in the design. **Note:** It saves the information of the deleted partitions in a tcl file, so that the same can be used to restore the deleted partitions. For example, in the diagram below, all the non-leaf partitions (marked in yellow) must be deleted and dumped in a tcl file for restoration p  *Data_type*: bool, optional
partition_name	Specifies the name of the partition to delete. *Data_type*: string, optional
`-undo_tcl_file` *fileName*	
	Specifies the file that can be sourced to undo deletion of partitions. With this parameter, the partition definition of the partition being deleted is written to the specified file. Later, if required, this file can be so the partition definition. *Data_type*: string, optional

Example

- The following command deletes the partition `p1`.
  ```
  delete_partitions p1
  ```
- The following command writes the partition definition of partition p1 in file ptn.tcl and then deletes it.
  ```
  delete_partitions p1 -undo_tcl_file ptn.tcl
  ```

Related Information

delete_pin_blockages

```
delete_pin_blockages
[-help]
{-name pinBlkgName | -all}
```

Deletes a pin blockage or all pin blockages.

Parameters

`-all`	Specifies that all pin blockages will be deleted. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `delete_pin_blockages` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_pin_blockages`
`-name pinBlkgName`	Specifies the name of the pin blockage. You can specify wildcards (?*) with this parameter. *Data_type*: string, optional

Example

The following command deletes the pin blockage `PtnPinBlkg1`:

```
delete_pin_blockages -name PtnPinBlkg1
```

Related Information

- `create_pin_blockage`
- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

delete_pin_from_pin_group

```
delete_pin_from_pin_group
[-help]
[-partition cellName]
-pin_group pinGroupName
-pins {pinName | pinNameList}
```

Removes a port from a specified pin group.

Parameters

`-partition` *`cellName`*	Specifies the name of the module. The module name is not required if the command is run on a top-level module. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `delete_pin_from_pin_group` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_pin_from_pin_group`
`-pin_group` *`pinGroupName`*	Specifies the name of the pin group that was created. *Data_type*: string, required
`-pins {`*`pinName`* `|` *`pinNameList`*`}`	Specifies the name(s) of the port(s) of the module. *Data_type*: string, required

Example

The following command removes ports `RASN1` and `RASN2` of module `SH17` from pin group `pin17`:

```
delete_pin_from_pin_group -partition SH17 -pin_group pin17 -pins {RASN1 RASN2}
```

  - Pin Group

delete_pin_groups

```
delete_pin_groups
[-help]
[-cell cellName]
-pin_group pinGroupName
```

Deletes a pin group or all pin groups that were created earlier.

Parameters

`-cell cellName`	Specifies the name of the module. The module name is not required if the command is run on a top-level module. *ata_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `delete_pin_groups` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_pin_groups`
`-pin_group pinGroupName`	Specifies the name of the pin group that was created. *Data_type*: string, required

Example

The following command deletes the pin group `PinGroup17` of module `SH17`:

```
delete_pin_groups -cell SH17 -pin_group PinGroup17
```

Related Information

- `update_pin_group`
- `create_pin_group`

delete_pin_guides

```
delete_pin_guides
[-help]
{ -pin pin_name | -pin_group pin_group_name | -net net_name | -net_group net_group_name | -name object_name | -all }
[-partition ptn_name | -net net_name | -net_group net_group_name]
```

Deletes a pin guide object in the floorplan. You can use this command during partition floorplanning.

Parameters

`-all`	Specifies that all pin guides will be deleted. *Data_type*: bool, optional
`-partition` *ptn_name*	Specifies the name of the module. The module name is not required if the command is run on a top-level module. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `delete_pin_guides` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_pin_guides`
`-name` *object_name*	Specifies the name of the partition pin guide object. If you specify this parameter, the command will automatically detect whether the object is a pin, pin group, net, net group, or bus. In case there are different objects with the same name, the command selects the object with the following precedence: • If a cell name is specified, the command selects the object with the following precedence: 1. pin 2. pin group 3. net 4. net group or bus • If a cell name is not specified, the command selects the object with the following precedence: 1. net 2. net group or bus For example, if the value of *objectName* is `P1`, and there is a pin group named `P1` as well as a bus named `P1`, the command will select the pin group named `P1`. *Data_type*: string, optional
`-net` *net_name*	For nets, specifies the name of the net. For buses, specifies the name of the bus or the bus radix. *Data_type*: string, optional
`-net_group` *net_group_name*	Specifies the name of the net group. *Data_type*: string, optional
`-pin` *pin_name*	Specifies the name of the pin. *Data_type*: string, optional
`-pin_group` *pin_group_name*	Specifies the name of the pin group. *Default:* By default the name is `defRGuideName`. *Data_type*: string, optional

Example

The following command deletes a pin guide object named `group_1`:

```
delete_pin_guides -name group_1
```

Related Information

- `create_pin_guide`
- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

edit_pin

```
edit_pin
[-help]
[-end {x y}]
[-fixed_pin]
[-global_location]
[-include_rectilinear_edge]
[-master_clone_aware]
[-offset_end value]
[-offset_start value]
-pin {pinName | pinNameList}
[-pin_depth pinDepthValue]
[-pin_width pinWidthValue]
[-quiet]
[-skip_wrapping_pins]
[-snap {track | usergrid | mgrid}]
[-spread_direction {clockwise | counterclockwise | both}]
[-start { x y}]
[-use { signal | clock | analog }]
[ {-layer {layerId | layerIdList} | {[-layer_horizontal layerId] [-layer_vertical layerId]} }
[-layer_priority ]
[-assign {x y} |
-spread_type {start | center | side | edge | range} |
-pattern {fill_track | fill_layer | fill_optimised | fill_diagonal | fill_sinusoidal |fill_checkerboard}]]
[-side sideName | -edge edgeNumber]
[-cell cellName | {-hinst hinstName  [-ref_master]} ]
[-fix_overlap [ -honor_constraint ]]
[-pattern {fill_track | fill_layer | fill_optimised | fill_diagonal | fill_sinusoidal | fill_checkerboard}
[-reverse_alternate ]]
[-spacing spacingValue [ -unit {micron | track} ]]
```

Modifies properties of pins, such as pin spreading, pin location, pin width and depth, spacing, snap-to location, and status. The `edit_pin` command provides the equivalent capabilities of the Pin Editor form.

Note: The `edit_pin` command does not support wildcards.

The `edit_pin` command honors the minimum area rule as follows:

- If neither the `-pin_width` nor the `-pin_depth` parameters have been specified, the `edit_pin` command takes the minimum pin width and the minimum area from the LEF file and calculates the pin depth accordingly.
- If only the `-pin_width` parameter has been specified, the `edit_pin` command takes the minimum area from the LEF file and calculates the pin depth accordingly.
- If only the `-pin_depth` parameter has been specified, the `edit_pin` command takes the minimum area from the LEF file and calculates the pin width accordingly.

If both the `-pin_width` and the `-pin_depth` parameters are specified, the `edit_pin` command takes these specified values, without enforcing the minimum area rule.

The `edit_pin` command is clone context aware. The command:

- Looks at routing blockages on clone and honors them while keeping pins of master with `-cell <>`.
- Looks at abutted macro blockages and honors them while keeping pins of master with `-cell <>`.
- Honors route blockage on master.

Note: The value of the parameters of the `edit_pin` command is not stored across multiple runs of the command – you need to specify the required value with every run of the command.
For example, if you do not specify the `-pin_width` parameter, the default pin width of the specified layer is used.

Note: The `edit_pin` command checks and corrects DRC violations and overlapping while placing internal pins. It supports pin placement on Metal 1 and accepts all layers for pin placement by default.

Note: The `edit_pin` command is used for manual pin assignment in nested partitions. It places pins of nested partitions similar to single level partitions.

Parameters

`-assign {x y}`	Pre-assigns a pin at the specified location. You can use this parameter with other parameters such as `-snap`, `-fixOverla` **Note**: `-assign {x y}` considers the local coordinates from the bounding box of the fence.  *Data_type*: point, optional
`-cell cellName`	Specifies the name of the module. If you do not specify a cell name, the command runs on the top-level cell. *Data_type*: string, optional
`-edge edgeNumber`	For rectilinear partitions, specifies the edge along which the pins will be placed. The edge number is an integer. The edg Edge 0 is the edge that has the smallest y value.  To spread pins on multiple rectilinear edges that are on the same side, use the `-side` parameter. For rectangular partitions, you can specify a side with the -side parameter. *Data_type*: int, optional
`-end {x y}`	For pin spreading along a range, specifies the coordinates where pins should end. This parameter is used with the `-spr` *Data_type*: point, optional
`-fixed_pin`	A value of 1 sets the pin status to Fixed. *Default*: The pin status is placed. *Data_type*: bool, optional
`-fix_overlap {0 | 1}`	With this parameter on, the `edit_pin` command tries to resolve pin-overlap with other/nearby objects. The pins are moved to the closest acceptable position such that pins do not overlap. *Default*: 1. Resolve pin-overlap is on. **Note**: This parameter applies only when pins are snapped to layer track. *Data_type*: bool, optional

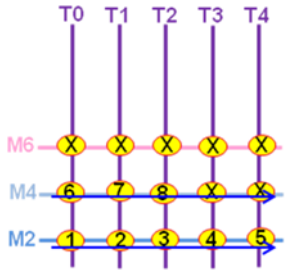
`-global_location`	Specifies that the global location should be considered by the command.
	Note: By default all locations that the `edit_pin` command considers are coordinates with respect to lower-left corner of pa accept coordinates with respect to the lower-left corner of the design.
	For example, in the following command, the pin will be placed 3u from the lower-left corner of the partition.
	`edit_pin -cell c -pin cIn -assign 0 3 -layer 2 -side left`
	When you use the `-global_location` parameter, the pin will be placed 3u from the lower-left corner of the design.
	`edit_pin -cell c -pin cIn -assign 0 3 -layer 2 -side left -global_location`
	Data_type: bool, optional

`-help`	Outputs a brief description that includes type and default information for each `edit_pin` parameter. For a detailed description of the command and all of its parameters, use the man command: `man edit_pin`
`-hinst hinstName`	Specifies the hinst name, including black box or committed partition and top. *Data_type*: string, optional
`-honor_constraint {0|1}`	Specifies whether user-defined pin constraints should be honored. The following constraints are honored when this parameter is set to on: • pin spacing • pin size • pin-to-corner distance • partition-allowed pin layers. *Default*: 0 (user-defined pin constraints are not honored) *Data_type*: bool, optional
`-include_rectilinear_edge`	Specifies that all the edges coming in the solution space should be included. *Data_type*: bool, optional
`-layer {layerId | layerName}`	Specifies the layer on which the pins will be assigned. Layers can be specified using the LEF layer names or layer ID nu **Note**: This parameter is optional but only when `-spread_type` is not specified. **Note:** For designs that have backside metal layers, both the backside and frontside layers are accepted. *Data_type*: bool, optional
`-layer_horizontal layerId`	Specifies the preferred horizontal layer on which the pins will be assigned. **Note:** For designs that have backside metal layers, both the backside and frontside layers are accepted. *Data_type*: string, optional
`-layer_vertical layerId`	Specifies the preferred vertical layer on which the pins will be assigned. **Note:** For designs that have backside metal layers, both the backside and frontside layers are accepted. *Data_type*: string, optional
`-layer_priority`	Specifies that the input layer is given based on its priority. *Data_type*: bool, optional
`-master_clone_aware`	Enables master-clone context awareness for feasibility checking. *Data_type*: bool, optional
`-offset_end value`	Sets the offset from the end of the edge (in microns) to be considered as the endpoint for placing the pin. **Note**: The `-offset_start` and `-offset_end` options can only be used with the `-edge` parameter. *Data_type*: float, optional
`-offset_start value`	Sets the offset from the start of the edge (in microns) to be considered as the start point for placing the pin. **Note**: The `-offset_start` and `-offset_end` options can only be used with the `-edge` parameter. *Data_type*: float, optional

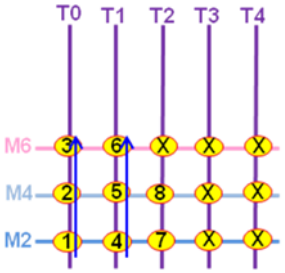
`-pattern {fill_track | fill_layer | fill_optimised | fill_diagonal | fill_sinusoidal | fill_checkerboard}`

Specifies the multi-layer-spread-pattern must be followed by the set of selected pins.

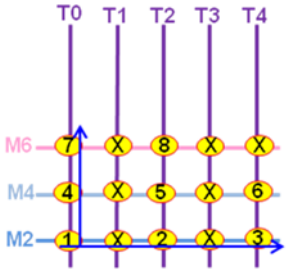
fill_track



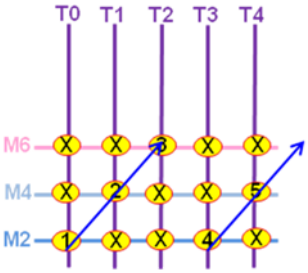
fill_layer



fill_optimised



fill_diagonal



fill_sinusoidal

	 fill_checkerboard
`-pin {pinName | pinNameList}`	Specifies the pins, or the list of pins of the specified module on which the command will run. **Note**: The naming convention to identify individual ports is based on the order in which the ports are stored inside the da port2, respectively. For example: VDD.port0, VDD.port1, VDD.port2 *Data_type*: string, required
`-pin_depth pinDepthValue`	Sets the depth of the pin in microns. *Default*: If you do not specify this parameter, the default depth of the specified layer is used. *Data_type*: float, optional
`-pin_width pinWidthValue`	Sets the width of the pin in microns. *Default*: If you do not specify this parameter, the default width of the specified layer is used. *Data_type*: float, optional
`-quiet`	Specifies that the messages should be suppressed. *Data_type*: bool, optional
`-ref_master`	Specifies that the clone's edge, spreadDirection, and offset are with respect to the master. *Data_type*: bool, optional
`-reverse_alternate`	Specifies that the reverse of the multi-layer-spread-pattern must be followed by the set of selected pins. For example, `fill_track -reverse_alternate`  *Data_type*: bool, optional

`-side sideName`	For rectangular partitions, specifies the side on which the pins will be placed. The values for `sideName` can be: top, botton **Note**: The value inside can only be specified with the `-assign` parameter. For rectilinear partitions, you can also specify an edge with the `-edge` parameter. **Note:** The `set_db assign_pins_edit_in_batch` attribute does not support the internal pins (where the side is INSIDE). *Data_type*: string, optional
`-skip_wrapping_pins`	Skips pin wrapping on the adjacent edge or the same edge from the other side. *Data_type*: bool, optional
`-snap {track | usergrid | mgrid}`	
	Specifies how the pins will be snapped. • `track`: Snaps pins to layer tracks. • `usergrid`: Snaps pins to the user-defined grid. • `mgrid`: Snaps pins to the manufacturing grid. *Default*: `track` *Data_type*: enum, optional
`-spacing spacingValue`	Displays the edge-track-to-edge-track spacing between pins for multi-pin editing. The spacing is either in micrometers o placed on every track with no empty tracks between them. Default: The spacing is set automatically. *Data_type*: string, optional
`-spread_direction {clockwise | counterclockwise | both}`	
	Specifies the direction in which the pins are spread. You can specify: • `clockwise`: Sets the pins in the clockwise direction. • `counterclockwise`: Sets the pins in the counter clockwise direction. • `both`: Sets the pins by looking for the closest legal location to the desired location in both directions. *Default*: `clockwise` *Data_type*: enum, optional
`-spread_type {start | center | side | edge | range}`	
	Specifies how to spread pins along a block's edge. • `start`: Uses the coordinates of the first pin specified with the `-pin` parameter as the starting point (anchor) for spreadi parameter. • `center`: If a single pin is specified with the `-pin` parameter, the pin will be placed at the center of the specified edge/sic points such that the center pin(s) of the group are placed at the center of the specified edge or side. • `side`: If you specify a side with the `-side` parameter and specify the `-spread_type side` parameter, the pins are spread and from bottom to top. • `edge`: If you specify an edge with the `-edge` parameter and specify the `-spread_type edge` parameter, the pins are spre points. • `range`: Spreads pins evenly along the block edge between points you specify with `-start {x y}` and `-end {x y}` para Editor determines the appropriate spacing. For rectilinear partitions, if the start and/or end points are not on the specified side, the start and/or end points are snappe *Data_type*: enum, optional
`-start {x y}`	For pin spreading along a range, specifies the coordinates where pins should start. This parameter is used with the `-spr` *Data_type*: point, optional

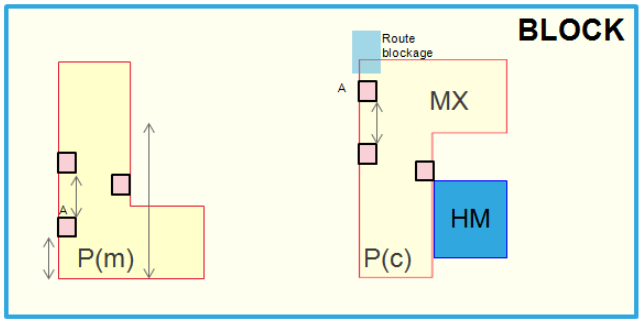
`-unit {micron | track}`	Specifies the unit in microns or in tracks. This parameter applies only to the unit of the -spacing parameter. *Default*: `micron` *Data_type*: enum, optional
`-use {signal | clock | analog}`	
	Specifies the +USE property of the partition pin. *Data_type*: stringl, optional

Example

The following command modifies the pins as specified here:

- the command runs on the module DTMF_CORE_INST1
- the command runs on all pins whose name starts with DTMF_CORE_INST1_OUTPIN
- the pins are spread on the edge number 2
- the use property is set to clock
- the pins are spread between the coordinates (17 23) and (117 123)
- the pins are assigned on the layer Metal3
- the pin status is set to Fixed
- the pins are snapped to layer tracks
- the unit is in tracks
- the spacing between pins for multi-editing is set to 2 tracks
- the pin depth is set to 10 microns.

  Note: The `-unit` parameter is set to track but that does not affect the unit of pin depth.
- the pins are moved to the nearest acceptable location as the `-fix_overlap` parameter is set to 1. However, the `-overlap_constraints` parameter is not specified.
  edit_pin
  ```
  -cell DTMF_CORE_INST1
  -pin {DTMF_CORE_INST1_OUTPIN}
  -spread_type range
  -edge 2
  -layer Metal3
  -use clock
  -fix_overlap 1
  -snap track
  -pin_depth 10
  -start {17 23}
  -end {117 23}
  -spacing 2
  -unit track
  -fixed_pin 1
  ```
- The `edit_pin` command looks at routing blockages on clone and honors them. In the figure below, the following command would not start pins on master from Y=0 as there is a route blockage on clone at desired location.
  ```
  edit_pin -hinst p(m) -spread_type start -start 0 0 -edge 0 -layer 2 -pin A*
  ```
  Also, the following command would not start pins on master from Y=10 as there is a macro with obstruction on clone at desired location.
  ```
  edit_pin -hinst p(m) -assign 10 5 -edge 2 -layer 2 -pin B -spread_direction {both}
  ```



- The following commands are used to edit pins in the batch mode:

```
set_db assign_pins_edit_in_batch true
edit_pin -hinst p(m) -spread_type start -start 0 0 -edge 0 -layer 2 -pin A*
...
...
edit_pin -hinst p(m) -assign 10 5 -edge 2 -layer 2 -pin B -spread_direction {both}
set_db assign_pins_edit_in_batch false
```

fix_feedthru_assign

```
fix_feedthru_assign
[-help]
-buffer string
[-delete_feed]
```

Fixes the assign statements that are associated with partitions by replacing them with the specified buffer. This helps to minimize the number of buffers that are added to the design when assign statements are deleted.

The `fix_feedthru_assign` command enables selective replacement of assign statements with real buffers.

Parameters

`-buffer` *`string`*	Specifies the buffer to be used for replacing assign statements. *Data_type*: string, required
`-delete_feed`	Removes input-output(s) assigns from within the partition module. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `fix_feedthru_assign` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man fix_feedthru_assign`

Example

The following command replaces the assign statements associated with partitions with the specified buffer.

```
fix_feedthru_assign -buffer abc
```

flatten_cover_cell

```
flatten_cover_cell
[-help]
[-inst {instanceName | instanceNameList}]
```

Dissolves and flattens any instance whose master has class `COVER`, but no subclass `BUMP`. You can use this command after loading a DEF file (`read_def`).

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `flatten_cover_cell` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man flatten_cover_cell`
`-inst {instanceName | instanceNameList}`	
	Specifies the instance, or a list of instances, to be flattened. If you are specifying a list, separate the instance names with a space. *Default*: If you do not specify this parameter, all instances whose masters have class `COVER` are flattened. *Data_type*: string, optional

Examples

- The following command flattens the cover cells named `coverCell1` and `coverCell2`
  ```
  flatten_cover_cell -inst {coverCell1 coverCell2}
  ```
- The following command flattens *all* cover cells
  ```
  flatten_cover_cell
  ```

Related Information

flatten_partitions

```
flatten_partitions
[-help]
[partition_name]
[-bring_back_row]
[-keep_pin_geometry]
[-no_inherit_physical]
```

Flattens (uncommits) the partition back to normal module status. This command should also be used to unassign blackbox pins *after* the blackbox is committed. To unassign blackbox pins *before* the blackbox is committed, use the `set_partition_pin_status` command. This command unassigns partition pins as well.

The `flatten_partitions` command supports partitions with flexmodels. It restores back flexmodel information if the committed partition has a flexmodel netlist.

To bring back row information for a partition, use the `-bring_back_row` parameter. If the partition rows are non-integer-multiple-height rows or are not aligned with the top-level rows, the `flatten_partitions` command will automatically create a power domain associated with the partition. The power domain will have the following characteristics:

- The timing library will the same as that for the top level.
- If a global net connection is defined in the partition block, the power domain will have the same global net connection. Otherwise the global net connection for the power domain will be set to the top-level net connection.
- The minimum gap values will be the same as the placement halo values for the partition.

The recommended use model for bringing back non-integer-multiple height rows or unaligned rows is as follows.

Top-down flow:

1. Create a power domain at full chip-level design.
2. Specify the same hierarchical instance as the partition

Bottom-up flow:

1. Create a power domain at top-level design.
2. Assign the instance block as a member of the power domain created in step 1.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `flatten_partitions` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man flatten_partitions`
`-bring_back_row`	Specifies that partition row information should be brought back for cases where: • the partition is not a power domain and row information in partition is different from top-level design, *and* • after flattening the partition, the rows of the partition space are not aligned with the top-level rows When you use this parameter, a power domain is created for the partition. *Default:* If you do not specify this parameter, the row information is *not* brought back in such cases. *Data_type*: bool, optional
`-keep_pin_geometry`	Specifies that for every partition pin, a DRCFILL metal of the type special route is placed on top of the partition pins. *Data_type*: bool, optional
`-no_inherit_physical`	Specifies that physical only cell instances are removed when partitions are flattened. *Data_type*: bool, optional
`partition_name`	Specifies the name(s) of the partition(s). You can specify any number of partitions. *Data_type*: string, optional

Example

The following command uncommits the partition status of partitions `sheet17` and `sheet25`:

```
flatten_partitions sheet17 sheet25
```

get_black_box_area

```
  get_black_box_area
[-help]
[-cell_density]
-inst cellName
[-macro_area]
[-stdcell_area]
```

Retrieves the standard cell area, macro area, and cell utilization value for the specified blackbox. If only the blackbox cell name is specified, the command reports the total blackbox area.

Note: You can use this command to report the black box area only if you had specified the blackbox using the `create_blackbox` command with the `-gate_area` parameter.

Parameters

`-cell_density`	Reports the standard cell utilization value for the blackbox. The standard cell utilization is calculated as follows: `standard cell area / (blackbox area - total macro area)` This parameter cannot be used if the blackbox was specified based on the total area or the gate count. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `get_black_box_area` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man get_black_box_area`
`-inst cellName`	Specifies the name of the blackbox cell. *Data_type*: string, required
`-macro_area`	Reports the area of the macros included in the blackbox area. This parameter cannot be used if the blackbox was specified based on the total area or the gate count. *Data_type*: bool, optional
`-stdcell_area`	Reports the area of the standard cell included in the blackbox area. This parameter cannot be used if the blackbox was specified based on the total area or the gate count. *Data_type*: bool, optional

Examples

- The following command retrieves the total blackbox area for the blackbox `bbox_inst1`:
  ```
  get_black_box_area -inst bbox_inst1
  ```
- The following command retrieves the standard cell area, macro area, and cell utilization value for the blackbox `bbox_inst2`:
  ```
  get_black_box_area -inst bbox_inst2 -stdcell_area -macro_area -cell_density
  ```

Related Information

- `create_blackbox`
- `delete_black_boxes`

  - Defining Blackboxes

get_clone_partition_orient

```
get_clone_partition_orient
[-help]
hinst
```

Retrieves the orientation information of the specified partition clone. You can use this command after using the `set_clone_partition_orient` command.

Parameters

`-help`	Outputs a brief description of the `get_clone_partition_orient` command. For a detailed description of the command, use the `man` command: `man get_clone_partition_orient`
`hinst`	Specifies the hinst of the partition clone whose orientation information has to be retrieved. This can be an hierarchical instance hinst of a partition or an instance hinst of a black box. **Note:** The hinst argument should be registered as a hinst and not as a string to support DPO usage. *Data_type*: (hinst), required

Example

The following command retrieves the the orientation information for the partition clone `TDSP_ARB_C1`:

```
get_clone_partition_orient TDSP_ARB_C1
```

Related Information

- `set_clone_partition_orient`
- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

get_partition_pin_status

```
get_partition_pin_status
[-help]
[-partition cellName]
[-pins {pinName | pinNameList}]
```

Retrieves the pin status that was defined with the `set_partition_pin_status` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `get_partition_pin_status` parameter. For a detailed description of the command and all of its parameters, use the man command: `man get_partition_pin_status`.
`-partition cellName`	Specifies the name of the partition. You can use wildcards (`*?`) with this parameter. *Data_type*: string, optional
`-pins pinName | pinNameList`	
	Specifies the name of the pin(s) of the partition. You can use wildcards (`*?`) with this parameter. *Default:* If the pin name is not specified, the command is run on all pins. *Data_type*: string, optional

Example

The following command tells the status of pin `DATA` of partition `EUG`:

```
get_partition_pin_status -pins DATA -partition EUG
```

Related Information

- `set_partition_pin_status`
- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

get_pin_constraint

```
get_pin_constraint
[-help]
[-dict_file string]
[[-global | -cell cell_name]
[-global | -pins pin_name_list]]
```

Retrieves information about the constraints set for a partition pin or an I/O pin using the `set_pin_constraint` command. It displays the information in a tabular format output report that includes constraints from other sources (top/bottom preferred layer and NDR-rule from `set_route_attributes`, reserved layer for partition, pin/net-group /guide constraints presence)) and segregates between user-defined, default, and lef values.

Parameters

`-cell cell_name`	Specifies the name of the module. The module name is not required if the command is run on a top-level module. You can use wildcards (*?) with this parameter. *Data_type*: string, optional
`-dict_file string`	Writes the output of the command in the specified text file (in dictionary format). *Data_type*: string, optional
`-global`	Specifies to get global constraints. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `get_pin_constraint` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man get_pin_constraint`
`-pins pin_name_list`	Specifies the name(s) of the partition pin(s). You can use wildcards (`*?`) with this parameter. *Data_type*: string, optional

Example

- The following command prints all the constraints set for the specified module.

```
get_pin_constraint -cell dtmf_chip
```

  The following result is displayed on the screen:

```
Default Global Values:
----------------------
Minimum pin-to-pin track spacing : 2
Pin to corner distance : 5

Template from tech LEF
------------------------------
| Layer | width | depth |
------------------------------
| 2 | 0.2800 | 0.2800 |
| 3 | 0.2800 | 0.2800 |
| 4 | 0.2800 | 0.2800 |
| 5 | 0.2800 | 0.2800 |
| 6 | 0.4400 | 0.4400 |
------------------------------

Global Constraint:
-------------------

Constraint on partition dtmf_chip :
-----------------------
Partition reserved layers { 1 2 3 4 5 6 7 }
--------------------------
| Side | allowed layer |
--------------------------

gui_highlight_feedthru_nets

```
gui_highlight_feedthru_nets
[-help]
net_map_file
[ net ]
```

Highlights all nets for which feedthrough buffers were inserted with the `add_partition_feedthrus` command. The highlighted feedthrough path consists of the nets, the terms that the nets connect to, and the instances that contain those terms.

Note: For the `gui_highlight_feedthru_nets` command to work, the `add_partition_feedthrus` command must be run with the `-net_mapping` parameter. The net mapping file generated with the `add_partition_feedthrus -net_mapping` parameter is used by the `gui_highlight_feedthru_nets` command to highlight the feedthrough nets.

To dehighlight the feedthrough nets, run the `gui_clear_highlight` command.

Note: It displays a warning message when used for a design with nested partitions and generates results based on single level partitions.

Parameters

net_map_file	Specifies the net mapping file that was generated with the `add_partition_feedthrus -net_mapping` parameter. *Data_type*: string, required
-help	Outputs a brief description that includes the type and default information for each `gui_highlight_feedthru_nets` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man gui_highlight_feedthru_nets`
net	Specifies the name of the net(s) whose feedthrough path should be highlighted. *Default*: The feedthrough paths of all nets specified in the net mapping file are highlighted. *Data_type*: string, optional

Examples

- The following command highlights all feedthrough nets specified in the net mapping file `nmpFile1`.
  ```
  gui_highlight_feedthru_nets nmpFile1
  ```
- The following command highlights all feedthrough nets that are specified in the net mapping file nmpFile1 whose name begins with `feedthruNet_core`.
  ```
  gui_highlight_feedthru_nets nmpFile1 feedthruNet_core*
  ```

Related Information

  - Highlighting the Nets for which Feedthrough Buffers Have been Inserted

gui_show_partition_wire_cross_over

```
gui_show_partition_wire_cross_over
[-help]
[partition_name]
[-out_file fileName]
[-exclude_net exNetFileName]
[-exclude_clock]
[-exclude_tristate]
[-exclude_high_fanout nrFan]
[-all_nets]
[-delta]
```

Displays and writes a file of wires that physically cross over partitions. You can use this command after routing the design.

Note: The `gui_show_partition_wire_cross_over` command supports designs with nested partitions.

Parameters

`-all_nets`	Reports nets that cross partitions that also connect to the ports of partitions. If this parameter is not specified, only nets that cross the partitions are reported. *Data_type*: bool, optional
`-delta`	Reports the total segment length of the wires crossing the block in the X and Y directions. *Data_type*: bool, optional
`-exclude_clock`	Excludes clock nets from the wire crossing information. *Data_type*: bool, optional
`-exclude_high_fanout` *nrFan*	Excludes nets with fanouts over nrFan from the display. *Data_type*: int, optional
`-exclude_net` *exNetFileName*	Specifies the filename that contains nets to be excluded from the display. *Data_type*: string, optional
`-exclude_tristate`	Excludes all tristate nets from the display. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `gui_show_partition_wire_cross_over` parameter. For a detailed description of the command and all of its parameters, use the man command: `man gui_show_partition_wire_cross_over`
`-out_file` *fileName*	Specifies the name of the output file of wire crossing information. *Default*: If you do not specify this parameter, the detailed information is output to the ptnName.wireCrossing file, where ptnName is the name of the partition. For master clone designs, three output files are created. These files can be used by the `add_partition_feedthrus` command for path based feedthrough insertions in master and clone designs. For example, when you specify, `gui_show_partition_wire_cross_over -out_file abc` The following files are generated: • abc.mc_connected_nets.txt: For all nets connected to master/clone partitions. • abc.mc_crossing_nets.txt: For all nets with wires over master/clone partitions (but not in the above file) and not intra partition nets. • abc.non_mc.txt: For all remaining nets which are not in above files and are not intra partition nets. **Note**: The default output file, abc.wireCrossing, is now only valid for non master/clone designs and has no significance for master and clone designs. *Data_type*: string, optional
partition_name	Specifies the name of the partition to show wire crossing. If you choose this option with other options, it must be the first specified when running this command. *Default*: If you do not specify this parameter, it will show all partition wire crossings. *Data_type*: string, optional

Example

The following command displays the routes crossing over partition, sheet17, and outputs the detail information into file, sheet17.crossing:

```
gui_show_partition_wire_cross_over sheet17 -out_file sheet17.crossing
```

The wire crossing report section lists the nets, their wire lengths, in micrometers, and the shape of the wire in relation to the partition.
For example, the following report segment is for a partition module named `sheet17`:

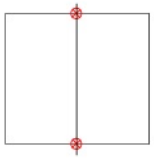
```
#########################################################
# Nets that cross partition module sheet17
# Box (335 335) (833 567)
```

```
# Format: Net <netName> <wireLength> <shape>
##########################################################

Net A 65 I
Net B 80 L
Net C 1050 T
Net D 132 X
...
```

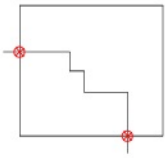
The first net in the report, A, has a wire length of 65 micrometers in an `I' shape, which indicates that the net crosses the partition on opposite sides, as follows:

```
Net A 65 I
```



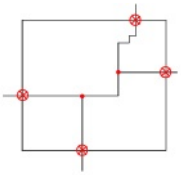
The second net in the report, B, has a wire length of 80 micrometers in an `L' shape, which indicates that the net crosses the partition on adjacent sides, as follows:

```
Net B 80 L
```



The third net in the report, C, has a wire length of 105 micrometers in an `T' shape, which indicates that the net crosses the partition on three sides, as follows:

```
Net C 105 T
```



The fourth net in the report, D, has a wire length of 132.30 micrometers in an `X' shape, which indicates that the net crosses the partition on all four sides, as follows:

```
Net D 132 X
```

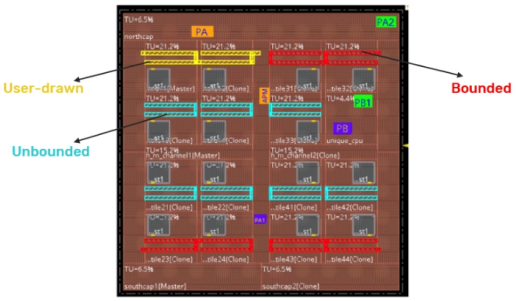
highlight_sync_obj

```
highlight_sync_obj
[-help]
[-obj {all bus_guides}]
```

Adds highlight color on sync objects during master-clone-aware bus guide operations. The colors used for highlighting are based on different color schema categories – user-drawn, bounded, or unbounded. These categories are derived from the last sync command (`Clone_partition_obj -sync` or `set_db floorplan_auto_sync_master_clone busGuides`) used. This command makes it easy to distinguish between different bus guide objects in the design.

- User-drawn bus guides are highlighted in yellow.
- Bounded bus guides are highlighted in red. Nets in bounded bus guides can be determined during sync operation. If either (or both) the source or driver partition is a master-clone, the tool can determine the equivalent net during sync (in master clone chains).
  For example: Consider A1-B1-C1 and A2-B2-C2 chains where A/B/C1 A/B/C2 are master clones. A1/2 pin k is connected to net n1 (in A1) and n2 (in A2). As we can easily determine n1 and n2 in the chains, this is a case of bounded bus guides.
- Unbounded bus guides are highlighted in blue. Nets in unbounded bus guides cannot be determined during sync operation. If both source or driver partition are unique or (special case master and clone but their equivalent pin is floating), the tool cannot determine the net during sync (in master and clone chains).
  For example: Consider UA1-B1-UC1 and UA2-B2-UC2 chains where B1 and B2 are master clones. UA1/UC1/UA2/UC2 are all unique but UA1/UA2 pin may be different. Here since we cannot determine equivalent nets of chains, this is a case of unbounded bus guides.



Parameters

`-help`	Outputs a brief description that includes the type and default information for each `highlight_sync_obj` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man highlight_sync_obj`
`-obj {all bus_guides}`	Specifies the object to be highlighted. *Data_type*: (enum)+, optional

Example

- The following command highlights busguides based on different color schema categories
  `highlight_sync_obj -obj bus_guides`

Related Information

- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

legalize_pins

```
legalize_pins
[-help]
[-auto_pair]
[-ignore {pin_spacing pin_width pin_depth pin_layer pin_min_area pin_on_track pin_abutment pin_non_nbr_abutment clones}]
[-internal_pins]
[-keep_layer]
[-keep_order]
[-move_fixed_pins]
[-pins {pinName | pinNameList}]
[-partitions ptnName]
[-snap_to_boundary]
[-verbose]
[-partitions ptnName | {-pins_file fileName [-exclude_partitions ptnName]}]
[-pins_file fileName  | -exclude_pin_file fileName]
```

Moves a pin from its existing location in the following cases:

- The pin overlaps with any other object or pin. The objects considered are:The pin violates pin-to-pins spacing constraints
  - stripes
  - vias
  - feedthrough buffers
  - routing blockages
  - pin blockages
- The pin is on a non-preferred layer, a non-reserved layer, or the Metal1 layer
- The pin is not on the routing track
- The pin does not honor corner mask settings

The pin is assigned to the nearest legal location.

Note: If this command is run on a blackbox that has one or more pins with a single LEF port but with multiple shapes within the LEF port, the command will remove these multiple shapes and create a single shape. If this command is run on a blackbox that has one or more pins with multiple LEF ports, the first LEF port will be processed as per the command and the remaining LEF ports will remain unchanged.

The `legalize_pins` command supports nested partitions and corrects the pin position of illegal pins across hierarchies. It gives a warning if the first level pin is placed in second level partition or vice versa and legalizes them to the nearest track. It also supports pin overlapping across N levels for overlapping partition boundaries.

The l`egalize_pins` command honors net weights and accordingly legalizes pins. For example, if there are 2 or 3 pins that can be put into a slot, the `legalize_pins` command automatically looks at the net weight of these pins and assigns the slot according the net weight priority.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `legalize_pins` parameter. For a detailed description of the command and all of its parameters, use the man command: `man legalize_pins`
`-auto_pair`	Automatically calculates the channel width or distance between pins in a design which will be considered for pairing. *Data_type*: bool, optional
`-exclude_partitions ptnName`	Specifies the list of excluded partition for pin file. *Data_type*: string, optional
`-exclude_pin_file fileName`	
	Specifies pin-list to be excluded for partition in a file. *Data_type*: string, optional
`-ignore {pin_spacing pin_width pin_depth pin_layer pin_min_area pin_on_track pin_abutment pin_non_nbr_abutment clones}`	

	Legalizes by taking the category(ies) of ignore types into account. *Data_type*: (enum)+, optional
`-internal_pins`	Legalizes internal pins by moving them to the closest track on the preferred routing layer. *Data_type*: bool, optional
`-keep_layer`	Maintains the pin layer while legalizing the pins. If the pin is on a layer that is not on the allowed partition layer list then an error is reported and the pin is not legalized. *Data_type*: bool, optional
`-keep_order`	Maintains the pin order while legalizing pins irrespective of the layers. Initially, the pins are legalized within the range of original pin locations. However, if the `legalize_pins -keep_order` command is unable to find a legal location, `legalize_pins` will try to find a valid location that is outside the original range and give warning message. If `legalize_pins` fails to find a valid location, it reports an error. **Note**: The option is only applicable for pins on the fence. It does not apply to internal pins. *Data_type*: bool, optional
`-move_fixed_pins`	If you use this parameter, the specified pins with a Fixed status can also be moved. **Note**: Pins that are not specified but have a Fixed status are not moved. *Default*: If you do not specify this option, the specified pins with a Fixed status are not moved. *Data_type*: bool, optional
`-partitions` *ptnName*	Specifies the partition for which the pins will be checked. This parameter is required if the partition is not the top-level module. **Note**: The `legalize_pins` command can also resolve I/O pins from overlapping power stripes. In this case, *ptnName* specifies the block-level design name. *Data_type*: string, optional
`-pins {`*pinName* `|` *pinNameList*`}`	
	Specifies that the command should be run on the specified pin(s) only. *Data_type*: string, optional

`-pins_file` *fileName*	Specifies the pin list for a partition in a file. In the pin file, the pins and nets are specified in the following format:
	`Partition: PtnName/BlockName`
	Pin1
	Pin2
	..
	`Partition: PtnName/BlockName`
	Pin1
	Pin2
	..
	`Nets:`
	netA
	netB
	..
	Note: While specifying the pin list in the pin_file, it is necessary to give the “Partition” keyword followed by the name of the partition or block. If this is not specified, no operations are performed. You can specify multiple partitions in the same pin_file.
	The `pin_file` does not support buses or wild cards for pin names. If a pin specified in the list or a partition is not present in the design, a warning is displayed.
	Data_type: string, optional

`-snap_to_boundary`	Snaps internal partition pins to the boundary and legalizes them. **Note**: The `-snap_to_boundary` parameter does not work with `-internal_pins` as both work on internal pins and their results are different. *Data_type*: bool, optional

`-verbose`	Reports all the existing pin violations. *Data_type*: bool, optional

Example

The following command legalizes pins in same the metal as they were present and moves fixed pins if they are placed illegally:

```
legalize_pins -keep_layer -move_fixed_pins
```

The following command accepts a file that contains the list of pins for partition A and partition B and legalizes them.

```
legalize_pins -partitions {A B} -pins_file pinLst.txt
```

where, the *pinList.txt*

```
Partition: top
out1
out2
out3
Partition: A
in1
in2
in3
Partition: B
pina
pinb
pinc
```

partition_floorplan Category Attributes

The root attributes in the `partition_floorplan` category are:

- partition_floorplan_export
- partition_floorplan_import

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `partition_floorplan` category, use the following command:

```
get_db -category partition_floorplan
```

partition_floorplan_export

`partition_floorplan_export {macro | special_route | pin_constraint}`

Default: `special_route` (default data + special route is always saved)

Data_type: enums={macro special_route pin_constraint}_list, read/write

Specifies the objects to be exported. This is used by the `write_partitions -floorplan_only` command to save the data to the fp file.

Related Commands

- `write_partitions`
- `assemble_design`

partition_floorplan_import

`partition_floorplan_import {macro | special_route | pin_constraint}`

Default: By default, it brings only defaults objects

Data_type: enums={macro special_route pin_constraint}_list, read/write

Specifies the objects to be imported. This is used by the `assemble_design -floorplan_only` command to load the data from the fp file.

Related Commands

- `write_partitions`
- `assemble_design`

partition_push_network

```
partition_push_network
[-help]
[-exclude_partitions partition_name_list]
[-filter string]
[-inst_prefix inst_prefix_name]
[-logical_only]
[-net_prefix net_prefix_name]
[-out_file_logical_only_nets string]
[-output_nets_for_wire_distribution string]
[-partition_net_dir file_name]
{-nets net_name_list | -in_file file_name | -buffer_only  | -inst inst_name_list }
[-check_only [-out_file file_name]]
```

Pushes down a network (std cells and connected wires) logically and physically into overlapping partitions. The `partition_push_network` command:

- Logically pushes down a set of nets into overlapping partitions by doing all the necessary logical port creations.
- Physically pushes down the special wires of the nets into overlapping partitions and does all the necessary partition pin creations. The pushed wires look exactly the same as the original wires.
- Creates Verilog assign statements wherever required to ensure that the pushed logic is logically equivalent to the original logic.

Notes:

- The `partition_push_network` command does not support designs with master and clone partitions. In such scenarios, only masters will be seen and the overlapping wires and logic will be pushed down into masters only.
- The `partition_push_network` command takes care of new nets connected at top level nets automatically post committing partitions.
- The `partition_push_network` command supports partially routed nets. It does not require the wires of a net to be DRC/LVS clean. Wires need not connect to the instance-pin of a driver or loads. Even if a wire is in the 5u radius of a source-instance-pin or a sink-instance-pin, the tool considers the net for pushdown.

Parameters

`-buffer_only`	Specifies that only all buffers, and their connected nets, will be considered for pushed down. *Data_type*: bool, required
`-check_only`	Informs which nets are going to be pushed down. *Data_type*: bool, optional
`-exclude_partitions` *partition_name_list*	
	Specifies that the instances/nets within the specified partition(s) will not be pushed down. *Data_type*: string, optional
`-in_file` *fileName*	Specifies the name of the file containing the list of net names to be considered for push down. *Data_type*: string, required
`-filter` *string*	Specifies that only instances/nets whose name matches this specified regular expression will be pushed down. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `partition_push_network` parameter. For a detailed description of the command and all of its parameters, use the man command: `man partition_push_network`
`-inst_prefix` *inst_prefix_name*	Specifies a custom prefix for instances that are pushed down. *Data_type*: string, optional
`-inst` *inst_name_list*	Specifies that all instances, and their connected nets, will be considered for pushed down. *Data_type*: string, required
`-logical_only`	Logically pushes down network into overlapping partitions. *Data_type*: bool, optional
`-net_prefix` *net_prefix_name*	Specifies a custom prefix for nets that are pushed down. *Data_type*: string, optional
`-nets` *net_name_lst*	Specifies that list of net names, and their connected instances, will be considered for pushed down. *Data_type*: string, required
`-out_file` *file_name*	Specifies a file name in which net names, to be pushed down, will be mentioned. This parameter is used with `-check_only`. *Data_type*: string, optional
`-out_file_logical_only_nets` *string*	
	Specifies a file name in which net names are mentioned. This parameter is used with `-logical_only`. *Data_type*: string, optional
`-output_nets_for_wire_distribution` *string*	
	Outputs the user-specified nets so that they can be used later during the `commit_partitions` command. *Data_type*: string, optional
`-partition_net_dir` *file_name*	
	Specifies the directory that consists of the names of the pushed nets corresponding to each partition. *Data_type*: string, optional

Example

- The following command consider nets n1, n2 and n3 for push down.
  ```
  partition_push_network -nets {n1 n2 n3}
  ```
- The following command generates a file, push_down_nets.txt, containing the names of nets that would have been considered for push down.
  ```
  partition_push_network -nets [get_db nets .name] -check_only -out_file push_down_nets.txt
  ```
- The following command generates a file, push_down_nets.txt, containing the names of nets (connected to the specified instances)that would be considered for push down.
  ```
  partition_push_network -inst [get_db insts .name] -check_only -out_file push_down_nets.txt
  ```
- The following command considers all buffers for push down.
  ```
  partition_push_network -buffer_only
  ```
- The following command considers all buffers and their connected nets for push down which have their hierarchical name (TCL) regexp matching to KK.*.
  ```
  partition_push_network -buffer_only -filter KK.*
  ```
- The following command considers all buffers and their connected nets for push down. The pushed down buffers will have their base names starting with II
  ```
  partition_push_network -buffer_only -inst_prefix II
  ```
- `The following command` considers all buffers and their connected nets for push down. The pushed down buffers will have their base names starting with II, and the pushed down nets will have their base names starting with NN_.`partition_push_network -buffer_only -inst_prefix II -net_prefix NN`

partition_push_special_wires

```
partition_push_special_wires
[-help]
[-check_only]
[-nets list_of_net_names]
```

Creates Verilog ports (connections) in partitions for nets whose special wires overlap a partition, so that the special wire of the net gets pushed down when the `commit_partitions` command is used.

Note: For pushdown of special wires in master and clone partitions, it checks for the symmetry of the special wire shapes. For symmetrical shapes only, the `partition_push_special_wires` command creates one port in the Verilog module and establishes a logical connection between the new port and the net of special wire over all master and clone hinsts (reuse of logical port in master and clones).

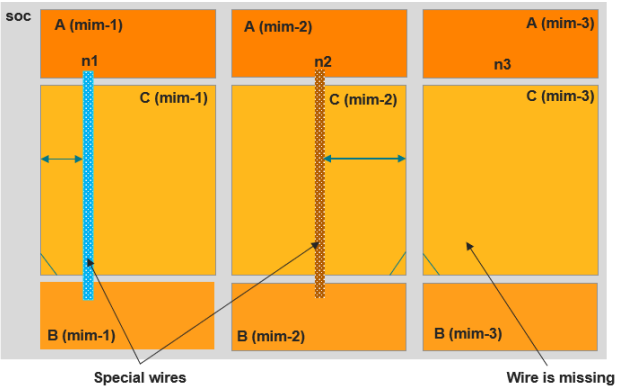
Note: If the original net was connected to a partition port of type inout, then an inout port is created inside the overlapping partition else only an input port is created.

Parameters

`-check_only`	When specified, the tool checks if the selected nets special-wires are symmetric over all hints of overlapping master clone cells or not. In master and clone partitions, it checks for the symmetry of nets and reports asymmetrical nets. When the `-check_only` parameter is not specified, the tool check the nets specified and creates logical ports only on valid nets. Data_type: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `partition_push_special_wires` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man partition_push_special_wires`
`-nets list_of_net_names`	Specifies the list of nets (Verilog nets) which have special wires to be pushed into blocks. *Data_type*: string, required

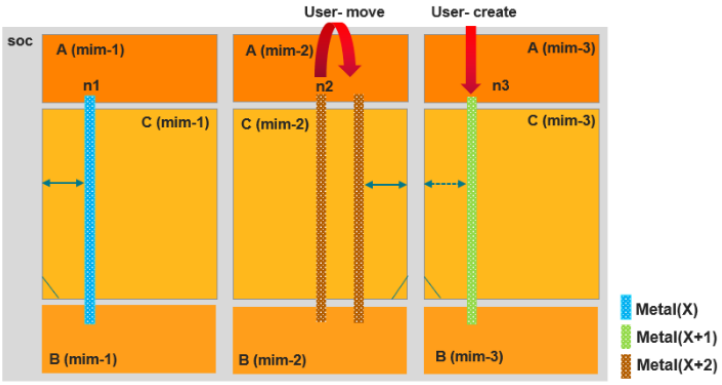
Example

- The following command checks the special wires of specified Verilog nets n1 and creates ports on valid nets.
  ```
  partition_push_special_wires -nets {n1}
  ```
- The following command checks if the special-wires of the specified nets are symmetric over all hints of overlapping master clone cells or not.
  ```
  partition_push_special_wires -nets {n1 n2} -check_only
  ```
- The following command checks if the special-wires of the specified nets are symmetric over all hints of overlapping master clone cells or not.
  ```
  partition_push_special_wires -nets {n1 n2} -check_only
  ```



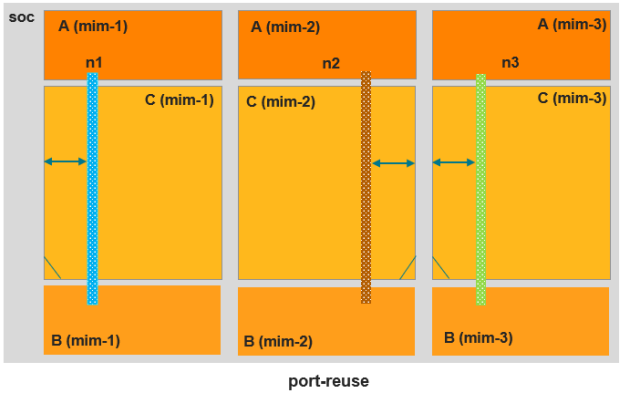
```
Report: C (mim-1) net n1 box missing in C mim-2
Report: C (mim-1) net n1 box missing in C mim-3
Report: C (mim-2) net n2 box missing in C mim-1
Report: C (mim-2) net n2 box missing in C mim-3
```

For pushdown, you must fix the wire asymmetry.



After the symmetry is fixed, the following command pushes down symmetrical nets:

```
partition_push_special_wires -nets {n1 n2}
```



```
Report: user Net n1, n2 and derived nets n3 pushdown, with one logical port
```

Related Information

place_cells_at_center_for_feedthrus

```
place_cells_at_center_for_feedthrus
[-help]
[-insts list_of_selected_insts]
```

Places all the instances corresponding to a given partition at its center to facilitate feed-through insertion in the flow during the floorplanning stage. It quickly changes the design status to “placed” by placing all unplaced cells in the middle of the partition, so that feedthrough can be run.

Note: It places all the cells on the same location (overlapping).

Note: It can handle rectilinear partition fences and nested designs.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `place_cells_at_center_for_feedthrus` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man place_cells_at_center_for_feedthrus`
`-insts list_of_selected_insts`	Specifies the name of the instances that will be placed at the center of the partition. You can use wildcards (*?) with this parameter. For example, the following command places all unplaced cells that have ECO in their name to the center of the partition: `place_cells_at_center_for_feedthrus -insts *ECO*` *Data_type*: string, optional

Example

The following command changes the design status to “placed” by placing all unplaced cells in the middle of the partition, so that feedthrough can be run.

```
place_cells_at_center_for_feedthrus
```

Related Information

- `add_partition_feedthrus`

place_partition_clone

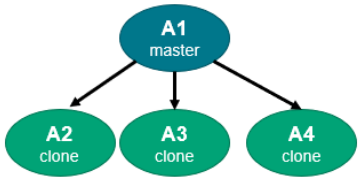
```
place_partition_clone
[-help]
-hinst partition_clone_hinst_name
-location {x y}
[-orient {r0 r80 mx my}]
[-skip_sync]
[-sync_objs {placeBlockage routeBlockage pinBlockage macros fences}]
```

Places the clones, set their orientation and syncs up the data with other hierarchical instances (master and clones) of the same module.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `place_partition_clone` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man place_partition_clone`
`-hinst partition_clone_hinst_name`	Specifies the name of partition clone hierarchical instance. *Data_type*: string, required
`-location {x y}`	Specifies location of the clone partition. *Data_type*: point, required
`-orient {r0 r80 mx my}`	Specifies orientation of the clone partition. The orientation can be one of the following: `r0, r180, mx, and my` *Data_type*: enum, optional
`-skip_sync`	When specified, the tool skips the sync-up of reference hinst (`-hinst`) objects with other hinsts of the same module. *Data_type*: bool, optional
`-sync_objs {placeBlockage routeBlockage pinBlockage macros fences}`	When specified, the tool does the sync-up of the specified objects from reference hinst with other hinsts of same module. The objects that can be synced up include placeBlockage, routeBlockage, pinBlockage, macros, and fences. *Data_type*: string, optional

Example



```
Hinst: A1 (master), A2 (clone), A3(clone), A4 (clone)
```

- The following commands places the clone A2 at location 2,5. If partition block has FP/def/route objs/data present, the command will sync the data from A2 to all other hinsts (A1 (master), A3 , A4 (clones)).
  ```
  place_partition_clones -hinst A2 -location {2 5}
  ```
- The following commands places the clone A3 at location 12,15 and changes the orientation to r180 (if not already R180). If partition block has FP/def/route objs/data present, the command will sync the data from A3 to all other hinsts (A1 (master), A2 , A4 (clones))
  ```
  place_partition_clones -hinst A3 -location {12 15} -orient r180
  ```
- The following commands places the master A1 at location 22,25. If partition block has FP/def/route objs/data present, the command will sync the data from A1 to all other hinsts (A2, A3, A4 (clones)).

```
place_partition_clones -hinst A1 -location {22 25}
```

- The following commands places the master A1 at location 22,25. If partition block has FP/def/route objs/data present, the command will not sync any data to other hinsts.

```
place_partition_clones -hinst A1 -location {22 25} -skip_sync
```

- The following commands places the clone A3 at location 12,15 and changes the orientation to r180 (if not already r80). If partition block has FP/def/route objs/data present, the command will not sync any data to other hinsts.

```
place_partition_clones -hinst A3 -location {12 15} -orient r180 -skip_sync
```

- The following commands places the clone A3 at location 12,15 and changes the orientation to r180 (if not already r180). If partition block has FP/def/route objs/data present, the command will sync the bus-guide data from A3 to all other hinsts (A1 (master), A2 , A4 (clones)).

```
place_partition_clones -hinst A3 -location {12 15} -orient r180 -sync_obj {bus_guide}
```

- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

read_black_box_netlist

```
read_black_box_netlist
[-help]
netlist_file
```

Loads a netlist_file for a black box. You can use this command to incrementally load an updated netlist_file for a blackbox. You can use this command before converting a blackbox to a fence.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `read_black_box_netlist` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man read_black_box_netlist`
`netlist_file`	Specifies the netlist_file name. The netlist_file can contain more than one black box netlist_file, but it should not contain any non-blackbox netlist_file. *Data_type*: string, required

Example

The following command loads the netlist_file `netlist_file_v1`.

```
read_black_box_netlist netlist_file_v1
```

Related Information

  - Blackbox Flow

read_hierarchical_def

```
read_hierarchical_def
[-help]
<def_files <...>>
[-add_blockage]
[-delete_blockages_over_partition_macro]
[-ignore_drcfill]
[-incremental_ilm_def]
[-rdl_def string]
[-rdl_orient {r0 r90 r180 r270 mx mx90 my my90}]
[-rdl_placement {x y}]
[-secondary {{suffix def_file_list}...}]
[-skip_fillers]
[-skip_nets] [-skip_pg] [-skip_routing string]
[-to_layer routing_layer_name]
[-top_cell_orient {r0 r90 r180 r270 mx mx90 my my90}]
[-top_cell_placement {x y}]
[-top_scope]
[-transform_file string]
[-use_top_def_die_area]
```

Merges DEF data from various blocks to a single chip database. The `read_hierarchical_def` command provides the following features:

- Takes the TOP DEF file and a set of block DEF files and merges them into a single chip database.
- The block and TOP Verilog files (or their DEF files) can be specified in any order. However, if there are empty Verilog module stubs of blocks in some of the parent Verilog files, ensure that the parent Verilog files are specified prior to the child Verilog files.
- There is no need to specify the LEF files for the blocks.
- During the course of this command, TOP rows will be cut around the block boundary, and all block rows will be brought back as is.
- Partition definitions are created for each of the assembled block as per the DIE AREA statement in the block DEF.
- The wire at the block boundaries will be stitched with the electrically connected net's wires at the TOP.
- All orientations of blocks are supported for assembly. Repeated blocks are also supported. Non-R0 master is also supported.

Parameters

`-add_blockage`	Specifies that the netlist is a reduced one and converts the undefined instances into blockages. *Data_type*: bool, optional
def_files <...>	Specifies DEF files to be merged. *Data_type*: list, required
`-delete_blockages_over_partition_macro`	
	Deletes top design placement and routing blockages overlapping partitions. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `read_hierarchical_def` parameter. For a detailed description of the command and all of its parameters, use the man command: `man read_hierarchical_def`
`-ignore_drcfill`	Ignores the special routing with DRCFILL shape attribute. *Data_type*: bool, optional
`-incremental_ilm_def`	Incrementally flatten the ILM def. *Data_type*: bool, optional
`-rdl_def string`	Specifies RDL def file. *Data_type*: string, optional
`-rdl_orient {r0 r90 r180 r270 mx mx90 my my90}`	

	Specifies orientation for RDL def. *Data_type*: enum, optional
`-rdl_placement {x y}`	Specifies offset of RDL def. *Data_type*: point, optional
`-secondary {{suffix def_file_list}...}`	
	Specifies the secondary DEF file(s) to load. *Data_type*: string, optional
`-skip_fillers`	Skip merging filler and decap cells. *Data_type*: bool, optional
`-skip_nets`	Skips merging signal nets section. *Data_type*: bool, optional
`-skip_pg`	Skips merging routing on pg nets. *Data_type*: bool, optional
`-skip_routing {[pg|signal] [regular|special] [high_layer_routing]}...`	
	Skips merging routing based on the settings specified. This setting can be any combination of the three optional keywords from the following set: • `[pg|signal]`: Specifies the type of the net on which the routing to be skipped. pg – pg net, signal – signal net, both if not specified. • `[regular|special]`: Specifies the type of routing to be skipped. regular – regular routing, special – special routing, both if not specified. • `[high_layer_routing]`: Specifies that only the routing on high layers to be skipped, where the layers are calculated automatically. If not specified, the routing on all layers are skipped. The layers can be specified with `-to_layer` option. In that case, the routing on the layers from top to the specified layer are skipped. **Note:** You must specify the `-to_layer` parameter explicitly if `high_layer_routing` is specified for `-skip_routing`. Otherwise, `high_layer_routing` has no effect. *Data_type*: string, optional
`-to_layer routing_layer_name`	Skips the routing of layers from top to the specified layer (inclusive) when the `high_layer_routing` option is specified for the `-skip_routing` parameter. *Data_type*: (layer), optional
`-top_cell_orient {r0 r90 r180 r270 mx mx90 my my90}`	
	Specifies orientation for topcell. *Data_type*: enum, optional
`-top_cell_placement {x y}`	Specifies placement for topcell. *Data_type*: point, optional
`-top_scope`	Merges routing on top scope nets only. *Data_type*: bool, optional
`-transform_file string`	Reports the final x and y offsets and orientation in the top-level of each LEF block that got replaced by DEF. *Data_type*: string, optional
`-use_top_def_die_area`	Enables the use of TOP DEF DIE AREA. *Data_type*: bool, optional

Example

- The following command merges DEF data from `top.def.gz` and `blockA.def.gz` to a single chip database.

```
read_hierarchical_def top.def.gz blockA.def.gz
```

read_partition_pins

```
read_partition_pins
[-help]
[-report_file string]
[-snap_modified_to_boundary]
{-partition string | -all}
{-partition_file string| -def_file string}
```

Loads either a partition floorplan file (from a saved partition design session) or a DEF file, and then displays the preassigned I/O pins for the partition. This command must be run for each partition in the design. You can use this command on a partition design after loading the top level floorplan and after running/loading placement and early global route data.

Note: The `read_partition_pins` command can load partition files that are saved using the `write_floorplan` command.

Parameters

`-all`	Specifies that pin positions for all the partitions should be loaded. *Data_type*: bool, optional
`-def_file string`	Specifies the full pathname of the partition def file. **Note:** You can specify a DEF file in the gzip format (with the .gz extension) also. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `read_partition_pins` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man read_partition_pins`
`{-partition_file string | -def_file string }`	
	Specifies the full path name of the partition floorplan file. *Data_type*: string, optional
`-partition string`	Specifies the name of the partition. *Data_type*: string, optional
`-report_file string`	Specifies the optional report filename that contains any pins deleted or newly added. *Data_type*: string, optional
`-snap_modified_to_boundary`	Snaps pins to the modified partition boundary. The pin is unplaced if it cannot be snapped to edge at same location in sam the `read_partition_pins` command does not snap it to the track and you need to run the `legalize_pins` command to snap *Data_type*: bool, optional

Example

The following command loads pin information from file `EUG.fp.ptn` for partition `EUG`

```
read_partition_pins -partition EUG -partition_file EUG.fp.ptn
```

report_partitions

```
report_partitions
[-help]
[top_cell]
```

Reports the partitions and clones in a correct tree like format.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `report_partitions` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_partitions`
top_cell	Specifies the top cell to print its cell partition tree. *Data_type*: string, optional

Example

The following command prints the partitions and clones in the design in a tree like format.

```
report_partitions
```

```
Format: partitionName, MasterOrClone, Orient, PartitionOrBlackBox (CommittedOrUncommited, Level, BottomUpLevel, In/Active): InstOrHInstName

report_pin_assignment_statistics

```
report_pin_assignment_statistics
[-help]
[-max_fanout fan_out_count]
[-max_register_fanout register_fan_out_count]
[-out_file pin_qor_file_name]
[-hinst hinst_name_list | -partition ptn_name_list]
```

Generates the pin QoR data for a specified partition(s).

Note:

- If a net is not routed, then, manhattan distance between source-sink pairs is be used to replace corresponding wire-length distance.
- For floating pins (from outside) of a partition,the pin is always assumed to be within the timing cone box.
- Pin QoR statistics is not generated for blackbox partitions

Parameters

`-help`	Outputs a brief description that includes type and default information for each `report_pin_assignment_statistics` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_pin_assignment_statistics`
`-hinst hinst_name_list`	Generates the pin QoR metrics for all pins of the specified hierarchical instance name or list of instance names. *Default*: All partition and clone hierarchical instances. *Data_type*: string, optional
`-max_fanout fan_out_count`	Specifies the maximum fanout count. The QoR report is not generated for a pin if the number of instances in its timing cone fanout exceeds this maximum fanout count, *Default*: 1000 *Data_type*: string, optional
`-max_register_fanout register_fan_out_count`	
	Specifies the maximum register fanout count. The QoR report is not generated for a pin if the number of registers in its timing cone fanout exceeds this maximum fanout count. *Default*: 50 *Data_type*: string, optional
`-out_file pin_qor_file_name`	Specifies an output report file for the pin QoR data. *Default*: `./pin_qor.txt` *Data_type*: string, optional
`-partition ptn_name_list`	Generates the pin QoR metrics for all pins of the partition or list of partitions. *Default*: All partition and clones. *Data_type*: string, optional

Example

- The following command creates a `pin_qor.txt` report file:
  ```
  report_pin_assignment_statistics
  ```
- The following command generates a reference pin QoR file named `pin_qor_reference.txt`.
  ```
  report_pin_assignment_statistics -out_file pin_qor_reference.txt
  ```
- The following command generates a target pin QoR file named `pin_qor_target.txt`.
  ```
  report_pin_assignment_statistics -out_file pin_qor_target.txt
  ```

report_two_pin_chain

```
report_two_pin_chain
[-help]
[-reset  |
[[-out_file file_name] [-through string]
[-no_overwrite ]
[-show_all ]
[-strict ]
[-tolerance value]]]
```

Reports two pin chains for nets, instterms, and hinstterms. This command can traverse through buffers, inverters, and assign-statements and report the complete two pin chain. You can specify any element of the chain to get the same results. The `report_two_pin_chain` command is used after pin assignment to analyse results and debug issues especially in cases where the expectation to align all partition pins across a two-pin chain is not met.

Parameter

`-help`	Outputs a brief description that includes type and default information for each `report_two_pin_chain` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_two_pin_chain`
`-no_overwrite`	When specified the report continues to display the previous 2-pin-chains also. *Default*: false *Data_type*: bool, optional
`-out_file file_name`	Specifies the file in which the 2-pin nets are traced and dumped. *Default*: stdout *Data_type*: string, optional
`-reset`	Removes GUI markers and GUI objects, created during previous invocations. No two pin chain reporting. *Default*: false *Data_type*: bool, optional
`-show_all`	Displays the intermediate instances of the chain also. *Default*: false *Data_type*: bool, optional
`-strict`	Strictly displays only pure two pin chains even at module port connections. *Default*: false *Data_type*: bool, optional
`-through string`	Specifies the list of names of net, instterms, hinstterms for which 2-pin chains are traced and dumped. *Data_type*: string, optional
`-tolerance value`	Specifies the tolerance range. This specified difference in ordinates treated as still aligned. *Default*: 1.0 microns *Data_type*: float, optional

Example

- In the following diagram P1, P2, W3/P3 are partitions and W3 is a non-partition verilog module.
  It shows a pure two pin connection where red and green pins aligned together in one chain.

  The following command reports this two pin chain passing through p2/I1/Y:

```
report_two_pin_chain -through p2/I1/Y
```

- The following command reports the two pin chains passing through `DTMF_INST/TDSP_CORE_INST/port_pad_data_out[13]`:

```
report_two_pin_chain -through DTMF_INST/TDSP_CORE_INST/port_pad_data_out[13]
```

```
Report:
2-pin-chain through: DTMF_INST/TDSP_CORE_INST/port_pad_data_out[13] ...
chain terminator: other pin of buffer is multi-fanout
net: DTMF_INST/TDSP_CORE_INST/port_data_in[13]

chip-io                        :output :fixed       : port_pad_data_out[13]
chain terminator: chip-io
```

- The following command reports the two pin chains passing through `F2/D2/A/out` and writes it to `report.txt` file:

```
report_two_pin_chain -through F2/D2/A/out -out_file report.txt
```

Related Information

- `assign_partition_pins`
- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

report_unaligned_nets

```
report_unaligned_nets
[-help]
[-align_distance distance]
[-align_feedthru_pins]
[-block_pins_within_distance distance]
[-ignore_length  length]
[-net_box_deviation]
[-no_highlight]
[-out_file filename]
[-report_all_within_channel_width width]
[-statistics]
[-verbose]
[[ -partition_to_partition {aligned | unaligned | layermismatch | sameptn  |nonnbr  | multifanout | all | unplaced | none} ]
[-top_to_partition {aligned | unaligned | layermismatch | sameptn  |nonnbr  | multifanout | all | unplaced | none} ]]
[-pin_file filename | -exclude_pin_file filename ]
```

Report the names of the nets where the pins are not aligned for the following cases:

- nets that have two pins on two different partitions and/or clones and are not connected to top level hard-macro, standard cell, or I/O.
- nets that have two pins that are connected to the same partition.
- nets that have one pin connected to top level hard-macro, standard cell, or I/O and the other pin connected to a partition or a clone.

Notes:

- The nets reported by this command are also highlighted in the artwork window.
- The `assign_partition_pins` command internally calls the `report_unaligned_nets` command to generate the summary report at the command line.
- The `report_unaligned_nets` command measures the average misalignment with standard deviation for multi-partition nets.
- The `report_unaligned_nets` command detects and reports pins that are placed on non-facing edges.

Parameters

`-align_distance` *distance*	Specifies the distance, in microns, up to which the pins are assumed to be aligned. With this parameter specified, the `report_unaligned_nets` command assumes that the pins are aligned within the specified distance even though they are not physically aligned. *Data_type*: float, optional
`-align_feedthru_pins`	Reports the deviation of partition pins from chain's source-target box. *Data_type*: bool, optional
`-block_pins_within_distance` *distance*	Reports nets connected to macro-pin which are within specified distance from nearest partition boundary. *Default*: 3 microns *Data_type*: float, optional

`-exclude_pin_file` *filename*	Specifies the pin list to be excluded for a partition in a file. In the pin file, the pins and nets are specified in the following format: `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Nets:` *netA* *netB* .. *netN* **Note:** While specifying the pin list in the pin_file, it is necessary to give the “Partition” keyword followed by the name of the partition or block. If this is not specified, no operations are performed. You can specify multiple partitions in the same pin_file. The pin_file does not support buses or wild cards for pin names. If a pin specified in the list or a partition is not present in the design, a warning is displayed. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `report_unaligned_nets` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_unaligned_nets.`
`-ignore_length` *length*	Specifies the length, in microns. It ignores the nets from checking unalignment whose length is greater the specified length value. *Default*: 5000 These ignored nets will be reported in the ignored category in the output report file. *Data_type*: float, optional
`-net_box_deviation`	Report the deviation of partition pins from the connectivity box of the partition. *Data_type*: bool, optional
`-no_highlight`	Disables the highlight capability. *Data_type*: bool, optional
`-out_file` *fileName*	Specifies an output report file. **Note**: Default name for report file is `<designName>_unaligned.rpt` *Data_type*: string, optional
`-partition_to_partition {aligned | unaligned | layermismatch | sameptn |nonnbr | multifanout | all | unplaced | none}`	

	Reports nets that have two pins on two different partitions and/or clones and are not connected to top level hard-macro, standard cell, or I/O. • `aligned`: Reports nets that have aligned pins. • `all`: Reports all categories of unaligned pins. • `layerMismatch`: Reports nets that have pins at an aligned location but different layers. • `multiFanout`: Reports nets that have multiple fanouts • `none`: Disables reporting of nets. • `nonNbr`: Reports nets that have two pins on two different partitions that are not adjacent. • `samePtn`: Reports nets that have two pins that are connected to the same partition. • `unaligned`: Reports nets that have unaligned pins. • `unplaced`: Reports nets that have unplaced pins. *Data_type*: (enum)+, optional
`-pin_file` *filename*	Specifies the pin list for a partition in a file. In the pin file, the pins and nets are specified in the following format: `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Partition:` *PtnName/BlockName* *Pin1* *Pin2* .. *PinN* `Nets:` *netA* *netB* .. *netN* **Note:** While specifying the pin list in the pin_file, it is necessary to give the “Partition” keyword followed by the name of the partition or block. If this is not specified, no operations are performed. You can specify multiple partitions in the same pin_file. The pin_file does not support buses or wild cards for pin names. If a pin specified in the list or a partition is not present in the design, a warning is displayed. *Data_type*: string, optional
`-report_all_within_channel_width` *width*	Reports all the unaligned nets within the specified channel width even if the `-ignore_length` parameter has been specified. *Data_type*: float, optional
`-statistics`	Reports average misalignment with standard deviation and layer difference count for aligned, layer mismatched, and unaligned ptnToPtn 2-pin nets of partitions. It is also used for reporting pin QOR. *Data_type*: bool, optional
`-top_to_partition {aligned | unaligned | layermismatch | sameptn |nonnbr | multifanout | all | unplaced | none}`	

	Reports nets that have one pin connected to top level hard-macro, standard cell, or I/O and the other pin connected to a partition or a clone. • `aligned`: Reports nets that have aligned pins. • `all`: Reports all categories of unaligned pins. • `layerMismatch`: Reports nets that have pins at an aligned location but different layers. • `multiFanout`: Reports nets that have multiple fanouts • `none`: Disables reporting of nets. • `nonNbr`: Reports nets that have two pins on two different partitions that are not adjacent. • `samePtn`: Reports nets that have two pins that are connected to the same partition. • `unaligned`: Reports nets that have unaligned pins. • `unplaced`: Reports nets that have unplaced pins. *Data_type*: (enum)+, optional
`-verbose`	Reports all categories in log file. By default, this parameter is not enabled and only the nets that have unaligned pins are reported in the log file. **Note**: There will be no change in the report file with use of verbose parameter. *Data_type*: bool, optional

The following are some of the attributes specified in the output report file to report the names of nets where the pins are not aligned:

- `layer mismatch`: Specifies nets that have pins at an aligned location but different layers.
- `non-neighbor`: Specifies nets that have two pins on two different partitions that are not adjacent.
- `ptnToPtn`: Specifies nets that have two pins on two different partitions and/or clones.
- `topToPtn`: Specifies nets that have one pin connected to top level hard-macro, standard cell, or I/O and the other pin connected to a partition or a clone.
- `unAligned`: Specifies nets that have unaligned pins.

Example

The following command creates an a.out report file:

```
report_unaligned_nets rptFile a.out -no_highlight -partition_to_partition all -top_to_partition all
```

A summary of the reported unaligned nets displays on the Innovus console and in the Innovus log file.
The following is a sample of the resulting a.out report file.

```

reset_partition_pins

```
reset_partition_pins
[-help]
-partition partitionName
{ -in_file floorplanFileName }
```

Removes the loading of partition pins by the `read_partition_pins` command. This is used to remove the pre-assignment of pins that were previously reassigned by the loading.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `reset_partition_pins` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man reset_partition_pins`
`-in_file floorplanFileName`	Specifies the full path name of the partition floorplan file. *Data_type*: string, optional
`-partition partitionName`	Specifies the name of the partition. *Data_type*: string, required

Example

The following command unloads pin positions for partition `EUG` from file `EUG.fp.ptn`:

```
reset_partition_pins -partition EUG -in_file EUG.fp.ptn
```

Related Information

reset_pin_constraint

```
reset_pin_constraint
[-help]
{[-global | -cell cell_name | -all_user ] [-global | -pins pin_name_list | -area {x1 y1 x2 y2} | -all_area | -side side_names]
[-global | -layer ] [-global | -location | -edge | -corner corner_number]
[[-pins pin_name_list [-location ] [-edge ]] |
[-corner_to_pin_distance [-corner corner_number]]]
[{-pins pin_name_list | -pin_template {layer_id_or_name_list}} -width ]
[{-pins pin_name_list | -pin_template {layer_id_or_name_list}} -depth ]
[[-layer [-side side_names]] | -pin_template {layer_id_or_name_list}]
[-spacing [-area {x1 y1 x2 y2}]
[-all_area ] [-side side_names]] }
[-depth [-special_wire ]] [-all_user ]
```

Removes the constraints for a partition pin. You can use this command after setting the pin's constraints with the `set_pin_constraint` command.

Parameters

`-all_area`	Specifies that spacing constraints on all areas should be removed. *Data_type*: bool, optional
`-all_user`	Specifies that all user specified constraints should be removed from all levels (`-global`, `-cell`, and `-pins` level). *Data_type*: bool, optional
`-area {x1 y1 x2 y2}`	Specifies that the area overlapping with partition for which the spacing constraints have been specified should be removed. *Data_type*: box, optional
`-cell cell_name`	Specifies the name of the cell (partition). The cell name is not required if the command is run on a top-level cell. *Data_type*: string, optional
`-corner corner_number`	Specifies the corner of the partition block. *Data_type*: int, optional
`-corner_to_pin_distance`	
	Specifies that the corner to pin distance constraints should be removed. *Data_type*: bool, optional
`-depth`	Specifies the pin depth related constraints should be removed. *Data_type*: bool, optional
`-edge`	Specifies that edge-related constraints should be removed. *Data_type*: bool, optional
`-global`	Specifies to reset global constraints. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `reset_pin_constraint` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man reset_pin_constraint`
`-layer`	Specifies that the layer-related constraints should be removed. *Data_type*: bool, optional
`-location`	Specifies that the location-related constraints should be removed. *Data_type*: bool, optional

`-pins` *pin_name_list*	Specifies the name(s) of the partition pin(s). You can use wildcards (`*?`) with this parameter. *Data_type*: string, optional
`-pin_template { layer_id_or_name_list}`	
	Specifies the metal layers for the width, depth, spacing constraints at global level and cell level. *Data_type*: string, optional
`-side` *side_name*	Specifies name of the side. Valid values are { N S E W } or { L B T R } or all. *Data_type*: string, optional
`-spacing`	Specifies that the spacing-related constraints should be removed. *Data_type*: bool, optional
`-special_wire`	Specifies that the depth constraint that is honored for special wire pins by the `commit_partitions` command should be removed. *Data_type*: bool, optional
`-width` *width*	Specifies that the pin width related constraints should be removed. *Data_type*: bool, optional

Example

The following command removes the spacing- and layer-related constraints for all partition pins in the partition `sheet14`.

```
reset_pin_constraint sheet14 -pins * -layer -spacing
```

route_hierarchical_clock

```
route_hierarchical_clock
[-help]
-dir ptn_parent_dir_name
-partition_net_dir ptn_net_dir_name
[-partition ptn_net_dir_name]
```

Runs `route_global_detail` on the nets specified in the net file (`<ptn_name>.net` file) provided for each of the specified partitions, in parallel, using EDP (parallel/distributed) framework.

Note:

Before running the `route_hierarchical_clock` command if you have a requirement to set any custom preferences or callbacks (For example,VIA preferences, routing layers preference etc), or perform any other operation, a file with name *`hier_clock_route_global_detail_route.tcl`* must be created in current run directory.

The *`hier_clock_route_global_detail_route.tcl`* file must have a procedure defined like below:

```
proc ::hier_clock_route_pre_global_detail_route {ptnName} {
Puts "called ::hier_clock_route_pre_global_detail_route $ptnName"
<body: operations/settings to be written in tcl format>
. . . .
}

proc ::hier_clock_route_post_global_detail_route {ptnName} {
Puts "called ::hier_clock_route_post_global_detail_route $ptnName"
<body: operations/settings to be written in tcl format>
. . . .
}
```

For example,

```
proc ::hier_clock_route_pre_global_detail_route {ptnName} {
Puts "called ::hier_clock_route_pre_global_detail_route $ptnName"
set bot_layer 6
set top_layer 9
set_db design_bottom_routing_layer $bot_layer
set_db design_top_routing_layer $top_layer
reset_db add_route_vias_auto
reset_db add_route_vias_ndr_only
set_db add_route_vias_ndr_only true

}

proc ::hier_clock_route_post_global_detail_route {ptnName} {
Puts "called ::hier_clock_route_post_global_detail_route $ptnName"
reset_db add_route_vias_auto
reset_db add_route_vias_ndr_only

}
```

Parameters

`-dir ptn_parent_dir_name`	Specifies the directory in which partition databases are present. *Data_type*: string, required
`-help`	Outputs a brief description that includes the type and default information for each `route_hierarchical_clock` parameter. For a detailed description of the command and all of its parameters, use the man command: `man route_hierarchical_clock`
`-partition_net_dir ptn_net_dir_name`	Specifies the directory in which net file for each partition is present. The net file contains the nets to be routed. *Data_type*: string, required
`-partition ptn_net_dir_name`	Specifies the list of partition names. *Data_type*: string, optional

Example

The following command routes the nets specified in the net files (./nets/tdsp_core.txt and ./nets/controller.txt), within the ./nets partition net directory, provided for each of the specified partitions (tdsp_core and controller)

```
route_hierarchical_clock -dir ./ptns -partition_net_dir ./nets -partition {tdsp_core controller}
```

where,

- ./ptns directory contains partitions, tdsp_core and controller.
- ./nets/tdsp_core.txt contains net names: N1, N2, N3
- ./nets/controller.txt contains net names: N4, N5

The result of this command is equivalent to the following tcl code:

```
 foreach ptnName $ptnNameList {
       cd $ptnParentDir/$ptnName
       read_db . $ptnName
       # select nets specified in $ptnNetDir/$ptnName.net
       # set routeGuide, if found in $ptnNetDir/$ptnName.rgf
       # source user-defined-procs for global detail route
       if {[file exists ${current_run_dir}/hier_clock_route_global_detail_route.tcl]} {
            source ${current_run_dir}/hier_clock_route_global_detail_route.tcl
       }
       # invoke call back : pre global detail route
       if {[info procs ::hier_clock_route_pre_global_detail_route] != {}} {
           ::hier_clock_route_pre_global_detail_route $ptnName
       }

       # run global NanoRoute on the selected nets
       set_db route_design_selected_net_only true
       route_global_detail
       set_db route_design_selected_net_only false

       # invoke call back : post global detail route
       if {[info procs ::hier_clock_route_post_global_detail_route] != {}} {
           ::hier_clock_route_post_global_detail_route $ptnName
       }

       # write def file
       write_def -routing $ptnName.def.gz
       }
```

set_blackbox_master_orient

```
set_blackbox_master_orient
[-help]
black_box_cell
{r90 r180 r270 mx mx90 my my90}
new_x_origin
new_y_origin
```

Converts the orientation of the master instance blackboxes from R0 to the specified orientation.

Parameters

black_box_cell	Specifies the name of the blackbox cell. *Data_type*: string, required
-help	Outputs a brief description that includes the type and default information for each `set_blackbox_master_orient` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man` set_blackbox_master_orient
new_x_origin	Specifies the new origin x-coordinate. *Data_type*: float, required
new_y_origin	Specifies the new origin y-coordinate. *Data_type*: float, required
{r90 r180 r270 mx mx90 my my90}	
	Specifies the new orientation value of the cell. The orientation value can be r90 r180 r270 mx mx90 my my90. *Data_type*: enum, required

Examples

- The following commands converts the orientation of the master blackboxes CORE_CELL120 to r90.
  `set_blackbox_master_orient CORE_CELL120` {r90}

Related Information

- `create_blackbox`
- `convert_blackbox_to_fence`
- `convert_fence_to_black_box`
- `delete_black_boxes`
- `set_blackbox_master_to_r0`

  - Handling of Blackboxes with Non-R0 Orientation

set_blackbox_master_to_r0

```
set_blackbox_master_to_r0
[-help]
[-check_only]
[-cells cellName]
```

Converts the orientation of the master instance blackboxes to R0. Partitioning-related commands such as `assign_partition_pins`, `commit_partitions`, `assemble_design`, `flatten_partitions`, `convert_blackbox_to_fence`, and `edit_pin` work only with those blackboxes whose master instances have an R0 orientation. If the design has master blackboxes whose orientation is non-R0, you can use the `set_blackbox_master_to_r0` command to change the orientation of these master blackboxes to R0.

Note: Orientations of corresponding clone instances are also relatively transformed.

Parameters

`-check_only`	Specifies that the command will not actually convert the orientation of any master blackbox; it only displays the number of master blackboxes whose orientation would have been changed had the command been run without the `-check_only` parameter. *Default:* The orientation of master blackboxes in the design are converted to R0. *Data_type*: bool, optional
`-cells cellName`	Specifies that cell, or the list of blackbox cells, whose orientation will be converted to R0. *Default:* The orientation of all master blackboxes is converted to R0. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `set_blackbox_master_to_r0` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man set_blackbox_master_to_r0`

Examples

- The following commands converts the orientation of all master blackboxes that have a non-R0 orientation to R0.
  ```
  set_blackbox_master_to_r0
  ```
- The following commands converts the orientation of the master blackboxes CORE_CELL120 and CORE_CELL121 to R0.
  ```
  set_blackbox_master_to_r0 {CORE_CELL120 CORE_CELL121}
  ```
- The following command uses the `-check_only` parameter. The command, therefore, does not actually convert the orientation of any master blackboxes; it only returns the number of blackboxes whose orientation would have been converted to R0 had the command been run without the `-check_only` parameter.
  ```
  set_blackbox_master_to_r0 -check_only
  ```

set_clone_partition_orient

```
set_clone_partition_orient
[-help]
hinst
{r0 r90 r180 r270 mx mx90 my my90}
```

Changes the orientation of the specified partition clone.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_clone_partition_orient` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man set_clone_partition_orient`.
hinst	Specifies the name of the partition clone whose orientation has to be changed. *Data_type*: (hinst), required
`{r0 r90 r180 r270 mx mx90 my my90}`	Specifies the orientation. The orientation can be one of the following: `r0`, `r90`, `r180`, `r270`, `mx`, `mx90`, `my`, and `my90`. *Data_type*: enum, required

Example

The following command sets the orientation of the partition clone name `TDSP_ARB_C1 to r270:`

```
set_clone_partition_orient TDSP_ARB_C1 r270
```

Related Information

- `get_clone_partition_orient`

set_partition_area_io

```
set_partition_area_io
[-help]
[-add_buffer bufferName | -no_add_buffer]
[-top extension]
[-bottom extension]
[-left extension]
[-right extension]
[-selected]
[-pin_on_boundary]
```

Specifies the name of the buffer to be used for feedthrough insertion in a flip chip design. Use this command before partitioning the flip chip design.

Parameters

-add_buffer *bufferName*	
	Specifies either the name of the buffer, or that there are no buffers to be inserted. *Default*: `-no_add_buffer` *Data_type*: string, optional
`-bottom` *extension*	Specifies how far, in microns, to expand the Area I/O cell box in the bottom direction when determining the size of the placement and routing obstructions to be pushed down. *Data_type*: int, optional
`-help`	Outputs a brief description that includes the type and default information for each `set_partition_area_io` parameter.For a detailed description of the command and all of its parameters, use the `man` command: `man set_partition_area_io`
`-left` *extension*	Specifies how far, in microns, to expand the Area I/O cell box in the left direction when determining the size of the placement and routing obstructions to be pushed down. *Data_type*: int, optional
`-no_add_buffer`	Specifies that no buffers are to be inserted. *Data_type*: bool, optional
`-pin_on_boundary`	Specifies the internal pin created to be placed at the intersection of the hole punch (placement obstruction) and the space reserved for the partition. If it is not specified, the default is that the internal pin is placed directly on top of the area I/O cell. *Data_type*: bool, optional
`-right` *extension*	Specifies how far, in microns, to expand the Area I/O cell box in the right direction when determining the size of the placement and routing obstructions to be pushed down. *Data_type*: int, optional
`-selected`	Specifies hole punches for all currently selected cells that overlap partitions if they are Area I/O cells. If you do not specify this parameter, the command specifies hole punches for all Area I/O cells that overlap partitions. *Data_type*: bool, optional
`-top` *extension*	Specifies how far, in microns, to expand the Area I/O cell box in the top direction when determining the size of the placement and routing obstructions to be pushed down. *Data_type*: int, optional

Related Information

- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

set_partition_pin_status

```
set_partition_pin_status
[-help]
[-selected_pin_status {fixed | placed | cover}]
[-pins {pinName | pinNameList}]
[-status {fixed | placed | unplaced | cover}]
{[-pins {pinName | pinNameList}
  -status {fixed | placed | unplaced | cover}
 [-partition partitionName]] }
```

Sets the pin status for a pin of a partition as fixed, placed, cover, or unplaced. The `set_partition_pin_status` command operates, like a lot of other pin commands, on the top cell in addition to on partitions. If the top cell name is specified, or if `set_partition_pin_status` receives a "*" as its first argument, the IO pin status is modified. You can use this command any time after assigning pins.

Note:

- Use this command to unassign blackbox pins before the blackbox is committed. To unassign blackbox pins after the blackbox is committed, use the `flatten_partitions` command instead.
- If this command is run on a blackbox that has one or more pins with a single LEF port but with multiple shapes within the LEF port, the command will remove these multiple shapes and create a single shape. If this command is run on a blackbox that has one or more pins with multiple LEF ports, the first LEF port will be processed as per the command and the remaining LEF ports will remain unchanged.

Parameters

`-partition` *partitionName*	Specifies the name of the partition. You can use wildcards (*?) with this parameter. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `set_partition_pin_status` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_partition_pin_status`.
`-pins` *pinName* | *pinNameList*	
	Specifies the name of the pin(s) of the partition. You can use wildcards (*?) with this parameter. *Data_type*: string, optional
`-selected_pin_status {fixed | placed | cover}`	
	Selects pins with only specified status. This options enables the `set_partition_pin_status` command to change the status of selected pins based on their present status and not just the names. • `fixed`: Selects pins with fixed status. • `placed`: Selects pins with placed status. • `cover`: Selects pins with cover status. *Data_type*: enum, optional
`-status {fixed | placed | unplaced | cover}`	
	Specifies the status of the pin. • `fixed`: Fixed pin status specifies the pin's location, orientation, and that it's location cannot be moved by automatic tools, but can be moved by interactive commands. **Note**: Fixed pins can be moved by automatic pin assignment commands by using the `-moveFixed` parameter. • `placed`: Placed pin status specifies the pin's location, orientation, and that it's location is fixed, but can be moved during automatic layout. • `unplaced`: Unplaced pin status specifies that the pin does not have a location. • `cover`: Cover pin status specifies the pin's location, orientation, and that it is a part of the cover macro. A cover pin cannot be moved by automatic tools or by interactive commands. *Data_type*: enum, optional

Example

The following command marks all partition pins to fixed:

```
set_partition_pin_status -partition * -pins * -status fixed
```

- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

set_partition_pin_use

```
set_partition_pin_use
[-help]
{design | partition}
pin
pin_use
```

Allows you to change the `USE` property of a partition pin.

Note: A partition pin can also be an I/O pin if the partition is a top-level cell.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `set_partition_pin_use` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man setPtnPinUse`
{design | partition}	Specifies the name of the partition, blackbox or top-level cell name. *Data_type*: string, required
pin	Specifies the pin name. *Data_type*: string, required
pin_use	The choices represent `USE` properties, SIGNAL | CLOCK | ANALOG, that you can change with this command. *Data_type*: string, required

Example

- The following command sets the `USE` property of pin `A` in partition `PTN1` to `CLOCK`:
  ```
  set_partition_pin_use PTN1 A CLOCK
  ```
- The following command sets the USE property for pin scan_clk to CLOCK:

  Original DEF:
  ```
  - scan_clk + NET scan_clk + DIRECTION INPUT + USE SIGNAL ;
  ```

  Run set_partition_pin_use to change USE to CLOCK:
  ```
  set_partition_pin_use [dbGet top.name] scan_clk CLOCK
  ```

  DEF after change:
  ```
  - scan_clk + NET scan_clk + DIRECTION INPUT + USE CLOCK ;
  ```

[-spacing spacing [-area {x1 y1 x2 y2}] [-side side_names]]}
[-depth depth [-special_wire ]]
```

Sets the constraints for partition pins or an I/O pins. You can use this command before assigning pins. The constraints can be applied on three different levels:

- Global pin constraint
- Cell specific pin constraint
- Pin specific constraint

If no pin specific constraints exist, then the cell level constraints are applied. If cell specific pin constraints are not defined, then global constraints are applied.

Note: To retrieve the pin constraints specified using the `set_pin_constraint` command, use the `get_pin_constraint` command. To remove the constraints for a partition pin, use the `reset_pin_constraint` command.

Parameters

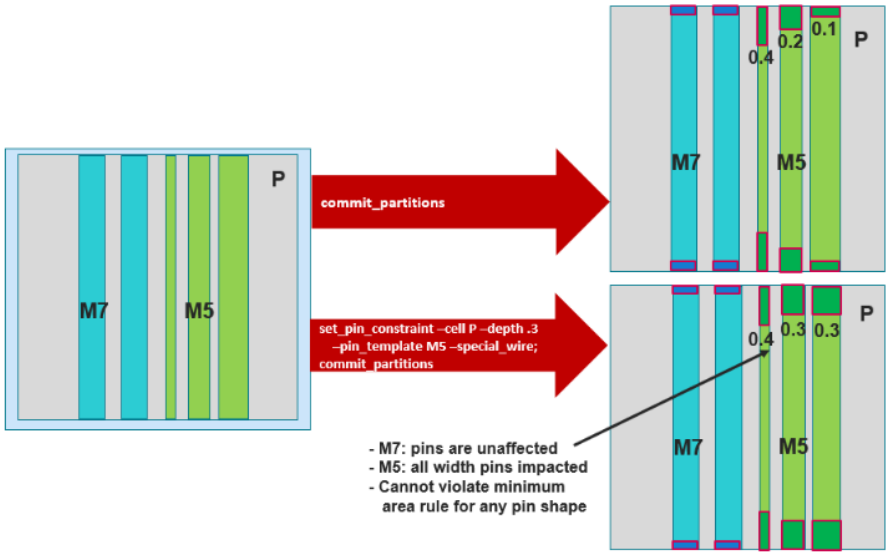
`-area {x1 y1 x2 y2}`	Specifies an area overlapping with partition where spacing constraint. *Data_type*: rect, optional
`-cell cell_name`	Specifies the name of the module. The module name is not required if the command is run on a top-level module. You can use wildcards (*?) with this parameter. *Data_type*: string, optional
`-corner corner_number`	
	Specifies the corner of the partition block. *Data_type*: int, optional
`-corner_to_pin_distance pin_distance`	
	Specifies the corner to pin distance in tracks. *Data_type*: int, optional
`-depth depth`	Specifies the pin depth in microns. *Data_type*: float, optional
`-edge edge_numbers`	Specifies the integer value where edge numbering starts from lower-left corner of a partition clock-wise. Edge `0` is the edge that has the smallest y value.  You can set multiple sides in the `-edge` option. This allows you to set multiple sides in a rectilinear design. *Data_type*: string, optional

`-global`	Specifies that the global constraints for spacing, width, and depth to be honored. **Note:** If no pin specific constraints exist, then the cell level constraints are applied. If cell specific pin constraints are not defined, then global constraints are applied. For example, the following command specifies that the global constraints are to be honored. `set_pin_constraint -global -spacing 2 -width 2 -pin_template { 2 3 4 }` *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `set_pin_constraint` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man set_pin_constraint`
`-layer {`*layerId* | *layerIdList*`}`	
	Specifies the metal layers for the partition pin. If you specify multiple layers, separate the layer names with a space. In this case, the command will constrain the pin to one of the specified layers. **Notes:** • This parameter does not restrict the pin to a location on the layer. If you want to restrict a pin on a particular location on a particular layer, use the `-location` parameter instead. • The `-layer` parameter cannot be used with the `-location` parameter. • The `-layer` parameter cannot be used with the `-spacing` parameter. • Layers can be specified using the LEF layer names or layer ID numbers. *Data_type*: string, optional
`-location {`*x y z*`}`	Specifies the x and y locations and z layer ID number of the partition pin. The x and locations are calculated with respect to the distance in microns from the lower left corner of the module. The layer number specified should be a preferred layer. Otherwise, the command will move the pin to a preferred layer. For example, `-location {10 12 7}` specifies that the pin should be constrained to a location 10 microns on the x axis and 12 microns on the y axis from the lower left corner of the partition on layer `Metal7`. **Notes:** • If the pin location as per the specified x and y locations is not on a track, the pin is snapped to the nearest track on the specified layer. • If you specify this parameter, the assigned pins have a *Placed* status. • The `-location` parameter cannot be used with the `-layer` parameter. *Data_type*: string, optional
`-match_route_early_global`	When specified, it changes the pin constraints to make them compliant with `route_early_global` and does the following for every partition: • Allows all layers from `design_top_routing_layer` to `design_bottom_routing_layer`. • Sets pin spacing as 1 **Note:** The changes in pin constraints impact the output of the pin assignment commands - `assign_partition_pins`, `assign_io_pins`, and `edit_pin`. *Data_type*: bool, optional
`-pins` *pin_name_list*	Specifies the name(s) of the partition pin(s). You can use wildcards (`*?`) with this parameter. *Data_type*: string, optional
`-pin_template {`*layer_id_or_name_list*`}`	
	Specifies the metal layers for the width, depth and spacing constraints at global level and cell level *Data_type*: string, optional
`-side` *side_name*	Specifies name of the side. Valid values are { N S E W } or { L B T R } or all. *Data_type*: string, optional

`-spacing min_space`	Specifies the minimum spacing between pins in pin pitch value, that is, the distance between tracks. For example, if you specify a value of `2`, the minimum pin spacing will be equal to the distance between track 1 and track 3.  *Data_type*: int, optional
`-special_wire`	Specifies the depth constraint to be set and honored for special wire pins. When `-special_wire` parameter is specified with the `-depth`, `-cell` and `-pin_template` parameters, it enables the depth on desired layers of specified cells to be honored for special wire pins by the `commit_partitions` command. *Data_type*: bool, optional
`-use_min_width_as_depth`	Minimum width should be used as the pin depth. *Data_type*: bool, optional
`-width width`	Specifies the pin width in microns. *Data_type*: float, optional

Example

- The following command specifies a width of 10 micrometers for all partition pins in the partition `sheet14`. These pins will be placed either on layer 2 or on layer 4.
  ```
  set_pin_constraint -cell sheet14 -pins * -layer {Metal2 Metal4}
  ```
- The following commands set the pin width and depth of layer `Metal2` for partition cell `ALU` to 0.4 and 0.6 respectively.
  ```
  set_pin_constraint -cell ALU -layer Metal2 -width 0.4
  set_pin_constraint -cell ALU -layer Metal2 -depth 0.6
  ```
- The following commands set the pin width of pin pGroup1 to 0.3 and pin depth of pin pGroup1 to default.
  ```
  set_pin_constraint -cell ALU -pins pGroup1 -width 0.3
  set_pin_constraint -cell ALU -pins pGroup1 -depth default
  ```
  With this example, all the pins of pGroup1 will have the width 0.3 and the default depth.
- The following commands set the minimum pin spacing for top and bottom edge of partition cell ALU to 1 track.
  ```
  set_pin_constraint -cell ALU -edge T -spacing 1
  set_pin_constraint -cell ALU -edge B -spacing 1
  ```
- The following command sets minimum pin spacing for all edges of partition cell TDSP to 3 tracks
  ```
  set_pin_constraint -cell TDSP -all -spacing 3
  ```
- The following command sets the sides, T and B, of layer 3 and 5 of partition cell ptn4
  ```
  set_pin_constraint -cell ptn4 -layer {3 5} -side {T B}
  ```
- The following command sets the edges, 2 and 0, of partition cell ptn4
  ```
  set_pin_constraint -cell ptn4 -pins * -edge {2 0}
  ```
- The following commands sets the pin depth of layer `M5` for partition cell `P` to 0.3 using the `-special_wire` parameter so that it is honored only by the `commit_partitions` command.
  ```
  set_pin_constraint-cell P -depth .3 -pin_template M5 -special_wire;
  commit_partitions
  ```



Related Information

set_promoted_macro_pin

```
set_promoted_macro_pin
[-help]
{-reset  | -report_only_file filename.tcl |
 {[-insts {inst_name | inst_name_list}]
  [-pins {pin_name | pin_name_list}]
  [-layers {layer_id | layer_id_list}]
  [-override ]
  [-abutted_to_boundary_only]}}
```

Selects or marks signal and/or PG pin shapes to be promoted later on. You can use this command before assigning pins.

Note: The `set_promoted_macro_pin` command should be called after specifying the maximum and minimum metal layer names for promoting macro pins using the `assign_pins_promoted_macro_max_layer` and `assign_pins_promoted_macro_min_layer` attributes, respectively.

Parameters

`-abutted_to_boundary_only`	Specifies that all macro pin shapes that are abutted to the partition boundary will be selected for promotion. The `-pins` parameter can also be used to select abutted pins. **Note:** You can use the `assign_pins_max_channel_width_as_abutted` attribute to enable thin channels in the design to be considered as abutted partitions in the pin assignment flow. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `set_promoted_macro_pin` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_promoted_macro_pin`
`-insts {inst_name | inst_name_list}`	
	Specifies the name of instances. You can also use wildcard (* or ?) for specifying the instance names. This parameter is optional. If `-insts` is not specified, all BLOCK, PAD, and AREAIO macros are selected. This is similar to specifying `-insts *` *Data_type*: string, optional
`-layers {layer_id | layer_id_list}`	
	Specifies the metal layer(s) of the macro pins. This parameter is optional. If `-layers` is not specified, all pin layers specified between the `assign_pins_promoted_macro_max_layer` and the `assign_pins_promoted_macro_min_layer` attributes range are selected. *Data_type*: string, optional
`-override`	Specifies to override specific option(s) where previous settings of these options will be removed and be replaced by new specified value(s). **Note:** All `set_promoted_macro_pin` commands are incremental with no conflict resolution, unless the `-override` option is used. *Data_type*: bool, optional
`-pins {pin_name | pin_name_list}`	Specifies the name of macro pins. You can also use wildcard (* or ?) for specifying the pin names. This parameter is optional. If `-insts` is not specified, all signal and P/G pins are selected. This is similar to specifying `-pins *` *Data_type*: string, optional
`-report_only_file filename.tcl`	Writes out all `set_promoted_macro_pin` settings in memory into an output TCL file. *Data_type*: string, optional
`-reset`	Resets all or specified promoted pin selections. *Data_type*: bool, optional

Examples

- The following command promotes the top most layer pins of selected macros

```
set_db assign_pins_promoted_macro_min_layer 4
set_db assign_pins_promoted_macro_max_layer 8
set_promoted_macro_pin -reset
set_promoted_macro_pin -insts {A B} -pins * -layers {7 8}
set_promoted_macro_pin -insts B -pins X -layers 8 -override
set_promoted_macro_pin -insts C -layers 5 -abutted_to_boundary_only
set_promoted_macro_pin -insts C -layers {8}
set_promoted_macro_pin -insts C -pins D[*] -layers {} -override
set_promoted_macro_pin -insts D -pins OUT
set_promoted_macro_pin -insts D -pins CLK -abutted_to_boundary_only
assign_io_pins
```

	A/CLK	A/VDD	B/X	B/VSS	C/D[*]	C/GND	D/CLK	D/OUT
M8	v	v	v	v	x	v		v
M7	v	v	x	v	x	x	v	v
M6		x	x	x		x	x	
M5		x		x	x	x		
M4				x		x

undo_uniquify_partition

```
undo_uniquify_partition
[-help]
-hinst hierarchical_instance_name
[-preserve_routes]
```

Brings back the recursion of cells in a netlist and restores the master and clone association.

Note: The `uniquify_partition` command is used to remove the master and clone association by uniquifying the netlist.

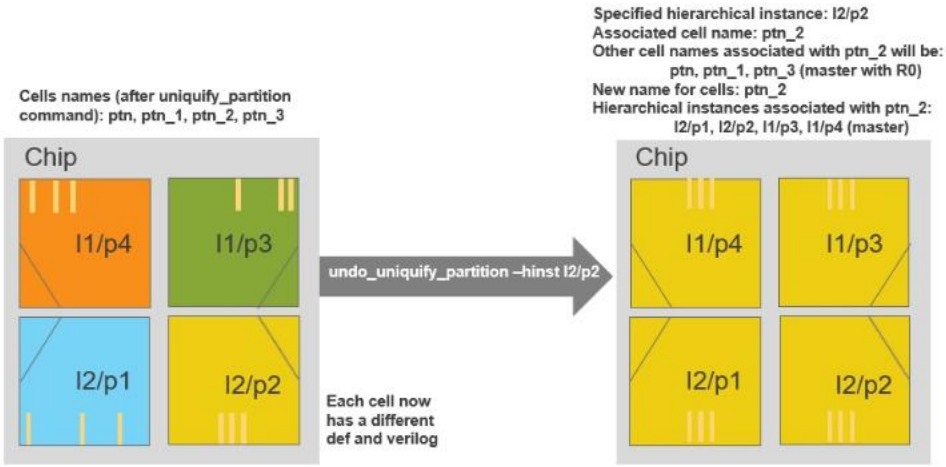
Parameters

`-help`	Outputs a brief description that includes the type and default information for each `undo_uniquify_partition` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man undo_uniquify_partition`
`-hinst hierarchical_instance_name`	Specifies name of the hierarchical instance that is used to bring back the recursion of cells in a netlist and restore the master and clone association. Based of the selected hierarchical instance, its cell (module) is identified. All other occurrences of the identified cell with the same naming format (`cellname_<number>`) are then renamed to the identified cell name. That means all instances will have the same cell name and definition again, thereby restoring the master and clone relationship. **Note:** • You can specify any hierarchical instance with the `undo_uniquify_partition` command. • Any hierarchical instance with R0 orientation can become a master. • The name of the cells will change to the name of the cell of the specified hierarchical instance. • The netlist and def of the cell of the hierarchical instance name specified with the `undo_uniquify_partition` command will be copied in all hierarchical instances. *Data_type*: string, optional
`-preserve_routes`	Preserves the routes during `undo_uniquify_partition`. *Data_type*: bool, optional

Example

The following command brings back the master and clone association for the cell name associated with `I2/p2`:

```
undo_uniquify_partition -hinst I2/p2
```



Related Information

- uniquify_partition
- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

uniquify_partition

```
uniquify_partition
[-help]
-hinst hierarchical_instance_name
```

Removes the master and clone association by uniquifying the cells (module) in the netlist.

Note: You can use the `undo_uniquify_partition` command to remove the uniquification and bring back the master and clone association.

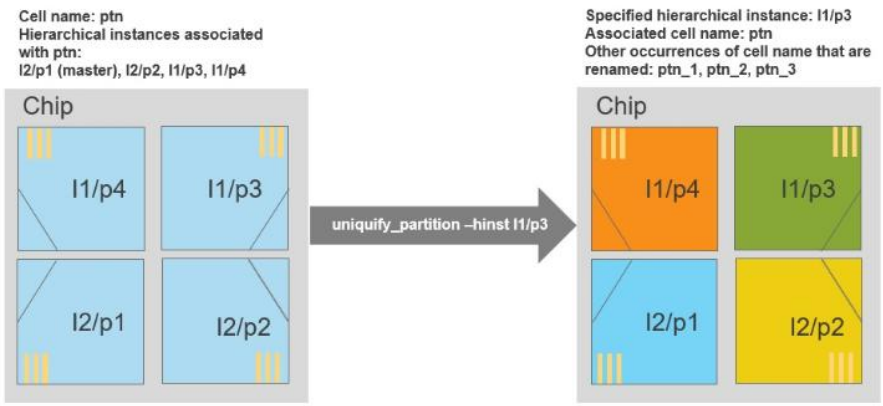
Parameters

`-help`	Outputs a brief description that includes the type and default information for each `uniquify_partition` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man uniquify_partition`
`-hinst hierarchical_instance_name`	Specifies the name of the hierarchical instance to uniquify. Based of the specified hierarchical instance, its cell (module) is identified. All other occurrences of the identified cell are renamed by adding the `_<number>` suffix (for example `cellname_<number>`) in order to uniquify the cell. **Note:** • You can specify any hierarchical instance with the `uniquify_partition` command. It does not necessarily have to be a master. • The `uniquify_partition` command preserves the orientation of the hierarchical instances. • The `uniquify_partition` command preserves the pin location of the hierarchical instances. • A new cell name is created for each hierarchical instance. *Data_type*: string, required

Example

The following command identifies the cell associated with `I1/p3` and then renames all other occurrences of the cell in order to remove the master and clone association.

```
uniquify_partition -hinst I1/p3
```



Related Information

- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

update_net_group

```
update_net_group
[-help]
-name
-add_nets {netName | netNameList}
```

Adds a net to specified net group that was created with the `create_net_group` command. A net can be a single net, bus name, or segment of a bus. You can use this command after defining a net group.

Note: If a net is a part of a net group, the net cannot belong to any other net group.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `update_net_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man update_net_group`
`-name`	Specifies the name of the created net group. *Data_type*: string, required
`-add_nets {`*`netName	netNameList`*`}`	
	Specifies the name of an individual net, bus, or segment of a bus. You can use wildcards (*?) with this parameter. *Data_type*: string, required

Examples

- The following command adds net ENOUT to net group bundle1:
  ```
  update_net_group bundle1 -add_nets ENOUT
  ```
- The following command adds the entire bus cpua to net group bundle2:
  ```
  update_net_group bundle2 -add_nets cpua
  ```
- The following command adds only bus segments 2 through 10 to net group bundle1:
  ```
  update_net_group bundle1 -add_nets cpua[2:10]
  ```

update_partition_cell_obs

```
update_partition_cell_obs
[-help]
[partition_name]
[-no_pin_cut_space | -has_pin_cut_space]
[-no_via_cut_space | -has_via_cut_space]
```

Recreates cell blockage for a specified partition, or all partitions. This reflects incremental changes, such as pin movement. You can use this command after editing the pin in a partition with the Pin Editor, or using the `edit_pin` command, to move pins in the partition.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `update_partition_cell_obs` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man update_partition_cell_obs`
partition_name	Specifies the partition to recreate the cell blockage. *Default*: All partitions *Data_type*: string, optional
`-no_pin_cut_space`	Specifies that no cut space will be created for pins in the partition cell blockage. **Note:** Blockages are always cut for power pins. *Data_type*: bool, optional
`-has_pin_cut_space`	Specifies that cut space will be created for pins in the partition cell blockage. **Note:** This is the default. *Data_type*: bool, optional
`-no_via_cut_space`	Specifies that no cut space will be created for vias in the partition cell blockage. *Data_type*: bool, optional
`-has_via_cut_space`	Specifies that cut space will be created for vias in the partition cell blockage. **Note:** This is the default. *Data_type*: bool, optional

Example

The following command recreates pin blockages for partition `EUG`:

```
update_partition_cell_obs EUG
```

Related Information

- `edit_pin`
- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

update_partition_cut

```
update_partition_cut
[-help]
[-partition string]
-cut_area x1 y1 x2 y2
```

Creates a partition rectangular cut from a partition. This object can be created after specifying a module guide to be a partition. Rectangular cuts can only occur on the edge of the partition guide. You can use this command after specifying partition.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `update_partition_cut` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man update_partition_cut`
`-cut_area x1 y1 x2 y2`	Specifies the coordinates of the cut area (*x1 y1 x2 y2*). *Data_type*: rect, required
`-partition string`	Specifies a partition to create a partition cut. If this option is not selected, the command loops through all the partitions an attempts to find the overlapped partition, then creates a partition cut for that partition. *Data_type*: string, optional

Example

The following command creates a partition cut area to modify a rectangular partition:

```
update_partition_cut 2353.8000 7123.000 2653.8000 8298.2000
```

Related Information

- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

update_pin_group

```
update_pin_group
[-help]
[-partition cellName]
-pin_group pinGroupName
-pins {pinName | pinNameList}
```

Adds a module port to specified pin group that was created by `create_pin_group` command. You can use this command after defining a net group.

Note: You can use this command for the top-level also.

Parameters

`-partition cellName`	Specifies the name of a module. This parameter is not required for top-level ports. *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `update_pin_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man update_pin_group`
`-pin_group pinGroupName`	
	Specifies the name of the created pin group. *Data_type*: string, required
`-pins {pinName | pinNameList}`	
	Specifies the name of a module port. You can specify wildcards (*?) with this parameter. *Data_type*: string, required

Example

- The following command adds the module SH17's port RASN to pin group pin17:
  ```
  update_pin_group -partition SH17 -pin_group pin17 -pins RASN
  ```
- The following command adds the top-level port ADDER to pin group PIN_GRP_TOP
  ```
  update_pin_group -pin_group PIN_GRP_TOP -pins ADDER
  ```

Related Information

write_black_box_lef

```
write_black_box_lef
[-help]
{-insts instName | -all}
[lef_file]
```

Creates a blackbox LEF file containing the pin definitions and obstructions.

Note: The `write_partitions` command also automatically saves this file, among others.

Parameters

`-all`	Specifies all blackbox instances. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `write_black_box_lef` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_black_box_lef`
`-insts instName`	Specifies the name of the blackbox instance. You can use wildcards (`*?`) with this parameter. *Data_type*: string, optional
lef_file	Specifies the LEF filename. If you do not specify a name, the default is *cellTypeName*`.lef`. *Data_type*: string, optional

Example

The following command creates a LEF file containing the pin definitions and obstructions for all blackbox instances that start with the letter `A` to a LEF file named `BBox.lef`:

```
write_black_box_lef A* lef_file BBox.lef
```

Related Information

- `write_partitions`
- `create_blackbox`

write_generalized_feedthru_paths

```
write_generalized_feedthru_paths
[-help]
[-dont_generalize_reverse_paths]
[-dont_generalize_sub_paths]
[-topological_out_file file_name]
-use_topological_file file_name
```

Automatically derives feedthrough topological paths from the user specified paths to cover all the chain connectivity probabilities in a master and clone hinst scenario. It reads an input topological file, in version 0.5 and creates the version 2.0 topological file.

Note: For the given set of master-clone hinst connectivity, based on floorplan, multiple user defined paths may be required for other same set hinst master and clones. The `write_generalized_feedthru_paths` command can automatically choose correct path for individual master and clone hinst, based on matching connectivity and floorplan, from the set of paths provided by the user.

Parameters

`-dont_generalize_reverse_paths`	
	When enabled, the generalization algorithm does not generalize reverse chain paths. *Data_type*: bool, optional
`-dont_generalize_sub_paths`	
	When enabled, the generalization algorithm does not generalize sub-paths. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes the type and default information for each `write_generalized_feedthru_paths` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_generalized_feedthru_paths`
`-topological_out_file file_name`	
	Specifies the name of the output topo 2.0 file that contains all paths for all master and clone chain. **Note:** This file should be used as an input file for the `add_partition_feedthrus` command. *Default:* path.topo *Data_type*: string, optional
`-use_topological_file file_name`	
	Specifies the user specified feedthrough path guidance file. The input topological file with new version 0.5 format contains a path for one master and clone chain/tree to derive path of all master and clone chains. **Note:** You can use the *Path Guidance GUI* form (*Partition - Feedthough Ports - Path Guidance)* to generate the topological file with new version 0.5 format. *Data_type*: string, required

Example

- The following command reads the topology file “a.topo” in version 0.5 and creates the version 2.0 topological file “path.topo”:

  ```
  write_generalized_feedthru_paths  -use_topological_file a.topo
  ```

- The following command reads the topological file “a.topo” in version 0.5 and creates the version 2.0 topological file “new.topo”:

  ```
  write_generalized_feedthru_paths  -use_topological_file a.topo -topological_out_file new.topo
  ```

Related Information

- `add_partition_feedthrus`
- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

write_net_groups_topo

```
write_net_groups_topo
[-help]
```

Creates a topological file (used by the `add_partition_feedthrus` command) for nets of the net group associated with a bus guide. The topology of nets for feedthrough is derived from the shape of the bus guide. All the partitions that the bus guide shape overlaps with, become a node in the topological path.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_net_groups_topo` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_net_groups_topo`

Example

- The following command writes the net group information to a topology file.
  ```
  write_net_groups_topo
  ```

Related Information

- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*

write_partition_pins

```
write_partition_pins
[-help]
{-partition partition_name | -all | -design| -selected}
out_file
```

Saves the pin assignment information for one or more partitions. You can subsequently load the saved pin assignment information with the `read_partition_pins` command. The `write_partition_pins` command also saves the pin assignment information for blackboxes.

Parameters

`-all`	Specifies that pin assignment information will be saved for all partitions, including the top-level design. *Default*: By default, the `write_partition_pins` command saves the pin assignment information for all partitions. *Data_type*: bool, optional
`-design`	Specifies that pin assignment information will be saved only for the top-level design. *Data_type*: bool, optional
`out_file`	Specifies the name of the file in which the partition pin assignment information will be saved. *Data_type*: string, required
`-help`	Outputs a brief description that includes the type and default information for each `write_partition_pins` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man write_partition_pins`
`-partition` *`partition_name`*	Specifies the name of the partition for which the pin assignment information is to be saved. *Data_type*: string, optional
`-selected`	Specifies that the pin assignment information will be saved for all the selected pins of the partitions, including the top-level design. *Data_type*: bool, optional

Example

The following command saves the pin assignment information for the partition named `tdsp_block` into a file named `tdsp_block_pin_info`.

```
write_partition_pins -partition tdsp_block tdsp_block_pin_info
```

Related Information

- `assign_partition_pins`
- `read_partition_pins`
- `reset_partition_pins`
- Partitioning the Design chapter in the *Innovus Stylus Common UI User Guide*
  - Saving the Partition Pins

write_partitions

```
write_partitions
[-help]
[partitions {list}]
[-floorplan_only]
[-no_std_cells]
[-no_trial_route]
[-verilog]
[-dir dirName]
[-module_model_tag tag_name]
[{[-no_floorplan | {[-no_netlist] [-def_unplaced]}]
[-def [-def_unplaced]]
[-def_no_cut_row]
[-top_level_no_partition_module]
{{[-partition_lib ptnLibName] [-partition_view ptnViewName] [-top_view topViewName]}}]]
```

Saves the partition information to the current directory or a specified directory. This command is run after running the `commit_partitions` command to generate timing budget files and stamp model files.

Notes:

- The `write_partitions` command does not write GNC rules in the partition floorplan file for multiple-supply voltage (MSV) designs.The Common Power Format (CPF) file contains this information.
- The `write_partitions` command supports partitions with flexmodels. If there are flexmodels at the top-level, then the saved top-level netlist contains flexmodels. If there are no flexmodels outside partitions, then the top-level netlist will be the original full netlist. Similarly, if a partition has flexmodels, then its partition netlist will contain flexmodes.
- The `write_partitions` command saves the design information to the global init_* variables in the *.global file.
- The `write_partitions` command supports multi-threading. This reduces the run time for huge designs by saving individual blocks in parallel.
- The `write_partitions` command saves mmmc data without timing information for partitions for which timing budgets are not derived.
- The `write_partitions` command automatically saves all the bus guide constraints with associated net groups. This enables bus routing at block level as per chip level constraints.
- The `write_partitions` command automatically saves all the cell padding information to each partition block data. This information is saved in partitioned block .fp file.
- The `write_partitions` command inherits all the attributes assigned to a net for block implementation flow. Preserving these attributes allows the Early Global Router and the NanoRoute Router to route the nets following specific requirements.
- The `write_partitions` command writes out a DEF file for each block with its scan information in the `<partition_name>.scandef.gz` format.
- The `write_partitions` command saves an additional file in each parent directory in the `<design_name>.pg.gz` format to support for PG-file in hierarchical flow. The `assemble_design` command loads this file when it is run with the `-fe` mode.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `write_partitions` parameter. For a detailed description of the command and all of its parameters, use the man command: `man write_partitions`
`-def`	Writes out the DEF format files for the design. *Data_type*: bool, optional
`-def_no_cut_row`	Specifies that, when row information is written to the DEF file, the rows are not cut against placement obstructions, block halos, or power domain fence minimum gaps. *Data_type*: bool, optional
`-dir dirName`	The directory name that will contain the partition information/files. *Data_type*: string, optional

`-floorplan_only`	Writes out incremental floorplan by pushing down floorplan changes from a full chip level design to a partition block. This option allows you to run `write_partitions` for a uncommitted partition without running the `partition` command. For committed partitions, `write_partitions -floorplan_only` reports an error. The `write_partitions -floorplan_only -dir` command honors blackboxes and saves limited floorplan information for blackboxes in the previously saved data created by the `write_partitions -dir` command. **Note:** After `write_partitions -floorplan_only` command, a non-committed partition still remains uncommitted. *Data_type*: bool, optional
`-def_unplaced`	When used with the `-def` parameter, specifies that the unplaced standard cells should also be saved to the DEF file. This is equivalent to the `-unplaced` parameter of the `write_def` command. When used with the `-pdef` parameter, specifies that the placed standard cells should also be saved to the PDEF file. *Data_type*: bool, optional
`-module_model_tag` *tag_name*	Specifies the module model tag to be used for saving the partition. This creates pnr and lef module models for each partition block. For top-level design, this also creates a pnr module model. This parameter is part of the iHDB flow. Before using this parameter, you must set the default central directory name (`set_module_model -default_dir` *default_model_data_directory*) where the module models data will be saved/loaded. **Note:** These block-level and top-level pnr models should be used for implementing the block-level and top-level designs, respectively. For example, if design dtmf has the ptn_wrapper partition and the default global data directory is /myproject/DATA. With `write_partitions -module_model_tag init,` a pnr model will be created for top-level design in the following directory: `myproject/DATA/dtmf/init/pnr`. For partition ptn_wrapper, a pnr and lef models will be created in the `/myproject/DATA/ptn_wrapper/init/pnr` and `/myproject/DATA/ptn_wrapper/init/lef` directories. *Data_type*: string, optional
`-no_floorplan`	Saves partitions without generating a floorplan file for the partitioned design. *Data_type*: bool, optional
`-no_netlist`	Saves partitions without generating a netlist file for the partitioned design. *Data_type*: bool, optional
`-no_std_cells`	When you specify this option, standard cells are not written in the DEF file. *Data_type*: bool, optional
`-no_trial_route`	When you specify this option, trial routed wires are not written in the DEF file. *Data_type*: bool, optional
partitions {*list*}	Specifies the names of each partition to be saved. *Data_type*: string, optional
`-partition_lib` *ptnLibName*	Specifies an OpenAccess database library directory where the top-level design and the block-level design for all the partitions will be saved. This parameter is used when saving the partition into an OpenAccess database. **Note:** For OpenAccess data, you can save the specified partitions using the *partitions* parameter. However, if the specified partition is a top-level design then all committed partitions must be saved just like no partition names are specified to avoid unbound references in OpenAccess. *Data_type*: string, optional
`-partition_view` *ptnViewName*	

	Specifies the view name for the top and the partition views. This parameter is used when saving the partition into an OpenAccess database. *Default:* The default value of the view is layout **Note:** • If `-partition_view` is specified, but not `-partition_lib`, then the current design lib is used. You do not have to use the `write_partitions` command to create a special library to hold the partition data. You can create the partition data into the same design library that holds the full-flat version of the design. In this case, cell views will be overwritten if they already exist. • If `-partition_view` is specified, but not `-top_view`, then all cell views created with the `write_partitions` command will have the *`ptnViewName`* appended to the top cell's cellview. In order to prevent overwriting the top cell's cellview if the name already exists, use the `-top_view` option to specify a different view name than the one used for the rest of the partitions being created by the `write_partitions` command. • If `-dir` is specified, but `-partition_view` is not, then the `write_partitions` command would be in the non-OA mode. If `-dir` and `-partition_view` are specified then the `dir` is created, but instead of putting design data into it, only the `cds.lib` is added to the directories created. *Data_type*: string, optional
`-top_level_no_partition_module`	Suppresses stub verilog modules for partitions in the top-level partition netlist. *Data_type*: bool, optional
`-top_view` *`topViewName`*	Specifies view name for top design. *Data_type*: string, optional
`-verilog`	Writes out an ASCII Verilog file to the saved partition directory. The netlist is always stored as a binary file, so this Verilog file is not used by `read_db`. It is sometimes useful to save the Verilog in addition to the other saved files to make it possible to send the Verilog directly to other tools, or to open it in an editor for debugging. *Data_type*: bool, optional

Example

- The following command saves the partition information/files in a directory `try3` hierarchically for each of the three partitions:
  ```
  write_partitions -dir try3 TOPCHIP_SP sheet17 sheet25 sheet7
  ```
- The following command saves the partition information/files in the OpenAccess database format. The information for the top and the block level designs (all blocks) will be written in the `libForOA` directory view with the name `ptnView1`. It saves partitions without generating a floorplan file or a net list for the partitioned design. It also does not write the standard cells or trialRoute wires in the DEF file.
  ```
  write_partitions -partition_lib libForOA -partition_view ptnView1 -no_floorplan -no_netlist -no_std_cells -no_trialroute
  ```

add_decomp_filler

```
add_decomp_filler
[-help]
-bottom_edge_endcap {cell_name}
-core_column_cell {cell_name}
-core_row_cell {cell_name_list}
[-offset_x offset_in_microns]
[-offset_y offset_in_microns]
[-power_domain power_domain_name]
[-prefix prefix_name]
-step_x step_in_microns
-step_y step_in_microns
-top_edge_endcap {cell_name}
-vertical_edge_endcap {cell_name}
```

Inserts breaker cells to divide the chip into several small parts. This reduces the run time of coloring while manufacturing the chip.

This command is run after `create_floorplan` and before `add_endcaps`.

Parameters

`-bottom_edge_endcap {cell_name}`	Specifies the CA-break end cap cell for rows, to make bottom_edge of endcap face core. *Data_type*: string, required
`-core_column_cell {cell_name}`	Specifies the CA-break filler cell for inserting into columns. *Data_type*: string, required
`-core_row_cell {cell_name_list}`	Specifies a list of CA-break filler cells inserted horizontally in the core rows. *Data_type*: string, required
`-help`	Outputs a brief description that includes type and default information for each `add_decomp_filler` parameter. For a detailed description of the command and all of its parameters, use the man command: `man add_decomp_filler`.

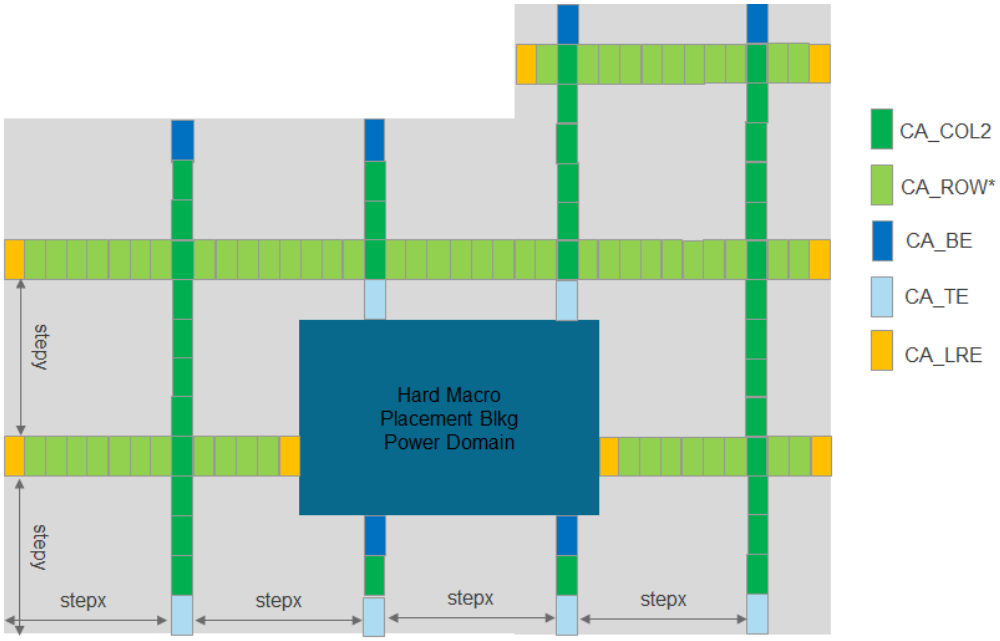
`-offset_x` *offset_in_microns*	Specifies the offset added to the first step in the horizontal direction. *Data_type*: float, required
`-offset_y` *offset_in_microns*	Specifies the offset added to the first step in the vertical direction. *Data_type*: float, required
`-power_domain` *power_domain_name*	Specifies the power domain for which CA-break filler cells are to be inserted. *Data_type*: string, optional **Note**: If the `-power_domain` option is used, the offset value is applied to the specified power domain. However, if the -power domain is not specified, the offset value is applied to all available power domains. To use different offset value for a specific power domain, you first need to delete the CA fillers from the power domain if it is already filled and then reinsert CA filler to the power domain with the target offset value.
`-prefix` *prefix_name*	Specifies the prefix of decomp cells. *Data_type*: string, optional
`-step_x` *step_in_microns*	Specifies the decomposition step in horizontal direction. *Data_type*: float, required
`-step_y` *step_in_microns*	Specifies the decomposition step in vertical direction. *Data_type*: float, required
`-top_edge_endcap {`*cell_name*`}`	Specifies CA-break end cap cell for rows, to make top_edge of endcap face core. *Data_type*: string, required
`-vertical_edge_endcap {`*cell_name*`}`	Specifies CA-break end cap cell inserted at the left and right edges as end caps. *Data_type*: string, required

Example

The code below shows the usage of the `add_decomp_filler` command.

```
add_decomp_filler
-core_row_cell {CA_ROW2 CA_ROW3} -core_column_cell {CA_COL2}
-top_edge_endcap CA_TE -bottom_edge_endcap CA_BE
-vertical_edge_endcap CA_LRE
-step_x 500 -step_y 500
```

Below is the graphical representation of the above example:



Related Information

- `create_floorplan`
- `add_endcaps`

add_endcaps

```
add_endcaps
[-help]
[-area x1 y1 x2 y2]
[-core_boundary_only]
[-power_domain powerDomainName]
[-prefix prefixName]
```

Places physical-only end cap cells at the ends of the site rows. A single-height cap cell is required at the end of each row. For deep N-well technology, the command can be used to insert row-caps to isolate p-well from top and bottom. Use `add_endcaps Category Attributes` to specify the row-cap cells. For deep N-well technology, `add_endcaps` also gets the end cap list from LEF if the end cap cell is specified with the following MACRO CLASS, but user definition has higher priority than LEF specification.

```
[CLASS ENDCAP {
| TOPEDGE | BOTTOMEDGE | LEFTEDGE | RIGHTEDGE
| LEFTTOPEDGE | RIGHTTOPEDGE
| LEFTBOTTOMEDGE | RIGHTBOTTOMEDGE
| LEFTTOPCORNER | RIGHTTOPCORNER
| LEFTBOTTOMCORNER | RIGHTBOTTOMCORNER}
} ]
```

Note: `add_endcaps` is always called after floorplan is done and before `add_well_taps`.

Note: End cap insertion honors core boundary, power domain boundary, placement blockage, fixed macro, and fixed macro halo

To delete the end cap cells, use the `delete_filler` command.

Note: This command is not meant for the insertion of multiple-height cells.

Parameters

`-area x1 y1 x2 y2`	Specifies the coordinates of the bounding box, in microns. By default, the core box that encloses all core rows is used. *Data_type*: rect, optional
`-core_boundary_only`	Specifies that end-cap cells are placed only within the core boundary. This ensures that end-cap cells do not get placed at locations where site rows are obstructed by blockages. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes type and default information for each `add_endcaps` parameter. For a detailed description of the command and all of its parameters, use the man command: `man add_endcaps`.
`-power_domain` *`powerDomainName`*	Specifies the power domain in which the end-cap cells are inserted. This identifies the area where to place the end-cap cells and connect to the correct power and ground nets. *Data_type*: string, optional
`-prefix` *`prefixName`*	Specifies the prefix for the placed instances. The generated name for the instance uses this prefix as `prefix_`*`uniqueString`*. *Prefix Default:* `ENDCAP` *Data_type*: string, optional ⓘ Do not use an underscore at the end of the prefix name.

Note: If the given leftEdge cell is the same as the rightEdge cell, and the cell and site symmetries allow it, the postCap instances will be flipped in the Y direction.

- add_endcaps_wall_pitch
- add_endcaps_wall_to_convex_corner_spacing

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `add_endcaps` category, use the following command:

```
get_db -category add_endcaps
```

add_endcaps_avoid_two_sites_cell_abut

`add_endcaps_avoid_two_sites_cell_abut {true | false}`

Default: `false`

Data_type: bool, read/write

Specifies to avoid two sites boundary cell abut to incorner cell in N10.

add_endcaps_bottom_edge

`add_endcaps_bottom_edge` *`ListOfCellNames`*

Default: ""

Data_type: string, read/write

Specifies the list of cells that have n-well cap on their bottom-edge when in `r0` orientation. Thus, these cells are used to cap a top-core row, or row at the bottom of a hard macro.

add_endcaps_boundary_tap

`add_endcaps_boundary_tap {true|false}`

Default: `false`

Data_type: bool, read/write

Specifies the boundary tap.

add_endcaps_boundary_tap_swap_flow

`add_endcaps_boundary_tap_swap_flow {true|false}`

Default: `true`

Data_type: bool, read/write

Specifies the boundary tap swap flow.

add_endcaps_cells

`add_endcaps_cells` *`ListOfCellNames`*

Default: `""`

Data_type: string, read/write

Specifies end cap cell candidates for N10 that are defined in LEF.

add_endcaps_create_rows

`add_endcaps_create_rows {true|false}`

Default: `false`

Data_type: bool, read/write

Creates rows for endtap cell techSites which do not have rows in the floorplan.

add_endcaps_double_height_incorner_protrusion

`add_endcaps_double_height_incorner_protrusion {true|false}`

Default: `false`

Data_type: bool, read/write

Allows the double height in-corner cell to protrude into core area.

add_endcaps_flip_y

`add_endcaps_flip_y {true|false}`

Default: `false`

Data_type: bool, read/write

Flips the orientation of the end cap instances in Y direction if the site symmetry allows it.

add_endcaps_incremental_left_edge

`add_endcaps_incremental_left_edge` *`ListOfCellNames`*

Default: ""

Data_type: string, read/write

Specifies the end cap lists with n-well at the left edge.

add_endcaps_incremental_right_edge

`add_endcaps_incremental_right_edge` *`ListOfCellNames`*

Default: ""

Data_type: string, read/write

Specifies the list of additional cells which should be treated as end cap by `check_endcaps` when checking the left edge of the core rows or rows starting at right edge of a hard macro.

Related Commands

`check_endcaps`

add_endcaps_left_bottom_corner

`add_endcaps_left_bottom_corner` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies the cell which has n-well cap on its left-bottom corner when in `r0` orientation. These cells are added on inner corners of core, or concave corner of a rectilinear hard macro.

add_endcaps_left_bottom_corner_even

`add_endcaps_left_bottom_corner_even` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies end cap with, n-well at the left-bottom corner, even sites.

add_endcaps_left_bottom_corner_neighbor

`add_endcaps_left_bottom_corner_neighbor` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies the cell to be abutted with the left side of leftBottomCorner in `r0` orientation.

add_endcaps_left_bottom_corner_odd

`add_endcaps_left_bottom_corner_odd` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the left-bottom corner, odd sites.

add_endcaps_left_bottom_edge

`add_endcaps_left_bottom_edge` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies the one cell that has n-well cap on its left-bottom edge when in `r0` orientation. Thus, this cell, in `r0` orientation, can be used to cap a row ending at left-bottom convex corner of a hard macro, or rectilinear core; and if allowed to flip in Y, it can be used on `my` rows that end in left-top convex corner. With both X and Y symmetry, it can cap all convex corners, though only `r0` rows at bottom, and `my` rows for top corners.

add_endcaps_left_bottom_edge_even

`add_endcaps_left_bottom_edge_even` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the left-bottom edge, even sites.

add_endcaps_left_bottom_edge_neighbor

`add_endcaps_left_bottom_edge_neighbor` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies the cell to be abutted with the right edge of leftBottomEdge in the `r0` orientation.

add_endcaps_left_bottom_edge_odd

`add_endcaps_left_bottom_edge_odd` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the left-bottom edge, odd sites.

add_endcaps_left_edge

`add_endcaps_left_edge` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies the one cell that has n-well cap on its left edge when in `r0` orientation. Thus, this cell is used to cap right edge of the core rows, or rows ending at left edge of a hard macro. This would be same as a post-cap, in a two well process.

add_endcaps_left_edge_bottom_border

`add_endcaps_left_edge_bottom_border` *`cellList`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the left edge, poly at the bottom boundary.

add_endcaps_left_edge_even

`add_endcaps_left_edge_even` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the left edge, even sites.

add_endcaps_left_edge_odd

`add_endcaps_left_edge_odd` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the left edge, odd sites.

add_endcaps_left_edge_top_border

`add_endcaps_left_edge_top_border` *`cellList`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the right edge, poly at the top boundary.

add_endcaps_left_top_corner

`add_endcaps_left_top_corner` *cellName*

Default: `""`

Data_type: string, read/write

Specifies the cell that has n-well cap on its left top corner when in `r0` orientation. Thus, this cell is added on inner corners of core, or concave corner of a rectilinear hard macro.

add_endcaps_left_top_corner_even

`add_endcaps_left_top_corner_even` *cellName*

Default: `""`

Data_type: string, read/write

Specifies end cap with n-well at the left-top corner, even sites.

add_endcaps_left_top_corner_neighbor

`add_endcaps_left_top_corner_neighbor` *cellName*

Default: ""

Data_type: string, read/write

Specifies the cell to be abutted with the left side of leftTopCorner in `r0` orientation.

add_endcaps_left_top_corner_odd

`add_endcaps_left_top_corner_odd` *cellName*

Default: `""`

Data_type: string, read/write

Specifies end cap with n-well at the left-top corner, odd sites.

add_endcaps_left_top_edge

`add_endcaps_left_top_edge` *`cellName`*

Default: `""`

Data_type: string, read/write

Specifies the cell that has n-well cap on its top-left edge when in `r0` orientation. Thus, in `r0` orient, it is the flipped-in-Y version of left-bottom edge cell.

add_endcaps_right_corner_bottom_border

`add_endcaps_right_corner_bottom_border` *`ListOfCellNames`*

Default: ""

Data_type: string, read/write

Specifies the inner right corner bottom border cell.

add_endcaps_right_corner_top_border

`add_endcaps_right_corner_top_border` *`ListOfCellNames`*

Default: ""

Data_type: string, read/write

Specifies the inner right corner top border cell.

add_endcaps_left_top_edge_even

`add_endcaps_left_top_edge_even` *`cellName`*

Default: `""`

Data_type: string, read/write

Specifies end cap with n-well at the left-top edge, even sites.

add_endcaps_left_top_edge_neighbor

`add_endcaps_left_top_edge_neighbor` *`cellName`*

Default: `""`

Data_type: string, read/write

Specifies the cell to be abutted with the right edge of leftTopEdge in the `r0` orientation.

add_endcaps_left_top_edge_odd

`add_endcaps_left_top_edge_odd` *`cellName`*

Default: `""`

Data_type: string, read/write

Specifies end cap with n-well at the left-top edge, odd sites.

add_endcaps_min_horizontal_channel_width

`add_endcaps_min_horizontal_channel_width` *`channelWidth`*

Default: `0`

Data_type: int, read/write

If horizontal channel width is smaller than specified value, addEndCap will cover this channel with hard blockage.

add_endcaps_min_jog_height

`add_endcaps_min_jog_height` *`jogHeight`*

Default: `0`

Data_type: int, read/write

If jog height is smaller than specified value, addEndCap will cover this jog with hard blockage.

add_endcaps_min_jog_width

`add_endcaps_min_jog_width` *`jogWidth`*

Default: `0`

Data_type: int, read/write

If jog width is smaller than specified value, addEndCap will cover this jog with hard blockage.

add_endcaps_min_vertical_channel_width

`add_endcaps_min_vertical_channel_width` *`channelWidth`*

Default: 0

Data_type: int, read/write

If vertical channel width is smaller than specified value, addEndCap will cover this channel with hard blockage.

add_endcaps_prefix

`add_endcaps_prefix` *`endcap-prefix`*

Default: `""`

Data_type: string, read/write

Adds prefix of EndCap cells.

add_endcaps_right_bottom_corner

`add_endcaps_right_bottom_corner` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies the cell that has n-well cap on its right bottom corner when in `r0` orientation. Thus, this cell is added on inner corners of core, or concave corner of a rectilinear hard macro.

add_endcaps_right_bottom_corner_even

`add_endcaps_right_bottom_corner_even` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the right-bottom corner, even sites.

add_endcaps_right_bottom_corner_neighbor

`add_endcaps_right_bottom_corner_neighbor` *`cellName`*

Default: ""

Data_type: string, read/write

The cell to be abutted with the right side of rightBottomCorner in `r0` orientation.

add_endcaps_right_bottom_corner_odd

`add_endcaps_right_bottom_corner_odd` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the right-bottom corner, odd sites.

add_endcaps_right_bottom_edge

`add_endcaps_right_bottom_edge` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies the cell that has n-well cap on its right bottom edge when in `r0` orientation. Thus, these cells are the flipped-in-X version of add_endcaps_left_bottom_edge cell. Usually one of these 2 is sufficient for a library.

add_endcaps_right_bottom_edge_even

`add_endcaps_right_bottom_edge_even` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the right-bottom edge, even sites.

add_endcaps_right_bottom_edge_neighbor

`add_endcaps_right_bottom_edge_neighbor` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies the cell to be abutted with the left edge of rightBottomEdge in the `r0` orientation.

add_endcaps_right_bottom_edge_odd

`add_endcaps_right_bottom_edge_odd` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the right-bottom edge, odd sites.

add_endcaps_right_edge

`add_endcaps_right_edge` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies the cell that has n-well cap on its right edge when in `r0` orientation. Thus, these cells are used to cap the left edge of the core-rows in `r0`. In 2 well process, this would be the pre-cap cell.

add_endcaps_right_edge_bottom_border

`add_endcaps_right_edge_bottom_border` *`cellList`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the right edge, poly at the bottom boundary.

add_endcaps_right_edge_even

`add_endcaps_right_edge_even` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the right edge, even sites.

add_endcaps_right_edge_odd

`add_endcaps_right_edge_odd` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the right edge, odd sites.

add_endcaps_right_edge_top_border

`add_endcaps_right_edge_top_border` *`cellList`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the right edge, poly at the top boundary.

add_endcaps_right_top_corner

`add_endcaps_right_top_corner` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies the cell that has n-well cap on their right top corner when in `r0` orientation. Thus, this cell, in `r0`, is added on right corner of core, or concave corner of a rectilinear hard macro.

add_endcaps_right_top_corner_even

`add_endcaps_right_top_corner_even` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the right-top corner, even sites.

add_endcaps_right_top_corner_neighbor

`add_endcaps_right_top_corner_neighbor` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies the cell to be abutted with the right side of rightTopCorner in `r0` orientation.

add_endcaps_right_top_corner_odd

`add_endcaps_right_top_corner_odd` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the right-top corner, odd sites.

add_endcaps_right_top_edge

`add_endcaps_right_top_edge` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies the cell that has n-well cap on its right top edge when in `r0` orientation. Thus, this cell is the `r180` version of add_endcaps_left_bottom_edge.

add_endcaps_right_top_edge_even

`add_endcaps_right_top_edge_even` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the right-top edge, even sites.

add_endcaps_right_top_edge_neighbor

`add_endcaps_right_top_edge_neighbor` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies the cell to be abutted with the left edge of rightTopEdge in the `r0` orientation.

add_endcaps_right_top_edge_odd

`add_endcaps_right_top_edge_odd` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies end cap with n-well at the right-top edge, odd sites.

add_endcaps_left_corner_bottom_border

`add_endcaps_left_corner_bottom_border` *`ListOfCellNames`*

Default: `""`

Data_type: string, read/write

Specifies the inner left corner, bottom border cell.

add_endcaps_left_corner_top_border

`add_endcaps_left_corner_top_border` *`ListOfCellNames`*

Default: `""`

Data_type: string, read/write

Specifies the inner left corner, top border cell.

add_endcaps_top_bottom_edge

`add_endcaps_top_bottom_edge` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies the cell that has an n-well cap on its top edge as well as bottom edge when in `r0` orientation.

add_endcaps_top_edge

`add_endcaps_top_edge` *`cellName`*

Default: ""

Data_type: string, read/write

Specifies the list of cells that have n-well cap on their top edge when in `r0` orientation. Thus, these cells are used to cap the bottom-core row, or row at top of a hard macro.

add_endcaps_use_even_odd_sites

`add_endcaps_use_even_odd_sites {none|even|odd}`

Default: `none`

Data_type: enum {none even odd}, read/write

Specifies to use even or odd poly sites.

- `none`: EVEN/ODD cells are not considered even if they are specified
- `even`: Need to specify EVEN boundary cell
- `odd`: Need to specify ODD boundary cell

add_endcaps_wall_keepout_from_vertical_boundary

add_endcaps_wall_keepout_from_vertical_boundary `{true|false}`

Default: 0.0

Data_type: double, read/write

Specifies the wall keep-out spacing from left/right boundary cell.

add_endcaps_wall_offset

`add_endcaps_wall_offset` *macro*

Default: 0.0

Data_type: double, read/write

Specifies the x coordinate of the first wall column.

add_endcaps_wall_pitch

`add_endcaps_wall_pitch` *macro*

Default: 0.0

Data_type: double, read/write

Specifies the wall pitch.

add_endcaps_wall_to_convex_corner_spacing

`add_endcaps_wall_to_convex_corner_spacing` *macro*

Default: 0.0

Data_type: double, read/write

Constraints the spacing between wall and convex corner.

add_filler_gaps

```
add_filler_gaps
min_gap
[-effort {none | low | medium | high}]
[-radius value_in_micron]
```

Moves placed standard cell instances to create gaps so that filler cells can be added. Tries to move cells to create a gap of the specified size. If enough space is not available, moves cells until they touch each other. If a gap already exists, and it is larger than the specified size, the command does not move cells to make it smaller.

By default, this command deletes all routing, because the routing is no longer valid due to the movement of the cells. To override this behavior, specify the following command:

```
set_db place_detail_preserve_routing true
```

This command has the following limitations:

- It does not moved `FIXED` cells.
- It does not guarantee to that all gaps will be larger than the specified minimum gap size.

Use this command after placement and before routing.

Parameters

min_gap	Specifies the minimum-size gap in which a filler cell can be added. Unit is micron. *Data_type*: float, required
`-effort {none | low| medium | high}`	Specifies the effort the command needs to spend for honoring the given gap constraint. • `none` effort specifies that no standard cell is moved for honoring the giving gap constraint. • `low` effort specifies that only single height standard cells can be moved within the same row. • `medium` effort specifies that only single height standard cells can be moved across the rows. • `high` effort specifies that the standard cells can be moved across rows, and double height standard cells can be moved within the same row. *Default*: `low` *Data_type*: enum, optional
`-radius` *value_in_micron*	Specifies the searching radius when solving the minimum filler gap. *Default*: 16 *Data_type*: float, optional

Example

- The following command moves standard cells within a row to create gaps of at least two microns between the cells:
  ```
  add_filler_gaps 0.168
  ```
- The following command specifies two site widths with each side width equal to `[lindex [lsort [get_db sites.size_x -u ] 0]`.
  ```
  add_filler_gaps [expr 2 * [lindex [ lsort [get_db sites.size_x -u ] 0]]
  ```

Related Information

- place Category Attributes
- set_db

add_fillers

```
add_fillers
[-area  x1   y1   x2   y2 ]
[-base_cells { filler_cell_name_list }]
[-create_rows {true | false}]
[-check_different_cells {true|false}]
[-check_drc {true | false}]
[-check_via_enclosure {true | false}]
[-density  targetUtilization ]
[-eco_mode {true | false}]
[-fill_gap]
[-fix_drc]
[-fix_horizontal_max_length_violation]
[-fix_vertical_max_length_violation]
[-honor_preroute_as_obs {true | false}]
[-mark_fixed]
[-check_min_hole {true | false}]
[-merge {true | false}]
[-power_domain powerDomainName ]
[-prefix prefixName ]
[-prevent_vertical_stack_max_length_violation]
```

Inserts filler cell instances in the gaps between standard cell instances. Filler cell instances provide continuity for the power and ground rails, as well as for n-wells. In most cases, use this command after placement and before detailed routing. If the design is routed, this command also does DRC checks of the filler cells added versus the wires in the design. It does not check versus adjacent cells. This command is fast enough to be used many times in the design flow.

Note: Before using `add_fillers`, run the `connect_global_net` command to provide global-net-connection rules for supply pins of the added fillers. Without these rules, the built-in design-rule checks of `add_fillers` will not be accurate.

To resolve adjacent instance DRC violations created by the insertion of filler cell instances, run the `verify_drc` command to mark these violations. Then, use the `add_fillers` command again with the `-fix_drc` parameter to replace the filler cell instances that are in violation.

Note: This command resolves only filler-related violations; it cannot resolve net-based violations. To repair net-based violations, reroute the violated net(s).

The `add_fillers` command recognizes up to eight implant layers and attempts to honor implant layer width and spacing rules within each implant layer. If it does not find the correct filler cell to add to an implant layer, it tries to add "no-implant" filler cells. If it cannot add the "no-implant" cells, it inserts a filler cell that is large enough that it does not violate the minimum width rule of the relevant implant

layer.

Use the `delete_filler` command to remove the added physical instances, including filler cell instances .

Note: This command supports multithreading.

> Some `add_fillers` parameters can also be specified with add_fillers Category Attributes. However, the parameters specified with `add_fillers` command apply to the current `add_fillers` invocation only, and supersede the parameters set by `add_fillers` attributes. For more information, see add_fillers Category Attributes.

Parameters

`-area` *x1 y1 x2 y2*	Adds filler cells to the specified area. If the area is not defined properly, does not add filler cells. Normally, designs are placed before filler cells are added. However, If you use this parameter and the design is not placed, you get a warning, and the command adds fillers in the specified area. • ***x1*** specifies the area's lower left point on the x axis. • ***y1*** specifies the area's lower left point on the y axis. • ***x2*** specifies the area's upper right point on the x axis. • ***y2*** specifies the area's upper right point on the y axis. *Data_type*: rect, optional

`-base_cells` *`filler_cell_name_list`*	Specifies the list of filler base cell names to add. Separate names with spaces and enclose the list with quotation marks (") or curly braces ({}). *Data_type*: string, optional
`-create_rows {true | false}`	Controls whether `add_fillers` creates rows in the floorplan if a cell's site does not have rows. *Default*: `true` *Data_type*: bool, optional
`-check_different_cells {true|false}`	Checks violations between different cell types. *Default*: `false` *Data_type*: bool, optional **Note**: Using this feature will increase the runtime of `add_fillers`.

`-check_drc {true | false}`	Controls postroute DRC violation checking against existing net routing, without considering adjacent cell DRC violations. This parameter does not disable regular placement checks. *Default*: `true` *Data_type*: bool, optional If filler cells are added after routing, the software checks for DRC violations between regular nets and the filler cells. When the inserted filler violates the existing routing, `add_fillers` tries to use other filler cells to replace the violating one; if it fails to fill the gap without violation, it leaves a gap. In 16.10, add_fillers has been enhanced with DRC. This flow would fill gaps as much as possible even with DRC, and will give the violation report and marker for easy debug. Also, the `-add_fillers_with_drc` attribute calls second add_fillers without DRC checking. If filler cells are added after routing, the software checks for DRC violations between regular nets and the filler cells. When the inserted filler violates the existing routing, add_fillers tries to use other filler cells to replace the violating one. If it fails to fill the gap without violation, it will insert a violated filler in the second pass and give the violation report and marker for easy debug when `-add_fillers_with_drc` attribute is turned on. Note: The setting of `place_detail_use_check_drc` attribute can affect `add_fillers` ability to add instances without causing DRC violations.

`-eco_mode {true | false}`	Controls whether the software resolves overlaps of standard cells with fillers by removing the overlapping fillers, and inserting new fillers in any existing or newly created gaps due to partial overlaps in eco flow. If this parameter is used after routing, the command also resolves DRC violations of filler geometries of all fillers with regular wires. *Default*: `false` *Data_type*: bool, optional
`-fill_gap`	Fills a gap between cells by adding a combination of cells, instead of by adding the single largest cell that fits, if doing so avoids leaving an unfilled single-width gap. *Data_type*: bool, optional
`-fix_drc`	Corrects DRC violations reported by `verify_drc` between filler cells and adjacent standard cells. *Data_type*: bool, optional **Note**: The `add_fillers` command resolves only filler-related violations; it cannot resolve net-based violations. To repair net-based violations, reroute the violated net(s). Use this parameter in subsequent runs of the `add_fillers` command, after adding filler cells and checking for violations with `verify_drc`. The command replaces filler cells that cause DRC violations with fillers that do not cause violations. If it cannot replace a violating filler cell without causing another violation, it leaves a gap.
`-fix_horizontal_max_length_violation`	Fixes horizontal max length violations. *Data_type*: bool, optional

`-fix_vertical_max_length_violation`	Fixes CPODE max length violations caused by filler cells. *Data_type*: bool, optional
`-honor_preroute_as_obs {true | false}`	Instructs `add_fillers` to honor the setting of the `place_detail_preroute_as_obs` attribute. When `honor_preroute_as_obs` is `true` and `place_detail_preroute_as_obs` is set, `add_fillers` treats preroutes on metal layers where filler cells have geometries and are enumerated by `place_detail_preroute_as_obs` as obstructions, and ignores preroutes on other layers. For example, if `place_detail_preroute_as_obs` is set to metal1 and metal2, and all the filler cell geometries are on metal1, `add_fillers` treats metal1 preroutes as obstructions but not metal2 preroutes. *Default*: `false` *Data_type*: bool, optional
`-mark_fixed`	Mark inserted fillers as FIXED. *Data_type*: bool, optional
`-merge {true | false}`	When checking for spacing violations, merge same-net geometries to determine width-dependent spacing. If the LEF file contains width-dependent rules, this parameter causes `add_fillers` to have the following behavior: • **true:** merges overlapping same-net objects to create a large rectangle. • **false:** uses the unmerged same-net object shapes. *Default*: `false` *Data_type*: bool, optional

`-check_min_hole {true | false}`	Calls `verify_drc` to check for minimum hole violations before adding filler cells and repairs the violations when `add_fillers` runs. *Default*: `false` *Data_type*: bool, optional
`-power_domain` *powerDomainName*	Specifies the power domain in which to add filler cells. *Default*: tries to add fillers to all power domains. *Data_type*: string, optional
`-prefix` *prefixName*	Specifies the prefix for the placed instances. *Default*: `FILLER` *Data_type*: string, optional
`-density` *targetUtilization*	Specifies the percent of free space remaining after placement to fill with given filler cell instances. Use `-density` to add gate-array core filler cells to use later in the design flow, along with gate-array core cells, for metal-only mask changes. *Range*: More than `0.0` (`0%`) and equal to or less than `1.0` (`100%`) *Default*: `1.0` *Data_type*: float, optional
`-check_via_enclosure {true | false}`	Calls `verify_drc` to check for via enclosure violations before adding filler cells and repairs the violations when `add_fillers` runs. *Default*: `false` *Data_type*: bool, optional

`-prevent_vertical_stack_max_length_violation`	Used before endcap insertion, inserts larger encaps at left/right boundaries to fix CPODE max length violations. *Data_type*: bool, optional

Examples

- The following commands insert filler cell instances for cells `FILL64`, `FILL16`, `FILL4`, `FILL2`, and `FILL1`:

```
add_fillers -base_cells {FILL64 FILL16 FILL4 FILL2 FILL1}
add_fillers -base_cells "FILL64 FILL16 FILL4 FILL2 FILL1"
add_fillers -base_cells [ list FILL64 FILL16 FILL4 FILL2 FILL1 ]
add_fillers -base_cells FILL64 FILL16 FILL4 FILL2 FILL1
```

- The following commands show the use of the `-density` parameter to set the utilization of `GACORE` filler cells to 50 percent:

```
# Place the design
place_design
# Now fill with GACORE cells up to 50% of remaining space
# area utilization
add_fillers -base_cells {gcore16 gcore8 gcore4} -prefix GACORE -density 0.5
# Now fill with the standard filler cells
add_fillers -base_cells {fill8 fill4 fill2 fill} -prefix FILLER
# Continue with routing
```

- The following command enable postRoute DRC checking for min hole violations and via enclosure violations:

```
add_fillers -base_cells {FILL16 FILL8 FILL4 FILL2} -check_drc true -check_min_hole
true -check_via_enclosure true
```

add_fillers Category Attributes

The root attributes in the add_fillers category are:

- add_fillers_cells
- add_fillers_avoid_abutment_patterns
- add_fillers_cell_name_style
- add_fillers_check_different_cells
- add_fillers_check_drc
- add_fillers_create_rows
- add_fillers_distribute_implant_evenly
- add_fillers_eco_mode
- add_fillers_horizontal_exception_cell
- add_fillers_honor_preroute_as_obs
- add_fillers_keep_fixed
- add_fillers_horizontal_max_length
- add_fillers_horizontal_repair_cell
- add_fillers_no_single_site_gap
- add_fillers_prefix
- add_fillers_preserve_user_order
- add_fillers_scheme
- add_fillers_swap_cell
- add_fillers_vertical_stack_exception_cell
- add_fillers_vertical_stack_left_edge_exception_cell
- add_fillers_vertical_stack_max_length
- add_fillers_vertical_stack_repair_cell
- add_fillers_vertical_stack_repair_edge
- add_fillers_vertical_stack_right_edge_exception_cell
- add_fillers_with_drc

- add_fillers_y_flip_type

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `add_fillers` category, use the following command:

```
get_db -category add_fillers
```

add_fillers_cells

`add_fillers_cells {{list-of-cells1} {list-of-cells2} ...}`

Default: `""`

Data_type: string, read/write

Specifies the filler cells to add with add_fillers. Enclose the filler cell names in quotation marks (") or curly braces ({ }). You can specify multiple cell lists at one time, using curly braces ({ }) to separate each one.

add_fillers_avoid_abutment_patterns

`add_fillers_avoid_abutment_patterns {{ 1:1 1:2 ...}}`

Default: `""`

Data_type: string, read/write

Specifies illegal abutment patterns.

add_fillers_cell_name_style

`add_fillers_cell_name_style {hier|flat}`

Default: `hier`

Data_type: enum {hier flat}, read/write

Adds physical cells into hierarchical modules, or as top level cells (flat).

add_fillers_check_different_cells

`add_fillers_check_different_cells {true | false}`

Default: `false`

Data_type: bool, read/write

Checks violations between different cell types.

Note: Using this feature will increase the runtime of `add_fillers`.

add_fillers_check_drc

`add_fillers_check_drc {true | false}`

Default: `true`

Data_type: bool, read/write

When `add_fillers` is called after routing, instructs the software to run DRC checks of filler pins with signal net wires. To disable the DRC checks, set this parameter to `false`.

add_fillers_create_rows

`add_fillers_create_rows {true | false}`

Default: `true`

Data_type: bool, read/write

Instructs `add_fillers` to create rows in the floorplan.

By default.if a cell's site does not have rows in the floorplan, `add_fillers` creates the rows.

add_fillers_distribute_implant_evenly

`add_fillers_distribute_implant_evenly {true | false}`

Default: `false`

Data_type: bool, read/write

Distributes implant evenly for fillers.

add_fillers_eco_mode

`add_fillers_eco_mode {true | false}`

Default: `false`

Data_type: bool, read/write

Controls whether the software resolves overlaps of standard cells with fillers by removing the overlapping fillers, and inserting new fillers in any existing or newly created gaps due to partial overlaps in eco flow. If this attribute is used after routing, the command also resolves DRC violations of filler geometries of all fillers with regular wires.

add_fillers_horizontal_exception_cell

`add_fillers_horizontal_exception_cell` *`list_of_cells`*

Default:

Data_type: string, read/write

Specifies the list of exceptional cells for horizontal stack checking.

add_fillers_honor_preroute_as_obs

`add_fillers_honor_preroute_as_obs {true | false}`

Default: `false`

Data_type: bool, read/write

Instructs `add_fillers` to honor the setting of `place_detail_preroute_as_obs`. By default, `add_fillers` does not consider any pre-Routes to be obstructions.

When this attribute is `1`, `add_fillers` treats pre-Routes on metal layers where filler cells have geometries as obstructions, and ignores pre-Routes on other layers. In most cases, this means that `add_fillers` treats pre-Routes on *metal1* as obstructions and ignores pre-Routes on other metal layers. For example, if `place_detail_preroute_as_obs` is set to *metal1* and *metal2*, and all the filler cell geometries are on *metal1*, `add_fillers` treats *metal1* pre-Routes as obstructions but does not treat *metal2* pre-Routes as obstructions.

`add_fillers` ignores `place_detail_preroute_as_obs` and inserts fillers in all legal sites.

add_fillers_keep_fixed

```
add_fillers_keep_fixed {true | false}
```

Default: `false`

Data_type: bool, read/write

Keeps the FIXED filler cells.

add_fillers_horizontal_max_length

```
add_fillers_horizontal_max_length instance_max_length
```

Default: `0.0`

Data_type: double, read/write

Specifies the instance max length (in micron) aligned in horizontal direction.

add_fillers_horizontal_repair_cell

```
add_fillers_horizontal_repair_cell list_of_cells
```

Default: `{}`

Data_type: string, read/write

Specifies the list of filler cells to fix horizontal max length violation.

add_fillers_no_single_site_gap

```
add_fillers_no_single_site_gap {true | false}
```

Default: `true`

Data_type: bool, read/write

Fills a gap between cells by adding a combination of cells, instead of by adding the single largest cell that fits, if doing so avoids leaving an unfilled single-width gap.

add_fillers_prefix

```
add_fillers_prefix prefix
```

Default: `""`

Data_type: string, read/write

Specifies the prefix for the added filler cells.

add_fillers_preserve_user_order

```
add_fillers_preserve_user_order {true | false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether using the user defined filler cells order for filler insertion.

Filler cells in each core list are sorted from largest to smallest.

add_fillers_scheme

```
add_fillers_scheme {locationFirst | cellFirst}
```

Default: `locationFirst`

Data_type: enum {locationFirst cellFirst}, read/write

Specifies the filler insertion scheme.

- `locationFirst` fills each given location with the best filler before proceeding to next location. It always starts with the first empty site.
- `cellFirst` inserts filler cells based on the user-specified list. The tool tries to insert the first filler from the user list in all possible locations before moving to the second cell in the list.

add_fillers_swap_cell

```
add_fillers_swap_cell {{cell swap pair1} {cell swap pair2} ...}
```

Default: `""`

Data_type: string, read/write

Swaps the specified cell pairs.

add_fillers_vertical_stack_exception_cell

`add_fillers_vertical_stack_exception_cell` *`list_of_cells`*

Default: `{}`

Data_type: string, read/write

Specifies the list of exceptional cells for vertical stack checking.

add_fillers_vertical_stack_left_edge_exception_cell

`add_fillers_vertical_stack_left_edge_exception_cell` *`list_of_cells`*

Default: `""`

Data_type: string, read/write

Specifies a list of cells in which only the left edge will not be checked for vertical stack violation.

add_fillers_vertical_stack_max_length

`add_fillers_vertical_stack_max_length` *`list_of_cells`*

Default: `0.0`

Data_type: double, read/write

Specifies the instance max length (in micron) aligned in the vertical direction.

add_fillers_vertical_stack_repair_cell

`add_fillers_vertical_stack_repair_cell` *`list_of_cells`*

Default: `{}`

Data_type: string, read/write

Specifies the list of filler cells to fix vertical stack violation.

add_fillers_vertical_stack_repair_edge

`add_fillers_vertical_stack_repair_edge {left|right}`

Default: `left`

Data_type: enum {left right}, read/write

Specifies the edge to use of vertical repair cell.

add_fillers_vertical_stack_right_edge_exception_cell

`add_fillers_vertical_stack_right_edge_exception_cell` *`list_of_cells`*

Default: `""`

Data_type: string, read/write

Specifies a list of cells in which only the right edge will not be checked for vertical stack violation.

add_fillers_with_drc

`add_fillers_with_drc {true | false}`

Default: `true`

Data_type: bool, read/write

Calls the second addFiller without DRC checking.

add_fillers_y_flip_type

`add_fillers_y_flip_type { integer : { first | last } ... }`

Default: `""`

Data_type: string, read/write

Defines the first or the last cell with certain cell size should be y-flipped.

add_gate_array_filler

```
add_gate_array_filler
[-help]
[-area x1 y1 x2 y2]
[-allow_shift_distance x y]
[-cell_orientation {R0|MX|MY|R180}]
[-offset_x offset_in_microns]
[-offset_y offset_in_microns]
[-power_domain powerDomainName]
[-prefix prefixName]
{-cell cellName -step_x step_in_microns -step_y step_in_microns}
```

Inserts GA filler cells with regular pattern in the pre-place stage.

The GA filler cells created by this command are marked as physical-only cells. This means that the `isPhysOnly` attribute of these GA filler cells is set to `true`. This is a prerequisite for the `place_eco -use_gate_array_filler_cells` command to map the unplaced ECO cells to the added GA filler cells, in case of a GA filler-based post-mask ECO.

Parameters

`-allow_shift_distance x y`	Specifies the distance between the new and the original position in the x and y directions. If you do not specify `-allow_shift_distance`, the GA filler will be removed if it is added at original location with a violation. If `-allow_shift_distance` is specified, the GA can be shifted to avoid violation. If a GA filler cannot be added at the original location because of the violation, it will be moved to the left side, right side, upside, or downside of the original location to ensure that there is no violation. The next filler keeps the step value with the original position of the moved filler.
`-area x1 y1 x2 y2`	Specifies the area in which GA fillers are to be inserted. If no area is specified, GA fillers will be inserted for the complete core area. *Data_type*: rect, optional
`-cell cellName`	Specifies the name of the filler cell to be used. *Data_type*: string, optional

`-cell_orientation {R0|MX|MY|R180}`	Specifies all legal orientations of GFILL instances. *Data_type*: string, optional
`-offset_x` *offset_in_microns*	Specifies the offset, in microns, from the origin in the horizontal direction. If the `-area` parameter is specified, the origin is (x1, y1) of the box defined by `-area`. If `-area` is not specified the origin is (0,0). *Data_type*: float, optional
`-offset_y` *offset_in_microns*	Specifies the offset, in microns, from the origin in the vertical direction. If the `-area` parameter is specified, the origin is (x1, y1) of the box defined by `-area`. If `-area` is not specified the origin is (0,0). *Data_type*: float, optional
`-power_domain` *powerDomainName*	Specifies the power domain for which fillers are to be inserted. *Data_type*: string, optional
`-prefix` *prefixName*	Specifies the prefix for the inserted GA filler cells. *Data_type*: string, optional
`-step_x` *step_in_microns*	Specifies the distance between GA fillers in the horizontal direction. *Data_type*: float, optional
`-step_y` *step_in_microns*	Specifies the distance between GA fillers in the vertical direction. *Data_type*: float, optional

Examples

- The following command adds GA fillers of type `GAFILL4` with spacing in horizontal and vertical direction of 20 microns. The first GAFILL4 will be placed at (10, 0).

```
add_gate_array_filler -cell GAFILL4 -step_x 20 -step_y 20 -offsetx 10
```

- The following command adds GA fillers of type `GAFILL4` with regular spacing 20 and start location (0, 0).

  ```
  add_gate_array_filler -cell GAFILL4 -step_x 20 -step_y 20
  ```

- The following command adds GA fillers of type `GAFILL4` with vertical and horizontal spacing of 10 microns in the area defined by coordinates 100 100 500 500.

  ```
  add_gate_array_filler -area 100 100 500 500 -cell GAFILL4 -stepx 10 -stepy 10
  ```

add_mim_cap

```
add_mim_cap
[-help]
-cell cellName
[-orient instanceName]
[-prefix prefixName]
[{-step_x step_in_microns -step_y step_in_microns} [-area {x1 y1 x2 y2}]]
[{-area {x1 y1 x2 y2} | -location {x y}}] [-location {x y} | -offset {x y}]
```

Adds Metal-Insulator-Metal (MIM) cap into the design. This command is used before placing the standard cells.

Parameters

`-area x1 y1 x2 y2`	Specifies the area box, in microns, that will be used to insert Mim caps. If this option is not defined, the whole core area will be used. This option can be used only with -`step_x` and `-step_y` and is excluded with `-location`. *Data_type*: rect, required
`-cell` *cellName*	Specifies the name of the cell. *Data_type*: string, required
`-help`	Outputs a brief description that includes type and default information for each `add_mim_cap` parameter. For a detailed description of the command and all of its parameters, use the man command: `man add_mim_cap`.
`-location {x y}`	Inserts one Mim cap only at the given location. *Data_type*: point, required
`-offset {x y}`	Shifts the area used to insert mim caps with the specified offset value in both horizontal and vertical direction. This option can be used only with -`step_x` and `-step_y` and is excluded with `-location`. *Data_type*: point, required
`-orient` *orientation*	Specifies the orientation of the mim cap cell. *Default*: `r0` *Data_type*: string, optional
`-prefix` *prefixName*	Specifies the prefix for the inserted mim cap. *Data_type*: string, optional
`-step_x` *step_in_microns*	Specifies the distance between mim caps in the horizontal direction. This option must be defined with `-step_y` and is excluded with `-location`. *Data_type*: float, optional
`-step_y` *step_in_microns*	Specifies the distance between mim caps in the horizontal direction. This option must be defined with `-step_x` and is excluded with `-location`. *Data_type*: float, optional

Examples

- The following command inserts the mim cap cell `mim_cell1`:

```
add_mim_cap -cell mim_cell1 -orient r0 -step_x 34.56 -step_y 34.56 -offset { 9.317 8.336 }
```

Related Information

add_spare_insts

```
add_spare_insts
[-help]
[-async netName]
[-clock netName]
-file fileName
[-fix_placed_insts {TRUE|FALSE}]
[-hinst moduleName | -power_domain domainName [-spare_module spareModuleName]]
[-prefix prefix]
[-tie {0 | 1}]
```

Specifies a file that lists spare cells to add to the netlist. You can use this command before or after standard cell placement.

- If you use this command before placement, the `place_design` command distributes and places the added instances without including them in spare modules. It adds the instances to the top level of the design by default.
- If you use this command after placement, the software places the added instances without creating spare modules or disturbing the existing placement. The distribution of the cells is dependent upon the number of instantiations of each cell type.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `add_spare_insts` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man add_spare_insts`.
`-async netName`	Specifies which net(s) to tie off the async pin(s). Default: async pins will be tied to the logical zero net. *Data_type*: string, optional
`-clock netName`	Specifies the clock net that is tied to the clock pins. *Data_type*: string, optional

`-file` *`fileName`*	Specifies a text file that lists the spare cells, and the number of each, to add to the netlist. The file has the following format: "*`cellName number`*" Begin each line of a comment with a number sign (`#`). *Data_type*: string, required
`-fix_placed_insts {TRUE|FALSE}`	Specifies not to move the existing placed instances to find location for newly added spare instances. *Data_type*: bool, optional
`-hinst` *`moduleName`*	Specifies the name of the module to which spares will be added. *Data_type*: string, optional
`-power_domain` *`domainName`*	Specifies the name of the power domain to which spares will be added. *Data_type*: string, optional
`-prefix` *`prefix`*	Specifies a prefix for the names of the newly added cells. *Default:* `FE_spare` *Data_type*: string, optional
`-spare_module` *`spareModuleName`*	Specifies the name of the module created for spares. *Data_type*: string, optional
`-tie {0 | 1}`	Specifies the logical net to which the cells are connected. *Default:* `1` *Data_type*: int, optional

Example

The following command adds instances of the cells specified in `spare_file` and ties them to logical net `0`. It ties the clock pins to `sysclk`:

```
add_spare_insts -file spare_file -tie 0 -clock sysclk
```

`spare_file` contains the following:

```
DFFNSRX2T1T10    1
INVX4T1T10       2
NOR2X2T1T10      2
```

The following command adds instances of the cells specified in spare.txt.It ties the async pin RN to net VDD:

```
add_spare_insts -file spare.txt -async VDD:RN
```

`spare.txt` contains the following:

```
SDFFRHQXL 5
```

add_tap_walls

```
add_tap_walls
[-help]
[-bottom]
-cell
[-layer layer_name]
[-left]
[-orientation {r0 mx my r180}]
[-pitch distance]
[-prefix prefix]
[-range x1 y1|x2 y2]
[-right]
[-top]
[-y_flip_side {left right both}]
```

Adds tap walls to the assigned left, right, top, and/or bottom side of a block.

Parameters

`-bottom`	Specifies the add tap-wall cell on the bottom side. *Data_type*: bool, optional
`-cell cellName`	Specifies the name of the cell to insert. *Data_type*:
`-help`	Outputs a brief description that includes type and default information for each `add_tap_walls` parameter. For a detailed description of the command and all of its parameters, use the man command: `man add_tap_walls`.
`-left`	Specifies the add tap-wall cell on the left side. *Data_type*: bool, optional
`-layer layer_name`	Specifies the layer name to check rule. *Data_type*: string, optional

`-orientation {r0 mx my r180}`	Specifies orientation of the added tap-wall cells. *Data_type*: enum, optional
`-pitch` *distance*	Specifies the distance from the center of one tap-wall cell to the center of the following wall-tap cell. *Data_type*: float, optional
`-prefix` *prefix*	Specifies the prefix of tap-wall cells to inserted. *Data_type*: string, optional
`-range` *x1 y1|x2 y2*	Specifies the {x1 y1} or {x2 y2} as the start or end point at the user given side. *Data_type*: point, optional
`-right`	Specifies the add tap-wall cell on the right side. *Data_type*: bool, optional
`-top`	Specifies the add tap-wall cell on the top side. *Data_type*: bool, optional
`-y_flip_side {left right both}`	Specifies the orientation of the added tap-wall cells. Defines whether flipping tap walls located at certain side in the Y direction if site symmetry allows it. By default, both left and right side tap walls are R0 or MX. If -y_flip_side is set to left, the left side tap walls would be MY or R180. If it is set to both, both left and right side tap walls would be MY or R180. *Data_type*: enum, optional

add_well_taps

```
add_well_taps
[-help]
[-area  x1   y1   x2   y2 ]
[-avoid_abutment]
[-cell  cellName ]
[-cell_interval  microns]
[-channel_offset offset_value]
[-checker_board]
[-fixed_gap]
[-in_row_offset  microns ]
[-power_domain  powerDomainName ]
[-prefix  prefixName ]
[-site_offset  number_of_sites ]
[-skip_row  number ]
[-start_row  number ]
[-termination_cells  termination_cell_list | {-top_termination_cell cell_list -
bottom_termination_cell cell_list}}-column_cells  tap_column_cell_list} [-
block_boundary_only {true | false}]]
[-well_cut_cells  list_of_well_cut_cells ]
[-fix_well_cut_cells]
[-pitch microns [-pitch_offset microns]]
[{-check_channel  | -vertical_boundary_spacing spacing_with_well_tap | -incremental
list_of_cells}]
[{-insert_cells list_of_cells | -incremental list_of_cells}]
```

Adds physical-only well-tap cells. Well-tap cells are physical-only filler cells that are required by some technology libraries to limit resistance between power or ground connections and wells of the substrate. Well-tap cells are placed in a preplaced status.

- To delete well-tap cells, use the `delete_filler` command.
- To verify well-tap placement, generate markers for violations caused by well-tap cells, and create a violation report, use the `check_well_taps` command.

Parameters

`-area x1 y1 x2 y2`	Specifies the coordinates of the bounding box, in microns. By default, the core box that encloses all core rows is used. • `x1`: Specifies the area's lower left point on the x axis. • `y1`: Specifies the area's lower left point on the y axis. • `x2`: Specifies the area's upper right point on the x axis. • *y2:* Specifies the area's upper right point on the y axis. *Data_type*:
`-avoid_abutment`	Specifies whether inserting well-taps avoids abutment in vertical and horizontal direction. Well-taps on every other row are shifted by `-site_offset`. *Data_type*:
`-block_boundary_only {true | false}`	Specifies whether to insert termination tap cells only for well tap columns on the block boundary. Default is false, termination cells are inserted on both core boundary row and block boundary row. *Data_type*: **Note:** This parameter works only when inserting termination cells.
`-bottom_termination_cell cell_list`	Specifies the list of termination cells to be used at the bottom. *Data_type*:
`-cell cellName`	Specifies the name of the cell in the technology library to use as a well-tap. The cell should be of class type CORE. *Data_type*:
`-cell_interval microns`	Specifies the maximum distance from the center of one well-tap cell to the center of the following well-tap cell in the same row. If well-tap cells cannot be placed at this location due to a placement blockage, the software searches for a legal location: first, towards the previous well-tap cell, and then farther away. Note that the minimum cell interval is 0.45 times the cell interval.
`-channel_offset offset_value`	Specifies the offset value between taps and blockage in channel. *Minimum*: 0 *Data_type*:

`-check_channel`	Inserts well taps inside channel. *Data_type*:
`-checker_board`	Places the well-tap cells in a checkered pattern, that is, with every other row offset by one-half `cell_interval`. In a row immediately above or below a row where the pattern can't be maintained (for example, bottom and top row, or row immediately above or below macros) well-taps are inserted with a pitch of one-half `cell_interval` in the section where the pattern can't be maintained. When a floorplan has hard blocks or placement blockages, the rows above and below the block (or blockage) will also have well-taps at one-half gap. *Data_type*: **Note:** When this parameter is specified, `-skip_row` and `-avoid_abutment` are ignored.
`-column_cells tap_column_cell_list`	Specifies the list of well tap columns that need to be terminated. This parameter must be specified for termination tap cell insertion. *Data_type*:
`-fix_well_cut_cells`	Fixes all the instances which belong to the `wellCutCell` list. *Data_type*:
`-fixed_gap`	Ensures that the specified gap is always maintained. That is, the software does not search for a legal location if it cannot place well-tap cells at the specified `-cell_interval`. Instead, it goes on to place well-tap cells at the next position. *Data_type*: You can modify the gap by using the `-pitch` and `-pitch_offset` parameters.

`-help`	Outputs a brief description that includes type and default information for each `add_well_taps` parameter. For a detailed description of the command and all of its parameters, use the man command: `man add_well_taps`.
`-incremental` *`list_of_cells`*	Checks whether any instances of the cells specified in the *`list_of_cells`* are within 0.45 times the `-cellGap` from the next well-tap cell in the same row. If so, does not add well-tap cells at that location. *Data_type*:
`-insert_cells` *`list_of_cells`*	Inserts mixed well-taps, and supports the LUP layer and boundary layer rules. *Data_type*:
`-in_row_offset` *`microns`*	Specifies the offset, in microns, of the first well-tap cell from the start of the site row. *Default*: `0` (first cell on beginning of row is the starting point). *Data_type*:
`-pitch` *`microns`*	Used with the `-fixed_gap` parameter to give the software added flexibility to place well-tap cells if it is unable to place a cell at the specified location. If you specify this parameter, the software first tries to fit the well-tap cells in the locations specified by `-cell_interval` or forced by `-fixed_gap`; if it cannot do so, it adds well tap cells at the closest location allowed by this parameter. *Data_type*:
`-pitch_offset` *`microns`*	Used with the `-fixed_gap` and `-pitch` parameters to give the software greater flexibility. If you specify this parameter, the software first tries to fit the well-tap cells in the locations specified by `-cell_interval` or forced by `-fixed_gap`; if it cannot do so, it adds well tap cells at the closest location allowed by this parameter. *Data_type*:

`-power_domain` *`powerDomainName`*	Specifies the power domain in which the well-tap cells are inserted. This is the area where the well-tap cells are placed and connected to the correct power and ground nets. *Data_type*:
`-prefix` *`prefixName`*	Specifies the prefix for the placed well-tap cells. The software adds an underscore and a unique string to the prefix, in the following format: `prefix_`*`uniqueString`*. *Prefix Default:* `WELLTAP` *Data_type*: ⓘ Do not include an underscore when you specify a prefix.
-site_offset *number_of_sites*	Specifies an offset value, in sites, when `-avoid_abutment` is specified. *Default:* `0` *Data_type*:
`-skip_row` *`number`*	Specifies the number of rows to skip between two rows of an identical pattern. *Data_type*: **Note:** If you specify `-checker_board`, this parameter is ignored. *Default*: `0` (No rows are skipped, so well-tap cells are added in the same pattern to every row)
`-start_row` *`number`*	Specifies the row number starting from the from bottom or left side of the design on which the well-tap cells must be placed. *Default*: 1 (first row from the bottom is the starting point) *Data_type*:

`-termination_cells` *cell_list*	Specifies the list of cells that can be used as termination taps. `add_well_taps` selects the best fit termination cells from this list and inserts them at the top and bottom of well tap column segment. The existing non-termination well taps are deleted as needed. If the well tap columns have already been terminated with a valid termination cell, the existing termination cell are kept in the incremental run and no changes are made. *Data_type*: **Note:** It is recommended that well tap columns are added before termination cell insertion. **Note:** This parameter must be specified for termination tap cell insertion.
`-top_termination_cell` *cell_list*	Specifies the list of termination cells to be used at the top. *Data_type*:
`-vertical_boundary_spacing` *spacing_with_well_tap*	Specifies vertical boundary spacing with well tap. `add_well_taps` will recognize all vertical boundaries and keep center of tap cells to these boundaries equal to or less than the specified distance when inserting. *Minimum*: -1 *Maximum*: 1.79769313486232e+308 *Data_type*:
`-well_cut_cells` `list_of_well_cut_cells`	Specifies the list of cells with the well cuts. The `add_well_taps -incremental` flow treats cells specified in this list as placement blockage because they cut the row and fix the latch up violations within them. *Data_type*:

Examples

- The following command places instances of well-tap cell `xyz` on every row in the design. Instances in the same row are at least 22.50 µm but no more than 50 µm apart. Each instance name is prefixed with `welltap_`.

```
add_well_taps -cell xyz -prefix welltap -cell_interval 50
```

- The following commands place instances of well-tap cell `xyz` in a checkered pattern. The first instance in the odd row numbers (`1`, `3`, `5`, and so on) is placed at `0` (zero) offset. The first instance in even row numbers (2, 4, 6, and so on) is placed at 50 µm offset. Instances in the same row are at least 45 µm but no more than 100 µm apart. Instances on the odd rows are named `wtap_odd_1`, `wtap_odd_2`, and so on. Instances on the even rows are named `wtap_even_1`, `wtap_even_2`, and so on.

```
add_well_taps -cell xyz -prefix wtap_odd -cell_interval 100 -skip_row 1
add_well_taps -cell xyz -prefix wtap_even -cell_interval 100 -skip_row 1 \
    -start_row 2 -in_row_offset 50
```

- The following command places instances of well-tap cell `WTAP` on every row in the design. Instances in the same row are at least 21.68 µm but no more than 48.2 µm apart. Before placing the instances, the software checks for cells named `WTAP` and `PSO1`, and if it finds any within the minimum gap (that is, 21.68 µm from the nearest well-tap cell in that row) it does not place any instances in that area.

```
add_well_taps -cell WTAP -incremental "WTAP PSO1" -cell_interval 48.2
```

- In the following commands, cell TAP is specified as general well tap and TAP_TERMINATION is specified as termination well tap. TAP cells and tap columns are inserted first, followed by TAP_TERMINATION cells as termination cells at the top and bottom of each TAP column.

```
add_well_taps -cell TAP -cell_interval 28

add_well_taps -termination_cells TAP_TERMINATION -column_cells TAP
```

add_well_taps Category Attributes

The root attributes in the add_well_taps category are:

- add_well_taps_avoid_abutment
- add_well_taps_avoid_vertical_well_abutment
- add_well_taps_block_boundary_only
- add_well_taps_bottom_tap_cell
- add_well_taps_bottom_termination_cell
- add_well_taps_cell
- add_well_taps_channel_offset
- add_well_taps_check_channel
- add_well_taps_column_cells
- add_well_taps_create_rows
- add_well_taps_disable_check_zone_at_boundary
- add_well_taps_in_row_offset
- add_well_taps_insert_cells
- add_well_taps_rule
- add_well_taps_site_offset
- add_well_taps_tap_function_cells
- add_well_taps_tap_termination_alignment
- add_well_taps_termination_align
- add_well_taps_termination_cells
- add_well_taps_top_tap_cell
- add_well_taps_vertical_boundary_spacing
- add_well_taps_top_termination_cell
- add_well_taps_well_cut_cells

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `add_well_taps` category, use the following command:

```
get_db -category add_well_taps
```

add_well_taps_avoid_abutment

`add_well_taps_avoid_abutment {true|false}`

Default: `false`

Data_type: bool, read/write

Specifies whether the inserted taps should avoid horizontal and vertical abutment.

add_well_taps_avoid_vertical_well_abutment

`add_well_taps_avoid_vertical_well_abutment {none ntap ptap all_tap}`

Default: `none`

Data_type: enum {none ntap ptap all_tap}

Specifies the type of well-tap cells to be forbidden from the vertical abutment.

add_well_taps_block_boundary_only

`add_well_taps_block_boundary_only {true|false}`

Default: `false`

Data_type: bool, read/write

Specifies whether to insert termination tap cells only for well tap columns on the block boundary. Default is false, termination cells are inserted on both core boundary row and block boundary row.

Note: This attribute works only when inserting termination cells.

add_well_taps_bottom_tap_cell

`add_well_taps_bottom_tap_cell cellName`

Default: `""`

Data_type: string, read/write

Specifies the cell to be used as the bottom tap for the add_endcaps boundary cell insertion flow.

add_well_taps_bottom_termination_cell

add_well_taps_bottom_termination_cell *cellList*

Default: `""`

Data_type: string, read/write

Specifies the list of bottom termination cells to be used.

add_well_taps_cell

`add_well_taps_cell` *cellName*

Default: `""`

Data_type: string, read/write

Specifies the name of the cell in the technology library to use as a well-tap. The cell should be of class type CORE.

add_well_taps_channel_offset

`add_well_taps_channel_offset` *offset_value*

Default: `0.0`

Data_type: double, read/write

Specifies the offset value between taps and the blockage in channel.

add_well_taps_check_channel

`add_well_taps_check_channel {true|false}`

Default: `false`

Data_type: bool, read/write

Specifies whether the blockage channel will be checked.

add_well_taps_column_cells

`add_well_taps_column_cells` *`cellist`*

Default: ""

Data_type: string, read/write

Specifies the maximum distance, in microns, between the tie-cell driver and the tie-pins. A value of `0` implies no distance constraint.

add_well_taps_create_rows

`add_well_taps_create_rows {true|false}`

Default: `false`

Data_type: bool, read/write

Creates rows for welltap cell techSites which do not have rows in the floorplan.

add_well_taps_disable_check_zone_at_boundary

`add_well_taps_disable_check_zone_at_boundary {none vdd vss both}`

Default: `none`

Data_type: enum {none vdd vss both}, read/write

Creates rows for welltap cell techSites which do not have rows in the floorplan.

add_well_taps_in_row_offset

`add_well_taps_in_row_offset` *`offset_value`*

Default: `0.0`

Data_type: double, read/write

Specifies the distance between the first welltap in a row and the start of the row.

add_well_taps_insert_cells

`add_well_taps_insert_cells {`*`cellName rule dense_layer dense__rule boundary_layer boundary_rule`*`}`

Default: `""`

Data_type: string, read/write

Inserts well-taps based on cell, layer, and interval.

- *`cellName`*: Specifies the cell name.
- *`rule`*: Cell with this rule would be added as a general tap cell for all placeable area. The center to center spacing of tap cells would be `≤ (2*$rule)` without `-checker_board` and `≤ (4*$rule)` with -`checker_board`.
  Note: Center of the tap cell is used to check the spacing.
- *`dense_layername`*: Specifies the dense layer name.
- *`dense_rule`*: Cell with dense layer would be added to the given layer regions only. Cell with dense layer must follow the dense rule. The center to center spacing of dense tap cells would be `≤ (2*$dense_rule)` without `-checker_board` and `≤ (4 *$dense_rule)` with `-checker_board`.
- *`boundary_layername`*: Specifies the boundary layer name.
- *`boundary_rule`*: A cell would be added for boundaries inside the given layer regions. The spacing between the boundary to the center of boundary tap cells would be ≤ $ boundary rule. Boundary layer regions which cover partial sites should be extended. Boundary taps can be located in or out of boundary layer regions.

Note:

- You can define multiple cells for -insert_cells by separating each cell by { }.
- There should be at lest one rule, dense layer or boundary layer, defined for each cell.
- The order of tap cell insertion is:
  a. Dense tap
  b. Boundary tap
  c. General tap
- If the area is covered by both dense layer region and boundary layer region, both layer rules must be satisfied.
- If `-insert_cells` is defined multiple times, the last setting is accepted by the tool.

add_well_taps_rule

`add_well_taps_rule` *`RuleValue`*

Default: `0.0`

Data_type: double, read/write

Specifies the rule to be honored when adding well taps.

add_well_taps_site_offset

`add_well_taps_site_offset` *`number_of_sites`*

Default: `1`

Data_type: int, read/write

Specifies an offset value, in number of sites, so that the vertical taps are aware of.

add_well_taps_tap_function_cells

`add_well_taps_tap_function_cells` *`cell_list`*

Default: `""`

Data_type: string, read/write

Specifies the list of tap function cells to be used.

add_well_taps_tap_termination_alignment

`add_well_taps_tap_termination_alignment [true | false]`

Default: `false`

Data_type: bool, read/write

Specifies whether to align well-taps and termination cells.

add_well_taps_termination_align

`add_well_taps_termination_align {left right center}`

Default: `left`

Data_type: enum {left right center}, read/write

Specifies the termination cell alignment.

add_well_taps_termination_cells

`add_well_taps_termination_cells` *`cellist`*

Default: `""`

Data_type: string, read/write

Specifies the list of cells that can be used as termination taps. The command `add_well_taps` selects the best fit termination cells from this list and inserts them at the top and bottom of well tap column segment. The existing non-termination well taps are deleted as needed. If the well tap columns have already been terminated with a valid termination cell, the existing termination cell are kept in the incremental run and no changes are made.

Note: It is recommended that well tap columns are added before termination cell insertion.

Note: This attribute must be specified for termination tap cell insertion.

Related Commands

- `add_well_taps`

add_well_taps_top_tap_cell

`add_well_taps_top_tap_cell` *`cellName`*

Default: `""`

Data_type: string, read/write

Specifies well taps inserted into top rows during enclosed end cap insertion.

Note: This attribute must be specified when `add_endcaps_boundary_tap` is set to `true`.

add_well_taps_vertical_boundary_spacing

`add_well_taps_vertical_boundary_spacing` *`spacing_value`*

Default: `-1.0`

Data_type: double, read/write

Specifies the spacing between the center of tap cell and vertical boundary.

add_well_taps_top_termination_cell

`add_well_taps_top_termination_cell` *`cellList`*

Default: `""`

Data_type: string, read/write

Specifies the list of top termination cells to be used.

add_well_taps_well_cut_cells

`add_well_taps_well_cut_cells` *`cellist`*

Default: `""`

Data_type: string, read/write

Specifies the list of cells with the well cuts. `addWellTap` considers the specified cells cutting the row.

check_filler

```
check_filler
[-help]
[-area x1 y1 x2 y2]
[-power_domain power_domain_name]
[-horizontal_max_length]
[-out_file fileName ]
[-report_gap microns | -adjacent_filler1]
[-vertical_stack_max_length]
```

Checks for locations that are missing filler cells, after adding the cells with the `add_fillers` command. Optionally, generates a report with details on sites that are missing filler cells.

If you run this command without any parameters, it reports the total number of sites in the core area that are missing filler cells.

Parameters

`-adjacent_filler1`	Checks for locations that are filled with adjacent one-site-width fillers. With this parameter, `check_filler` flags any one-site-width filler placed next to each other as a violation. To enable this parameter, you must first specify a one-site-width filler by using the following command: `set_db add_fillers_cells fillerCellList` *Data_type*: bool, optional
`-area {x1 y1 x2 y2}`	Specifies a bounding box for the area in which to check for missing filler cells. *Default:* Entire core area *Data_type*: rect, optional
`-horizontal_max_length`	Checks if the horizontal stack length violates the maximum limit. *Data_type*: bool, optional
`-out_file fileName`	Writes the output of the `check_filler` command to the specified file. *Data_type*: string, optional

`-help`	Outputs a brief description that includes type and default information for each `check_filler` parameter. For a detailed description of the command and all of its parameters, use the man command: `man check_filler`.
`-power_domain` *`power_domain_name`*	Checks for missing filler cells in the specified power domain. The software checks for missing filler cells in all power domains if you do not specify this parameter. *Data_type*: string, optional
`-report_gap` *`microns`*	Checks only for gaps of the specified size- ignores any other gap, whether larger or smaller. *Data_type*: float, optional
`-vertical_stack_max_length`	Checks if the vertical stack length violates the maximum limit. *Data_type*: bool, optional

Examples

The following command checks the entire core area after running `add_fillers` and reports the number of sites that are missing filler cells:

```
check_filler
```

The software reports the following:

```
*INFO: Total number of gaps found: 85
```

The following command checks within the specified bounding box at coordinates {0 0 100 100} and reports the number of sites that have a gap of exactly 0.14 microns:

```
check_filler -report_gap 0.14 -area {0 0 100 100}
```

The software reports the following:

```
*INFO: Total number of 0.140 microns width gap found: 3
```

- add_fillers Category Attributes
- delete_filler

check_library

```
check_library
[-help]
[-place [-cell cell_name|-all_lib_cell ][-legal_frequency ] [-file fileName] ]
```

Checks the problematic cells that cause issues such as bad geometries for DRC and bad pin access for routing. You can specify a library cell or a partition cell. It also performs checks for the multi-height cell legal frequency. The report is dumped into an output file.

Parameters

`-all_lib_cell`	Specifies to check all library cells. *Data_type*: bool, optional
`-cell cell_name`	Specifies the cell to check. *Data_type*: (base_cell)+, optional
`-file fileName`	Specifies the name of the output file. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `check_library` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man check_library`.
`-legal_frequency`	Specifies to check multi-height cell legal frequency. *Data_type*: bool, optional
`-place`	Specifies to do library checking for placement. *Data_type*: bool, optional

Example

- The following command checks the `buf01` cell:

```
check_library -place -cell buf01

Estimated cell power/ground rail width = 0.021 um

*info: running library checker ...

*info: total 1 cell checked.

*reporting cell (buf01) ...

reporting cell drc : "legal"

reporting cell pin access : "legal"

reporting cell symmetry : cell (buf01) has lef symmetry X Y

reporting cell pin alignment : "legal"

reporting cell legal frequency ...
cell (buf01) legalization frequency: one legal location out of every 1.25 sites
```

check_place

```
check_place
[-no_check_pin_access]
[-clear_marker]
[-honor_preroute_for_filler]
[-ignore_filler_in_density]
[-ignore_out_of_core]
[-inst list_of_instances]
[-io_pin_blockage]
[-macro_blockage]
[-no_hard_fence]
[-no_preplaced]
[-no_halo]
[violationReportFileName]
[-selected_only]
```

Checks `FIXED` and `PLACED` cells for violations, adds violation markers to the design display area, and generates a violation report. Use the Violation Browser to see the violation markers.

Rules as to what constitutes a placement violation are different for `FIXED` and `PLACED` cells. For example, `FIXED` cells in obstruction areas are not considered to be violations, but `PLACED` cells are considered to be violations.

This command considers preplaced instances and macros as `FIXED`.

Note: The utilization value reported by `check_place` and the density value reported by `time_design` might differ because `check_place` considers padding when calculating utilization but `time_design` does not consider padding when calculating density.

You can delete padding by running the `delete_all_cell_padding` command before running `check_place`.

Note: If `set_db place_detail_legalization_inst_gap` is defined, check_place will report the gaps that violate the specified spacing.

The `check_place` command checks for the following violations:

- Implant max cover length. If this violation is detected, GUI adds markers for every instance. As per this violation rule the implant shapes cannot be fully covered horizontally by neighbor shapes on both top and bottom opposite sides. If check_place detects the violation, GUI adds markers for every instance
- Region and fence violations (Instances placed outside their region or fence)
- Out of core area violations (Instances placed partly or wholly outside the core area)

- Not placed on placement grid (Standard cells not on the placement grid, or blocks not on the manufacturing grid). If the design is using the FinFET technology, check_place will also check if standard cells and blocks are not aligned on the FinFET grid and report violations.
- Row orientation violations (Instances whose orientation is illegal for their row; may short power to ground)
- Tech site violations (Instances placed on tech sites not matching their cells and instances that do not have rows for their tech sites)
- Overlapping with other instance (Placed instances that overlap with other instances)
- Pin access violations (Instances with at least one signal pin that does not have routing access due to pre-wires)
- Orientation violations (Instances whose orientation is not legal based on its cell symmetry rules)
- Routing/placement blockage violations in the core area (Instances placed in an obstruction created by pre-wires or routing blockage)
  The command does not check fixed macros.
- Placement blockage violations in the core area (for example, placed instances in an obstruction created by prerouted wires or a routing blockage, placed instances that overlap a placement blockage area).
  Note: The command does not check fixed instances overlapping placement or routing blockages by default.
- Site orientation violations (Instances whose orientation does not match the tech site orientation)
- Not of fence violations (Instances placed inside a fence to which it does not belong)
- Prints implant layer names in the Implant Layer Spacing violation. The implant Spacing Violation would be as follows:

  ```
  Implant_Spacing_Violation
  $instance1 implant layer $layer1 has corner touch violation to $instance2 implant
  layer $layer2
  VT group name: $Group  Base layer: $layer
  MinWidth: $width  MinSpacing:$spacing    ShiftDistance: $value
  Box=$box
  ```

  Note: It only works for the static check of the `checkPlace` command.

In addition to checking for violations, the command reports the following:

- Number of placed instances in the design
- Number of unplaced macros in the design

- Placement density, in terms of used sites over available sites

Parameters

`-no_check_pin_access`	Specifies whether to check for pin access violations. *Data_type*: bool, optional
`-clear_marker`	Removes the violation markers from a previous `check_place` run, without rerunning `check_place`. *Data_type*: bool, optional
`-honor_preroute_for_filler`	Checks for placement blockage violations on physical instances placed under preroutes or specified by the `place_detail_preroute_as_obs` attribute. By default, `check_place` does not treat filler cells placed under preroutes as violations, even though they are placement/routing blockages; however, it does treat standard cells placed under preroutes as violations. *Data_type*: bool, optional
`-ignore_filler_in_density`	Ignores filler cells in calculating utilization. *Data_type*: bool, optional
`-ignore_out_of_core`	Skips instances outside the core design area. *Data_type*: bool, optional
`-inst` *`list_of_instances`*	Specifies the list of instances to check. *Data_type*: string, optional
`-io_pin_blockage`	Instructs legalization routines to treat top-level I/O pins as fixed metal obstructions while placing standard cell instances at the block level. There is a minor run-time penalty with this parameter, so it is not turned on by default. *Data_type*: bool, optional

`-macro_blockage`	Checks for overlap between hard macro and macro-only blockage and reports macro blockage violation. By default, macro-only blockage is ignored for both hard macro and standard cell. With this setting, it is treated as a placement obstruction for macros. *Data_type*: bool, optional
`-no_halo`	Skips block halos. Uses the place-and-route boundary for the placement overlap check. *Data_type*: bool, optional
`-no_hard_fence`	Ignores fence and region placement constraints. *Data_type*: bool, optional
`-no_preplaced`	Does not check fixed instances. When this parameter is specified, `check_place` treats fixed instances as placement blockages. *Data_type*: bool, optional
`-selected_only`	Specifies to check only the selected instances legality. *Data_type*: bool, optional
violationReportFileName	Specifies the report file. If you do not specify this parameter, the command displays a summary report. The report file is more detailed than the summary report, and lists every instance with a violation. *Data_type*: string, optional

Note: If a design is loaded where a macro is fixed in an orientation that is not supported according to its LEF, running `check_place` changes the orientation and the position of the macro, even if the `-no_preplaced` option is specified.

Example

Here is an example:

Cell positions before check_place:

```
FPFEL0_SLM/fpicl/fpiclmsc/ThermRemote_FP_1: {544.32 648}
FPFEL0_SLM/fpicl/fpiclmsc/ThermRemote_FP_2: {544.32 669.6}

< CMD> check_place
**WARN: (ENCDB-1266): Both given orientation and original orientation not legal,
```

```
FPFEL0_SLM/fpicl/fpiclmsc/ThermRemote_FP_1 changes to orientation R0
**WARN: (ENCDB-1266): Both given orientation and original orientation not legal,
FPFEL0_SLM/fpicl/fpiclmsc/ThermRemote_FP_2 changes to orientation R0
Design has 3 cells with cell padding or block halo.
Begin checking placement ... (start mem=690.9M, init mem=714.5M)
*info: Placed = 1098
*info: Unplaced = 0
Placement Density:0.00%(0/407468)
Finished check_place (cpu: total=0:00:07.6, vio checks=0:00:00.0; mem=696.2M)
```

Cell positions after check_place:

```
FPFEL0_SLM/fpicl/fpiclmsc/ThermRemote_FP_1: {544.446 648}
FPFEL0_SLM/fpicl/fpiclmsc/ThermRemote_FP_2: {544.446 669.6}
```

create_gate_array_filler_group

```
create_gate_array_filler_group
[-help]
-gate_array_cells gaCellList
-gate_array_fillers gaFillerCellList
-group groupName
```

It creates gate array filler groups for the post-mask `place_eco` flow. When a filler group is created, `place_eco -use_gate_array_filler_groups true` can only place the GA cells at the GA filler location that is included in the same filler group.

This command can be used multiple times to define several gate array groups for `place_eco`. If one filler group name is defined many times, the last one will be kept.

Parameters

`-gate_array_cells` *gaCellList*	Specifies the list of GA cells. The * wildcard is supported to specify the cell list. *Data_type*: string, required
`-gate_array_fillers` *gaFillerCellList*	Specifies the list of GA filler cells. **Note**: One GA cell or GA filler cell cannot be defined in two groups, otherwise it will give error. *Data_type*: string, required
`-group` *groupName*	Specifies the group name. *Data_type*: string, required

Example

The following commands show the flow for GA Filler groups:

```
innovus> create_gate_array_filler_group -gate_array_cells GA_cell_list -
gate_array_fillers GA_filler_list -group group

innovus> place_eco -use_gate_array_filler_groups true
```

create_inst_space_group

```
create_inst_space_group
[-help]
-group_name groupName
-inst listOfInstances
{[{[ -spacing_y Distance] [-spacing_x Distance]} [-checking_box {all|cross_only}]] | [-
spacing_radial Distance]}
```

Creates space group for instances with a specific vertical or horizontal-distance constraint. You need to run the following command before `create_inst_space_group`.

```
>set_db place_detail_check_inst_space_group true
```

The `create_inst_space_group` information can be saved in DB.

Parameters

`-checking_box {all cross_only}`	Checks all area or the intersection area from `-spacing_x` & `-spacing_y`. • `cross_only`: Checks the intersection area of -`spacing_x` and -`spacing_y`. If any instance violates both -`spacing_x`and -`spacing_y`, it is marked as a violation. • `all`: Checks all area covered by `spacing_x` and `spacing_y`. If any instance violates -`spacing_x` or -`spacing_y`, it is marked as a violation. The constrained box is ended by core/blockage/power domain/hard macro/row boundary. *Default*: `cross_only` *Data_type*: enum, optional
`-group_name` *groupName*	Specifies the name of the instance group. *Data_type*: string, required
`-help`	Outputs a brief description that includes type and default information for each `create_inst_space_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_inst_space_group`.
`-inst` *listOfInstances*	Specifies all instances that belong to the same space group by name. *Data_type*: string, required
`-spacing_radial` *Distance*	Specifies the radial distance, in microns. *Data_type*: float, optional
`-spacing_x` *Distance*	Specifies the distance, in microns, between each specific instance in the X direction. *Data_type*: float, optional
`-spacing_y` *Distance*	Specifies the distance, in microns, between each specific instance in the Y direction. *Data_type*: float, optional

Related Information

create_pg_keep_out

```
create_pg_keep_out
[-help]
[-bottom value]
[-left value]
[-pin <string>]
[-right value]
[-top value]
{-cell lib_cell_name | -inst instance_name} {-layer layer_name | -layer_id  layer_id}
```

Defines the PG keepout box for a cell or a pin.

Parameters

`-bottom value`	Specifies the value to expand the keepout box on the bottom side. *Data_type*: float, optional
`-cell` *`lib_cell_name`*	Specifies the lib cell that needs to be constrained by the PG keepout box. *Data_type*: string, required
`-help`	Outputs a brief description that includes type and default information for each `create_pg_keep_out` parameter. For a detailed description of the command and all of its parameters, use the man command: `man create_pg_keep_out`
`-inst` *`instance_name`*	Specifies the instance that needs to be constrained by the PG keepout box. *Data_type*: string, required
`-layer` *`layer_name`*	Specifies the layer on which the PG keepout box is applied. The layer is the LEF/OA name of routing layers. *Data_type*: string, required
`-layer_id` *`layer_id`*	Specifies the layer ids on which the PG keepout box is applied. The layer id is the layer number of routing layers. *Data_type*: string, required
`-left` *value*	Specifies the value to expand the keepout box on the left side. *Data_type*: float, optional
`-pin` *`pin_name`*	Specifies the pin that needs to be constrained by the PG keepout box. *Data_type*: string, optional
`-right` *`value`*	Specifies the value to expand the keepout box on the right side. *Data_type*: float, optional
`-top` *`value`*	Specifies the value to expand the keepout box at the top. *Data_type*: float, optional

Example

The following command keeps `mycustomcell/the_m4_pin` away from M5 power stripes:

```
create_pg_keep_out -cell mycustomcell -pin the_m4_pin -layer M5
```

Related Information

- `delete_pg_keep_out`

create_pipeline_bus_guide

```
create_pipeline_bus_guide
[-help]
[-net_group netGroupNames]
[-width_factor value]
[-layer id1:id2]
[-report fileName]
[-spacing value {-report filename}]
```

Generates bus-guide for the pipeline netgroup. The bus-guide is used to guide the router for expected path. It can be used in the analysis flow or after the pipeline flops are inserted in the netlist.

Note: The bus-guide width is scalable by the width factor. Default width factor is 1.0. The bus width equals to the (width factor) x (the largest pitch of given routing layers) x (the number of bus bits) + 1 extra pitch. The extra pitch is added to account for the possibility that bus-guides do not line up exactly with the routing grid.

Parameters

`-net_group` *netGroupNames*	Specifies the netgroup name(s) that the bus-guide is created for. *Default*: `""` *Data_type*: string, optional
`-width_factor` *value*	Specifies the width factor of bus-guide. *Default*: `1.0` *Data_type*:
`-layer` *id1:id2*	Specifies the layer(s) to use for the generated bus-guide. It can be a single layer or layer range. *Default*: `all` *Data_type*: float, optional
`-report` *fileName*	Specifies the analysis report file name. *Default*: `<filename>.rpt` *Data_type*: string, optional
`-spacing` *float*	Specifies the maximum space between flops. *Default*: `""` *Data_type*: float, optional

Example

- The following command writes out a report file 'busguide.rpt' which tells the total estimated length of bus (in microns), the number of stages that will be needed (based on the given spacing of 200 um), and location of each stage of PFFs for all net groups on all routing layers.
  ```
  create_pipeline_bus_guide -spacing 200 -report busguide.rpt
  ```
- The following command create bus-guide for net group 'NG1' on routing layers 2, 3, and 4. The bus-guide width is 2 times the default width.
  ```
  create_pipeline_bus_guide -net_group NG1 -width_factor 2.0 -layer 2:4
  ```

create_pipeline_net_group

```
create_pipeline_net_group
[-help]
-net_group_name netGroupName
[-end_reserve reserveDistanceInMicrons]
[-end_term termList]
[-inst instNameListOrRegularExp]
[-net listOfNetnamesOrRegularExp]
[-start_reserve reserveDistanceInMicrons]
[-start_term termList]
```

Creates Net Groups for Pipeline Flip-Flop (PFF) Placement and Reporting. This command can be used for analysis before the flops exist in the netlist; or it can be used post flop insertion to add a new net group.

Parameters

`-end_reserve` *reserveDistanceInMicrons*	Specifies a distance value from the end points on block boundary to the internal connection inside the block, which is accounted for in each stage distance value. The unit is in micron. *Data_type*: float, optional
`-end_term` *termList*	Specifies the end points of net groups. *Data_type*: string, optional
`-net_group_name` *netGroupName*	Specifies the name of the net group. *Data_type*: string, required
`-inst` *instNameListOrRegularExp*	Creates net group of all nets connected to the given instances. All the instances must be flip-flops or latches. All the nets attached to the D and Q pins are put into the PFF net group. *Data_type*: string, optional
`-net` *listOfNetNamesOrRegularExp*	Creates net group of all given nets. *Data_type*: string, optional
`-start_reserve` *reserveDistanceInMicrons*	Specifies a distance budget from internal connections inside block to the start point of the PFF net. This value is added to the first stage distance when calculating equidistant spacing for each stage. The unit is in micron. *Data_type*: float, optional
`-start_term` *termList*	Creates net group of all data nets between the given end points. The PFF-chain is traced from the startTerm, through D and Q terminals of PFF(s) until an endTerm is matched. *Data_type*: string, optional

Example

- The following command creates a net group named `netGroup1' for Pipeline Flip-Flop (PFF) of all data nets between `blockA/DATA_OUT*` and `blockB/DATA_IN*`:

  ```
  create_pipeline_net_group netGroup1 -start_term blockA/DATA_OUT* -end_term
  blockB/DATA_IN*
  ```

- The following command creates a net group named `netGroup2` for all nets connected with all instance names that begin with `PIPELINE_INST/in`:

  ```
  create_pipeline_net_group NetGroup2 -inst PIPELINE_INST/in*
  ```

- The following command creates a net group named `netGroup3` for all net names that begin with `SUM_P4`.

  ```
  create_pipeline_net_group NetGroup3 -net SUM_P4*
  ```

Related Information

- delete_pipeline_net_group
- update_pipeline_net_group

create_scan_chain

```
create_scan_chain
[-help]
[-name]
[-start {ftname | instPinName}]
[-stop {ftname | instPinName}]
```

Specifies a scan chain or a group in a design. The actual tracing of the scan chain is performed by the `trace_scan` or `reorder_scan` command. If scan chain specification fails, use the `trace_scan -verbose` command to see where the scan chain stops.

Note: Scan groups are sometimes called scan partitions.

ⓘ This command is not necessary for scan chains that are already specified in DEF or TDF files.

Parameters

-name	Specifies the scan chain or scan group in a design. *Data_type*: string, required
-start {*ftname* | *instPinName*}	Specifies the: • Starting scan pin name for the scan chain or scan group. • Design input pin name. • linstance output pin name. *Data_type*: string, required
-stop {*ftname* | *instPinName*}	Specifies the: • Stopping scan pin name for the scan chain or scan group. • Design output pin name. • Instance input pin name. *Data_type*: string, required

Example

The following command sets scan chain `test_si` with a starting I/O pin name and a stopping pin name:

```
create_scan_chain test_si -start test23 -stop test_so
```

  - Optimizing and Reordering Scan Chains

create_scan_chain_partition

```
create_scan_chain_partition
-name partitionName
{-all | -scan_chains chainName}
```

Defines a group (a partition) of compatible scan chains for the scan reordering flow. The software can swap elements in scan chains in the partition. Swapping elements helps reduce the total scan wire length in the partition and improves local congestion in the design.

To enable swapping, type the following command:

```
set_db reorder_scan_allow_swapping true
```

Parameters

`-all`	All scan chains in the specified partition are compatible. *Data_type*: bool, required
`-scan_chains chainName`	Only the specified scan chains in the specified partition are compatible. *Data_type*: string, required
`-name partitionName`	Specifies a name for the partition and a list of the scan chains that belong to the partition. The scan flops in these chains are swappable. *Data_type*: string, required

Example

The following commands define two scan chains using `create_scan_chain` command, and define one partition using `create_scan_chain_partition`. The `reorder_scan_allow_swapping` attribute allows the software to swap elements between compatible chains.

```
create_scan_chain chain1 -start SI1 -stop SO1

create_scan_chain chain2 -start SI2 -stop SO2

create_scan_chain_partition -name clk1Domain chain1 chain2

set_db reorder_scan_allow_swapping true

reorder_scan
```

Related Information

create_spare_module

```
create_spare_module
-module_name moduleName
-cells {cellName [number] [cellName [number] ] …}
[-clock netName]
[-reset netName:pinName [pinName] …]
[-tieoffs {tieCellName [tieCellname] } ]
[-tie_low {pinList | *} ]
[-use_cell_as_prefix]
```

Creates a spare module made up of the specified cells.

Parameters

`-cells {`*`cellName`* `[`*`number`*`] [`*`cellName`* `[`*`number`*`] ] …}`	Specifies the names of the cells, and the number of each, to add to the spare module. If you do not specify the number of cells to add, the `set_db add_tieoffs_max_fanout` attribute controls the number of cells. *Data_type*: string, required
`-clock` *`netName`*	Specifies a clock net to connect to the clock pins of the instances in the spare module. *Data_type*: string, optional
`-module_name` *`moduleName`*	Specifies a name for the spare module. *Data_type*: string, required
`-reset` *`netName`*`:`*`pinName`* `[`*`pinName`*`]`	Specifies a net and the pins to connect to the reset pins of sequential spare cells in the spare module. If you do not specify this parameter, these reset pins are not connected. *Data_type*: string, optional
`-tieoffs` *`tieCellName`* `[`*`tieCellName`*`]`	Specifies tie-high and tie-low cells to add to the spare module. The software recognizes whether the pins are high or low. *Data_type*: string, optional
`-tie_low {`*`pinList`* `| *}`	Specifies the pins to connect to the specified tie-low cell. Pins not specified here will be connected to `1'b1` or the tie-high cell. If no tie-low cells are specified with the `-tieoffs` parameter, it connects the pins to `1'b0`. *Data_type*: string, optional Use the following format for the pin list: `<pinList>` :: {*`cellName`*: <*`pin`*>} … `<pin>` :: *`pinName`* |*
`-use_cell_as_prefix`	Adds the master cell name as a prefix to the name of gates that are instantiated inside the module. The software adds `spr_gate_`*`n`* as a prefix by default; when you specify `-use_cell_as_prefix`, it prepends the master cell name to the default prefix. *Data_type*: bool, optional

Examples

The following command creates spare module `mod1` with cells `cellA`, `cellB`, and `tiehi4`:

```
create_spare_module -cells {cellA cellB} -tieoffs tiehi4 -module_name mod1
```

The following command creates spare module `mod1` with the following gates: `and_spr_gate_1`, `and_spr_gate_2`, `nand_spr_gate_1`, `nor_spr_gate_1`:

```
create_spare_module -cells {and 2 nand nor} -module_name mod1 -use_cell_as_prefix
```

Related Information

- `add_tieoffs Category Attributes`
- `delete_spare_module`

delete_all_cell_padding

`delete_all_cell_padding`

Removes placement padding specified by `set_cell_padding` for all cells. If you run this command before running `check_place`, `check_place` does not consider the cell padding when calculating effective utilization. For more information, see `check_place` and `set_cell_padding`.

Parameters

None

Examples

The following set of commands specifies the cell padding for `HDSDFRSPQ1` and `HDSDFRSPQ2`, and then deletes all padding by using `delete_all_cell_padding`:

```
set_cell_padding HDSDFRSPQ1 2
set_cell_padding HDSDFRSPQ2 2
delete_all_cell_padding
```

Related Information

- `check_place`
- `set_cell_padding`
- `report_cell_padding`
- Placing the Design chapter in the *Innovus Stylus Common UI User Guide*.
    - Adding Padding

delete_all_scan_cells

```
delete_all_scan_cells
[-help]
```

Unassigns all assigned scan cells. This command can be called after importing the design if there are scan cell specifications in library; or else it can be used after the `set_scan_cell` command.

Parameters

None

Example

The following set of commands deletes all scan cells after loading design:

```
read_db init.enc.dat top
delete_all_scan_cells
```

Related Information

- `read_db`
- `set_scan_cell`
- Placing the Design chapter in the *Innovus Stylus Common UI User Guide*.
    - Optimizing and Reordering Scan Chains

delete_base_cell_edge_type

```
delete_base_cell_edge_type
[-help]
-base_cell cellName
-edge_type edgeType
```

Deletes the cell edge type constraint of the specified cell.

Parameters

`-base_cell` *`cellName`*	Specifies cell name to remove constraint. *Data_type*: string, required
`-edge_type` *`edgeType`*	Specifies the name of edge type to be removed. *Data_type*: string, required
`-help`	Outputs a brief description that includes type and default information for each `delete_base_cell_edge_type` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_base_cell_edge_type`.

Related Information

- `place Category Attributes`
- `report_cell_edge_type`

delete_cell_edge_spacing

```
delete_cell_edge_spacing
[-help]
type1
type2
```

Deletes the spacing rule between two edge types. The edge types specified must be predefined.

Note: This command only deletes the cell edge constraint specified by Tcl and does not delete the edge spacing defined in LEF.

Parameters

type1	Specifies edge type1 for edge spacing. *Data_type*: string, required
type2	Specifies edge type2 for edge spacing. *Data_type*: string, required
-help	Outputs a brief description that includes type and default information for each `delete_cell_edge_spacing` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_cell_edge_spacing`.

Related Information

- `place Category Attributes`
- `report_cell_edge_spacing`

delete_cell_padding

```
delete_cell_padding
[-help]
base_cell
```

Deletes the padding for a cell or list of cells. If a regular expression or a list of cells is provided, this command returns the number of cells for which the padding was deleted.

Parameters

base_cell	Specifies the cell name for which padding has to be deleted. The cell name can be a regular expression, or a list of cell names or expressions. *Data_type*: string, required
-help	Outputs a brief description that includes type and default information for each `delete_cell_padding` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_cell_padding`.

Examples

- The following command deletes padding for the cells with prefix `FF_SCAN`:
  ```
  delete_cell_padding FF_SCAN*
  ```
- The following command deletes padding for all cells that have names starting with `BUF`, `INV`, and `DLY`. If a matched cell name does not have padding information, it is ignored without any message.
  ```
  delete_cell_padding {BUF* INV* DLY*}
  ```
- The following command deletes padding for cell `FF_SCAN1` and cell `FF_SCAN2`:
  ```
  delete_cell_padding {FF_SCAN1 FF_SCAN2}
  ```

Related Information

- place Category Attributes
- report_cell_padding
- set_cell_padding

delete_cell_stack_area

```
delete_cell_stack_area
[-help]
[-cell cell_name]
[-group group_name]
```

Deletes the cell stack area definition.

Parameters

`-cell` *cell_name*	Specifies the cell(s) for which the cell stack area definition needs to be deleted. *Data_type*: string, optional
`-group` *group_name*	Specifies the group(s) for which the cell stack area definition needs to be deleted. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `delete_cell_stack_area` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_cell_stack_area`

Related Information

- `place Category Attributes`
- `report_cell_stack_area`
- `set_cell_stack_area`

delete_cell_stack_group

```
delete_cell_stack_group
[-help]
[-name group_name]
```

Deletes cell stack group definition.

Parameters

`-name` *group_name*	Specifies the group(s) for which the cell stack group definition is to be deleted. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `delete_cell_stack_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_cell_stack_group`

Related Information

- `place Category Attributes`
- `report_cell_stack_group`
- `set_cell_stack_group`

delete_cell_virtual_align

```
delete_cell_virtual_align
[-help]
[-cells cells]
```

Deletes the cells that need to be virtually aligned.

Parameters

`-cells` *cells*	Specifies the lib cells that require virtual alignment. *Data_type*: (base_cell)+, optional
-help	Outputs a brief description that includes type and default information for each `delete_cell_virtual_align` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_cell_virtual_align`

Related Information

- `place Category Attributes`
- `report_cell_virtual_align`
- `specify_cell_virtual_align`

delete_filler

```
   delete_filler
[-cells baseCellNameList]
[-area {x1 y1 x2 y2}]
[-inst instanceName ]
[-prefix prefix ]
[-keep_fixed]
```

Removes physical cell instances, such as filler cells, end-cap cells, and well-tap cells, from standard cell rows.

> Some `delete_filler` parameters can also be specified with `add_fillers` category attributes. However, the parameters you specify with `delete_filler` apply to the current `delete_filler` invocation only, and supersede attributes set by `add_fillers` category. For more information see add_fillers Category Attributes.

Parameters

`-area {x1 y1 x2 y2}`	Specifies the bounding box within which physical instances are deleted. The argument type is a box, in microns. *Data_type*: rect, optional **Note:** Only those filler cells that are completely contained within the area are deleted.
`-cells` *`baseCellNameList`*	Specifies a base cell name or list of base cell names to delete. *Data_type*: string, optional
`-keep_fixed`	Physical instances whose place_status is **FIXED** are not deleted. *Data_type*: bool, optional
`-prefix` *`prefix`*	Delete physical instances whose name starts with *`prefix`*. Does not support wildcards. *Data_type*: string, optional
`-inst` *`instanceName`*	Specifies the name(s) of the instance(s) to delete. You can use wildcards (`*?`) with this parameter. *Data_type*: string, optional

Examples

- The following command deletes all physical-only instances from the design:
  ```
  delete_filler -cells [ get_db -u [ get_db insts -if { .is_physical } ]
  .base_cell.name ] -prefix ""
  ```
- The following command deletes only the instances whose base_cell name is `xyz` and whose names have a `wtap_even` prefix.
  ```
  delete_filler -cells xyz -prefix wtap_even
  ```
- The following command deletes all physical instances with the name prefix `FILLER`:
  ```
  delete_filler -prefix FILLER
  ```
- The following commands delete all physical instances whose base_cell names are `FILL2`, `ecp17`, and `wtp5`:

```
delete_filler -cells "FILL2 ecp17 wtp5" -prefix ""
delete_filler -cells [ list FILL2 ecp17 wtp5 ] -prefix ""
delete_filler -cells {FILL2 ecp17 wtp5} -prefix ""
delete_filler -cells FILL2 ecp17 wtp5 -prefix ""
```

- The following command deletes all physical instances with prefix `WELLTAP` in the specified bounding box of {0 0 300 300} except those instances with place_status `FIXED`:

```
delete_filler -prefix WELLTAP -area {0 0 300 300} -keep_fixed
```

Related Information

- add_fillers
- add_fillers Category Attributes
- check_filler

delete_gate_array_filler_group

```
delete_gate_array_filler_group
[-help]
-group groupName
```

Deletes the gate array filler groups created by `create_gate_array_filler_group`.

Parameters

-help	Outputs a brief description that includes type and default information for each `delete_gate_array_filler_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_gate_array_filler_group`
-group *groupName*	Specifies the name of the group to be deleted. The * wildcard is supported. *Data_type*: string, required

Related Information

- `create_gate_array_filler_group`
- `place Category Attributes`

delete_inst_padding

```
delete_inst_padding
[-suppress] { inst | -all }
```

Deletes the padding for the specified instances, or all instance-based padding, in the design.

Parameters

`-all`	Deletes padding for all instances. *Data_type*: string, required
`-help`	Outputs a brief description that includes type and default information for each `delete_inst_padding` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_inst_padding`
inst	Deletes the padding on the specified instance. *Data_type*: bool, optional
`-suppress`	Suppresses verbose messages. *Data_type*: bool, optional

- The following command deletes padding for one instances named `U27316`:

  ```
  delete_inst_padding U27316
  ```

  It outputs following:

  ```
  Delete Padding for Instant [U27316].
  ```

Note: `delete_inst_padding` deletes padding for either all instances or single instance. Wildcard is not supported yet.

Related Information

- `delete_all_cell_padding`
- `report_inst_padding`
- Placing the Design chapter in the *Innovus Stylus Common UI User Guide*.
    - Adding Padding

delete_inst_space_group

```
delete_inst_space_group
[-help]
-group_name groupName
```

Deletes instance space group by a specific group name.

Parameters

`-group_name` *groupName*	Specifies the name of the instance group. *Data_type*: string, required
`-help`	Outputs a brief description that includes type and default information for each `delete_inst_space_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_inst_space_group`.

Related Information

- `create_inst_space_group`
- `place Category Attributes`
- `report_inst_space_group`

delete_mim_cap

```
delete_mim_cap
[-help]
[{[-cell cellName] [-prefix prefixName]} [-area x1 y1 x2 y2]]
```

Deletes the mim caps from the design based on cell type or prefix. This command can be used after `add_mim_cap`.

Parameters

`-area x1 y1 x2 y2`	Deletes only the Mim caps that are in the specified box. The `-cell` or `-prefix` options are required when this option is specified. *Data_type*: rect, optional
`-cell cellType`	Deletes the mim caps by cell type. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `delete_mim_cap` parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_mim_cap`.
`-prefix prefixName`	Deletes the mim caps by prefix. *Data_type*: string, optional

Examples

- The following command deletes the mim cap cell `mim_cell1`:

  ```
  delete_mim_cap -cell mim_cell1
  ```

Related Information

- `add_mim_cap`

delete_pg_keep_out

```
delete_pg_keep_out
[-help]
{-cell lib_cell_name | -inst instance_name | -all }
[-layer layer_name | -layer_id  layer_id]
```

Deletes PG keep out boxes in design for user defined objects.

Parameters

`-all`	Removes all PG keepout boxes in design. *Data_type*: bool, optional
`-cell` *lib_cell_name*	Specifies the lib cell to remove the PG keepout box applied to the specified cell. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each delete_pg_keep_out parameter. For a detailed description of the command and all of its parameters, use the man command: `man delete_pg_keep_out`
`-inst` *instance_name*	Specifies the instance to remove the PG keepout box applied to the specified instance. *Data_type*: string, optional
`-layer` *layer_name*	Specifies the names of the layers to delete the PG keepout box applied on the specified metal layers. *Data_type*: string, optional
`-layer_id` *layer_id*	Specifies the layer IDs to delete the PG keepout box applied on the specified metal layer. *Data_type*: string, optional

Related Information

- create_pg_keep_out
- report_pg_keep_out

delete_pipeline_net_group

```
delete_pipeline_net_group
[-help]
-net_group_name netGroupName
```

Deletes pipeline net groups including the subgroups created inside the net groups.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `delete_pipeline_net_group` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_pipeline_net_group`.
`-net_group_name` *netGroupName*	Specifies the name of the net group. *Data_type*: string, optional

Example

- The following command deletes a net group named `netGroup1':
  ```
  delete_pipeline_net_group netGroup1
  ```

Related Information

- `create_pipeline_net_group`
- `place_pipelines`
- `report_pipelines`
- `update_pipeline_net_group`

delete_scan_cell

```
delete_scan_cell
[-help]
cell_name
```

Removes the scan cell specification from a library cell. This command can be called after importing design if there are scan cell specifications in library; or else it can be used after `set_scan_cell`.

Parameters

cell_name	Specifies the cell from which to remove the scan specification. *Data_type*: string, required
-help	Outputs a brief description that includes type and default information for each `delete_scan_cell` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_scan_cell`.

Example

The following command removes the scan specification from the cell named `FF_SCAN`:

```
delete_scan_cell FF_SCAN
```

Related Information

- `delete_all_scan_cells`
- `set_scan_cell`
- `report_scan_cells`
- Placing the Design chapter in the *Innovus Stylus Common UI User Guide*.
    - Optimizing and Reordering Scan Chains

delete_scan_chain

```
delete_scan_chain
[-help]
[-name chainName]
```

Removes a scan chain specification from the design. Use this command if there is scan chain specified or traced.

When you are debugging a new scan chain specification, it is useful to delete all scan chains and start over.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `delete_scan_chain` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_scan_chain`.
`-name` *chainName*	Specifies the name of the scan chain to remove from the design. If you do not specify a scan chain name, the command deletes all scan chains. *Data_type*: string, optional

Example

The following commands load the scan information from a DEF file, remove the scan chain `ABC`, and output the scan information to a DEF file:

```
read_def
delete_scan_chain ABC
write_def -scan_chain
```

Related Information

- `create_scan_chain`
- `create_scan_chain_partition`
- `read_def`
- `report_scan_chain`
- `write_def`
- Placing the Design chapter in the *Innovus Stylus Common UI User Guide.*
    - Optimizing and Reordering Scan Chains

delete_scan_chain_partition

```
delete_scan_chain_partition
[-help]
{-all | -partition partitionName1 partitionName2 ...}
```

Deletes scan chain partitions. The partitions are used to group scan chains so elements in compatible scan chains can be swapped. The scan chains are then reordered on a per-chain basis.

Specify scan chain partitions with the following command: `create_scan_chain_partition`.

Parameters

`-all`	Deletes all partitions from compatible groups. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes type and default information for each `delete_scan_chain_partition` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_scan_chain_partition`.
`-partition` *partitionName1 partitionName2 …*	Specifies the partitions to delete. *Data_type*: string, optional

Example

The following command deletes partition `clk1Domain`:

```
delete_scan_chain_partition clk1Domain
```

Related Information

- `create_scan_chain`
- `create_scan_chain_partition`
- `reorder_scan`
- `reorder_scan Category Attributes`

    - Optimizing and Reordering Scan Chains

delete_spare_module

```
delete_spare_module
[-help]
hinst_name
```

Deletes the instantiation of a created spare module and all the spare instances under the hinst.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `delete_spare_module` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man delete_spare_module`.
`hinst_name`	Specifies the instantiation to delete. *Data_type*: string, required

Example

The following code shows the creation of the spare module SPGM, placement of the module and its instances in the design, and deletion of the hInst of "SPGM_spr_1":

```
#create a spare module
create_spare_module -moduleName SPGM -cell {DFFNSRX2 INVX4 \ NOR2X2} -clock sysclk

#instantiation the spare module and place them in the design
place_spare_modules -moduleName SPGM -channel -minWidth 4.7 -maxWidth 10 \ -minLength 11 -
stepx 10 -stepy 10 -util 0.6

#delete one instantiation of the spare module
delete_spare_module top/SPGM_spr_1
```

Related Information

    - Placing Spare Cells and Spare Modules

gui_clear_scan_chains

```
gui_clear_scan_chains
[-help]
[scanPartitionName]
```

Removes scan chains from the display.

Parameters

scanPartitionName	Specifies the scan partition name to remove from the display. *Data_type*:

Related Information

- Placing the Design chapter in the *Innovus Stylus Common UI User Guide*
  - Optimizing and Reordering Scan Chains

gui_clear_spare_cells

`gui_clear_spare_cells`

Removes spare cell instances from the display.

Parameters

None

Related Information

- `add_spare_insts`
- `gui_show_spare_cells`
- Place Menu chapter of *Innovus Stylus Common UI Menu Reference*.

gui_show_scan_chains

```
gui_show_scan_chains
[-help]
[scan_chain_name]
```

Displays a scan chain. You must load the scan information, place the design, and view the design in the Placement view. Use this command after scan chains are traced.

Parameters

scan_chain_name	Specifies the scan chain. *Default:* If you do not specify this parameter, the software displays all scan chains. *Data_type*: string, optional

Examples

- The following command displays all scan chains in the design:
  ```
  gui_show_scan_chains
  ```
- The following command displays the scan chain whose name is `chain0`.
  ```
  gui_show_scan_chains chain0
  ```

Related Information

- `create_scan_chain`
- `gui_clear_scan_chains`
- `report_scan_chain`
- Placing the Design chapter in the *Innovus Stylus Common UI User Guide*
  - Optimizing and Reordering Scan Chains
- Place Menu chapter of *Innovus Stylus Common UI Menu Reference*.

gui_show_spare_cells

`gui_show_spare_cells`

Displays the results of placing the spare instances. You must specify the spare cell types or spare instances before placing the design.

Parameters

None

Examples

The following set of commands displays all spare instances defined by the `set_spare_insts` command:

```
set_spare_insts -cell ADDFXLT1T10
place_design
gui_show_spare_cells
```

Related Information

- `gui_clear_spare_cells`
- `place_design`
- `set_spare_insts`
- Place Menu chapter of *Innovus Stylus Common UI Menu Reference*.

place_clones

```
   place_clones
[-help]
[-clones cloneinstance(s)orientation(s)]
[-master_partition instance name]
```

Places all clone instances with relative location and relative orientation according to the master partition instances. Adjusts instance orientation based on the clone orientation.

Use this command after running `place_design`.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `place_clones`. For a detailed description of the command and all of its parameters, use the man command: `man place_clones`
`-clones` *`cloneinstance(s)orientation`*	Specifies clone instances with relative location. *Data_type*: list, optional
`-master_partition` *`instance name`*	Specifies the master partition instance. *Data_type*: string, optional

Related Information

- `place_design`
- Place Menu chapter of *Innovus Stylus Common UI Menu Reference*.

place_connected

```
place_connected
[-help]
-attractor macro/IO list
[-fixed]
[-move_fixed]
[-place_status]
{-level integer  | -sequential all_connected | direct_connected | -
stop_points instance_name |-before_points instance_name | -instance_pin instance/pin}
[{-stop_points instance_name | -key_cell cell_name}]
[{-before_points instance_name | -key_cell cell_name}]
[{-instance_pin instance/pin | -key_cell cell_name}]
[ {-attractor_pin pin_list } [-instance_pin instance/pin] ]
```

Places the specified standard cells close to the specified attractor with legal location. The attractor can be IOs, hard macros, fixed standard cell. The recommended flow is to run this command before `place_design`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each place_connected parameter.
`-attractor macro/IO list`	Specifies target hard macros, IOs, or fixed standard cell for attracting standard cells. Wildcards is supported. Tool processes attractors in list one by one. If there are instances shared by different attractors, the locations of shared instances are determined by the later one. In that case, the placement result may vary with different order of objects in list. *Data_type*: string, required
`-attractor_pin pin_list`	Places only standard cells connected with specified pins of attractors close to attractor. Wildcards is supported. Without this setting, standard cells connected with all pins of attractors are pulled. *Data_type*: string, optional

`-before_points` *instance_name*	Specifies that the attracting is stopped before the specified instances. *Data_type*: string, optional
`-fixed`	Sets the placement status as fixed. *Data_type*: bool, optional
`-instance_pin` *instance/pin*	Pulls all instances specified in the list close to the attractor. This option requires only full instance pin name. Wildcards is supported. Option `-attractor_pin` needs to be used with this option. *Data_type*: string, optional
`-key_cell` *cell_name*	Places specified type of cells close to attractors, as well as other logics between the key cell and attractor. Wildcards is supported. Without this setting, all standard cells connected with attractors are pulled. *Data_type*: string, optional
`-level` *integer*	Pulls all instances within certain logic level of connections to the attractor close to attractors. This option is mutually exclusive with `-sequential`, and user must specify one of them. *Data_type*: int, optional
`-move_fixed`	Specifies that instances with the fixed status can also be moved close to the attractor. *Data_type*: bool, optional
`-place_status`	Specifies instances being placed is in “placed” status. By default, the pulled cells are marked as “fixed”. *Data_type*: bool, optional

`-sequential` *`all_connected	direct_connected`*	Pulls sequential cells connected with the attractor close to the attractor. • `all_connected`: attracts all sequential cells from/to attractor; combinational logics between the sequential instance and attractor are attracted as well. • `direct_connected`: attracts sequential cells directly connected with attractor. *Data_type*: enum, optional
`-stop_points` *`instance_name`*	Pulls all instances connected between the attractor and the specified stop point close to attractors. This option requires full instance name or instance pin name. Wildcards is supported. *Data_type*: string, optional

Examples

- The following command places all instances directly connected with all pins of `RAM1` close to `RAM1`.

  ```
  place_connected -attractor RAM1 -level 1
  ```

- The following command pulls all sequential cells from `RAM1` and all combinational cells between `RAM1` and the sequential cells close to `RAM1`.

  ```
  place_connected -attractor RAM1 -sequential all_connected
  ```

- Only the sequential cells from “IN*” pins of `RAM1` and their combinational logics are caught to be placed nearby `RAM1`.

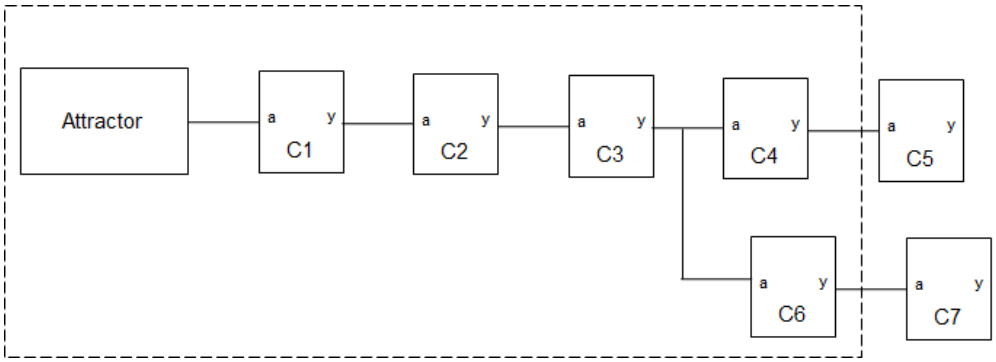
  ```
  place_connected -attractor RAM1 -sequential all_connected -attractor_pin IN*
  ```

- The following command picks out instances that are `"BUF1X"` cell type and directly connected with `RAM1`, and places them close to `RAM1` with `"placed"` status.

  ```
  place_connected -attractor RAM1 -level1 -key_cell BUF1X -place_status
  ```

- The following command places instances, C1, C2, C3, C4, C6, close to the attractor RAM1.

  ```
  place_connected -attractor RAM1 -before_points {C5 C7}
  ```



Related Information

- `place_design`

place_design

```
place_design
[-help]
[-concurrent_macros]
[-incremental]
[-no_pre_place_opt]
[-sdp]
```

Places standard cells based on the global settings for placement, RC extraction, timing analysis, and early global routing. It also relieves the congestion and reorders the scan cells. Also performs the following operations:

- Pre-placement optimization
- Scan tracing and scan reordering
- Placement optimization during the placement process
- Incremental placement on an already placed design

Use the `place_design` command after performing general floorplanning, including macro placement, regioning (if applicable), and power planning on the design. The design could be in the unplaced state, or in a state that the existing placement is to be replaced.

- To run timing-driven placement (the default), make sure the timing constraints are loaded in the design.
- To run scan reorder (the default), specify the scan chain or import the scan DEF data before running this command.

By default, `place_design` performs timing-driven placement with scan reordering, except during prototyping, when it runs in non-timing-driven mode. To change this behavior, run set_db with the following `place` Category attributes prior to running `place_design`:

- `place_global_reorder_scan false`

Or, in prototyping mode:

- `place_design_floorplan_mode`

If there are no timing constraints, `place_design` assumes non-timing-driven mode.

Notes:

- `place_design` supports multiple-CPU processing. For information, see "Multiple-CPU Processing Commands" and "Accelerating the Design Process by Using Multiple-CPU

Processing".

- `place_design` multithreading.
- The `get_metric` command can be used with the `place_design` command to retrieve metrics.
- `place_design` honors the `proto_place_effort` attribute.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `place_design` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man place_design`.
`-concurrent_macros`	When this option is enabled, place_design will do concurrent timing driven placement of macros and standard cells. Also, `place_design -concurrent_macros` by default calls `place_macro_detail` to legalize macros. This parameter works only when the design is already placed. When `place_design -concurrent_macros` is run, it sets the value of the `place_opt_run_global_place` attribute to `seed`. *Data_type*: bool, optional ⚠ When the `set_db place_global_place_io_pins` attribute is set to true, the `place_design -concurrent_macros` command places the placed and unplaced I/O pins in the mixed placer flow and optimize their locations to reduce wire length and congestion. This support is a limited-access feature in this release. It is enabled by a variable specified using the `set_limited_access_feature` command. To use this feature, contact your Cadence representative to explain your usage requirements, and make sure this feature meets your needs before deploying it widely.

`-incremental`	Runs placement incrementally. This parameter works only when the design is already placed. *Data_type*: bool, optional **Note:** Using this parameter defaults to `-no_pre_place_opt`.
`-no_pre_place_opt`	Disables pre-place optimization during the placement run. By default, the command removes all cells with the specified buffer footprint (same as with the `delete_buffer_trees` command), except when using the `-incremental` parameter. *Data_type*: bool, optional
`-sdp`	Enables SDP-aware (Structured Data Path) placement. *Data_type*: bool, optional

Examples

- The following commands disable scan chain reordering:
  ```
  set_db place_global_reorder_scan false
  place_design
  ```
- The following command disables the pre-placed buffer tree removal:
  ```
  place_design -no_pre_place_opt
  ```
- After the design is placed, the following command performs incremental placement, and disables the pre-placed buffer tree removal:
  ```
  place_design -incremental
  ```

place_detail

```
place_detail
[-area {x1 y1 x2 y2}]
[-eco {true|false}]
[-inst list_of_instances]
```

Corrects flawed cell locations and reports corrections or instance overlap problems. You do not need a fully placed design to run `place_detail`. The `place_detail` command only makes changes if the placement is not legal, such as for instance overlap, incorrect orientation, constraint violations, and placement/routing blockage violations. You can use the `check_place` command to highlight placement violations in the design. The `place_detail` command is called automatically at the end of each major super command such as `place_opt_design`, `opt_design`, and `ccopt_design` to ensure that the final placement is violation-free. If any instances are moved manually, `place_detail` can be run to legalize any cell placements that may have resulted in violations due to this manual movement.

To place unplaced instances, use the `place_eco` command. Use this command after finding an error with the `check_place` command.

`place_detail` only operates on the cells which have the 'placed' placement status.

Note: You can also use `place` attributes to specify parameters for this command. If you use `place` attributes, the parameters apply every time you run `place_detail` in the current session, unless they are overwritten by the `place_detail` settings.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `place_detail` parameter. For a detailed description of the command and all of its parameters, use the man command: `man place_detail`
`-area {x1 y1 x2 y2}`	Specifies the *x1*, *y1, x2*, and *y2* coordinates of the `place_detail` area. *Data_type*: rect, optional **Note**: The coordinates for the `-area` option should be provided in brackets, else the tool will report an error.
`-eco {true|false}`	Activates the ECO mode for the post-route design. *Data_type*: bool, optional
`-inst list_of_instances`	Specifies a list of instances for place_detail to legalize only. *Data_type*: string, optional

Example

- The following command refines the placement in the specified area:

```
place_detail -area {7.925 29.762 11.702 27.531}
*** Starting place_detail (0:04:48 mem=991.9M) ***
Move report: Detail placement moves 0 insts, mean move: 0.00 um, max move: 0.00 um
        Runtime: CPU: 0:00:00.0 REAL: 0:00:00.0 MEM: 991.9MB
Summary Report:
Instances move: 0 (out of 6 movable)
Mean displacement: 0.00 um
Max displacement: 0.00 um
Runtime: CPU: 0:00:00.0 REAL: 0:00:00.0 MEM: 991.9MB
*** Finished place_detail (0:04:48 mem=991.9M) ***
```

place_fix_congestion

```
place_fix_congestion
-help
-area x1 y1 x2 y2
```

Relieves the congestion of the design. This command performs incremental placement based on `route_early_global` congestion results and improves the congestion hot spots by spreading out the cells. It is mostly used after `place_opt_design`, but sometimes it can be used after pre-CTS optimization as well. Since this command tends to move many cells around, it should not be run after post-CTS optimization.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `place_fix_congestion` . For a detailed description of the command and all of its parameters, use the man command: `man place_fix_congestion`
`-area x1 y1 x2 y2`	Specifies the x1, y1, x2, and y2 coordinates of the area in which `place_fix_congestion` will run. **Note**: If you do not specify this option, `place_fix_congestion` will run on the complete design. *Data_type*: rect, optional

Related Information

- `place_opt_design`
- `route_early_global`

place_inst

```
place_inst
[-help]
inst
location
orient
[{-fixed | -placed | -soft_fixed}]
```

Places a leaf instance in the core box. Instance is snapped to the site whose lower-left corner is the nearest to the location specified. If the location specified is outside of the core box, then the instance is snapped to site whose lower-left corner is nearest to the location specified. Instance is not checked for legality–it can overlap other boxes, either placed or fixed, and it can be placed within placement blockages. If no orientation is specified, or if an illegal orientation is specified, `place_inst` will orient the instance with the default orientation of the site in which the instance is being placed. You can check the legality of the placed instance by the `check_place` command.

Note: If you place a master instance blackbox to non-r0 orient, the new non-r0 orient will be converted to r0 orient. For more information, see "Handling of Blackboxes with Non-r0 Orientation" in the Partitioning the Design chapter of the *Innovus Stylus Common UI User Guide*.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `place_inst` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man place_inst`.
`inst`	Specifies the leaf instance name. *Data_type*: (inst), required
`location`	Specifies x and y coordinates of new origin. • *`x`*: Specifies the lower-left x coordinate of the instance on the x axis. • *`y`*: Specifies the lower-left y coordinate of the instance on the y axis. *Data_type*: point, required
`orient`	Specifies the orient of the instance. Specify one of the following values: `r0`, `r90`, `r180`, `r270`, `mx`, `mx90`, `my`, or `my90`. *Default*: `r0` *Data_type*: enum, optional For more information on orient keys, see "Orientation Key" in the Floorplanning the Design chapter of the *Innovus Stylus Common UI User Guide*.
`-fixed | -placed | -soft_fixed`	Specifies that the cell being placed is in the `fixed`, `placed`, or `soft_fixed` status. *Default*: `-fixed` *Data_type*: bool, optional

Example

- The following command places the instance `SH22/I40` with mirrored through Y axis orient at location `1500.3, 980.3` in the floorplan. The instance SH22/I40 is fixed by default and the placement program will not move this instance later:
  ```
  place_inst SH22/I40 1500.3 980.3 my
  ```

- The following command places the instance SH22/I51 with default `R0` orient at location 398.7, 1480.2 in the floorplan. The instance SH22/I52 has 'placed' status and it can be moved during optimization, clock synthesis, or place_detail:

  ```
  place_inst SH22/I51 398.7 1480.2 -placed
  ```

Related Information

- `check_place`
- Floorplanning the Design chapter of the *Innovus Stylus Common UI User Guide*.
- Partitioning the Design chapter of the *Innovus Stylus Common UI User Guide*.

place_jtag

```
place_jtag
[-help]
-row_number nrRow
[-row_top_number nrRowTop]
[-row_bottom_number nrRowBottom]
[-row_left_number nrRowLeft]
[-row_right_number nrRowRight]
[-hard_macro {true | false}]
[-area_io {true | false}]
[-io_net_weight netWtValue]
[-block_net_weight netWtValue]
[-contour {true | false}]
[-ignore_scan {true | false}]
[-orient_top orientation]
[-orient_bottom orientation]
[-orient_left orientation]
[-orient_right orientation]
```

Places JTAG cells. Use this command for JTAG and other cells where placement is required to be close to the perimeter I/Os.

Note: The command does not honor MSMV design.

Parameters

`-area_io {true | false}`	Considers the area around I/O cells as a legal placement location. When specifying this parameter, the `-io_net_weight` parameter is applied to the nets that are connected to the Area I/O cells. *Default*: `false` *Data_type*: bool, optional
`-block_net_weight netWtValue`	Specifies the weight for nets connecting to blocks. This allows `place_jtag` to place more critical block nets in a smaller area. *Default*: `20` *Maximum value:* `512` *Data_type*: int, optional

`-contour {true | false}`	Creates an outline along the boundary of the chip, with its width based on the number of standard cell rows, as specified by the `-row_number` parameter(s). You can specify different values for `-row_top_number`, `-row_bottom_number`, `-row_left_number`, and `-row_right_number`. *Default*: `false` *Data_type*: bool, optional
`-help`	Outputs a brief description that includes type and default information for each `place_jtag` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man place_jtag`.
`-hard_macro {true | false}`	Includes the boundaries of the hard macros in the JTAG placement. *Default*: `false` *Data_type*: bool, optional
`-ignore_scan {true | false}`	Ignores all scan-in pins, scan enable pins, clock pins, and asynchronous control pins. *Default*: `false` *Data_type*: bool, optional ⚠ `place_jtag` relies on the timing library to provide information, such as what pins are scan-in, scan enable, clk, and async control. If the timing library does not have the scan-in and scan enable information, `place_jtag` is not able to ignore them. In this case, before you run `place_jtag`, you must specify those terms using the `set_scan_cell` command.

`-io_net_weight` *netWtValue*	Specifies the weight for nets connecting to I/Os. This allows `place_jtag` to place more critical I/O nets in a smaller area. *Default*: `100` *Maximum*: `512` *Data_type*: int, optional `-io_net_weight` applies to the nets that are connected to any I/O cell, whether it is a standard peripheral I/O cell or an Area I/O cell. This behavior is different from `-block_net_weight`, which specifies the weight of the nets connected to blocks separately from the I/O nets.
`-row_number nrRow`	Specifies the number of standard cell rows to place the JTAG instances. *Data_type*: init, optional *Minimum*: 0 *Maximum*: 10000
`-row_bottom_number` *nrRowBottom*	Specifies the number of standard cell rows at the bottom of the core area to place JTAG logic. *Data_type*: init, optional *Minimum*: 0 *Maximum*: 10000
`-row_left_number` *nrRowLeft*	Specifies the number of standard cell row heights at the left of the core area to place JTAG logic. *Data_type*: init, optional *Minimum*: 0 *Maximum*: 10000
`-row_right_number` *nrRowRight*	Specifies the number of standard cell row heights at the right of the core area to place JTAG logic. *Data_type*: init, optional *Minimum*: 0 *Maximum*: 10000

`-row_top_number` *nrRowTop*	Specifies the number of standard cell rows at the top of the core area to place JTAG logic. *Data_type*: init, optional *Minimum*: 0 *Maximum*: 10000
`-orient_bottom` *orientation*	Considers the specified orientation at each side first and then looks for other legal orientations. Specify one of the following values: `R0 R90 R180 R270 MX MX90 MY MY90`. *Data_type*: string, optional
`-orient_left` *orientation*	Considers the specified orientation at each side first and then looks for other legal orientations. Specify one of the following values: `R0 R90 R180 R270 MX MX90 MY MY90`. *Data_type*: string, optional
`-orient_right` *orientation*	Considers the specified orientation at each side first and then looks for other legal orientations. Specify one of the following values: `R0 R90 R180 R270 MX MX90 MY MY90`. *Data_type*: string, optional
`-orient_top` *orientation*	Considers the specified orientation at each side first and then looks for other legal orientations. Specify one of the following values: `R0 R90 R180 R270 MX MX90 MY MY90`. *Data_type*: string, optional

Examples

The following command places the JTAG instances within four standard cell rows at the top and bottom of the chip and within four times the standard cell row height at the sides of the chip:

```
place_jtag -row_number 4
```

The following command places the JTAG instances within ten standard cell rows at the top and bottom of the chip and within ten times the standard cell row height at the sides of the chip. It increases the I/O net weight to `256`.

```
place_jtag -row_number 10 -io_net_weight 256
```

place_opt_design

```
place_opt_design
[-help]
[-expanded_views]
[-incremental]
[-incremental_timing]
[-num_paths number_of_paths]
[-report_dir outputDirectory]
[-report_prefix outputFileName]
[-timing_debug_report]
```

Executes pre-CTS flow with both placement and pre-CTS optimization.

Earlier, users had to perform the following two steps to do placement and pre-CTS optimization:

1. `place_design`
2. `opt_design -pre_cts`

With `place_opt_design` command, users need to run only a single command to do placement and pre-CTS optimization.

Combining the two commands, `place_design` and `opt_design -pre_cts`, provides better integration between placement and optimization to achieve faster runtime and better PPA.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `place_opt_design` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man place_opt_design`.
`-expanded_views`	Prints timing information for each active view at the end of the command restoring all pruned views if absent. *Data_type*: bool, optional

`-incremental`	Specifies `place_opt_design` to be run in the incremental mode. In the incremental mode `place_opt_design` incrementally improves the existing placement based on the critical timing paths and congestion. The command then re-optimizes the netlist based on the new placement. The optimization in incremental `place_opt_design` does DRV fixing, WNS, and TNS optimization. The input to `place_opt_design -incremental` can be either a partial placement or full placement with placement violations, and the output is a legal placement as `refinePlace` is called at the end. This can be used if you want to further improve the congestion and timing QoR or if there is a minor floorplan change and this by default, congestion-driven, and timing-driven. It also honors density screens and floorplan constraints. If you run `place_opt_design` and notice some areas of congestion, you can introduce density screens and run `place_opt_design -incremental`. As `place_opt_design -incremental` honors density screens, it would spread out some of the cells, reducing congestion in that area. In contrast, `refinePlace` would not do this as it only works on the hard placement violations such as cell overlaps, while density screens is a "soft" constraint. There is no scan-reordering done in `place_opt_design -incremental`. **Note**: Early clock flow mode `place_opt_design -incremental` reuses the existing early clock flow clock tree without any logical or physical modification and makes adjustments only to useful skew using virtual delays. It is also essential to note that the CCOpt clock tree spec must not be deleted between the original and incremental `place_opt_design` steps, just like it must not be done between `place_opt_design` and `ccopt_design`, otherwise any useful skew will be lost. *Data_type*: bool, optional

`-incremental_timing`	In the `incremental_timing` mode, `place_opt_design` does incremental DRV and timing optimization. In this mode, `place_opt_design` incrementally optimizes the critical timing path. Also, the optimization in incremental timing `place_opt_design` does DRV fixing, WNS, and TNS optimization. *Data_type*: bool, optional
`-num_paths` *number_of_paths*	Specifies the number of paths reported in the timing report. By default, all timing paths are reported. *Data_type*: integer, optional
`-report_dir` *outputDirectory*	Specifies the output directory in which the timing/drv reports will be saved. *Data_type*: string, optional
`-report_prefix` *outputFileName*	Specifies the file name prefix for the timing/drv reports that are generated at the end of `place_opt_design`. *Data_type*: string, optional
`-timing_debug_report`	When specified, generates a machine-readable timing debug report after completing placement and preCTS optimization. This report is used for debugging timing results using the timing debug feature in Stylus. **Note**: You can specify the number of paths to be reported using the `-num_paths` parameter. *Data_type*: bool, optional

place_pad

```
place_pad
[-help]
pad
[orient]
{x y}
```

Places an I/O pad instance. This command can be used before the `place_design` command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `place_pad` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man place_pad`.
`{x y}`	Coordinates of new origin. The option is a point and a must. *Data_type*: point, required
`orient`	Specifies the orient of the pad cell. Specify one of the following values: `r0`, `r90`, `r180`, `r270`, `mx`, `mx90`, `my`, and `my90`. *Default:* `r0` *Data_type*: string, optional
`pad`	Specifies the pad instance name. *Data_type*: string, required

Example

The following command places the I/O pad instance with mirrored axis orient, rotated 90 degrees counter clockwise:

```
place_pad SH14/I412 498.3 5000.8 mx90
```

Related Information

- place_design

place_pipelines

```
place_pipelines
[-net_groups {netGroupName}]
[-region {true | false }]
[-status {fixed | placed}
[-timing]
[-density utilization_value]
```

Places the registers of the specified pipeline flip-flops (PFF) net group(s) so that the distances between the stages of each group are roughly equal. This command can be used if the pipeline net groups are specified in the design.

Parameters

`-net_groups {`*`netGroupName`*`}`	Specifies the PFF net group, or a list of net groups, to place. By default, all PFF net groups in design are considered. *Data_type*: string, optional
`-region {true | false}`	Creates region constraints for flops in each stage of pipeline, to allow adjustments at a later stage. *Default:* `false` *Data_type*: bool, optional
`-status {fixed | placed}`	Places the PFFs with fixed placement status, or placed status. *Default:* `placed` *Data_type*: enum, optional
`-timing`	Automatically finds reserve lengths. The option is of type boolean and is optional. *Data_type*: bool, optional
`-density` *`utilization_value`*	Specifies the expected utilization of regions for flops. *Minimum:* `0` *Maximum:* `1` *Data_type*: float, optional

Example

- The following command places the registers of all pipeline flip-flops (PFF) net groups at equal distance:

  ```
  place_pipelines
  ```

- The following command places the registers of pipeline flip-flops (PFF) net group named `netGroup1` at equal distance and marked the registers status `FIXED`:

  ```
  place_pipelines -net_groups netGroup1 -status fixed
  ```

Related Information

- `create_pipeline_bus_guide`

place_spare_modules

```
place_spare_modules
-module_name moduleName
{-num_modules integer | -step_x stepDistance -step_y stepDistance}
[-area x1 y1 x2 y2]
[-channel
    {-max_width maxWidth}
    {-min_width minWidth}
    {-min_length minLength}]
[-offset_x offsetDistance]
[-offset_y offsetDistance]
[-power_domain powerDomainName]
[-prefix prefix]
[-density utilizationFactor]
```

Instantiates a created spare module, and places spare modules across the design. You can run this command before or after placement. If you run it after placement, it calls `place_eco`.

Parameters

`-area x1 y1 x2 y2`	Specifies box coordinates (x1, y1, x2, and y2) in micron. *Data_type*: rect, optional
`-channel`	Places spare modules in thin channels between placement blockages. *Data_type*: bool, optional
`-max_width maxWidth`	Specifies the maximum channel width, in microns. The `maxWidth` determines whether the placeable area between two macro blocks is considered a channel. *Data_type*: float, optional
`-min_length minLength`	Specifies the minimum channel length, in microns. The `minLength` must be greater than the specified `maxWidth`. *Data_type*: float*, optional*

`-min_width` *minWidth*	Specifies the minimum channel width, in microns. The *minWidth* should be greater than the width of the largest-space cell provided. *Data_type*: float, optional
`-module_name` *moduleName*	Specifies the name of the spare module. This module must have been created using the `create_spare_module` command. *Data_type*: string, required
`-num_modules` *integer*	Specifies the total number of spare modules to add. The software calculates how far apart to place the modules. *Data_type*: int, optional
`-offset_x` *offsetDistance*	Specifies the offset along the x axis, in microns, from the left core boundary. *Data_type*: float, optional
`-offset_y` *offsetDistance*	Specifies the offset along the y axis, in microns, from the bottom core boundary. *Data_type*: float, optional
`-power_domain` *powerDomainName*	Specifies the power domain in which to place the spare modules. *Data_type*: string, optional
`-prefix` *prefix*	Specifies a prefix to add to the automatically generated prefix for spare modules. The software already uses the prefix spr_*n* for spare modules. If you specify `-prefix spareMod`, the instances of this module are named `spareMod_spr_1, spareMod_spr_2, spareMod_spr_3`, and so on. *Data_type*: string, optional
`-step_x` *stepDistance*	Specifies the distance, in microns, between the instantiated spare modules along the x axis. The *stepDistance* must be greater than the spare module bounding box. *Data_type*: float, optional

`-step_y` *`stepDistance`*	Specifies the distance, in microns, between the instantiated spare modules along the y axis. The *`stepDistance`* must be greater than the spare module bounding box. *Data_type*: float, optional
`-density` *`utilizationFactor`*	Specifies the utilization factor of the spare modules. *Value Range:* Greater than 0.0; less than 1.0. *Data_type*: float, optional

Note: The `place_spare_modules` command does not honor `-density` when `-num_modules` switch is used.

Command Order

Run this command after running `create_spare_module`.

Examples

The following command instantiates module `mod1` and places the instantiations at intervals of 50 microns along the x and y axis. It places the instantiations at an offset of 5 microns from the left core boundary and the bottom core boundary:

```
place_spare_modules -module_name mod1 -step_x 50 -step_y 50 -offset_x 5 -offset_y 5
```

The following commands create spare module SPGM with cells DFFNSRX2, INVX4, and NOR2X2 using clock net sysclk; then instantiates module SPGMand places the instantiations between channels that are between 4.7 um and 10.0 um wide and at least 11.0 um long. The step size is 10 um in the x direction and 10 um in the y direction and the maximum utilization rate is 60 percent:

```
create_spare_module -module_name SPGM -cell {DFFNSRX2 INVX4 \
  NOR2X2} -clock sysclk
place_spare_modules -module_name SPGM -channel -min_width 4.7 -max_width 10 \
  -min_lengthgth 11 -step_x 10 -step_y 10 -density 0.6
```

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `place` category, use the following command:

```
get_db -category place
```

place_cell_edge_spacing

`place_cell_edge_spacing {cell_edge_type1 cell_edge_type2 spacing}`

Default: `""`

Data_type: string, read-only

Specifies the list of cell edge-type spacing values from `LEF CELLEDGESPACINGTABLE` or OA techfile that

affects the placer. It specifies the min-spacing between different edge-types of std-cells, in a list format: `{cell_edge_type1 cell_edge_type2 spacing}`. The edge-type names match the base_cell's right_edge_type and left_edge_type attribute values.

place_design_floorplan_mode

`place_design_floorplan_mode {true | false}`

Default: `false`

Data_type: bool, read/write

Runs placement in the floorplan mode. This mode is used for prototyping and runs quickly to gauge the feasibility of the netlist, but might not place design components in legal locations.

Note: When `place_design_floorplan_mode` is set to `true`, it disables congestion-driven placement. Attribute `place_global_cong_effort` is set to low.

place_design_refine_macro

`place_design_refine_macro  {true | false}`

Default: `false`

Data_type: bool, read/write

Specifies whether to run `place_macro_detail` after `place_design -concurrent_macros`. When `place_design -concurrent_macros` is run, it sets the value of `place_opt_run_global_place` attribute to `seed`.

place_design_refine_place

`place_design_refine_place {true | false}`

Default: `true`

Data_type: bool, read/write

Specifies whether to run detailed placement (`place_detail`) at the end of `place_design`, to legalize placed instances.

place_detail_activity_power_driven

```
place_detail_activity_power_driven {true | false}
```

Default: `false`

Data_type: bool, read/write

When `true`, it turns on the activity-driven tweakage, and flow change depends on the effort.

If the `design_power_effort` attribute is set to `high`, `place_design_refine_place` is automatically set to `true`.

place_detail_allow_border_pin_abut

```
place_detail_allow_border_pin_abut {true | false}
```

Default: `false`

Data_type: bool, read/write

Some libraries have cells with pin geometry that is not set back by half-routing pitch from the normal PR-boundary of that cell. In cases where the pin geometries touch the cell PR_boundary, placement of an instance of this cell can cause a DRV violation with a normal pin geometry of the other cells. To avoid these DRVs, placer will add one Site padding to the cell-side during pre-processing, thus satisfying the min-spacing rules. The `place_detail_allow_border_pin_abut` attribute disables this pre-emptive DRV avoidance behavior, and no auto-padding is done when the option is set to `true`.

place_detail_allow_single_height_row_symmetry_x

```
place_detail_allow_single_height_row_symmetry_x siteName
```

Default: `""`

Data_type: bool, read/write

Specifies a single height row tech-site, which allows symmetry X during detail place.

place_detail_check_cut_spacing

```
place_detail_check_cut_spacing {true | false}
```

Default: `false`

Data_type: bool, read/write

Enables the via-to-via spacing check during `place_detail` and `check_place`. The checking is limited to single-cut via only. Via-array spacing is not supported yet.

This is turned on by default for 16nm and below process designs.

Related Commands

- `check_place`

place_detail_check_inst_space_group

```
place_detail_check_inst_space_group {true | false}
```

Default: `false`

Data_type: bool, read/write
Specifies whether the distance between instances that belong to the same space group would be honored during placement.

Related Commands

- `check_place`

place_detail_check_route

```
place_detail_check_route {true | false}
```

Default: `false`

Data_type: bool, read/write

Considers pre-routed FIXED signal wires and avoids creating DRC violations between FIXED signal wires and instance pins. When this attribute is not specified, place_detail ignores FIXED signal wires.

Note: Using this attribute might result in longer run time.

If you specify `place_detail -io_pin_blockage`, you do not need to specify `-check_route` for signal pins because `place_detail` will treat the signal pins similar to supply pins for blockages. However, signal wires still need this attribute.

place_detail_eco_max_distance

`place_detail_eco_max_distance` *micron*

Default: `0.0`

Data_type: double, read/write

Specifies max distance, in microns, in the horizontal or vertical direction for the `place_detail` ECO mode.

For example, if the original location of the instance is at (x0 y0) and the specified eco max distance is M, the search window will be (x0-M, yo-M) (x0+M y0+M). The maximum movement should be less than 2M.

If `place_detail_eco_max_distance` is not defined by the user, and the user does `place_detail -eco`, the value of `place_detail_eco_max_distance` is internally set to 10 Standard Cell height units.

Note: This option will impact both `place_detail -eco` and `place_detail -inst`.

place_detail_eco_priority_insts

`place_detail_eco_priority_insts {placed|fixed|eco}`

Default: `placed`

Data_type: enum {placed fixed eco}, read/write

Specifies the instance priority for `place_detail` ECO mode.

- `placed`: Treats current instances as placeable but with higher priority.
- `fixed`: Treats placed instances as fixed.
- `eco`: Treats ECO instances with higher priority.

place_detail_fixed_shifter

`place_detail_fixed_shifter {true | false}`

Default: `false`

Data_type: bool, read/write

Specifies whether to set the shifters to `FIXED` status after placing them.

When set to `true`, the level shifters are `FIXED` after placement. However, the placement for some of the

level shifters can be skipped due to the following reasons:

- The shifter has no connections outside its power domains.
- The shifter has no valid location.

place_detail_honor_inst_pad

```
place_detail_honor_inst_pad {true | false}
```

Default: `false`

Data_type: bool, read/write

Honors padding from `set_inst_padding` in detail placement.

place_detail_irdrop_aware_effort

```
place_detail_irdrop_aware_effort {none low medium high}
```

Default: `none`

Data_type: enum {none low medium high}, read/write

Used to enable the IR-aware feature in refinePlace. You can use the following settings to specify IR-drop optimization effort level to be used during `place_detail`.

You can specify the following optimization effort levels:

- `none`: Disables the feature, default value.
- `low`: Moves the IR-violating instances to nearby rows (in the vertical direction). The aggressor has the same priority as the other instances during legalization.
- `medium`: : Moves the IR violating instances in both horizontal and vertical directions. The aggressor has higher priority than the other instances during legalization.
- `high`: Moves the aggressor instances to nearby rows. The aggressor has higher priority than the other instances during legalization and considers the IR-drop violation as a hard rule during legalization. This option is not recommended in this version.

place_detail_io_pin_blockage

```
place_detail_io_pin_blockage {true | false}
```

Default: `false`

Data_type: bool, read/write

Treats ioPins from top-level as pre-routes during DRV checks in legalization.

place_detail_ir_aware_max_drive_strength

`place_detail_ir_aware_max_drive_strength` *`maxDriveStrength`*

Default: `0.0`

Data_type: double, read/write

Specifies the current density value for the IR critical instances above which the instances gets padded during `place_detail`. This means that the IR critical instances with the current density value more than the specified value gets padded.

Note: There may be larger cell movement with this option, which can degrade the timing. So, it is preferred to be used at the pre-CTS stage in the flow. The current density values for the IR-critical instances are dumped in the Voltus Reports.

place_detail_irdrop_aware_timing_effort

`place_detail_irdrop_aware_timing_effort {none|standard|high}`

Default: `high`

Data_type: enum, read/write

Specifies the timing-effort level to be used during IR-aware `place_detail`.

You can specify the following timing effort levels:

- `none`: Disables the feature, `place_detail` is not timing aware. Tool uses the default value.
- `medium`: `place_detail` is timing aware and minimizes the movement of the timing sensitive instances during `place_detail`.
- `high`: `place_detail` is timing aware and does not move the timing sensitive instances during `place_detail`.

place_detail_irdrop_region_number

`place_detail_irdrop_region_number` *`valueOfDebugIrdrop`*

Default: `100`

Data_type: int, read/write

Specifies the total number of regions in which the tool identifies the IR-violating instances. The tool dumps the IR-violating instances inside these regions in the reports.

place_detail_legalization_inst_gap

`place_detail_legalization_inst_gap` *`minimum_gap`*

Default: `0`

Data_type: int, read/write

Specifies the minimum gap between instances (unit sites).

place_detail_m3_stripe_push_down

`place_detail_m3_stripe_shrink` *`site_units`*

Default: `-1`

Data_type: int

Specifies the width threshold in site units for virtual push down of M3 stripe to M2 for M1 pin-access.

If the default value is set to `-1`, it indicates that no M3 stripe will be pushed down. If the default value is set to `0`, it indicates that all M3 stripes will be pushed down. If the default value is larger than `0`, then all M3 stripes having width greater than the specified value will be pushed down.

place_detail_m3_stripe_shrink

`place_detail_m3_stripe_shrink` *`site_units`*

Default: `0`

Data_type: int, read/write

Specifies the shrink effort of the virtual M2 stripe by given total site units. This global should work with place_detail_m3_stripe_push_down.

If the default value is set to `0`, it indicates that the entire pushed down M3 stripe is used to evaluate M1 pin access. If the default value is set to more than `0`, it indicates that M3 stripe will shrink by the specified value before it is pushed down to M2. The left side will shrink first. For example, if the specified value is set to `1`, the M3 stripe will shrink by 1 site on left, and if the specified value is set to `2`,

1 site on left will shrink, along with 1 site on right.

place_detail_max_shifter_depth

`place_detail_max_shifter_depth` *microns*

Default: `999` (no effect)

Data_type: double

Specifies the maximum distance from a horizontal or vertical side that a shifter can be placed.

place_detail_max_shifter_column_depth

`place_detail_max_shifter_column_depth` *microns*

Default: `999.0` (no effect)

Data_type: double, read/write

Specifies the maximum distance from a vertical side that a shifter can be placed.

place_detail_max_shifter_row_depth

`place_detail_max_shifter_row_depth` *microns*

Default: `999` (no effect)

Data_type: double, read/write

Specifies the maximum distance from a horizontal side that a shifter can be placed. The distance is measured from the power domain boundary, not from the edge of the placeable areas and accounts for gaps.

place_detail_no_filler_without_implant

`place_detail_no_filler_without_implant {true | false}`

Default: `false`

Data_type: bool

Specifies that there is no cell without the implant obs. For designs in which all standard cells and fillers have implant obs, you can specify this option to preserve enough spacing during `place_detail` for later filler insertion.

place_detail_use_gate_array_filler_groups

```
place_detail_use_gate_array_filler_groups {true | false}
```

Default: `false`

Data_type: bool, read/write

Specifies that the filler cell instances will only be replaced by logic instances that belong to same GA groups.

place_detail_use_no_diffusion_one_site_filler

```
place_detail_use_no_diffusion_one_site_filler {true | false}
```

Default: `false`

Data_type: bool, read/write

Specifies that all one-site fillers do not have diffusion obs. For designs in which all one-site fillers without diffusion obs, you can use this option to preserve enough spacing during refinePlace for later filler insertion. This option can override the setting of `place_detail_legalization_inst_gap` to `false`.

place_detail_context_aware_legal

p`lace_detail_context_aware_legal {none|all|optional|required|user|ignore_soft}`

Default: `all`

Data_type: enum* {none all optional required user ignore_soft}, read/write

Instructs placer to support cell edge to cell edge spacing constraints as defined in the LEF files.

The `optional`, `required`, `user`, `ignore_soft` argument values can be used separately or together, but they are exclusive to `all` and `none`.

place_detail_color_aware_legal

```
place_detail_color_aware_legal {true | false}
```

Default: `false`

Data_type: bool, read/write

Enables placer to honor and fix double pattern constraints between adjacent cells.

Note: This attribute does not affect cell to pre-route color DRC checks.

place_detail_pad_fixed_insts

`place_detail_pad_fixed_insts {true | false}`

Default: `false`

Data_type: bool, read/write

Specifies whether the `place_detail` command honors cell padding on `FIXED` instances.

place_detail_pad_physical_cells

`place_detail_pad_physical_cells {true | false}`

Default: `false`

Data_type: bool, read/write

Honors padding overlap with physical cells.

place_detail_preroute_as_obs

`place_detail_preroute_as_obs`

Default: `""`

Data_type: string, read/write

Specifies layers on which preroute are taken as OBS.

You can change this behavior by using the following command before running placement:

`set_db place_detail_preroute_as_obs`

Note: This attribute is not recommended for Advanced nodes of 20nm and below.

place_detail_preserve_routing

`place_detail_preserve_routing {true | false}`

Default: `true` (`place_detail` deletes all routed wires.)

Data_type: bool, read/write

Preserves all routed wires. This option does not effect the behavior of `place_design`, but is applicable in calls to `place_detail`, either stand-alone, or internal to `opt_design`.

place_detail_remove_affected_routing

```
place_detail_remove_affected_routing {true | false}
```

Default: `false`

Data_type: bool, read/write

Specifies whether `place_detail` removes wires connected to moved cells only or to all cells.

Removes all wires, whether connected cells were moved or not.

place_detail_sdp_alignment_in_refine

```
place_detail_sdp_alignment_in_refine {true | false}
```

Default: `false`

Data_type: bool, read/write

Enables SDP legalization/alignment for each `place_detail` run during detailed cell placement.

place_detail_swap_eeq_cells

```
place_detail_swap_eeq_cells {true | false}
```

Default: `false`

Data_type: bool, read/write

Determines whether master cells can be replaced by EEQ cells during detailed placement to improve routability. After detailed placement, the software reports the number of replacements. EEQ cells are defined in the LEF file.

place_detail_use_check_drc

```
place_detail_use_check_drc {true | false}
```

Default: `false`

Data_type: bool, read/write

Enables the FGC based DRC engine in legalization.

Enables the FGC engine inside placement for DRC checking. This DRC engine is the same as one used by NanoRoute and `check_drc`.

place_detail_use_diffusion_transition_fill

```
place_detail_use_diffusion_transition_fill {true | false}
```

Default: `false`

Data_type: bool, read/write

Specifies that the design has fillers with jogged diffusion obs. Use this attribute for designs where fillers with jogged diffusion obs are to be inserted between cells with varying diffusion widths.

place_detail_wire_length_opt_effort

```
place_detail_wire_length_opt_effort {none | medium | high}
```

Default: `medium`

Data_type: enum {none medium high}, read/write

Optimizes wire length by swapping cells. Optimization can reduce the total wire length up to two percent without degrading placement. In high-effort mode, it might add up to ten percent to the run time.

place_global_activity_power_driven_effort

```
place_global_activity_power_driven_effort {standard|high}
```

Default: `standard`

Data_type: enum {standard high}, read/write

Specifies `place_global_activity_power_driven_effort` mode.

place_global_align_macro

```
place_global_align_macro {true|false}
```

Default: `true`

Data_type: bool, read/write

Enables mixed-placer to align nearby same-size macros during the global placement.

place_global_allow_3d_stack

`place_global_allow_3d_stack {true|false}`

Default: `false`

Data_type: bool, read/write

Enables the 3D placement.

place_global_clock_power_driven_effort

`place_global_clock_power_driven_effort {none|standard|high}`

Default: `low`

Data_type: enum {low standard high}, read/write

Specifies the `place_global_clock_power_driven_effort` mode.

place_global_activity_power_driven

`place_global_activity_power_driven {true|false}`

Default: `false`

Data_type: bool, read/write

Identifies and constrains power-critical nets to reduce switching power.

place_global_auto_blockage_in_channel

`place_global_auto_blockage_in_channel {none | soft| partial}`

Default: `none`

Data_type: enum {none soft partial}, read/write

Creates placement blockages in narrow channels between macros before Global Placement

- `soft`: Creates a soft blockage automatically by calling the `finish_floorplan` command.
- `partial`: Creates a partial blockage whose density will be determined automatically.

- `none`: Prevents the creation of blockage automatically by placer.

Note: The "soft" option only prevents cells being placed inside the channels during global placement. place_detailr called by optimization can still place the cells inside the channels.

Note: The threshold to activate the soft blockage insertion when the option is set to "soft" is when the channels between macros are less than 50 um in width.

place_global_clock_gate_aware

```
place_global_clock_gate_aware {true | false}
```

Default: `true`

Data_type: bool, read/write

Specifies that placement is aware of clock gate cells in the design.

Note: `-place_global_clock_gate_aware` finds better placement for clock gating elements towards the center of gravity for fanout.

place_global_clock_power_driven

```
place_global_clock_power_driven {true | false}
```

Default: `true`

Data_type: bool, read/write

Improves clock wirelength and subsequently clock power by adding more weight to clock nets between clock gates and their respective Flops.

place_global_cong_effort

```
place_global_cong_effort {low | medium | high | extreme |auto}
```

Default: `auto`

Data_type: enum {low medium high extreme auto}, read/write

Specifies the effort level for relieving congestion.

Specify one of the following values:

- `auto`: Automatically determines whether the design is congested and performs extra congestion driven effort for highly congested designs.

- `high`: Runs more iterations of placement in an effort to achieve better congestion results. This parameter increases the run time.
- `low`: Runs fewer iterations of placement to arrive quickly at a legal placement. This parameter might decrease placement quality.
- `medium`: Runs placement on designs at a normal effort level.

place_global_cpg_effort

```
place_global_cpg_effort {low | medium | high}
```

Default: `low`

Data_type: enum {low medium high}, read/write

Specifies the effort level of pushing instances to the guided locations during the CPG flow.

With higher level, placement will increase the force to push instances to the guided locations, but might degrade wire length and timing QOR.

place_global_cpg_file

```
place_global_cpg_file cpgFileName
```

Default: `""`

Data_type: string, read/write

Specifies the CPG guide file. When this option is specified, the CPG flow is turned ON automatically.

Note: To run the CPG flow, you must save a guide file from the old version database and read it during the mixed placement flow on the new version netlist.

place_global_enable_advanced_pipeline

```
place_global_enable_advanced_pipeline {true | false}
```

Default: `false`

Data_type: bool, read/write

Enables advanced pipeline placement.

place_global_enable_distributed_place

```
place_global_enable_distributed_place {true | false}
```

Default: `false`

Data_type: bool, read/write

Enables distributed placement platform.

Note: This attribute is part of a limited-access feature in this release. It is enabled by a variable specified using the `set_limited_access_feature` command. To use this feature, contact your Cadence representative to explain your usage requirements, and make sure this feature meets your needs before deploying it widely.

place_global_ignore_scan

```
place_global_ignore_scan {true | false}
```

Default: `true`

Data_type: bool, read/write

Global placement disregards scan connections while placing scan groups. Before you place the design, you must already have specified the scan cells with the `set_scan_cell` command, or the scan cell information must be in the timing library.

Note:

- This attribute cannot skip scan definition checking. No matter whether the option is false or true, scan chain definition must be imported before the global placement if the netlist has a scan connection.
- Scan groups are sometimes called scan partitions.

place_global_ignore_spare

```
place_global_ignore_spare {true | false}
```

Default: `false`

Data_type: bool, read/write

Disregards spare cell connections while placing spare cells. Before you place the design, you must already have specified the spare cells with the `set_spare_insts` command, or the spare cell information must be in the timing library.

`place_design` ignores spare cell connections.

Note: The placer disconnects high-fanout (nets with more than 75 terminals) from spare cells, even when this parameter is set to `0`.

place_global_max_density

`place_global_max_density` *value*

Default: `-1.0`

Data_type: double, read/write

Controls maximum density of local bins during global placement. Sets the maximum density of core area so that the placement engine aggressively minimizes the wirelength, while satisfying the maximum density constraint. This helps to achieve better timing results in low utilization designs. After global placement, the density control is removed.

Use a value between 0 (zero percent) and 1 (100 percent). For example, a value of 0.5 indicates that the maximum density in the entire design will be 50 percent or less.

Note: It is recommended that the `place_global_max_density` value should be greater than standard cell utilization of design.

Note: Using this attribute might degrade congestion and timing QOR of Global placement.

place_global_module_aware_spare

`place_global_module_aware_spare {true | false}`

Default: `false`

Data_type: bool, read/write

Places spare cells in the netlist within a hierarchical module, even if no region or fence constraints are specified.

- When this parameter is `true`, spare cells in a logical hierarchy are placed within the bounds of the hierarchy.
- When this parameter is `false`, spare cells are spread out within the placement area, and are not bound to a hierarchical module.

place_global_module_padding

```
place_global_module_padding {module factor}
```

Default: "" (empty string)

Data_type: string, read/write

Specifies a module in which to add padding (placement clearance) and a factor to use to calculate the padding dimension. Adding padding reduces placement density and localized congestion (hotspots) by spreading out cell instances in the specified modules. Module padding provides guidance for global placement only, and is ignored during placement legalization (`place_detail`).

- `module`: Specifies a hierarchical instance to which the factor applies. You can use "prefix matching" when you specify the instance name. For example, you can use the following command to specify the module padding for all u_ram_block_{2,4,6} module.

  ```
  set_db place_global_module_padding {u_ram_block_ 2.0}
  ```

- `factor`: Specifies a factor to use to calculate the padding dimension. The placer multiplies the instance area of all cell instances under the specified module by the factor. For example, a factor of 2 means that the placer "sees" each cell as twice its actual size. In most cases, a factor of 1.2 (which increases the area by 20 percent) is good enough. The placer ignores factors that are less than 1.0.

place_global_place_io_pins

```
place_global_place_io_pins {true | false}
```

Default: false

Data_type: bool, read/write

Moves placed and unplaced I/O pins, based on the placement of connected instances in an attempt to find a better I/O pin placement than the one specified in the I/O pin placement or floorplan file. At the end of global placement, the I/O pin location is legalized.

When the value of this parameter is `false`, I/O pins are ignored during global placement and no legalization is done at the end.

If `place_design` does not place the standard cells, for example if all instances are fixed or if there is no placeable area, then `place_design` also skips I/O pin assignment.

place_global_sdp_alignment

```
place_global_sdp_alignment {true | false}
```

Default: `false`

Data_type: bool, read/write

Ensures SDP alignment during the global cell placement.

The user-specified SDP alignment is preserve during the global cell placement.

place_global_sdp_place

```
place_global_sdp_place {true | false}
```

Default: `false`

Data_type: bool, read/write

Enables SDP placement for `place_opt_design` command and where placer will place SDP cells closely as a group.

place_global_reorder_scan

```
place_global_reorder_scan {true | false}
```

Default: `true`

Data_type: bool, read/write

Ignores scan chain connectivity during placement and performs scan chain reordering after placement.

If you specify `false` for this parameter, the software does not perform scan chain reordering after placement.

place_global_soft_guide_strength

```
place_global_soft_guide_strength {low | medium | high}
```

Default: `low`

Data_type: enum {low medium high}, read/write

Instructs placement engine to place those modules which have been specified as softguide in the

floorplan file closer. The degree of closeness depends on the strength given.

In case, there are fixed/preplaced instances, the module placed gets affected by those fixed instances and therefore placed close to them.

place_global_timing_effort

```
place_global_timing_effort {medium|high}
```

Default: `medium`

Data_type: enum {medium high}, read/write

Specifies the level of effort for timing driven global placer.

Note: `place_global_timing_effort high` is not recommended for congested designs.

⚠ This option is part of a limited-access feature in this release. It is enabled by a variable specified using the `set_limited_access_feature` command. To use this feature, contact your Cadence representative to explain your usage requirements, and make sure this feature meets your needs before deploying it widely.

place_global_uniform_density

```
place_global_uniform_density {true | false}
```

Default: `false`

Data_type: bool, read/write

Enable even cell distribution for designs with less than 70% utilization.

place_hard_fence

```
place_hard_fence {true | false}
```

Default: `true (place_detail honors the constraints)`

Data_type: bool, read/write

Specifies whether `place_detail` and `check_place` honor or ignores the fence and region placement constraints while legalizing placed instances.

Note: In optimization, the fence and region constraints are disabled by default in non-MSV designs for better timing enclosure, which is controlled by `set_db opt_honor_fences` with the `false` default value.

For the fence and region constraints to be honored by optimization commands, both `set_db opt_honor_fences` and `set_db place_hard_fence` must be set to `true`.

place_opt_post_place_tcl

`place_opt_post_place_tcl` *`tcl_file`*

Default: `""`

Data_type: string, read/write

Sources the tcl script after placement and before running optimization inside `place_opt_design`.

place_opt_run_global_place

`place_opt_run_global_place {none seed full}`

Default: `full`

Data_type: enum {none seed full}, read/write

Changes the Global Placement behavior inside `place_opt_design`.

- `none`: Skips place_design and runs only preCTS Optimization inside `place_opt_design`.
- `seed`: Uses seed placement from Concurrent Placement or other sources and runs incremental standard cell placement, then runs preCTS optimization.
- `full`: Runs full global placement and preCTS optimization.

When `place_design -concurrent_macros` is run, it sets the value of `place_opt_run_global_place` to `seed`.

place_spare_update_timing_graph

`place_spare_update_timing_graph {true | false}`

Default: `true`

Data_type: bool, read/write

Updates timing graph during `place_spare_modules`.

place Category Object Attributes

To view help for any object type attribute across different object types, type the following command:

```
help attributeName
```

For example, for help on all the place_status objects, type this:

```
help place_status*
```

For help on a specific object attribute, use this:

```
help inst place_status_cts
```

The following categories of object attributes are available in the place category:

Object Category Name	Attributes
bump	place_status
inst	place_status place_status_cts place_status_effective
port	place_status

reorder_scan

```
reorder_scan
[-help]
[-add_scan_port_prefix prefix]
[-clock_aware {true | false}]
[-keep_power_domain_ports {true | false}]
[-prefer_horizontal {true | false}]
[-prefer_vertical {true | false}]
[-scan_effort {low | medium | high}]
[-skip_mode {skipNone | skipBuffer}]
```

Reorders the scan cells after running placement. Controls the skipping and removal of buffers and inverters in the scan chain. Use this command after running placement with the ignore scan connection attribute (`place_global_ignore_scan true`), and after specifying the scan chain or loading scan chain information in the DEF or TDF files.

Set attributes for this command with the reorder_scan Category Attributes.

This command automatically detects multiple power domains and minimizes the number of scan chains that pass through them. It respects rectilinear and rectangular power domain boundaries. If a scan chain crosses power domains that operate at the same voltage, the software does not insert level shifters. If the scan chain crosses power domains operating at different voltages, the software inserts the appropriate level shifters.

If scan reorder fails, use the `trace_scan -verbose` command to see where the scan chain stops.

Note: Parameters set by this command override the attribute settings of the reorder_scan category.

Note: This command supports multithreading.

Parameters

`-add_scan_port_prefix` *prefix*	Specifies the prefix to be added to scan hports. *Default:* `""`

`-clock_aware {true | false}`	Specifies whether scan reordering is clock tree aware. • When `true`, scan reordering is clock tree aware, and is clock tree driven. • When `false`, scan reordering is not clock tree aware, and is wirelength driven. *Default:* `false` (The software is not clock tree aware) *Data_type*: bool, optional This parameter can also have the value `0, 1` or any floating point number between `0` and `1`. If this parameter is not specified, or if `0` is specified for this parameter, this indicates: Do not consider clock tree at all. If the value is close to `1`, this indicates: Give greater consideration to clock tree.
`-keep_power_domain_ports {true | false}`	Maintains or corrects the hierarchical ports without deleting or inserting shifters, and reorders the remaining scan chain. To turn this option off, use `reorder_scan -keepPDports false` or `reorder_scan_keep_hport false`. *Default:* `true` *Data_type*: bool, optional **Note:** This parameter works in the MSV flow only.
`-prefer_horizontal {true | false}`	Specifies that the preferred direction for scan reordering connections is horizontal. Reorders the scan chain to snake a sideways "S" configuration if the block is short and wide or the design has vertical routing congestion. *Default:* `false` *Data_type*: bool, optional **Note:** If both `-prefer_vertical` and `-prefer_horizontal` are set to `true`, the software does not honor the setting and treats them both as if they were `false`.

`-prefer_vertical {true | false}`	Specifies that the preferred direction for scan reordering connections is vertical. Reorders the scan chain to snake a vertical "S" configuration if the block is long and narrow or the design has horizontal routing congestion. *Default:* `false` *Data_type*: bool, optional **Note:** If both `-prefer_vertical` and `-prefer_horizontal` are set to `true`, the software does not honor the setting and treats them both as if they were `false`.
`-scan_effort`	Specifies the effort level for reordering scan chains. *Default:* `-medium` *Data_type*: enum, optional Specify one of the following values: • `-high`: Runs more iterations of scan reorder to achieve better net length. Using this parameter increases the run time. • `-low`: Runs fewer iterations of scan reorder to minimize net length quickly. • `-medium`: Runs a normal number of iterations.
`-skip_mode {skipNone | skipBuffer}`	Specifies how scan reordering handles buffers and inverters in the scan chain. *Default:* `skipNone` *Data_type*: enum, optional Specify one of the following: • `-skip_none`: Specifies that buffers and inverters remain after the scan chain reorder. • `-skip_buffer`: Ignores buffers in the scan chain. If a buffer or inverter is not connected elsewhere in the design, `reorder_scan` removes the buffer.

Example

The following command reconnects the scan chain so that buffers are skipped:

```
reorder_scan -skip_mode skipBuffer
```

Related Information

- `reorder_scan Category Attributes`
- `trace_scan`
- Placing the Design chapter in the *Innovus Stylus Common UI User Guide*
  - Optimizing and Reordering Scan Chains
- Place Menu chapter in the *Innovus Stylus Common UI Menu Reference*.

reorder_scan Category Attributes

The root attributes in the reorder_scan category are:

- reorder_scan_add_scan_port_prefix
- reorder_scan_clock_aware
- reorder_scan_comp_logic
- reorder_scan_enable_for_partition
- reorder_scan_keep_hport
- reorder_scan_keep_hinst_port_name
- reorder_scan_prefer_horizontal
- reorder_scan_prefer_vertical
- reorder_scan_effort
- reorder_scan_skip_mode
- reorder_scan_swap_effort

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `reorder_scan` category, use the following command:

```
get_db -category reorder_scan
```

reorder_scan_add_scan_port_prefix

`reorder_scan_add_scan_port_prefix` *prefix*

Default: `""`

Data_type: string, read/write

Specifies the prefix to be added to scan hports.

reorder_scan_clock_aware

`reorder_scan_clock_aware {true|false}`

Default: `false` (The software is not clock tree aware.)

Data_type: bool, read/write

Specifies whether scan reordering is clock tree aware.

- When `true`, scan reordering is clock tree aware, and is clock tree driven.
- When `false`, scan reordering is not clock tree aware, and is wirelength driven.

reorder_scan_comp_logic

`reorder_scan_comp_logic {true|false}`

Default: `false`

Data_type: bool, read/write

If set to `true`, enables `trace_scan` trace through multiple input logic gates (whose input/output pin is not defined in the input scan DEF) in the scan path.

Note: When `-reorder_scan_comp_logic` is set to true, there can be multiple valid scan paths. In that case, `trace_scan` will select one of the valid paths. However, it is recommended that you specify the relevant gate's input/output pin to avoid trace through alternative paths.

Related Command

- `trace_scan`

reorder_scan_enable_for_partition

`reorder_scan_enable_for_partition {true|false}`

Default: `false`

Data_type: bool, read/write

Enables `reorder_scan` for a design with partition.

reorder_scan_keep_hport

```
reorder_scan_keep_hport {true|false}
```

Default: `true`

Data_type: bool, read/write

Maintains or corrects the hierarchical ports without deleting or inserting shifters, and reorders the remaining scan chain.

Note: This parameter works in the MSV flow only.

reorder_scan_keep_hinst_port_name

```
reorder_scan_keep_hinst_port_name filename
```

Default: `""`

Data_type: string, read/write

Specifies a file that lists the names of hierarchical instances whose ports cannot be changed, removed, duplicated, or reordered during scan reordering.

reorder_scan_prefer_horizontal

```
reorder_scan_prefer_horizontal {true|false}
```

Default: `false`

Data_type: bool, read/write

Specifies that the preferred direction for scan reordering connections is horizontal. Reorders the scan chain to snake a sideways "S" configuration if the block is short and wide or the design has vertical routing congestion.

Note: If both `-reorder_scan_prefer_vertical` and `-reorder_scan_prefer_horizontal` are set to `true`, the software does not honor the setting and treats them both as if they were `false`.

reorder_scan_prefer_vertical

```
reorder_scan_prefer_vertical {true|false}
```

Default: `false`

Data_type: bool, read/write

Specifies that the preferred direction for scan reordering connections is vertical. Reorders the scan chain to snake a vertical "S" configuration if the block is long and narrow or the design has horizontal routing congestion.

reorder_scan_effort

```
reorder_scan_effort {low|medium|high|auto}
```

Default: `auto`

Data_type: enum {low medium high auto}, read/write

Specifies the effort level for reordering scan chains.

Specify one of the following values:

- `high`: Runs more iterations of scan reorder to achieve better net length. Using this parameter increases the run time.
- `low`: Runs fewer iterations of scan reorder to minimize net length quickly.
- `medium`: Runs a normal number of iterations.

reorder_scan_skip_mode

```
reorder_scan_skip_mode {skip_none|skip_buffer|skip_floating_buffer}
```

Default: `skipNone`

Data_type: enum {skip_none skip_buffer skip_floating_buffer}, read/write

Specifies how scan reordering handles buffers and inverters in the scan chain.

Specify one of the following:

- `skip_none`: Specifies that buffers and inverters remain after the scan chain reorder.
- `skip_buffer`: Ignores buffers in the scan chain. If a buffer or inverter is not connected elsewhere in the design, `reorder_scan` removes the buffer.
- `skip_floating_buffer`: Skips only buffers in the floating section and keeps the buffers that belong to an ordered section.

  Note: During scan reordering, the order of scan elements in the ordered section must be kept as importing scan specification. However, the order of the floating elements can be changed.

Related Command

- reorder_scan

reorder_scan_swap_effort

```
reorder_scan_swap_effort {low|medium|high}
```

Default: `high`

Data_type: enum {low medium high}, read/write

Specifies the effort level for reorder_scan different chains swapping.

Related Command

- reorder_scan

report_cell_edge_spacing

`report_cell_edge_spacing`

Reports all the cell edge spacing rules in both terminal and log file.

Parameters

None

Related Information

- `delete_cell_edge_spacing`
- `set_cell_edge_spacing`

report_cell_edge_type

```
report_cell_edge_type
[-help]
[-out_file cellName]
[-file fileName]
```

Reports the edge type of the specified cell.

Parameters

`-cell cellName`	Specifies the cell name for which edge type is to be reported. If the cell name is not specified, all the cell edge types are reported in the edge_type.rpt file report file. *Data_type*: string, optional
`-out_file fileName`	Specifies the file name to dump cell edge type(s) . If no file name is specified, the edge_type.rpt file is used to generate the report. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `report_cell_edge_type` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_cell_edge_type`.

Related Information

- `set_cell_edge_type`

report_cell_padding

```
report_cell_padding
[-help]
[-cell cellName]
[-out_file fileName]
```

Prints the number of cells, which contain user-specified padding, to the log file. Optionally, you can obtain a complete list of cells with their padding information in a file using the `-file` parameter. The format of this file is same as used in the `set_cell_padding` command, that is, *`cellName padding`* (in grid units).

Parameters

`-cell` *`cellName`*	Specifies the cell name to report padding. *Data_type*: string, optional
`-out_file` *`fileName`*	Specifies the generated file name to dump cell padding. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `report_cell_padding` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_cell_padding`.

Examples

The following steps show the usage of `report_cell_padding` command:

1. Specify the following padding using the `set_cell_padding` command:

   ```
   set_cell_padding FF_SCAN 2
   set_cell_padding DFFSHQX1 5
   set_cell_padding DFFSRX4 4
   ```

2. Run the `report_cell_padding` command. After running this command, you get the value `3` and the following message is printed to the log file:

```
3 cells have padding.
```

3. To print the above-mentioned list of cells in the file `myfile`, specify the following command:

```
report_cell_padding -out_file myfile
```

4. After running this command, the following contents of `myfile` are displayed:

```
FF_SCAN 2
DFFSHQX1 5
DFFSRX4 4
# 3 cells have padding.
```

Related Information

- `set_cell_padding`

report_cell_stack_area

```
report_cell_stack_area
[-help]
[-cell cell_name]
[-file file_name]
[-group group_name]
```

Reports the cell stack area definition for cells.

Parameters

`-cell cell_name`	Specifies the cell(s) for which the cell stack area definition needs to be reported. *Data_type*: string, optional
`-file file_name`	Specifies the file name in which the reported information is saved. By default, all cell stack groups are reported to the `cell_stack_area.rpt` file. *Data_type*: string, optional
`-group group_name`	Specifies the group(s) for which the cell stack area definition needs to be reported. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `report_cell_stack_area` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_cell_stack_area`

Related Information

- `delete_cell_stack_area`
- `set_cell_stack_area`

report_cell_stack_group

```
report_cell_stack_group
[-help]
[-file file_name]
[-name group_name]
```

Reports the cell stack group definition.

Parameters

`-file` *file_name*	Specifies the file name in which the reported information is saved. By default, all cell stack groups are reported to the `cell_stack_group.rpt` file. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `report_cell_stack_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_cell_stack_group`
`-name` *group_name*	Specifies the group(s) that needs to be reported. *Data_type*: string, optional

Related Information

- `delete_cell_stack_group`
- `set_cell_stack_group`
- Place Menu chapter in the *Innovus Stylus Common UI Menu Reference*.

report_cell_virtual_align

```
report_cell_virtual_align
[-help]
[-cells cells]
```

Reports the cells that need to be virtually aligned.

Parameters

`-cells` *cells*	Specifies the lib cells that require virtual alignment. *Data_type*: (base_cell)+, optional
`-help`	Outputs a brief description that includes type and default information for each `report_cell_virtual_align` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_cell_virtual_align`

Related Information

- `delete_cell_virtual_align`
- `set_cell_virtual_align`

report_congestion

```
report_congestion
[-help]
[-3d]
[-hotspot]
[-include_blockage]
[-num_hotspot number]
[-overflow]
```

Reports the average congestion and the local hotspot score. Route needs be called before using this command.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `report_congestion` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_congestion`.
`-3d`	Honors 3d congestion map. When specified, it enables the layer-based congestion reporting.
`-hotspot`	Reports the local hotspot score. It reports the maximum and total hotspot area. Hotspot score refers to the contiguous area of gcells (there is some normalization done internally) which have routing overflow. Typically, a max hotspot score < 100 indicates that the design is routable. • Max hotspot – It is the largest contiguous area of gcells with overflow • Total hotspot – It is the total of all hotspots Greater the number of adjacent gcells with overflow, bigger will be the hotspot. **Note:** You can use this parameter to view the congestion hotspot regions seen by the router after global route. *Data_type*: bool, optional
`-include_blockage`	Includes blockage area in the hotspot report. *Data_type*: bool, optional
`-num_hotspot` *number*	Specifies the number of hotspots to be reported. *Data_type*: int, optional
`-overflow`	Reports horizontal and vertical overflow. *Data_type*: bool, optional

Examples

- The following command reports the congestion:

```
report_congestion -overflow
```

Output:

```
Usage: (10.0%H 8.1%V) = (2.425e+05um 3.107e+05um) = (72854 61452)
Overflow: 210 = 7 (0.01% H) + 202 (0.33% V)

```

Related Information

- place_fix_congestion

report_density_in_area

```
report_density_in_area
-area
```

Outputs placement density for a specific area in the design. Considers placement blockages and honors the metal layers specified by the `place_detail_preroute_as_obs` attribute. The argument type is box in units of microns. This command is optimized for small area interactive queries.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `report_density_in_area` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_density_in_area`
`-area`	Specifies box coordinates (*`x1, y1, x2, y2`*) in micron. • *x1:* Specifies the area's lower left point on the x axis. • *y1:* Specifies the area's lower left point on the y axis. • *x2:* Specifies the area's upper right point on the x axis. • *y2:* Specifies the area's upper right point on the y axis. *Data_type*: rect, required

Examples

The following command reports the placement density for the specific area 2835.342 3381.807 4807.673 4530.904:

```
report_density_in_area 2835.342 3381.807 4807.673 4530.904
```

The output of this command is:

```
StdInstArea/freeSpace = 27.0%(197105.76/728824.32)

macroInstArea/totArea = 67.7%(1539687.84/2272665.60)

powerMetalArea/totArea = 0.0%(0.00/2272665.60)
```

```
PlacementObsArea/totArea = 0.0%(0.00/2272665.60)

Utilization in area (2835342 3381807) (4807673 4530904) = 27.04%
```

report_density_map

```
report_density_map
[-help]
[-grid_length rowHeight]
[-grid_unit microns]
[-ignore_block {true|false}]
[-ignore_filler {true|false}]
[-threshold density]
```

Generates a map that uses colors to represent placement density and generates a placement density report. If you run this command without parameters, it generates a map with a threshold of 0.75 and measures the grid in row height.

Note: You can also use `report_pin_density Category Attributes` to set the threshold, and specify whether the map displays bins in microns or rows.

Use this command any time after placement.

Use the *Display Density Map* form to select colors and step-size for the density levels in the map.

Parameters

`-grid_unit` *microns*	Specifies the value (in micron) of side of square grid for density calculations. *Data_type*: float, optional
`-grid_length` *rowHeight*	Specifies the value (in row-height) of side of square grid for pin density calculations. *Data_type*: int, optional
`-help`	Outputs a brief description that includes type and default information for each `report_density_map` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_density_map`.
`-ignore_block {true|false}`	Skips block cells instances from both supply and demand calculation. *Data_type*: bool, optional
`-ignore_filler`	Ignores the density of fillers in the post-filler density heat map to show the density of standard cells . *Default*: `false` *Data_type*: bool, optional
`-threshold` *density*	Specifies a threshold density value for the grid. Any grid under the threshold value is not reported. The value must be positive. *Data_type*: float, optional

Example

The following are output from command `report_density_map`. It generates a map with default threshold of 0.75 and measured in row height:

```
powerDomain TOP: bins with density > 0.75 = 0.519 % ( 6 / 1156 )

bin size: 59 sites by 10 row(s). total 1156 bins ( 34 by 34 )

density range #bins %

0.75 - 0.8 5 0.4325

0.8 - 0.85 1 0.08651
```

```
total 6 0.519
```

    - Display Density Map

report_inst_padding

```
report_inst_padding {inst_name | -all}
```

Reports the padding for a specific instance, or all instance padding in the design. This command can be used if there is instance padding specified.

Parameters

`-all`	Reports all instance padding in the design. *Data_type*: bool, required
`inst_name`	Reports the padding for the specified instance. *Data_type*: string, required

Example

The following command reports the padding for a specified instance named U19567:

```
report_inst_padding U19567
```

It outputs following:

```
Padding for Instant [U19567] is 2.
```

Related Information

  - *Adding Padding*

report_inst_space_group

```
report_inst_space_group
[-help]
[-file fileName]
[-group groupName]
```

Reports all instance space groups into the inst_space_group.rpt file by default.

Parameters

`-file` *fileName*	Specifies the file name to dump space group. *Data_type*: string, optional
`-group` *groupName*	Specifies the name of the group to be reported. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `report_inst_space_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_inst_space_group`.

Related Information

- `create_inst_space_group`
- `delete_inst_space_group`

report_jtag_inst

```
report_jtag_inst
[-out_file]
```

Displays JTAG information specified by the `set_jtag` command or creates an output file that contains the information.

Parameters

`-out_file`	Specifies the name of the file. If you do not specify this parameter, the command prints the information to the screen without saving it in a file. *Data_type*: string, optional

Related Topics

report_pg_keep_out

```
report_pg_keep_out
[-help]
[-file file_name]
{-cell lib_cell_name | -inst instance_name}
```

Reports all PG keepout boxes in the design if no option is specified.

Parameters

`-cell` *lib_cell_name*	Reports PG keepout boxes applied to the specified lib cell only. *Data_type*: string, optional
`-file` *file_name*	Specifies the file name where all the details are dumped. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each report_pg_keep_out parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_pg_keep_out`
`-inst` *instance_name*	Reports PG keepout boxes applied to the specified instance only. *Data_type*: string, optional

Related Information

- `create_pg_keep_out`
- `delete_pg_keep_out`

report_pin_density

```
report_pin_density
[-help]
[-area <x1 y1 x2 y2>]
```

Outputs pin density for the design.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `report_pin_density` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_pin_density`
`-area`	Species the box coordinates in microns. • *x1*: Specifies the area's lower left point on the x axis. • *y1*: Specifies the area's lower left point on the y axis. • *x2*: Specifies the area's upper right point on the x axis. • *y2*: Specifies the area's upper right point on the y axis. *Data_type*: rect, optional The argument type is box in units of microns.

Examples

The following command reports the pin density for the specific area 93.85, -645.08, 102.83, -640.33:

```
report_pin_density -area 93.85 -645.08 102.83 -640.33
calculate placement pin density in box (93.85, -645.08, 102.83, -640.33)
Pin Density = 0.391304.
= total # of pins 36 / total Instance area 92.00.
```

Related Information

- report_pin_density Category Attributes
- report_pin_density_map

report_pin_density_map

```
report_pin_density_map
[-help]
[-step step_value]
[-grid_unit micron]
[-grid_length numberRow]
[-threshold density]
```

Generates a map that uses colors to represent pin density and generates a pin density report. Use this command any time after placement.

> You can also use report_pin_density Category Attributes to set the threshold and specify whether the map displays bins in microns or rows.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `report_pin_density_map` parameter. For a detailed description of the command and all of its parameters, use the man command: `man report_pin_density_map`
`-step` *step_value*	Specifies the range step for displaying the pin density map. *Default*: `0.05` *Data_type*: float, optional
`-grid_unit` *micron*	Specifies the value of side of square grid for pin density calculations. *Default:* `50` *Minimum*: `0.000000` *Maximum:* `1000.000000` *Data_type*: int, optional
`-grid_length` *numberRow*	Specifies the value (in row-height) of side of square grid for pin density calculations. *Default:* `10` *Minimum:* `1` *Maximum:* `100` *Data_type*: float, optional
`-threshold` *density*	Specifies a threshold density value over which the densities must be reported. Any grid under the threshold value is not reported. The value must be positive. *Default*: `0.5` *Minimum*: `0.000000` *Maximum*: `2.000000` *Data_type*

Examples

The following command reports the pin density map:

```
report_pin_density_map
*** Starting report pin density ***
default core: bins with pin density > 0.5 = 0 % (0 / 1)
bin size: 90 sites by 10 row(s). total 1 bins ( 1 by 1 )
pin density range   #bins     %
total                 0       0
```

Related Information

- report_pin_density
- report_pin_density Category Attributes

report_pin_density Category Attributes

The root attributes in the report_place category are:

- report_pin_density_map_grid_unit
- report_pin_density_map_grid_size
- report_pin_density_map_threshold
- report_pin_density_map_display_step

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `report_pin_density` category, use the following command:

```
get_db -category report_pin_density
```

report_pin_density_map_grid_unit

`report_pin_density_map_grid_unit` *micron*

Default: 50.0

Data_type: double, read/write

Specifies the value (in micron) of side of the square grid for pin density calculations.

report_pin_density_map_grid_size

`report_pin_density_map_grid_size` *numberRow*

Default: `10`

Data_type: int, read/write

Specifies the value (in row-height) of side of the square grid for pin density calculations.

report_pin_density_map_threshold

`report_pin_density_map_threshold` *`density`*

Default: `0.5`

Data_type: double, read/write

Specifies the threshold value over which the densities must be reported.

report_pin_density_map_display_step

`report_pin_density_map_display_step` *`step_value`*

Default: `.05`

Data_type: double, read/write

Specifies the range step for displaying the pin density map calculations.

report_pipelines

```
report_pipelines
[-help]
[-net_groups netGroupNames]
[{-spacing value  | -timing  | -ps_per_um } -out_file fileName]
```

The command can be used for analysis before the flops exist in the netlist. It can also be used post flop insertion to either report expected average wire-length between stages of a pipeline net group, or to report the achieved average distance between the placed stages of the pipeline. When used for analysis, the command reports expected number of PFF stages for each net group based on the user-specified value. Optionally the command generates bus-guides for reported route-path.

Parameters

`-out_file` *fileName*	Specified the output for additional information from the command. The output includes expected placement location of PFF at each stage in analysis flow. *Data_type*: string, optional
`-net_groups` *netGroupNames*	Restricts the report to the net group name specified. If no net group name is specified, all pipeline net groups are reported. *Data_type*: string, optional
`-spacing` *value*	Given the target approximate wire-length spacing between stages, `-spacing` suggests the number of flop stages to insert. *Data_type*: float, optional
`-timing`	`-timing` is used to automatically estimate the number of pipeline FFs needed, based on timing delay on routing layers and the clock cycle requirement. It is mutually exclusive to option `-spacing` because the spacing can be decided automatically. *Data_type*: bool, optional
`-ps_per_um`	`-ps_per_um` is used to automatically find maximum spacing using pspm model. *Data_type*: bool, optional

Example

- The following command reports expected number of PFF stages for net group "`netGroup1`" if the distance between each stage is around 300 microns:

  ```
  report_pipelines -net_groups netGroup1 -spacing 300
  ```

- The following command reports the expected number of PFF stages for net group `netGroup1` if the distance between each stage is around 300 microns. Additional information of expected placement location of each stage are written in the file `PFF.rpt`:

  ```
  report_pipelines -net_groups netGroup1 -spacing 300 -out_file PFF.rpt
  ```

Related Information

- `place_pipelines`
- `delete_pipeline_net_group`

report_place_density Category Attributes

The root attributes in the report_place category are:

- report_place_density_map_grid_size
- report_place_density_map_grid_unit
- report_place_density_map_ignore_block
- report_place_density_map_ignore_filler
- report_place_density_map_threshold

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `report_place_density` category, use the following command:

```
get_db -category report_place_density
```

report_place_density_map_grid_size

`report_place_density_map_grid_size` *numberRows*

Default: 10

Data_type: int, read/write

Specifies the horizontal or vertical dimension of a grid in the map, measured in number of rows. If you specify a value less than `1`, the software uses 1.

report_place_density_map_grid_unit

`report_place_density_map_grid_unit` *microns*

Default: `50.0`

Data_type: double, read/write

Specifies the horizontal or vertical dimension of a grid in the map, measured in microns.

report_place_density_map_ignore_block

`report_place_density_map_ignore_block {true | false}`

Default: `false`

Data_type: bool, read/write

Skips block cells instances from both supply and demand calculation.

report_place_density_map_ignore_filler

`report_place_density_map_ignore_filler {true | false}`

Default: `false`

Data_type: bool, read/write

Ignores the density of fillers in the post-filler density heat map to show the density of standard cells.

report_place_density_map_threshold

`report_place_density_map_threshold` *`density`*

Default: `0.75`

Data_type: double, read/write

Specifies a threshold density value for the grid. Any grid under the threshold value is not reported. The value must be positive. Cadence recommends an upper limit of `1.20`.

Related Command

- `report_density_map`

report_scan_cells

`report_scan_cells`

Displays a list of the scan cells that are read from the timing library or by the `set_scan_cell` command. This command can be called in any stage of flow after importing design if there are scan cell specifications in library; or else it can be used after the `set_scan_cell` command.

Parameters

None

Example

Following is an example of the output from `report_scan_cells`:

```
ScanFF SEDFFXL
  FT SI is test_scan_in
  FT SE is Scan Enable Clock
  FT QN is test_scan_out_inverted
  FT Q is test_scan_out
ScanFF SEDFFX4
  FT SI is test_scan_in
  FT SE is Scan Enable Clock
  FT QN is test_scan_out_inverted
  FT Q is test_scan_out
...
```

Related Information

report_scan_chain

```
report_scan_chain
[-help]
[-chain chainName]
[-out_file fileName]
[-verbose {true|false}]
```

Prints the scan chain information.

Parameters

`-chain` *chainName*	Specifies the scan chain name. *Data_type*: string, optional
`-out_file` *fileName*	Specifies the output file name of scan chain. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `report_scan_chain` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man report_scan_chain`.
`-verbose {true|false}`	Prints out more message. *Data_type*: bool, optional

Related Information

- `delete_scan_chain`
- `create_scan_chain`

report_scan_chain_partitions

```
report_scan_chain_partitions
[-help]
```

Generates a report that lists compatible scan chains in scan chain partitions.

Specify scan chain partitions with the following command:

`create_scan_chain_partition`

Parameters

None

Example

To see a list of the compatible scan chain groups in a design with one partition, `clk1Domain`, that has two compatible scan chains, type the following command:

```
report_scan_chain_partitions
```

The command outputs the following messages:

```
Info: Scan Chain Partition Group set to:

      Partition group: clk1Domain

                chain: chain1

                chain: chain2
```

reset_jtag

```
reset_jtag
{-cell leaf_cellName
 | -inst instanceName
 | -hinst hierarchicalInstanceName
 | -group hierarchicalInstanceName | cellName}
```

Unspecifies instances that were specified by the `set_jtag` command. This command can be used if there is instance specified by the `set_jtag` command.

Parameters

`-cell leaf_cellName`	Unmarks all instances of a specified cell type as JTAG instances. *Data_type*: string, optional
`-group hierarchicalInstanceName | cellName`	Unmarks all hierarchical instances or intermediate instances as JTAG instances. *Data_type*: string, optional
`-hinst hierarchicalInstanceName`	Unspecifies a hierarchical JTAG instance. *Data_type*: string, optional
`-inst instanceName`	Unspecifies a JTAG instance. You can use wildcards (`*` or `?`) with this parameter. *Data_type*: string, optional

Example

- The following command unspecifies cell `jtag_FlipFlop` that was specified by the `set_jtag` command:

  ```
  reset_jtag -cell jtag_FlipFlop
  ```

- The following command unspecifies all instance names that begin with `instG` that were specified by the `set_jtag` command:

  ```
  reset_jtag -inst instG*
  ```

Related Information

reset_selective_blockage_gate

```
reset_selective_blockage_gate
[-help]
[-cells cellName]
[-insts instName]
```

Specifies cells and instances that are forbidden to be placed inside the soft blockage during legalization.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `reset_selective_blockage_gate` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reset_selective_blockage_gate`.
`-cells cellName`	Specifies the cell type name as illegal for soft blockage. You can use wildcards (`*` or `?`) with this parameter. *Data_type*: string, optional
`-insts` *`instName`*	Specifies the instance name as illegal for soft blockage. You can use wildcards (`*` or `?`) with this parameter. *Data_type*: string, optional

Examples

The following command specifies that cell `NR2RLX1` and all instance names that begin with `MEMCTLU` cannot be moved into soft blockage during legalization.

```
reset_selective_blockage_gate -cells NR2RLX1 -insts MEMCTLU*
```

Related Information

- `set_selective_blockage_gate`

reset_spare_insts

```
reset_spare_insts
[-help]
{-cell cellName | -inst instName | -hinst hinstName}
```

Asserts the specified instance is not a spare gate. This command can be used after `set_spare_insts`.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `reset_spare_insts` parameter. For a detailed description of the command and all of its parameters, use the man command: `man reset_spare_insts`.
`-cell` *cellName*	Specifies the name of the spare cell to be reset. Wildcards are supported. *Data_type*: string, optional
`-hinst` *hinstName*	Specifies the name of the spare hierarchical instance to be reset. Wildcards are supported. *Data_type*: string, optional
`-inst` *instName*	Specifies the name of the spare instance to be reset. Wildcards are supported. *Data_type*: string, optional

Examples

- In the following example, “AND2X1” cell is defined as a spare cell in the design. The example shows the query result of the spare cell of AND2X1:

```
get_db insts -if {.is_spare == true && .base_cell.name == AND2X1}

inst:DTMF_CHIP/spr_484/spr_gate0 inst:DTMF_CHIP/spr_483/spr_gate0
inst:DTMF_CHIP/spr_482/spr_gate0 inst:DTMF_CHIP/spr_481/spr_gate0
inst:DTMF_CHIP/spr_480/spr_gate0 inst:DTMF_CHIP/spr_479/spr_gate0
inst:DTMF_CHIP/spr_477/spr_gate0
```

- The following example resets the spare cell instance, `spr_477`, with the `-inst` option. As a result, the spare cell is removed from spare module list and is not a spare gate any more:

```
@innovus 15> get_db inst:DTMF_CHIP/spr_477/spr_gate0 .is_spare
true
@innovus 18> reset_spare_insts -inst spr_477/spr_gate0
Resetting spare instance [spr_477/spr_gate0].
Reset 1 spare instances.
@innovus 19> get_db inst:DTMF_CHIP/spr_477/spr_gate0 .is_spare
false
```

- The following commands reset the spare cell hierarchical instance, `spr_479`, with the `-hinst` option, removes it from the spare module list, and it is not a spare gate any more.

```
@innovus 21> get_db inst:DTMF_CHIP/spr_479/spr_gate0 .is_spare
true
@innovus 23> reset_spare_insts -hinst spr_479
Resetting spare mode HInst [spr_479].
@innovus 24> get_db inst:DTMF_CHIP/spr_479/spr_gate0 .is_spare
```

- The following commands reset the spare cell type, `AND2X1`, using the `-cell` option. All the instances of the `AND2X1` cell type are removed from spare module list and it is not a spare gate any more.

```
@innovus 25> reset_spare_insts -cell AND2X1
Resetting all spare instances of cell [AND2X1].
@innovus 26> get_db insts -if {.is_spare == true && .base_cell.name == AND2X1}
```

Related Information

- `set_spare_insts`
- Place Menu chapter of *Innovus Stylus Common UI Menu Reference*.
- Placing the Design chapter of *Innovus Stylus Common UI User Guide*.

set_cell_edge_spacing

```
set_cell_edge_spacing
[-help]
{edgeType1 edgeType2
-spacing spacing
[-except_abutted | -forbidden_spacing ][-except_non_filler_in_between] } | [-reset]
```

Creates the cell edge spacing rule as in `CELLEDGESPACINGTABLE` in LEF.

⚠ The tool by default supports the latest Tcl settings. If a user tries to change the edge spacing, the tool will generate a warning message that resetting edge spacing would overwrite the old value.

Note: This command is not supported for save and restore design.

Parameters

`-except_abutted`	Specifies that two abutted macros of the given edge types are also allowed. *Data_type*: bool, optional
`edgeType1`	Specifies edge `edgeType1` for edge spacing. *Data_type*: string, required
`edgeType2`	Specifies edge `edgeType2` for edge spacing. *Data_type*: string, required
`-except_non_filler_in_between`	Specifies that the edge spacing is only for adjacent instances. If two MACROs (cells) have a edge-spacing rule, say 0.8 micron, then normally the rule applies regardless of presence of another macro (cell) in the gap between. When the `-except_non_filler_in_between` option is used, the rule is exempted when a non-filler cell is present between the two constrained cell edges. *Data_type*: bool, optional
`-forbidden_spacing`	Forbids `edgeType1` and `edgeType2` without the space.
`-help`	Outputs a brief description that includes type and default information for each `set_cell_edge_spacing` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_cell_edge_spacing`
`-reset`	Resets the cell edge spacing to LEF. *Data_type*: bool, optional
`-spacing` *`spacing`*	Specifies edge spacing between *`edgeType1`* and *`edgeType2`*. If there is no spacing defined between two edge types, it indicates that there is no spacing constraint (or 0.0 µm) between them. *Data_type*: float, required

Example

The following command creates `0.18 µm` spacing between `grp1` and `grp2`:

```
set_cell_edge_spacing grp1 grp2 0.18
```

Related Information

- `delete_cell_edge_spacing`
- `report_cell_edge_spacing`

set_cell_edge_type

```
set_cell_edge_type
[-help]
-cell cellName
{-left edgeType | -right edgeType | -bottom edgeType | -reset}
[{-left edgeType | -right edgeType} [-cell_row rowNumber]]
[{-left edgeType | -right edgeType} [-half {top | bottom}]]
[{-top edgeType | -bottom edgeType} [-range {x y}]] [{-cell cellName} [-reset ]]
```

Specifies edge type for cell edges as `EDGETYPE` in macro LEF. It allows to specify one edge at a time for a particular cell.

To ensure the correct edge type specification, edge types asserted by `set_cell_edge_type` command should be pre-defined by the `set_cell_edge_spacing` command.

For example:

```
set_cell_edge_spacing grp1 grp2 0.18
set_cell_edge_type -cell BUF1X -left grp1
```

If the edge type is specified without corresponding spacing rule, tool gives a warning and ignores the edge type specification.

Note: This command is not supported for save and restore design.

Parameters

`-bottom` *edgeType*	Specifies an edge type on the bottom side. *Data_type*: string, optional
`-cell` *cellName*	Specifies cell to which to add edge constraint. *Data_type*: string, optional

`-cell_row` *rowNumber*	Specifies the row number for horizontal edge type.
	You can define different edge types for each row of multiple height cells using `-cell_row`.
	For example, there is triple height cell CKBUF.
	 	The following commands define different edge types for different rows of the CKBUF cell.
	`set_cell_edge_type -cell CKBUF -right grp1 -cell_row 1`
	`set_cell_edge_type -cell CKBUF -right grp2 -cell_row 2`
	In the above example, grp1 is applied to the first row (bottom row) of the right edge, grp2 is applied to the second row of right edge, and no specific edge type is defined for the third row of right edge and is of DEFAULT type.
	The legal value of `-cell_row` is from 1 to n, where n is the number of cell height of the cell.
	Data_type: int, optional

`-help`	Outputs a brief description that includes type and default information for each `set_cell_edge_type` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_cell_edge_type`
`-half {top bottom}`	Defines the edge types for the top or bottom half of the specified row of the cell The following example associates the edge type 'grp1' with the bottom row, top half of the multi-height cell SDFF8: `set_cell_edge_type -cell SDFF8 -right grp1 -cell_row 1 -half top`

`-left` *edgeType*	Specifies an edge type on the left side. *Data_type*: string, optional
`-range {x y}`	Specifies the range for the vertical edge type. *Data_type*: point, optional
`-reset`	Resets the specified cell constraint to lef status. *Data_type*: bool, optional
`-right` *edgeType*	Specifies an edge type on the right side. *Data_type*: string, optional
`-top` *edgeType*	Specifies an edge type on the top side. *Data_type*: string, optional

Examples

- The following commands specify one edge at a time for the `BUF1X` cell

```
set_cell_edge_type -cell BUF1X -left grp1

set_cell_edge_type -cell BUF1X -right grp1 -cell_row 1

set_cell_edge_type -cell BUF1X -right grp1 -cell_row 2
```

- The following commands define different edge types for the first row(bottom row) , right edge of the multi-height cell SDFF8.

```
set_cell_edge_type -cell SDFF8 -right grp1 -cell_row 1 -half top

set_cell_edge_type -cell SDFF8 -right grp2 -cell_row 1 -half bottom
```

  In the above example, grp1 is applied to the first row (bottom row) of the right top-half edge, and grp2 is applied to the first row (bottom row) of right-bottom edge.

set_cell_padding

```
set_cell_padding
-cells leaf_cellName
{-padding padding | [[-right_side padding] [-left_side padding] [-top_side padding] [-
bottom_side padding]]}
```

Specifies leaf cells to which to add -right_side (placement clearance) and a factor to use to calculate the -right_side dimension. The placer adds the -right_side on the right sides of the specified cells during placement. The -right_side is retained during optimization and CTS.

Use the `get_db` command to query.

If there are congestion problems, delete the -right_side by using the `delete_all_cell_padding` command. For information, see `delete_all_cell_padding -right_side`.

Parameters

`-bottom_side` *padding*	Specifies a factor to calculate the padding dimension on the bottom side. *Minimum*: `0` *Maximum*: `500` *Data_type*: int, optional
-cells leaf_cellName	Specifies the cell name(s) of a cell type to which the factor applies. You can use wildcards (`*`) with this parameter. *Data_type*: string, required
`-left_side` *padding*	Specifies a factor to calculate the padding dimension on the left side. *Data_type*: int, optional
`-padding` *padding*	Specifies a factor to use to calculate the padding dimension. The placer multiplies the placement SITE by the factor. It reads the placement SITE value from the technology file. The factor should be integer number only. The unit of padding on left/right side is the number of sites. The unit of padding on top/bottom side is the number of rows. *Data_type*: int, required
-right_side padding	Specifies a factor to use to calculate the -right_side dimension. The placer multiplies the placement SITE by the factor. It reads the placement SITE value from the technology file. The factor should be integer number only. *Data_type*: int, optional
`-top_side` *padding*	Specifies a factor to calculate the padding dimension on the top side. *Minimum*: `0` *Maximum*: `500` *Data_type*: int, optional

Example

The following command adds -right_side that is twice the placement SITE to leaf cells named `FJK2`:

```
set_cell_padding -right_side FJK2 2
```

set_cell_stack_area

```
set_cell_stack_area
[-help]
-cell cell_name
-group group_name
-rect {x1 y1 x2 y2}
```

Defines the cell area that needs to be involved while calculating stack rule of the corresponding group.

Parameters

`-cell` *cell_name*	Specifies the cell name that has the stack constraint. *Data_type*: string, required
`-help`	Outputs a brief description that includes type and default information for each `set_cell_stack_area` parameter. For a detailed description of the command and all of its parameters, use the man command: man `set_cell_stack_area`
`-group` *group_name*	Specifies the cell group name with the stack constraint. **Note**: The group name must be pre-defined in the LEF file or by the `set_cell_stack_group` command. *Data_type*: string, required
`-rect {x1 y1 x2 y2}`	Specifies the constraint rectangular area with respect to the cell origin. If the whole cell is constrained, the rectangular coordinates match the cell boundary. If the rectilinear area in cell is constrained, divide the rectilinear area into multiple rectangular area then define each rectangular area in separate command lines. *Data_type*: rect, required

Related Information

- delete_cell_stack_area
- report_cell_stack_area
- set_cell_stack_group

set_cell_stack_group

```
set_cell_stack_group
[-help]
-name group_name
{-max_horizontal_length max_continuous_length }
```

Defines the stack rule of a cell group.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_cell_stack_group` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_cell_stack_group`
`-max_horizontal_length` *`max_continuous_length`*	Specifies the maximum continuous length in horizontal direction. *Data_type*: float, required
`-name` *`group_name`*	Specifies the cell group name with the stack constraint. *Data_type*: string, required

Related Information

- `delete_cell_stack_group`
- `report_cell_stack_group`

set_cell_virtual_align

```
set_cell_virtual_align
[-help]
[-cells cells]
[-mask <id>]
[-pin_x_location location_in_microns]
```

Aligns a filler cell that does not have any pin or obs geometries to align, but the cell still needs to be aligned. For example, a GA-Filler cell after the post-mask ECO becomes a logic cell and needs to be correctly aligned for the router to eco-route it.

The `set_cell_virtual_align` command can be used to provide mask for the first track inside the cell, or 'offset' to the first track (or both). You need to specify `-mask` or `-pin_x_location`.

The command auto-detects the layer for vertical alignment. If as per the placement initialization there is no need for vertical alignment (site-width and vertical-track-pitch are same, pin-mask are not fixed), the virtual alignment is turned off. this means that the `set_cell_virtual_align` command will not help.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_cell_virtual_align` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_cell_virtual_align`
`-cells` *cells*	Specifies the lib cells that require virtual alignment. *Data_type*: (base_cell)+, required
`-mask` *virtual_mask_value*	Specifies the virtual mask value for the first track in the cell. If you specify `-mask` only, the offset of the first track in the core is used as the offset. *Data_type*: int, optional
`-pin_x_location` *location_in_microns*	Specifies the location of the virtual geometry from the cell boundary. If you specify offset only, the track can be of any mask-color, as long as offset matches. *Default*: First track location *Data_type*: float, optional

Related Information

- `delete_cell_virtual_align`
- `report_cell_virtual_align`

set_inst_padding

```
set_inst_padding
-inst instName
{-padding padding | [[-right_side padding] [-left_side padding] [-top_side padding] [-
bottom_side padding]]}
```

Specifies a value (number of sites) for the right side for an instance. Padding expands the area of an instance, so that the software leaves extra space around the instance during global placement (`place_design`), which helps reduce congestion in both the horizontal and vertical directions. The `place_detail` and `check_place` commands ignore instance -right_side.

Adding instance -right_side reduces horizontal and vertical congestion, but also decreases utilization.

Note: To remove instance -right_side, use the `delete_inst_padding` command.

Parameters

`-bottom_side` *padding*	Specifies the amount at the bottom, in number of rows. *Data_type*: uint, optional
`-inst` *instName*	Specifies the instance to pad. You can use wildcards (`*`) when you specify the instance. *Data_type*: string, required
`-left_side` *padding*	Specifies the amount of padding on the left side, in number of sites. *Data_type*: uint, optional
`-padding` *padding*	Specifies the amount of padding to add, in the number of sites. *Data_type*: uint, optional
`-right_side` *padding*	Specifies the amount of padding on the right side, in number of sites. *Data_type*: uint, optional
`-top_side` *padding*	Specifies the amount at the top, in number of rows. *Data_type*: uint, optional

Example

The following command adds -right_side of 2 sites around instance named U27316:

```
set_inst_padding -right_side U27316 2
```

It outputs following:

```
Padding for Instant [U27316] is 2.
```

The following command adds -right_side of 3 sites for all instances with prefix U2:

```
set_inst_padding -right_side U2* 3
```

It outputs following:

```
Specified Instant -right_side for [U27313] to 3.

Specified Instant -right_side for [U27314] to 3.

Specified Instant -right_side for [U27315] to 3.

Specified Instant -right_side for [U27316] to 3.

Added -right_side for 4 insts.
```

set_jtag

```
set_jtag
{-help}
{-cell leafCellName
    | -inst instName
    | -inst_group
    | -hinst hInstName
    | -group {hInstName | cellName}
    | -group_within_area {hInstName | cellName width height} }
```

Specifies instances to place with the `place_jtag` command. This command should be used before the `place_jtag` command.

Parameters

`-cell` *`leafCellName`*	Marks all instances of the specified cell type as JTAG instances. *Data_type*: string, optional
`-group` *`hInstName	cellName`*	Marks all hierarchical instances or intermediate instances as JTAG instances. *Data_type*: string, optional
`-group_within_area` *`hInstName	cellName width height`*	Marks all instances inside the hierarchical instance or intermediate cells as JTAG instances, and specifies a rectangular width and height where all instances or cells are placed within that rectangular region. *Data_type*: string, optional
-help	Outputs a brief description that includes type and default information for each `set_jtag` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man set_jtag`.
`-hinst` *`hInstName`*	Marks a hierarchical instance as a JTAG instance. *Data_type*: string, optional
`-inst` *`instName`*	Marks an instance as a JTAG instance. You can use a wildcard (`*`) character for this parameter. *Data_type*: string, optional
`-inst_group`	Marks the instGroup name to be made JTAG instance. *Data_type*: string, optional

Example

- The following command specifies that the cell `jtag_FlipFlop` will be placed when using the `place_jtag` command:

  ```
  set_jtag -cell jtag_FlipFlop
  ```

- The following command specifies that all instance names that begin with `instG` will be placed when using the `place_jtag` command:

```
set_jtag -inst instG*
```

set_jtag_to_unplaced

`set_jtag_to_unplaced`

Changes the placement status of JTAG inst from FIXED to PLACED. This command can be used after the `place_jtag` command.

Parameters

None

Examples

The following set of commands places all Jtag instances of cell INVX1 as FIXED, and then using `set_jtag_to_unplaced` to change their status to PLACED:

```
set_jtag -cell INVX1
place_jtag
set_jtag_to_unplaced
```

set_lockup_element

```
set_lockup_element
{-cell leafCellName | -inst instName}
[-scan_in ftname]
[-scan_out ftname]
```

Specifies a cell or instance as a lockup element. Lockup elements are present in scan chains where the chain crosses between two different clock domains or clock phases. Use this command after running placement.

Parameters

`-cell` *leafCellName*	Specifies the cell to be a lockup element. *Data_type*: string, required
`-scan_in` *ftname*	Specifies the name of the scan input. *Data_type*: string, optional
`-inst` *instName*	Specifies the instance to be a lockup element. *Data_type*: string, required
`-scan_out` *ftname*	Specifies the name of the scan output. *Data_type*: string, optional

Example

The following command specifies that cell `TLATX1` is a lockup element with a scan input pin `D` and an output pin `Q`:

```
set_lockup_element -cell TLATX1 -scan_in D -scan_out Q
```

Related Information

set_scan_cell

```
set_scan_cell
[-help]
[scan_cell]
[-scan_in ftname]
[-scan_out ftname]
[-scan_clock ftname]
[-scan_enable ftname]
```

Specifies scan cells that are not listed in the timing library.

Parameters

scan_cell	Specifies name of the scan cell. *Data_type*: string, required
-scan_in *ftname*	Specifies the name of the scan input. *Data_type*: string, optional
-scan_out *ftname*	Specifies the name of the scan output. *Data_type*: string, optional
-scan_clock *ftname*	Specifies the name of the scan clock. *Data_type*: string, optional
-scan_enable *ftname*	Specifies name of the scan enable f-term or pin names. *Data_type*: string, optional

Example

The following command specifies cell `SDFFQ` to be a scan cell:

```
set_scan_cell SDFFQ -scan_in SI -scan_out Q
```

set_selective_blockage_gate

```
set_selective_blockage_gate
[-help]
[-cells cellName]
[-insts instName]
```

Specifies cells and instances that are allowed to be placed inside the soft blockage during legalization.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `set_selective_blockage_gate` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man set_selective_blockage_gate`.
`-cells cellName`	Specifies the cell type name as legal for soft blockage. You can use wildcards (`*` or `?`) with this parameter. *Data_type*: string, optional
`-insts instName`	Specifies the instance name as legal for soft blockage. You can use wildcards (`*` or `?`) with this parameter. *Data_type*: string, optional

Examples

The following command specifies that cell `NR2RLX1` and all instance names that begin with `MEMCTLU` are allowed to be moved into soft blockage when legalization. `s`

```
et_selective_blockage_gate -cells NR2RLX1 -insts MEMCTLU*
```

Related Information

- `reset_selective_blockage_gate`

set_spare_insts

```
set_spare_insts
{-help}
{-cell leafCellName
   |-insts instanceName
   | -hinst {hierarchicalInstanceName | groupName}}
```

Specifies spare gates to place. To localize spare gate placement, guide the module containing the spare gate during the floorplanning session. This command should be used before placing the design.

Parameters

`-cell` *leafCellName*	Specifies the cell type names of the spare gate cells. You can use this parameter to specify leaf cells (standard cells)--you cannot use it to specify spare modules. You can use wildcards with this parameter. *Data_type*: string, optional
`-help`	Outputs a brief description that includes type and default information for each `set_spare_insts` parameter. For a detailed description of the command and all of its parameters, use the `man` command: `man set_spare_insts`.
`-hinst` {*hierarchicalInstanceName* | *groupName*}	Specifies a hierarchical instance or group that contains spare gate cells. A hierarchical instance acts as one unit (a submodule). The units are evenly spaced and are close together when they are distributed. This command does not recognize wildcards in hierarchical instance or group names. *Data_type*: string, optional
`-insts` *instanceName*	Specifies the leaf instance names of the spare gates. You can use wildcards when specifying instance names. *Data_type*: string, optional

Examples

- The following command specifies all cell types `YFD2S_SPG` to be spare gates:

  ```
  set_spare_insts -cell YFD2S_SPG
  ```

- The following command specifies instance `SH16/I1022` to be a spare gate:

  ```
  set_spare_insts -insts SH16/I1022
  ```

- The following command specifies that all instances in `SH16` to be spare gates:

  ```
  set_spare_insts -insts SH16/*
  ```

- The following command treats all instances with the cell type `NAND2X1` as spare cells. If the design uses some of these cells as spares and some as not spare, use the `-insts` parameter instead.

  ```
  set_spare_insts -cell NAND2X1
  ```

Related Information

swap_well_taps

```
swap_well_taps
[-help]
[-both_violation cellName]
-cells cellNameList
[-check_only]
[-default_cell cellName]
-diffusion_forbidden_spacing float
[-left_violation cellName]
[-right_violation cellName]
[-skip_cells cellNameList]
[-swap_report reportName]
[-violation_report reportName]
```

Swaps to custom tap cell to avoid OD spacing rule.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `swap_well_taps` parameter. For a detailed description of the command and all of its parameters, use the man command: `man swap_well_taps`.
`-both_violation cellName`	Specifies well taps to swap if only violating rules on both sides. *Data_type*: string, optional
`-cells cellNameList`	Specifies well taps to swap if there is violation of rules. *Data_type*: string, optional
`-check_only`	Checks violations only without swapping tap cells. *Data_type*: bool, optional
`-default_cell cellName`	Specifies to swap to default well tap first. This must be one of cells. *Data_type*: string, optional

`-diffusion_forbidden_spacing` *float*	Specifies forbidden spacing rule. *Data_type*: float, required
`-left_violation` *cellName*	Specifies well taps to swap if only violating rules on the left side. *Data_type*: string, optional
`-right_violation` *cellName*	Specifies well taps to swap if only violating rules on the right side. *Data_type*: string, optional
`-skip_cells` *cellNameList*	Specifies the cells that would skip the rule check. *Data_type*: string, optional
`-swap_report` *reportName*	Reports the swapped instances. *Data_type*: string, optional
`-violation_report` *reportName*	Reports the violated instances. *Data_type*: string, optional

Related Information

- `add_well_taps`
- `add_well_taps Category Attributes`

trace_jtag

```
trace_jtag
-in_file jtagPinFile
-out_file jtagInstanceFile
```

Traces JTAG logic between the I/O pins and the pins of given leaf instances. The input file contains a list of pins of instances that are the endpoints of JTAG logic. The command writes out a Tcl file that lists all the JTAG logic traced. You can then source the file to add this information to the Innovus database.

Parameters

`-in_file` *jtagPinFile*	Specifies a file that lists the endpoints of JTAG logic. In the file, list each leaf instance or list the cell and its port. *Data_type*: string, required • To list the leaf instances, use the `instpin` statement, as follows: `instpin` *leafInstanceNamepinName* • If all instances of a cell are used only in JTAG logic, you can list that cell and its port by using the `cellport` statement, as follows: `cellport` *cellTypeNameportName* To avoid tracing non-JTAG cells, the cells you specify in a `cellport` statement must be JTAG-only cells. The cell type cannot be an intermediate cell. It must have at least one physical leaf instance.
`-out_file` *jtagInstanceFile*	Specifies the JTAG logic file in Tcl format. *Data_type*: string, required

Example

The following commands trace the JTAG logic based on the input file `jtag.leaf`, write the output file `jtag.out`, and add the logic specified in the file to the Innovus database:

```
trace_jtag -in_file jtag.leaf -out_file jtag.out
source jtag.out
```

Following is an example of an output file:

```
set_jtag -inst regA
set_jtag -inst regB
set_jtag -inst regC
set_jtag -inst regD
set_jtag -inst regE
set_jtag -inst regF
set_jtag -inst regG
set_jtag -inst regH
```

trace_scan

```
trace_scan
[-help]
[-comp_logic | -no_comp_logic]
[-lockup | -no_lockup]
[-verbose]
```

Records the total number of elements in the scan chain in the log file, and records the starting and ending scan points if the `-verbose` option is used. The `reorder_scan` command automatically calls `trace_scan` internally if you have not previously run `trace_scan`. The `trace_scan` command is used after specifying scan chains using the `create_scan_chain` command.

Note: If scan chains are specified by reading in a DEF file, the software does a native scan trace. The scan DEF file is stored in the database and, when the `trace_scan` command runs, the software matches the scans and honors the ordered sections.

Parameters

`-comp_logic`	Traces through multiple input gate on the scan path.
`-no_comp_logic`	Does not trace through multiple input gate on the scan path.
`-lockup`	Specifies that the tracing detects lockup latches automatically. **Note:** If the lockup elements are flops (non scan flip-flops), the lockup elements must be identified using the `set_lockup_element` command prior to running `trace_scan` in its default mode.
`-no_lockup`	Specifies that the tracing will not detect lockup elements. This is the default.
`-verbose`	Prints the information stored in the logv file, i.e starting and ending scan points, and the cell instance names that `trace_scan` determines are part of the scan chain. If scan chain tracing fails, use this parameter to see where the scan chain tracing stops.

Examples

The following set of commands traces all scan chains defined by `create_scan_chain` command:

```
create_scan_chain chain0 -start BG_scan_in_1 -stop BG_scan_out_1
```

```
create_scan_chain chain1 -start BG_scan_in_2 -stop BG_scan_out_2
create_scan_chain chain2 -start BG_scan_in_3 -stop BG_scan_out_3
trace_scan
```

Related Topics

update_inbound_cell_site

```
update_inbound_cell_site
[-help]
[-n_filler site_name]
[-nn_filler site_name]
[-p_filler site_name]
[-pp_filler site_name]
[-new site_name]
[-original site_name]
[-vertical]
```

Change sites for the cells whose site definitions do not match the site definitions used by Innovus. This is applicable only for specific nodes.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `update_inbound_cell_site` parameter. For a detailed description of the command and all of its parameters, use the man command: `man update_inbound_cell_site`
`-n_filler` *`site_name`*	Specifies the site name of the N-filler cell. *Data_type*: string, optional
`-nn_filler` *`site_name`*	Specifies site name of NN-filler cell. *Data_type*: string, optional
`-p_filler` *`site_name`*	Specifies the site name of the P-filler cell. *Data_type*: string, optional
`-pp_filler` *`site_name`*	Specifies site name of PP-filler cell. *Data_type*: string, optional
`-new` *`site_name`*	Specifies the new site name of the IB cell *Data_type*: string, optional
`-original` *`site_name`*	Specifies the original site name of the IB cell. *Data_type*: string, optional
`-vertical`	Specifies vertical IB transform. *Data_type*: bool, optional

update_pipeline_net_group

```
update_pipeline_net_group
net_group_name
[{-inst instNameListOrRegularExp |
      -start_term termList -end_term termList |
      -net listOfNetnamesOrRegularExp }]
[-start_reserve distInMicrons] [-end_reserve distInMicrons]
```

Modifies the existing net group attributes or converts an existing net group added during floorplanning to be of type pipeline. This command can be used if there are existing pipeline net groups in the design.

Parameters

`-end_reserve` *`ReserveDistanceInMicrons`*	Specifies a distance value from the end points on block boundary to the internal connection inside the block that needs to be added to the last stage distance, to achieve equidistant spacing. The unit is in micron. *Data_type*: float, optional
`-inst` *`instNameListOrRegularExp`*	Modifies net group to add all nets connected to the given instances. The instances must all be flip-flops or latches. All the nets attached to the D and Q pins are put into the PFF net group. *Data_type*: string, optional
`-net` *`listOfNetNamesOrRegularExp`*	Creates net group of all given nets. *Data_type*: string, optional
`-start_reserve` *`ReserveDistanceInMicrons`*	Specifies a distance budget from internal connections inside block to the start point of the PFF net. This value is added to the first stage distance when calculating equidistant spacing for each stage. The unit is in micron. *Data_type*: float, optional
`-start_term` *`termList`*	Modifies net group to add all data nets between the given end points. The PFF-chain is traced from the startTerm, through D and Q terminals of PFF(s) until an endTerm is matched. *Data_type*: string, optional
`-end_term` *`termList`*	Modifies net group to add all data nets between the given end points. The PFF-chain is traced from the startTerm, through D and Q terminals of PFF(s) until an endTerm is matched. *Data_type*: string, optional
`net_group_name`	Specifies the name of net group. *Data_type*: string, required

Example

The following command modifies the existing net group named `netGroup1` between `blockA/DATA_OUT*` and `blockB/DATA_IN*` with a budget distance 10 microns from internal connections inside the blockA to the start point of `DATA_OUT*` :

```
update_pipeline_net_group netGroup1 -start_term blockA/DATA_OUT* -end_term blockB/DATA_IN*
-start_reserve 10
```

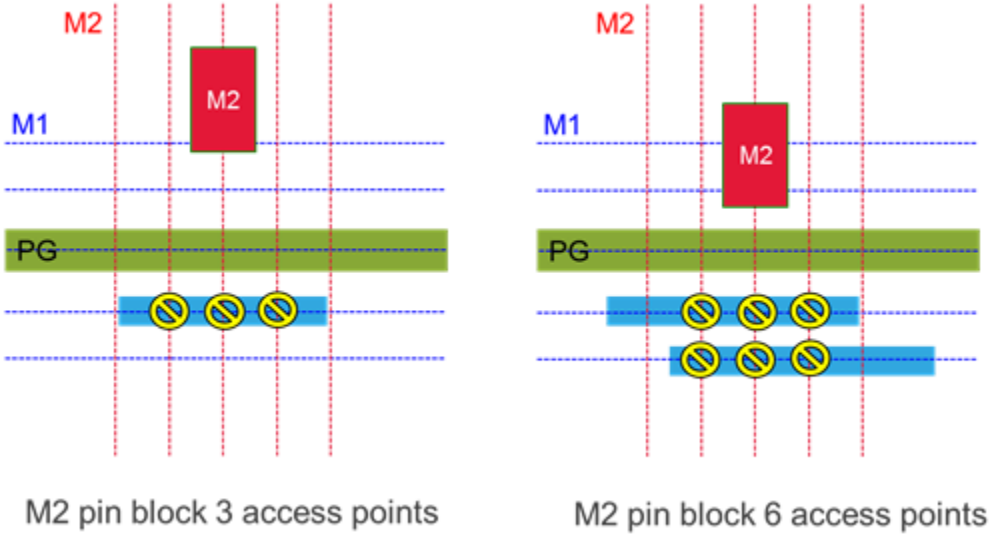
update_vertical_cell_edge_constraint

```
update_vertical_cell_edge_constraint
[-help]
{-file tclFile | -update_db }
[[-check_m2_only ] | [-check_m2_to_m1_only ]]
```

Generates the bottom and top cell edge constraints for 10nm libraries to avoid vertical cell abutment that may cause pin access issue on M1 and M2. The vertical M2 fat PIN or OBS has impact on the abutted cell when it is near to the top and bottom boundaries. It can cause DRC violations between M2 PIN/OBS, block some of the M1 pin access points in the abutted cell, and make router hard to access those M1 PINs.

The following graphic show an example of how fat M2 Pin/OBS may block 3 or 6 access points.



The `update_vertical_cell_edge_constraint` command generates vertical cell edge constraints based on the cell libraries and LEF rules. Placer is aware of these constraints and avoids the bad placement patterns.

Parameters

`-check_m2_only`	Checks M2 to M2 pins only in abutted 2 cells when generating cell edge constraints. *Data_type*: bool, optional
`-check_m2_to_m1_only`	Checks M2 to M1 pins only in abutted 2 cells when generating cell edge constraints. *Data_type*: bool, optional
`-help`	Outputs a brief description that includes type and default information for each `update_vertical_cell_edge_constraint` parameter. For a detailed description of the command and all of its parameters, use the man command: `man update_vertical_cell_edge_constraint`.
`-file` *`tclFile`*	Specifies file name to output vertical tcl constraint. *Data_type*: string, optional
`-update_db`	Updates the constraints to DB. *Data_type*: bool, optional

Note:

- You must specify `-file` or `-update_db`.
- The `-file` option is for the debug mode, and you need to source the tcl file to let placer know about the constraints.
- The `-updated` option is for the standard flow usage. It reads the constraints automatically.

pack_align_macros

```
pack_align_macros
[-help]
```

The `pack_align_macros` command executes the following two steps:

- Aligns macros of the same size (initially placed together) on the entire design.
- Pushes macros (or pack of macros) to core corners and marks them fixed.

The `pack_align_macros` command honors the min space/forbidden space.

Figure 1: Macros before running `pack_align_macros`

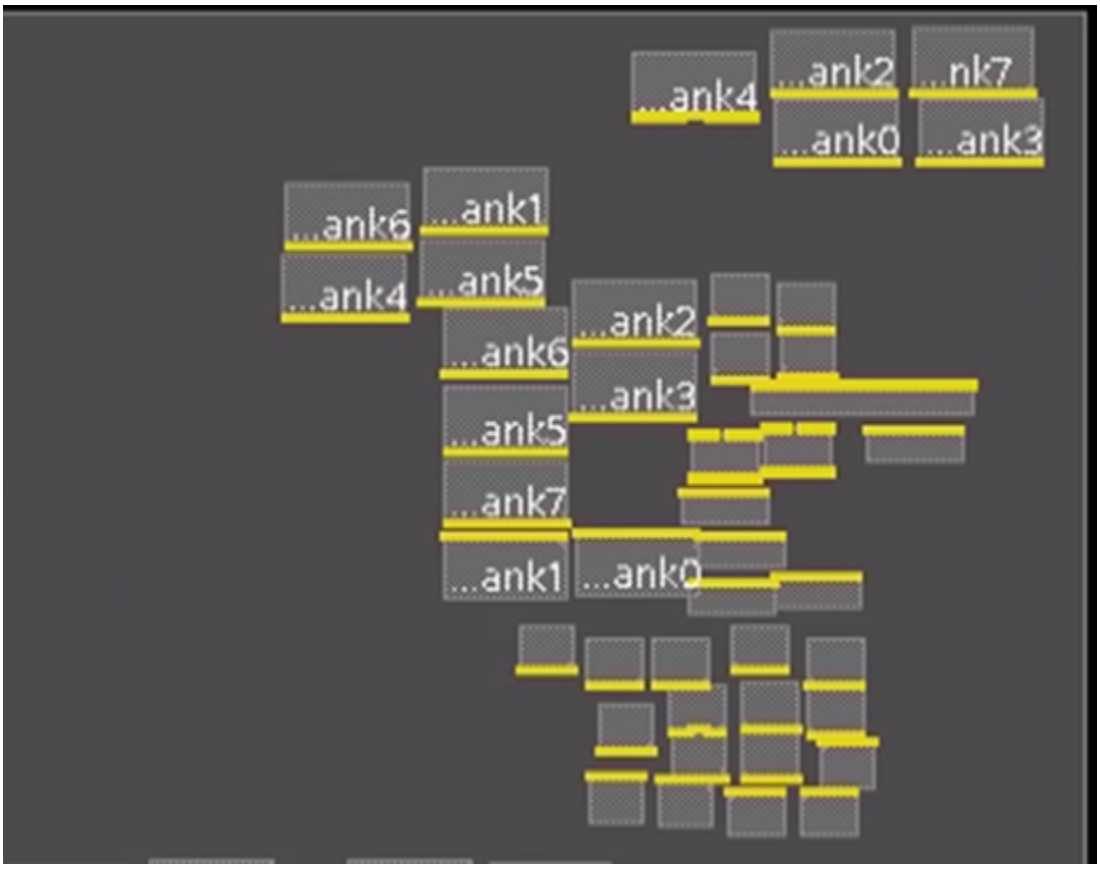


Figure 2: Macros aligned after running `pack_align_macros`

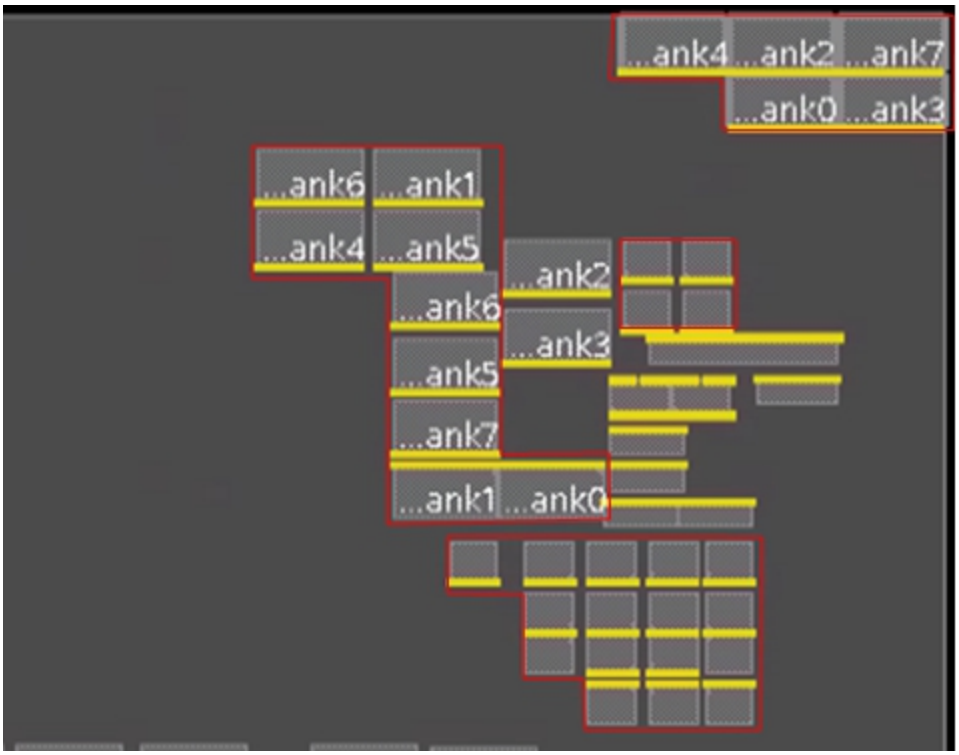
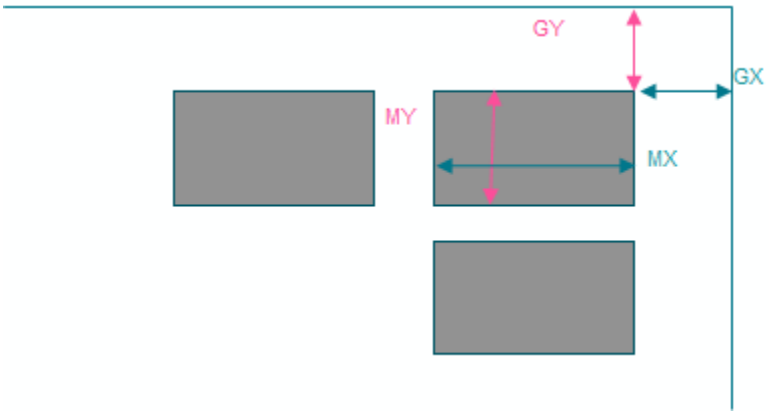


The Figure 1 and Figure 2 show a design before and after running the `pack_align_macros`, respectively. The Figure 2 shows that the push till the core corner takes place when the gap between the core corner and the corner of the nearest macro satisfies the following condition:
GY <= MY And GX <= MX



Parameters

None

Power Calculation Commands and Attributes

- encrypt_thermal_file
- get_dynamic_power_simulation
- get_default_switching_activity
- power Category Attributes
- propagate_activity
- query_power_data
- read_activity_file
- read_activity_map_file
- read_power_db
- report_inst_power
- report_power
- report_unannotated_nets
- reset_power_activity
- set_default_switching_activity
- set_dynamic_power_simulation
- set_instance_temperature_file
- set_power
- set_power_calculation_temperature
- set_power_include_file
- set_power_output_dir
- set_switching_activity
- set_twf_attribute
- set_virtual_clock_network_parameters
- write_power_constraints
- write_tcf

encrypt_thermal_file

```
encrypt_thermal_file
[-input ASCII.txt]
[-output $encrypted_conductivity.txt]
```

Specifies to encrypt the file containing the thermal conductivity value for layers, and to protect foundry's thermal conductivity parameters used for power map generation. This encrypted file is then specified with the `report_power -thermal_conductivity_inputs` parameter for generating a tile-based power map file.

Parameters

```
-input ASCII.txt
```

	Specifies the name of the ASCII thermal file that needs to be encrypted. This file contains the thermal conductivity parameters used for power map generation.
	The `-input` parameter supports both layer type and layer name based thermal conductivity file.
	The following is a snippet of the input thermal conductivity file content (layer type based file):
	`Metal 430`
	`Silicon 250`
	`Dielectric 0.6`
	Data_type: string, optional

`-output` *`$encrypted_conductivity.txt`*	

	Specifies the name of the encrypted output thermal file.
	The following is a snippet of the encrypted thermal conductivity file content:
	`Metal $encryption_value`
	`Silicon $encryption_value`
	`Dielectric $ecncryption_value`
	Data_type: string, optional

Examples

- The following command encrypts the specified input file (`format_1.txt`) to generate the encrypted output file (`format_1_encr.txt`):
  ```
  encrypt_thermal_file -input encrypt/format_1.txt -output encrypt/format_1_encr.txt
  ```
  The encrypted file (`format_1_encr.txt`) is then specified for generating a tile-based power map file, as shown below:
  ```
  report_power \
      -out_file                    static.rpt \
      -thermal_power_map_tileS     {5 5}\
      -thermal_power_map_format    stack \
      -thermal_power_map_file      powermap_format1_encr_in.txt \
      -thermal_conductivity_inputs ./encrypt/format_1_encr.txt
  ```

Related Information

get_dynamic_power_simulation

```
get_dynamic_power_simulation
[-help]
[-activity_pattern]
[-period]
[-resolution]
```

Displays the following information about a `set_dynamic_power_simulation` parameter in the system log file and in the system console:

- Parameter name
- Current value

If you do not specify a parameter, the software displays information for all of the `set_dynamic_power_simulation` parameters.
The `get_dynamic_power_simulation` command prints only the user-specified value for the parameters. If a parameter has not been set using the `set_dynamic_power_simulation` command, the `get_dynamic_power_simulation` command does not output any information in the console.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `get_dynamic_power_simulation` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_dynamic_power_simulation`.
`parameter_names`	Displays information for the specified parameters. You can specify one or more parameters. See `set_dynamic_power_simulation` for description of the parameters you can specify.

Examples

The following command displays the current setting of the `-period` parameter:

```
get_dynamic_power_simulation -period
```

The software displays the following information:

```
-period {20}
```

Related Information

- `power Category Attributes`
- `set_default_switching_activity`
- `set_dynamic_power_simulation`
- "Dynamic Power and IRDrop Analysis" in the *Voltus Stylus Common UI User Guide*

get_default_switching_activity

```
get_default_switching_activity
[-help]
[-clip_activity_to_domain_freq]
[-clock_gates_enable]
[-clock_gates_output]
[-clock_gates_output_ratio]
[-comb_clockgate_ratio]
[-duty]
[-global_activity]
[-icg_ratio]
[-input_activity]
[-macro_activity]
[-period]
[-seq_activity]
```

Displays the following information about a `set_default_switching_activity` parameter in the system log file and in the system console:

- Parameter name
- Current value

If you do not specify a parameter, the software displays information for all of the `set_default_switching_activity` parameters.
The `get_default_switching_activity` command prints only the user-specified value for the parameters. If a parameter has not been set using the `set_default_switching_activity` command, the `get_default_switching_activity` command does not output any information in the console.

Parameters

`-help`	Outputs a brief description that includes type and default information for each `get_default_switching_activity` parameter. For a detailed description of the command and all of its parameters, use the man command: `man set_default_switching_activity`.
`parameter_names`	Displays information for the specified parameters. You can specify one or more parameters. See `set_default_switching_activity` for description of the parameters you can specify.

Examples

The following command displays the current setting of the `-period` parameter:

```
get_default_switching_activity -period
```

The software displays the following information:

```
-period {20}
```

power Category Attributes

The root attributes in the `power` category are:

To set the value of any root attribute, use the `set_db` command:

```
set_db attribute_name value
```

To get the current value of any root attribute, use the `get_db` command:

```
get_db attribute_name
```

To get the current value of all attributes in the `power` category, use the following command:

```
get_db -category power
```

power_add_simulation

```
power_add_simulation {true | false}
```

Default: `false`

Data_type: bool

Specifies to add simulation if there are no simulation vectors or if all primary sources are not annotated by vectors. This parameter can be used to ensure complete design coverage. Event simulation is done for primary sources like primary input, flops, and macros.

This attribute is only applicable to the event-based power analysis flow (`power_method event_based`).

Related Commands

- `set_power`

power_adjust_input_activity_in_iterations

```
power_adjust_input_activity_in_iterations {true | false}
```

Default: `true`

Data_type: bool

Specifies whether to keep the input activity fixed or automatically adjust the activity value for each iteration of state propagation. This attribute is only applicable to the power target flow (`power_enable_power_target_flow true`).

Related Commands

- `set_power`

power_adjust_macro_activity_in_iterations

```
power_adjust_macro_activity_in_iterations {true | false}
```

Default: `true`

Data_type: bool

Specifies whether to keep the macro activity fixed or automatically adjust the activity value for each iteration of state propagation. This attribute is only applicable to the power target flow (`power_enable_power_target_flow true`).

Related Commands

- `set_power`

power_analysis_temperature

```
power_analysis_temperature temperature
```

Default: " "

Data_type: double

Specifies the temperature for static power calculation.

Note: Static power calculation gets the temperature value of each instance from the following sources (in order of precedence):

- Instance temperature file
- `power_analysis_temperature` attribute
- The current operating condition temperature

Related Commands

- `report_power`

power_annotation_detail_report

```
power_annotation_detail_report {true | false}
```

Default: `false`

Data_type: bool

Specifies to generate a detailed annotation report per instance in the Vector Profiling flow (`power_method vector_profile`). When specified, it creates the `AnnotationDetail.rpt` file in the user-specified output directory.

Related Commands

- `report_power`

power_auto_twf_delay_annotation

```
power_auto_twf_delay_annotation {true | false}
```

Default: `false`

Data_type: bool

Specifies to automatically detect the zero-delay vectors and perform delay annotation. As a result, you do not need to specify additional parameters (`set_db power_use_zero_delay_vector_file` and `read_activity_file -zero_delay`) to indicate the vectors that have delay annotation. This attribute is applicable only to the event-based power analysis flow.

Related Commands

- `report_power`

power_average_rise_fall_cap

```
power_average_rise_fall_cap {true | false}
```

Default: `false`

Data_type: bool

Specifies to use the average of rise and fall capacitance from the liberty file.

Related Commands

- `report_power`

power_block_independent_peakpower

```
power_block_independent_peakpower {true | false}
```

Default: `false`

Data_type: bool

Specifies to identify the worst power interval of each block, and run power analysis of the full design using the worst interval of each block. This attribute allows you to perform power and current analysis for design blocks that have independent peak power intervals.

When set to `false`, power analysis is performed using the common worst interval found using simulation of all vectors together.

Related Commands

- `report_power`

power_bulk_pins

```
power_bulk_pins {bulk_pin_list}
```

Default: `""`

Data_type: string

Defines power and ground bulk LEF pins for the design.

Use this attribute when library cells have bulk pins defined in LEF but the liberty file does not contain power associated with these pins. If a liberty file does not have body bias definition, power analysis does not distribute power to the body bias domain.

Related Commands

- `report_power`

power_capacity

```
power_capacity {low|medium|high}
```

Default: `low`

Data_type: enum

Enables segmented power processing. When this attribute is specified, the software performs concurrent processing of vector simulation annotation, power calculation, and report construction.

This attribute enables performance optimization with some trade-off on memory consumption and runtime. The arguments of `power_capacity` are:

- `low` - reduces memory for a flat run.
- `medium` - further reduces memory with moderate increase in runtime (1.2X).
- `high` - maximum memory reduction at about 2X runtime.

The `power_capacity` attribute is used for reducing memory when processing long simulation vectors. In case of the FSDB and SHM format activity file, the runtime can increase up to 2X.

Related Commands

- `report_power`

power_case_insensitive_mapping

```
power_case_insensitive_mapping {true | false}
```

Default: `false`

Data_type: bool

Specifies whether instance name mapping between the RTL netlist and GATE level netlist in the mapping file is case-sensitive or case-insensitive. When set to `true`, name mappings are case-insensitive.

Related Commands

- `report_power`

power_clock_source_as_clock

```
power_clock_source_as_clock {true | false}
```

Default: `false`

Data_type: bool

Specifies to use the correct clock frequency for activity calculation. If you stop the arrival of the clock signal by setting `set_case_analysis` to `false` , the transition density at the output net of the flop is calculated using the correct clock frequency instead of the default frequency.

Related Commands

- `report_power`

power_comprehensive_automapping

```
power_comprehensive_automapping {true | false}
```

Default: `false`

Data_type: bool

Specifies to perform all-inclusive instance name mapping between the RTL netlist and GATE level netlist. When set to `true`, the software honors all possible naming rules (includes handling of characters like '[' , ']', '.', '/', '\\', '_', ':' and handling of strings like "MBFF", "_reg", "_MB_" etc.) for better annotation coverage.

This feature is applicable to both file-based mapping (`read_activity_map_file -rtl_to_gate | -two_column_mapping_file`) and automatic mapping (`power_enable_auto_mapping`). When `power_comprehensive_automapping` is specified with either `-rtl_to_gate` or `-two_column_mapping_file`, the RTL mapping entries are given priority over the automatic rule-based mapping entries and are used to annotate the design objects.

Related Commands

- `report_power`

power_constant_override

```
power_constant_override {true | false}
```

Default: `false`

Data_type: bool

Specifies to give higher precedence to propagated constants defined using the `set_case_analysis` command. It allows propagated constants to override global activity.

Related Commands

- `report_power`

power_corner

```
power_corner {min|max}
```

Default: `max`

Data_type: string

Defines the library corner (for non-MMMC setup).

- `min` corner means power calculator will use min timing libraries for the power calculation.
- `max` corner means power calculator will use max timing libraries for the power calculation.

Related Commands

- `report_power`

power_create_driver_db

```
power_create_driver_db {true | false}
```

Default: `false`

Data_type: bool

Specifies to determine all the drivers/receivers on the ground net.

Related Commands

- report_power

power_current_generation_method

```
power_current_generation_method {avg | peak}
```

Default: `avg`

Data_type: string

Specifies the current waveform generation method during dynamic power analysis. The two possible arguments of this attribute are:

- `avg` - Specifies to use the average current value of each time step. The output current filename is *`filename`*`.ptiavg`. The default value is `avg`.
- `peak` - Specifies to use the peak current value of each time step. The output current filename is *`filename`*`.ptipeak`. It is recommended to use the `peak` method when using the Composite Current Source Power (CCSP) Liberty files.

Related Commands

- report_power

power_db_name

```
power_db_name filename
```

Default: `""`

Data_type: string

Specifies the name of the binary power database file (`filename.db`).

You can specify this attribute in scenarios where more than one db is generated and you need to track which one was generated in which mode when the restoring the db, or if your design has several blocks and analysis is done on one block all the time and all the databases are named `power.db`.

Related Commands

- report_power

power_decap_cell_list

```
power_decap_cell_list cell_list
```

Default: `""`

Data_type: string

Specifies the physical only cells, such as decap cells, to include in the power report.

Note: This is only supported for Static Power Analysis.

Related Commands

- report_power

power_default_frequency

```
power_default_frequency value
```

Default:

Data_type: double

Specifies to set the default frequency in the MHz unit for net not annotated by TWF. You can specify a numerical value without unit.

Related Commands

- report_power

power_default_slew

```
power_default_slew value
```

Default:

Data_type: string

Specifies to set the default slew in the ps unit for net not annotated by TWF. You can specify a numerical value without unit.

Related Commands

- report_power

power_default_supply_voltage

```
power_default_supply_voltage value
```

Default:

Data_type: string

Specifies to set a default voltage for power nets in a scenario where the power engine cannot determine the voltage of these nets. The default value of this attribute is `1.0`.

Related Commands

- report_power

power_disable_clock_gate_clipping

```
power_disable_clock_gate_clipping {true | false}
```

Default: `true`

Data_type: bool

Specifies to enable clock gate output clipping so that the output transition density of an ICG cell does not exceed the input clock pin transition density.

Related Commands

- report_power

power_disable_leakage_scaling

```
power_disable_leakage_scaling {true | false}
```

Default: `false`

Data_type: bool

Specifies to exclude leakage power during scaling factor computation when target power is specified using the `set_power` command. When this option is set to `true`, the leakage power does not get scaled, and only the internal and switching components are scaled to meet the user-specified total power.

This attribute is relevant only for the `set_power` commands for which total power is specified, and has no effect for the `set_power` command specified with the `-internal`, `-switching`, or `-leakage` parameters.

Related Commands

- `report_power`

power_disable_static

```
power_disable_static {true | false}
```

Default: `true`

Data_type: bool

When set to `true` in the dynamic vector-based or dynamic vectorless flows, the command performs only dynamic analysis and turns-off static power calculation.

Related Commands

- `report_power`

power_distribute_switching_power

```
power_distribute_switching_power {true | false}
```

Default: `false`

Data_type: bool

Specifies to equally distribute the switching power among all drivers if a net has more than one driver. When set to `false`, stores all switching power on one of the net drivers.

Related Commands

- `report_power`

power_distributed_combine_report_format

```
power_distributed_combine_report_format {none | detailed | reduced}
```

Default: `reduced`

Data_type: string

Specifies to generate consolidated XP power reports. This parameter allows you to combine power reports that are stored across multiple partition directories to give a single unified view of power data. The possible arguments of this parameter are:

- `none` - generates distributed reports.
- `reduced` - generates consolidated reports for the following:
  - power.missingdata.* (static and dynamic flows)
  - power.stateprop.* (dynamic flow)
  - power.stats.setpower (dynamic flow)
- `detailed` - generates consolidated reports for the following:
  - power.rpt (static and dynamic flows)
  - power.instpwr.rpt (static flow)
  - power.lib.rpt (static flow)
  - power.pgpinpwr.rpt (static flow)
  - power.pgnet.detailed.rpt
  - power.missingdata.* (static and dynamic flows)
  - power.pgnet.detailed.rpt (static and dynamic flows)

- power.stateprop.* (dynamic flow)
- power.stats.setpower (dynamic flow)
- pg_trigger.txt (dynamic flow)
- trigger.txt (dynamic flow)
- *.totalcurrent (dynamic flow)
- voltus_power.cellstat (static and dynamic flows)
- voltus_power.ptifiles (static and dynamic flows)

Related Commands

- report_power

power_distributed_setup

```
power_distributed_setup file
```

Default: ""

Data_type: string

Specifies a file containing the customized setup details for running power analysis in the distributed mode.

The specified file has 4 columns:

```
INST/CELL <name> hier/block <power.inc>
```

where,

- `INST/CELL`: Keyword indicating cell or instance to be run in the distributed mode. Cell can be useful for repeated DEF blocks.
- *name* : Name of the hierarchical block or instance.
- `hier/block`: Keyword indicating hierarchy or block. `hier` implies that the full hierarchy will be preserved by including the DEFs from top to the block, and `block` implies that only the lower level DEF will be included
- *power.inc* : name of the power include file. This column is optional.

The unspecified instance/cell will be run with the top level as a single group. Each distributed block/instance should have corresponding TWF and SPEF to improve runtime.

Note: Each hierarchy or block will be run independently from other hierarchies/blocks, thus the external load or cell seen at the pin of the hierarchy/block can be different from flat analysis. If the partition boundary analysis is important, distributed processing is not recommended.

Related Commands

- report_power

power_domain_based_clipping

```
power_domain_based_clipping {true | false}
```

Default: `false`

Data_type: bool

Determines the frequency to be used to clip propagated activity that is too high. When set to `false`, the frequency of the fastest clock in the design is used. If you set this attribute to `true`, the fastest clock domain on the net is used to clip propagated activity.

Related Commands

- report_power

power_dynamic_glitch_filter

```
power_dynamic_glitch_filter value
```

Default: `-1`

Data_type: double

Sets the absolute threshold time (in ns) for filtering glitches in net toggles. When you specify a time value for this parameter, glitches in net toggles that are equal to or smaller in width than the specified time value are removed.

Related Commands

- `report_power`

power_enable_auto_queue

```
power_enable_auto_queue {true | false}
```

Default: `false`

Data_type: bool

Specifies to automatically determine the queue for power jobs. This attribute is used in the Voltus-XP distributed power flow with hierarchical DEFs. In the XP flow, partitions are divided into multiple queues depending on the number of CPUs (For example, Default queue: 1 CPU, Small Queue: 2 CPUs, Medium; 4 CPUs, Large : 8 CPUs, and so on.). By default, all power partitions run on the same queue. When the attribute is set to `true`, the blocks can run on different queues depending on the size (number of instances) of the blocks. The `power_enable_auto_queue` attribute will be beneficial when there are uneven power block partitions. For example, if there are some blocks with 20-30M instances and there are some with 3-5M instances. Using this attribute, bigger blocks will be automatically assigned to a bigger queue, resulting in better runtime.

Related Commands

- `report_power`

power_enable_auto_mapping

```
power_enable_auto_mapping {true | false}
```

Default: `false`

Data_type: bool

Specifies to automatically perform instance name mapping between the RTL netlist and GATE level netlist. This attribute allows you to map the RTL vector to the Gate level netlist without a mapping file.

You can the `read_activity_file -name_mapping_rule <filename>` command parameter to specify a file containing customized or design-specific rules.

Related Commands

- `report_power`

power_enable_disk_mapping

```
power_enable_disk_mapping {true | false}
```

Default: `false`

Data_type: bool

Specifies to enable disk caching of the toggles. Therefore, the toggles are stored in the disk instead of keeping them in memory. This has made large vectors or long simulation duration runs possible even with lesser available memory. This attribute is only applicable to the event-based power analysis flow (`power_method event_based`) in the XP mode.

Example:

The following command specifies to enable disk caching of toggles:

```
set_db power_method event_based power_enable_disk_mapping true power_enable_xp true
```

Related Commands

- `report_power`

power_enable_duty_propagation_with_global_activity

```
power_enable_duty_propagation_with_global_activity {true | false}
```

Default: `false`

Data_type: bool

Specifies to propagate duty cycle with the global switching activity setting for all data nets in the dynamic vectorless analysis flow.

Related Commands

- report_power

power_enable_dynamic_current_slew_load_interpolation

```
power_enable_dynamic_current_slew_load_interpolation {true | false}
```

Default: `false`

Data_type: bool

Specifies to use the charge-based slew load interpolation. When this attribute is set to `true`, Power Analysis takes dynamic currents from the 4 nearest slew/load values and performs either a 4-way (lower slew, lower load, upper slew, upper load) or a 2-way (lower slew, upper slew OR lower load, upper load) interpolation to calculate the dynamic current waveform. The attribute allows you to derive a more realistic dynamic current waveform based on the exact slew load values from the .lib dynamic current table.

Related Commands

- report_power

power_dynamic_scale_clock_by_frequency

```
power_dynamic_scale_clock_by_frequency { freq_Afactor_Afreq_Bfactor_Bfreq_Cfactor_C... }
```

Default: `""`

Data_type: string

Specifies the scale factors for the clock frequency values. This parameter allows you to perform frequency scaling for clocks running at relatively low frequencies, thereby ensuring higher toggle coverage for limited simulation period. The parameter is applicable only to the dynamic vectorless flow. The following units are supported for frequency: Hz, KHz, MHz, and GHz.

Related Commands

- report_power

power_dynamic_scale_clock_by_name

```
power_dynamic_scale_clock_by_name { clk_A factor_A clk_B factor_B clk_C factor_C ... }
```

Default: `""`

Data_type: string

Specifies the scale factors for the low frequency clocks. This parameter allows you to perform frequency scaling for clocks running at relatively low frequencies, thereby ensuring higher toggle coverage for limited simulation period. The parameter is applicable only to the dynamic vectorless flow. The following units are supported for frequency: Hz, KHz, MHz, and GHz.

Related Commands

- report_power

power_dynamic_vectorless_ranking_methods

```
power_dynamic_vectorless_ranking_methods {load | clock | vector_activity}
```

Default: `""`

Data_type: string

Specifies to change the ranking method from the default to the following:

- `load` - Prioritizes scheduling cells with higher fanout
- `clock -` Prioritizes scheduling cells associated with faster clocks
- `vector_activity` - Prioritizes scheduling cells with higher activity

Related Commands

- `report_power`

power_enable_dynamic_scaling

```
power_enable_dynamic_scaling {true | false}
```

Default: `false`

Data_type: bool

Enables `set_power` scaling for dynamic power analysis. The power and scaling specifications are used to scale dynamic current on both the power and ground currents of the specified instance/cell.

This attribute honors the user-defined average (static) power for leaf-level instances and hierarchies (instances/cells/modules) along with power net specification in the dynamic current scaling flows such that the average of the dynamic current is equal to the assigned average power. When you specify this attribute, the average of the dynamic current of these leaf-level instances will match the scaled static power numbers.

⚠ This attribute is not supported in the state-propagation-based vectorless flow (`power_enable_state_propagation true`). It is applicable only to the probability-based vectorless flow.

Related Commands

- `set_power`
- `report_power`

power_enable_flop_state_propagation

```
power_enable_flop_state_propagation {true | false}
```

Default: `false`

Data_type: int

Enables accurate clock state propagation for sequential cells. When this attribute is set to `true`, flops propagate in a manner that toggles on the output pins are in sync with the clock. This attribute helps to align the output pins' toggles with the clock toggles.

Related Commands

- `set_power`
- `report_power`

power_enable_generated_clock

```
power_enable_generated_clock {true | false}
```

Default: `true`

Data_type: bool

Specifies to get generated clock frequency during activity propagation for static power analysis.

Related Commands

- set_power

power_enable_input_net_power

```
power_enable_input_net_power {true | false}
```

Default: false

Data_type: bool

Specifies to calculate the switching power of input nets.

Related Commands

- set_power

power_enable_interactive_reports

```
power_enable_interactive_reports {true | false}
```

Default: false

Data_type: bool

Specifies to generate multiple dynamic reports based on the power analysis run done for a netlist. When this attribute is set to true, you can generate various types of power reports interactively using the report_power command without the need to perform power calculation on the same netlist again.
The power_enable_interactive_reports attribute is useful when you need to generate reports for the unaltered netlist within the same power analysis session.

This attribute is applicable only to the event-based power analysis flow with area-based partitioning (power_use_physical_partition) in the XP mode.

Example:

The following command specifies to enable interactive generation of power reports:

```
set_db power_method event_based power_use_physical_partition true power_partition_count 2 power_enable_interactive_reports true
power_enable_xp true
```

Related Commands

- set_power

power_enable_mt_state propagation

```
power_enable_mt_state_propagation {true | false}
```

Default: true

Data_type: bool

Specifies to enable multi-threading in state propagation to help improve the runtime for large simulations. For example, when the attribute was specified for a design with 300 million instances and simulation duration of 120 microseconds, the runtime has improved from 21 hours to 1.5 hours.

This attribute is only applicable to the event-based power analysis flow (power_method event_based).

Related Commands

- set_power

power_enable_multithread_reports

```
power_enable_multithread_reports {true | false}
```

Default: false

Data_type: bool

Specifies to enable multi-threading for generation of power calculation reports. When set to true, it improves the memory and runtime for power reporting in

large designs with more than 100 million instances.

Related Commands

- set_power

power_enable_power_target_flow

```
power_enable_power_target_flow {true | false}
```

Default: false

Data_type: bool

Specifies to enable the power target flow. When set to true, the tool allows you to specify power targets for full-chip power analysis. You can use the set_power command to specify the power targets for full-chip, physical block, logical block, and power/ground net. When these targets are specified, Voltus will automatically scale the toggle rates of clock gate ratio, input, macro, and sequential activities to meet the specified power targets.

Related Commands

- set_power

power_enable_pba_for_tempus_pi

```
power_enable_pba_for_tempus_pi {true | false}
```

Default: false

Data_type: bool

Specifies to enable the Path-Based Analysis (PBA) for slack calculation in the Tempus Power Integrity (Tempus PI) flow. By default, the Graph-Based Analysis (GBA) is used. This attribute is only applicable to the state-propagation-based vectorless flow (set_db power_method dynamic_vectorless power_enable_state_propagation true).

Related Commands

- set_power

power_enable_rtl_dynamic_vector_based

```
power_enable_rtl_dynamic_vector_based {true | false}
```

Default: false

Data_type: bool

Specifies to take an RTL or partial VCD/FSDB file as input and use that for dynamic vector-based flow. This attribute allows you to estimate current even for instances which are missing from the activity file.

You must use this attribute in conjunction with the power_method dynamic_vectorbased attribute.

Related Commands

- set_power

power_enable_scan_report

```
power_enable_scan_report {true | false}
```

Default: false

Data_type: bool

Specifies to generate all the scan mode analysis reports. The following reports will be generated:

- voltus_power.scanff.duplicated.rpt - flip-flops that are specified in multiple chains

- `voltus_power.scanff.missing.rpt` - flip-flops that are missing in the scan control file but exist in the design
- `voltus_power.scanff.nonassigned.rpt` - flip-flops that do not exist in the design and are dropped from the scan control file
- `voltus_power.scanff.nonscan`.rpt - assigned flip-flops that have no scan-out pin
- `voltus_power.scanff.nonswitched.rpt` - non-switching flip-flops in the scan control file
- `voltus_power.scanff.rpt` - detailed scan chain report containing global statistics for all scan chains and statistics for each scan chain in the design
- `voltus_power.scanff.stateconflict.rpt` - flip-flops that have conflicting state assignment

Related Commands

- `report_power`

power_enable_slew_based_ccs_pin_cap

```
power_enable_slew_based_ccs_pin_cap {true | false}
```

Default: `false`

Data_type: bool

Specifies to use the Composite Current Source (CCS) capacitance value based on the slew given in the input pin section of the library cell in the Liberty file. If it is set to `true`, the tool honors the CCS pin capacitance; if it is set to `false`, it takes `max_capacitance` from .lib. This attribute can be used when timing windows and/or a Tempus timing session is not available.

Related Commands

- `set_power`

power_enable_state_propagation

```
power_enable_state_propagation {true | false}
```

Default: `false`

Data_type: bool

Specifies to enable the vectorless state-propagation-based dynamic analysis flow.

For more information, refer to the **State-Propagation-Based Vectorless Methodology** section in the " *Dynamic Power and IRDrop Analysis* " chapter of the *Voltus User Guide*.

Related Commands

- `set_power`

power_enable_tempus_pi

```
power_enable_tempus_pi {true | false}
```

Default: `false`

Data_type: bool

Specifies to enable the Tempus PI analysis flow. When this attribute is set to `true`, data path scheduling is timing-aware, that is, scheduling is based on timing slacks. This attribute is only applicable to the state-propagation-based vectorless flow (`set_db power_method dynamic_vectorless power_enable_state_propagation true`).

For more information, refer to the **Tempus Power Integrity Analysis** chapter in the *Voltus User Guide*.

Related Commands

- `set_power`

power_enable_xp

```
power_enable_xp {true | false}
```

Default: `false`

Data_type: bool

Specifies to run standalone report generation in the XP mode.

Related Commands

- set_power

power_enhanced_blackbox_avg

```
power_enhanced_blackbox_avg {true | false}
```

Default: `false`

Data_type: bool

Specifies to use the average toggle rate of related inputs for enhanced blackbox propagation.

Related Commands

- set_power

power_enhanced_blackbox_max

```
power_enhanced_blackbox_max {true | false}
```

Default: `false`

Data_type: bool

Specifies to use the maximum toggle rate of related inputs for enhanced blackbox propagation.

Related Commands

- set_power

power_equivalent_annotation

```
power_equivalent_annotation {true | false}
```

Default: `false`

Data_type: bool

Specifies to enable equivalent annotation for Q or Qbar pins when only one of them is annotated.

Related Commands

- set_power

power_event_based_leakage_power

```
power_event_based_leakage_power {true | false}
```

Default: `false`

Data_type: bool

Specifies to calculate state-dependent leakage power. When this attribute is set to `true`, it calculates leakage power and current based on the state of an instance at each time point.

For example, at time 0ns, instance instA is in state !I ZN (0 on input, 1 on output), and at time 71ns, the instance is in state I !ZN (1 on input, 0 on output). The

leakage power is calculated based on the different states of instA at different time points.

Related Commands

- set_power

power_external_load_config_file

```
power_external_load_config_file filename
```

Default: None

Data_type: string

Specifies to honor the user-specified load capacitance values for power calculation. This attribute allows you to specify an external load capacitance file when you have a timing window file without the EXTERNAL_LOAD constructs.

File Format:

The format of the user-specified input file is:

```
INST|CELL    blockName    external_load_flle
```

Here, the format of *external_load_flle* is:

```
NET|PORT       name       load_value
```

Examples:

Configuration file:

```
INST         TOP          top_wcard.load
```

External load file (top_wcard.load):

```
UNIT pF
NET   result     0.02
NET   overflow   0.02
```

Related Commands

- set_power

power_extraction_tech_file

```
power_extraction_tech_file filename
```

Default: ""

Data_type: string

Specifies the extraction technology file to be used for top-level power-grid extraction.

Related Commands

- set_power

power_extractor_include

```
power_extractor_include filename
```

Default: ""

Data_type: string

Specifies the extractor (ZX) commands and variables in the form of an include file. This parameter is applicable only for the standalone report generation flow in the XP mode (power_enable_xp true).

Related Commands

- set_power

power_fanout_limit

```
power_fanout_limit value
```

Default: `-1`

Data_type: int

Specifies the fanout limit for nets. If an instance has nets more than or equal to the fanout limit, its switching/internal/leakage power is taken to be zero.

Related Commands

- set_power

power_force_library_merging

```
power_force_library_merging {true | false}
```

Default: `false`

Data_type: bool

Specifies to force merge PGVs even if there are some minor conflicts in the merging libraries. This parameter is applicable only for the standalone report generation flow in the XP mode (`power_enable_xp true`).

Related Commands

- set_power

power_from_x_transition_factor

```
power_from_x_transition_factor value
```

Default: `0.5`

Data_type: double

Specifies how transitions from X to 0/1 are counted.

Related Commands

- set_power

power_from_z_transition_factor

```
power_from_z_transition_factor value
```

Default: `0.25`

Data_type: double

Specifies how transitions from Z to 0/1 are counted.

Related Commands

- set_power

power_generate_activity_mapping_report

```
power_generate_activity_mapping_report  {true | false}
```

Default: `false`

Data_type: bool

Specifies to generate the `activity_mapping.rpt` report in the vector-based dynamic power flow. This report gives the list of signal name mappings between the Golden (RTL netlist - input name in the vector file) and Revised (Gate netlist - annotated design object name) netlists that were used in the flow. The report

displays the list of annotated and unannotated objects and helps to debug the mapping file for unannotated design objects.

`activity_mapping.rpt` supports activity mapping done through the following methods:

- User-specified mapping file (`read_activity_map_file -two_column_mapping_file`)
- Conformal-generated RTL mapping file (`read_activity_map_file -rtl_to_gate`)
- Voltus auto-generated mapping file (`power_enable_auto_mapping`).

Related Commands

- `set_power`

power_generate_current_for_rail

```
power_generate_current_for_rail railnames
```

Default: `""`

Data_type: string

Generates current files for the specified rail.

By default, the command generates current files for all power rails.

Related Commands

- `set_power`

power_generate_flop_ranking_data

```
power_generate_flop_ranking_data directoryname
```

Default: `""`

Data_type: string

Specifies the name of the directory where the flop ranking data is saved.

Related Commands

- `set_power`

power_generate_static_report_from_state_propagation

```
power_generate_static_report_from_state_propagation  {true | false}
```

Default: `false`

Data_type: bool

Specifies to directly generate the static power analysis result based on the RTL-VCD input and state-propagation. When this attribute is specified, the RTL vector power analysis flow does not require the generation of a TCF/FSDB file. This attribute is applicable only to the RTL vector-based dynamic power analysis flow.

Related Commands

- `set_power`

power_generate_leakage_power_map_based_on_calculated_leakage

```
power_generate_leakage_power_map_based_on_calculated_leakage  {true | false}
```

Default: `false`

Data_type: bool

Specifies to scale the instance leakage power by directly multiplying the user-specified scaling factor with the final calculated leakage power value, instead of scaling the leakage power value from the input dotlib.

If this parameter is not specified, the user-specified scaling factor will be applied on the leakage power values from the input dotlib.

Related Commands

- set_power

power_grid_libraries

```
power_grid_libraries library_list
```

Default: ""

Data_type: string

Specifies the name of the Cadence power cell libraries (.cl). You can also specify a list of defined power-grid libraries having decap cells tagged in them.

Note: When specifying a list of PGVs, you must specify the technology library as the first PGV library in the list, followed by the standard and macro PGV libraries. The selection between the standard and macro PGV library is order based. Therefore, if multiple power-grid libraries are specified for a cell, the power engine maps the cell with the first library after the technology library.

Related Commands

- set_power

power_handle_glitch

```
power_handle_glitch {true | false}
```

Default: false

Data_type: bool

A transition is defined as a glitch when the time difference between two sequential toggles are less than half of the rise transition time + fall transition time in the vector-based static power calculation. Both static and dynamic current are derated for glitch transitions. The same derate factor is used for both power and current.

If set to true, glitch power will be identified and calculated according to this definition and it will be reported in a separate column. Switching or internal power calculation does not include power due to glitches.

If set to false, glitch power will not be identified, and the respective power will be calculated as normal signal switches. Hence, the total power will be a little higher.

Related Commands

- set_power

power_handle_tristate

```
power_handle_tristate {true | false}
```

Default: false

Data_type: bool

When set to true, all tristate device enable pin values will be taken into account when determining the propagation of the activity through tristate gates.

Related Commands

- set_power

power_hier_delimiter

```
power_hier_delimiter character
```

Default: None

Data_type: string

Specifies the hierarchical delimiter in the DEF file. You can use this attribute to override the existing hierarchical delimiter.

Related Commands

- set_power

power_honor_combinational_logic_on_clock_net

```
power_honor_combinational_logic_on_clock_net {true | false}
```

Default: `true`

Data_type: bool

Specifies the behavior of combination logic on clock net.

- `true` (default) - specifies to honor activity propagation through combinational logic.
- `false` - specifies that the combination logic will be treated like a combinational clockgate.

Related Commands

- set_power

power_honor_negative_energy

```
power_honor_negative_energy {true | false}
```

Default: `true`

Data_type: bool

When set to `true`, specifies that the software will keep negative internal energy numbers from the `.lib` internal power table. When set to `false`, negative power is treated as 0.

Related Commands

- set_power

power_honor_net_activity

```
power_honor_net_activity {true | false}
```

Default: `true`

Data_type: bool

Specifies to use activity from the `Net` section of the Switching Activity Interchange Format (SAIF) file for power calculation and optimization, and to ignore the pin-based state-dependent path delay (SDPD) activity. The default value of this attribute is `true`.

When this attribute is set to `false`, the power calculation engine can use both the net-based and pin-based activity. In this case, precedence will be given to activity from net or pin that appears later in the SAIF file.

Related Commands

- set_power

power_honor_non_mission_leakage

```
power_honor_non_mission_leakage {true | false}
```

Default: `false`

Data_type: bool

Supports modeling of well-to sub-leakage information when the circuit power supply is off for the level shifter cells. This is referred to as the non-mission mode leakage power calculation. The leakage power for a level shifter cell depends on the state of each PG pin. The Liberty file contains sections for PG pin conditions of each mode/state and non-mission mode leakage power for each PG pin of that mode.

When this attribute is set to `true`, Voltus identifies the pg_pin mode and assigns non-mission mode leakage power associated with the mode.

The use model of the non-mission mode leakage power calculation feature is:

```
power_honor_non_mission_leakage true
power_off_pg_nets {VDD VDDO}
```

Example:
Let us consider a level shifter cell with the PG mode "`retained_VDDO_off`" and the following `pg_pin_condition`:

```
pg_setting_value (retained_VDDO_off) {
pg_pin_condition : "!VBB*VDD*VDDI ";
pg_pin_active_state (VBB, V1);
pg_pin_active_state (VDD, V2);
pg_pin_active_state (VDDI, V2);
```

When you specify a list of PG nets to be turned off along with the `power_honor_non_mission_leakage` attribute, all cells/instances that have the PG state "`retained_VDDO_off`" associated with the specified PG pin condition, will use the corresponding non-mission leakage power.

Related Commands

- `set_power`

power_hybrid_analysis

```
power_hybrid_analysis {true | false}
```

Default: `false`
Data_type: `bool`

Specifies to perform both vector-based and vectorless power analysis in a single session.

Related Commands

- `set_power`

power_ignore_control_signals

```
power_ignore_control_signals {true | false}
```

Default: `true`

Data_type: bool

Specifies that control signals will be ignored when propagating activity. It is recommended to set this parameter to `true`. When set to `true`, the control pins (reset, preset) will not impact the sequential instance's output pin activity during activity propagation.

Related Commands

- `set_power`

power_ignore_data_phase_for_clock

```
power_ignore_data_phase_for_clock {true | false}
```

Default: `false`

Data_type: bool

Specifies to ignore data frequency in the clock path for the clock instances in the design. When this attribute is set to `true`, the software propagates only the fastest clock pin frequency instead of the data pin frequency for activity propagation through clock network. In the default mode, the software picks the fastest frequency between the data phase and clock phase on that pin.

Related Commands

- set_power

power_ignore_end_toggles_in_profile

```
power_ignore_end_toggles_in_profile {true | false}
```

Default: false

Data_type: bool

By default, the software profiles the toggles in the user-selected vector time window by steps including the toggles at the start/end boundary of the window. In each step, the toggles on the start boundary edge of the step is counted in the current step; the toggles on the end boundary edge is counted in the next step.

When this attribute is set to false, the toggles on the end boundary edge is also counted in the last step, as there is no next step to it. This may lead to double count of the power profile for the last step, especially for zero-delay vector profiling.

When this attribute is set to true, the software ignores the toggle on the end boundary of the last step.

Related Commands

- set_power

power_ignore_glitches_at_same_time_stamp

```
power_ignore_glitches_at_same_time_stamp {true | false}
```

Default: true

Data_type: bool

Specifies to ignore glitches at the same transient time in the vector-based static and dynamic power analysis flow. When this attribute is set to true, only the last signal value change is honored, and all the preceding value changes at the same time stamp are ignored. The last signal value will overwrite the previous value for the same signal at the same time stamp, so the last value will represent the state of the signal at that time stamp.

Related Commands

- set_power

power_ignore_inout_pin_cap

```
power_ignore_inout_pin_cap {true | false}
```

Default: false

Data_type: bool

When set to true, ignores the bidirectional pin capacitances (direction : inout) defined for I/O cells in the .lib file, when calculating switching power and internal power; this also includes the default capacitance value for inout pins.

Related Commands

- set_power

power_include_file

```
power_include_file file
```

Default: " "

Data_type: string

Specifies a power analysis include file. You can use this file to specify certain commands of the dynamic engine which do not have a Voltus equivalent. This attribute is used to pass the legacy power analysis commands and report_power command options only in the dynamic mode (vectorbased and vectorless). If the power_method attribute is set to static, the power_include_file attribute is ignored. The power_include_file attribute is required only if the power_static_netlist attribute is set to def.

Related Commands

- set_power

power_include_initial_x_transitions

```
power_include_initial_x_transitions {true | false}
```

Default: true

Data_type: bool

Controls how the initial X state toggle should be counted. The initial X state means the state at time 0.

When set to true, this means that the software counts the power caused by the X->0 or X->1 toggle. When set to false, the software does not count the power caused by the initial X state toggle.

Related Commands

- set_power

power_include_sequential_clock_pin_power

```
power_include_sequential_clock_pin_power {true | false}
```

Default: false

Data_type: bool

Reports the clock pin power of flip-flops as part of the clock network power.

Related Commands

- set_power

power_include_timing_in_current_file

```
power_include_timing_in_current_file {true | false}
```

Default: false

Data_type: bool

Specifies to write timing bits for non-switching instances in the current files during the state-propagation-based flow. When specified, rail analysis will report effective instance voltage (EIV) for both switching and non-switching instances. If the parameter is set to false, rail analysis will report EIV for the switching instances only.

Related Commands

- set_power

power_ir_derated_timing_view

```
power_ir_derated_timing_view view_name
```

Default: " "

Data_type: string

Specifies the name of the timing view used to calculate timing slack and to rank the flops in the Tempus PI flow. This attribute must be specified if there are multiple views.

The power_ir_derated_timing_view attribute defines the timing view used to detect the IR-sensitive paths using a lower voltage than the actual analysis. This lower voltage simulates the IR-drop for each instance in the design. The software uses this view to prioritize the end-points that need to be prioritized for switching.

This attribute is only applicable to the state-propagation-based vectorless flow (set_db power_method dynamic_vectorless power_enable_state_propagation true).

Related Commands

- set_power

power_keep_clock_gate_ratio_in_iterations

```
power_keep_clock_gate_ratio_in_iterations {true | false}
```

Default: false

Data_type: bool

Specifies whether to keep the clock gate output (CGO) fixed or automatically adjust the value for each iteration of state propagation. This attribute is only applicable to the power target flow (power_enable_power_target_flow true).

Related Commands

- set_power

power_leakage_scale_factor_for_temperature

```
power_leakage_scale_factor_for_temperature view_name
```

Default: 1.0

Data_type: double

Performs a linear scaling of the leakage power for temperature in all libraries. This replaces the k-factor for temperature in the .lib file. For process and voltage, the scaling will continue to be based on the corresponding k-factors in the .lib file. A value of 0.8 scales the leakage power in the library to 80 percent. A value of 1.2 scales the leakage power in the library to 120 percent.

Related Commands

- set_power

power_lib_files

```
power_lib_files in_file <file1[file2] ...
```

Default: ""

Data_type: string

Specifies the name of the timing library file(s) for dynamic power analysis. This attribute allows you to run the dynamic power analysis flow without reading a dotlib into design database to reduce background memory consumption. You must have an external TWF file to run this flow as the timing engine will not be invoked from within Voltus. This flow is recommended for large designs where front-end processing of timing libraries is high. Some of the database query commands will not work if this attribute is used.

Related Commands

- set_power

power_library_preference

```
power_library_preference {voltage | ecsm_ccsp}
```

Default: voltage

Data_type: string

Instances of the same cell can be attached to different power domains in a design. If you have specified different PVT libraries, then the software will by default bind each instance to the closest library definition.

You can use this attribute to select either the closest Effective Current Source Model (ECSM)/Composite Current Source-power (CCSP), or the closest voltage library for the instance:

- voltage: when specified, enables library binding to the closest voltage library.

- `ecsm_ccsp`: when specified, enables library binding to the closest ECSM/CCSP library.

Related Commands

- `set_power`

power_match_state_for_logic_x

```
power_match_state_for_logic_x value
```

Default: `0`

Data_type: string

Controls how the logic X will be evaluated in the boolean function of the '`when`' state of a power table.

The attribute uses the following arguments:

- `0` - regards X as 0
- `1` - regards X as 1
- `x/X` - regards X as neither `0` nor `1`, that is, whenever there is any X logic in it, the boolean function will be evaluated `0` (false).

Related Commands

- `set_power`

power_multibit_flop_toggle_behavior

```
power_multibit_flop_toggle_behavior { simultaneous | independent | sbff }
```

Default: `independent`

Data_type: enum

Specifies the toggle behavior of multi-bit flip-flops (MBFF). The possible arguments are:

- `simultaneous`: The multiple bits of the MBFF will toggle or not toggle at the same time. The MBFF will be considered as one flip-flop.
- `independent`: The multiple bits of the MBFF will toggle independently. The MBFF will be considered as one flip-flop.
- `sbff`: The MBFF will be considered as multiple Single-Bit Flip-Flops (SBFFs). Each bit will be considered as one flip-flop, and will toggle independently.

Related Commands

- `set_power`

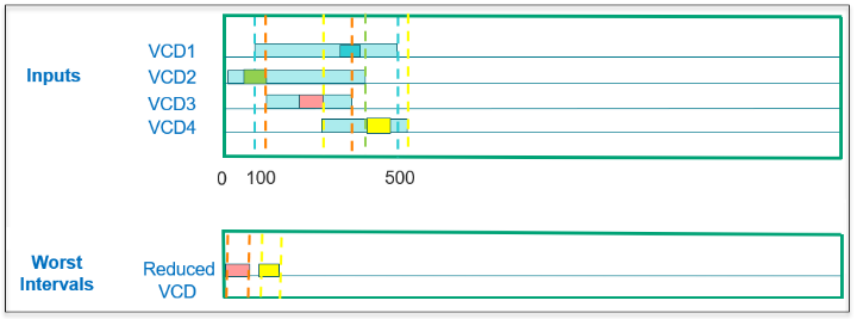
power_multi_scenario_simulation

```
power_multi_scenario_simulation {true | false}
```

Default: `false`

Data_type: bool

Specifies to create a long vector by combining multiple vectors and to identify the worst power intervals across the combined vector. The long vector includes all scenarios that are used sequentially and are non-overlapping.



This attribute allows you to perform power and current analysis using worst peak power interval across multiple simulation vectors.

Related Commands

- `set_power`

power_merge_switched_net_currents

```
power_merge_switched_net_currents {true | false}
```

Default: `false`

Data_type: bool

Specifies to merge switched net currents into always-on currents. For designs with a large number of switched nets, this attribute helps improve performance by merging switched net instance currents with always-on instance currents. However, when this attribute is set to `true`, you will not be able to use the generated current files to run power-up analysis.

Related Commands

- `set_power`

power_method

```
power_method { static | dynamic_vectorless | dynamic_vectorbased | dynamic_mixed_mode | event_based | vector_profile }
```

Default: `static`

Data_type: enum

Specifies the type of analysis to be performed. You can perform two types of power analysis, namely static and dynamic.

- `static` - specifies to perform static power analysis to calculate average power.

Dynamic power analysis can be a vector-based or vectorless approach.

- `dynamic_vectorbased` - uses the full VCD output of a logic simulator to identify the instances that are switching and when they switch.
- `dynamic_vectorless` - uses the timing arrival window information from a static timing analysis tool to determine when instances switch. A timing arrival window describes when a signal can change within a clock cycle. An additional algorithm then determines the instances that switch.
- `dynamic_mixed_mode` - specifies to combine the vector-based and vectorless (mixed) dynamic analysis. This flow can be used in the following cases:
  - **case 1**: vectors are not available for every block of a full-chip design.
    In this case, the software uses the vectorless methodology for blocks with incomplete vectors
  - **case 2**: blocks with vectors having unannotated combinational/ sequential logic.
    In this case, the software performs state propagation for the missing combinational/ sequential logic. It uses the vectorless methodology for a logic cone that does not have the primary inputs or flops annotated from the vector, and then performs state propagation

    To enable the dynamic mixed mode analysis flow, you must specify the following commands:

    ```
    set_default_switching_activity -clock_gates_output 2.0 -global_activity <activity>
    set_db power_method dynamic_mixed_mode
    read_activity_file -scope <> -block <> -> (for available blocks)
    ```
- `event_based -` specifies to enable event-based power analysis. This method supports multiple power analysis flows simultaneously. When specified, the

tool performs accurate state-based power estimation for all events of a scenario in a design. Event-Based Power Analysis is applicable to all event-based vectors, such as VCD, FSDB, SHM, and PHY. You can specify this method to generate and analyze multiple types of power analysis flow reports in a single run.

The following table shows the additional options required for the different flows:

Power Analysis Flows	Additional Options for `-method event_based`
Static	`no additional option required`
Average Power & Current	`-write_static_currents`
Dynamic Vectorbased	`-write_dynamic_currents`
Mixed Mode	`-add_simulation`
Dynamic Vectorless	
Profiling	`-worst_step_size`

- `vector_profile` - specifies to enable vector profiling. This is used to identify windows with maximum activity and power which can then be used to drive dynamic vector-based power analysis.

Related Commands

- `set_power`

power_min_leaf_count

`power_min_leaf_count` *value*

Default: `0`

Data_type: int

Specifies the minimum number of leaf instances required for writing the hierarchy data in the profiling database. It allows you to restrict the number of hierarchies for which waveforms are reported in the profiling database when using both the `power_write_profiling_db` attribute and `report_power -hierarchy` parameters.

Any hierarchy whose leaf instance count in its complete sub-tree is less than the `power_min_leaf_count` value will be skipped from getting reported in the profiling database. This attribute can be used to skip very small hierarchies and as a result save on the database writing time and disk space.

Related Commands

- `set_power`

power_off_pg_nets

`power_off_pg_nets` *net_list*

Default: `""`

Data_type: string

The name of the power rails that will be turned off. The net name can contain instance hierarchy if appropriate. The software will take this data into account when figuring out the list of power gates which are switched off.

Note: A net is turned off if all connected power gates are turned off by control signals. When a net is off, all of the instances connected to the net will only contribute leakage current into the connecting nets.

Related Commands

- `set_power`

power_output_current_data_prefix

```
power_output_current_data_prefix prefix
```

Default: ""

Data_type: string

Specifies a prefix to the static or dynamic current files generated by the software. When power analysis is done in the multi-CPU mode, the output current data directory name and the underlying current files will also use the same prefix by default.

Related Commands

- set_power

power_output_dir

```
power_output_dir directory
```

Default: ""

Data_type: string

Specifies the name of the directory that power information will be output to.

Related Commands

- set_power

power_partition_count

```
power_partition_count value
```

Default: 0

Data_type: integer

Specifies the number of physical partitions or jobs for a distributed run in the area-based partitioning flow. This attribute is only applicable to the event-based power analysis flow (power_method event_based) in the XP mode. The power_partition_count attribute must be specified with the power_use_physical_partition attribute.

Related Commands

- set_power

power_partition_twf

```
power_partition_twf {true | false}
```

Default: false

Data_type: bool

Specifies to read the input TWF data (flat or hierarchical TWF files), and generate block-level TWFs.This attribute must be specified when the block/partition level TWF files are not available.

Related Commands

- set_power

power_pin_based_twf

```
power_pin_based_twf {true | false}
```

Default: false

Data_type: bool

Specifies whether to generate pin-based TWF or net-based TWF.

- When set to `false`, a net-based TWF file is generated. Net-based TWF file is smaller in size and therefore results in faster processing.
- When set to `true`, a pin-based TWF file is generated. Pin-based TWF file is bigger in size and requires longer processing time, however, is more accurate because the slews numbers are pin-based.

Note: This attribute must be used with the `read_sdc` command.

Related Commands

- `set_power`

power_precision

`power_precision` *value*

Default: `8`

Data_type: int

Specifies precision of decimal range [1-8] to ensure consistent decimal places are displayed for each power component. This attribute is used for precision handling in `report_instance_power` and `report_power`.

Related Commands

- `report_power`

power_pre_simulation_empty_period

`power_pre_simulation_empty_period` *value*

Default: `""`

Data_type: string

Specifies to add an empty pre-simulation period before simulation during IR drop analysis. Power analysis is not done for the pre-simulation period and flat dynamic currents are created.

Related Commands

- `report_power`

power_pre_simulation_period

`power_pre_simulation_period` *value*

Default: `""`

Data_type: string

Specifies to set a pre-simulation period for IR drop analysis. Pre-simulation is used for generating power analysis reports and dynamic currents.

Related Commands

- `report_power`

power_pre_simulation_power_exclude_period

`power_pre_simulation_power_exclude_period` *value*

Default: `""`

Data_type: string

Specifies to exclude power analysis during the pre-simulation period used for IR drop analysis. Pre-simulation is used only to create dynamic currents and not used for power reports.

Related Commands

- report_power

power_quit_on_activity_coverage_threshold

```
power_quit_on_activity_coverage_threshold  threshold_value
```

Default: 1.0

Data_type: double

Specifies the activity (VCD/FSDB/TCF) coverage threshold value. This attribute allows you to control the acceptable activity coverage that you are expecting and enforce the software to quit when it does not meet the criteria. When you specify the threshold value, the software exits if the real activity coverage is below the threshold.

Related Commands

- report_power

power_read_rcdb

```
power_read_rcdb  {true | false}
```

Default: false

Data_type: bool

Specifies to write a SPEF file containing only the total C for signal nets and pass it to the Dynamic Power engine. Dynamic power analysis requires only the total C for signal nets. Therefore, instead of writing a large SPEF file (with distributed RC) from the RCDB, this attribute specifies to create and pass a SPEF file with only total C for all the signal nets. This significantly reduces the parasitic annotation time in the Dynamic Power engine.

Related Commands

- report_power

power_relax_arc_match

```
power_relax_arc_match  {true | false}
```

Default: true

Data_type: bool

Specifies to relax arc match requirements. This attribute is used only when the exact arc is not found in a .lib. When set to true, the internal energy is calculated as an average of multiple arcs with relaxed arc matching. If this attribute is set to false, relaxed arc search is not done and 0 internal energy is returned.

Related Commands

- report_power

power_report_black_boxes

```
power_report_black_boxes {true | false}
```

Default: false

Data_type: bool

Specifies to report cells that are used as black boxes.

A black box is a cell which is either missing from the liberty file or has no functionality defined in the liberty file.

Related Commands

- report_power

power_report_idle_instances

```
power_report_idle_instances {true | false}
```

Default: `false`

Data_type: bool

Specifies to generate a report (`idleinstance.rpt`) that lists all the idle or non-switching instances.

The following is a snippet of the `idleinstance.rpt` report:

```
DFF22/DFF    F
DFF42/DFF    F
...
```

Here, the first column is the instance name and the second column is the type of instance (`F` indicates flop and `C` indicates combinational).

Related Commands

- report_power

power_report_instance_switching_info

```
power_report_instance_switching_info {all | output_logic | none}
```

Default: `none`

Data_type: enum

Specifies to generate a report for combinational instance switched during state-propagation. In the output file, it contains the toggle time, instance name, input pin event, and output pin event for each switching event of the combination gate. The possible arguments of this attribute are:

- `all` - Specifies to report instance toggle information for both input and output pins. When this attribute is set to `all`, the switching of both the input and output pins of all the instances are reported in the `voltus_power.stateprop.switchinst` file and the switching of flops are reported in the `voltus_power.stateprop.switchsrc` file.
- `output_logic` - Specifies to report instance toggle information for the output pins only. When this attribute is set to `output_logic`, the switching of the output pins of all the instances are reported in the `voltus_power.stateprop.switchinst` file and the switching of flops are reported in the `voltus_power.stateprop.switchsrc` file.
- `none` - Disables generation of instance toggle report. This is the default option. When this attribute is set to `none`, only switching of flops are reported in the `voltus_power.stateprop.switchsrc` file. The file does not report switching of instances.

This attribute is used for generating switching details of state-propagation and should be specified only for debugging purpose.

The following is a snippet of the `voltus_power.stateprop.switchinst` report:

```
*-------------------------------------------------
*Switch Time   Instance Name   Pin Name   Logic
*-------------------------------------------------
*
   0.097        B11/BUFF         I        rise
   0.097        DFF11/DFF        Q        rise
...
```

Here,

- `Switch Time`: switching time of instances that can be either combinational or sequential
- `Instance Name`: instance name
- `Pin Name`: input/output pin of the instance
- `Logic`: present logic of the pin that can be either "rise" or "fall"

Related Commands

- report_power

power_report_instance_switching_list

```
power_report_instance_switching_list filename
```

Default:

Data_type: string

Specifies to generate a report (`voltus_power.stateprop.switchlist`) containing all the switching times for the specified instances when the `power_enable_state_propagation` attribute is set to `true`.

The format of the specified file is:

```
instname1
instname2
...
```

The following command is an example of the state-propagation-based dynamic vectorless flow, and also specifies to generate a report (`voltus_power.stateprop.switchlist`) containing all the switching times for the instances specified in the `inst_list` file:

```
set_db power_method dynamic_vectorless power_enable_state_propagation true power_report_instance_switching_list inst_list
```

The following is the format of the `voltus_power.stateprop.switchlist` report:

```
*-----------------------------------------------------------------------------------------
*Instance Name   Pin Name   Pin Direction   Frequency   Switch Time
*-----------------------------------------------------------------------------------------
*
```

Here,

- `Instance Name`: instance name that can be either combinational or sequential
- `Pin Name`: name of the input/output pin of the instance
- `Pin Direction`: indicates whether the pin is an INPUT (I) or OUTPUT (O) pin
- `Frequency`: clock frequency
- `Switch Time`: gives the switching pattern for the instance, that is, <*time1*> <*logic*> <*time2*> <*logic*>. The logic of the pin can be "`r`" or "`f`". `r` indicates rise and `f` indicates fall.

The following is a snippet of the `voltus_power.stateprop.switchlist` report:

```
*-----------------------------------------------------------------------------------------
*Instance Name   Pin Name   Pin Direction   Frequency   Switch Time
*-----------------------------------------------------------------------------------------
*
   DFF11/DFF        QN        O              100       0.106 f 10.107 r
   DFF11/DFF        Q         O              100       0.097 r 10.099 f
   DFF11/DFF        CP        I              100       0.059 r 5.056 f 10.059 r 15.056 ...
...
```

Related Commands

- `report_power`

power_report_library_usage

```
power_report_library_usage {true | false}
```

Default: `false`

Data_type: bool

Specifies to report library usage statistics in a text report. The report contains information such as, cell name, library format used (CCSP/ECSM/NLPM) for each cell, library name, and so on. This attribute allows you to perform library integrity checking for debugging purpose.

The format of the text report with sample content is given below:

Example:

```
#cell_name  net_name    op_voltage  lib_voltage   lib_format     missing_tables   library_name
```

```
INV         VDD,VDDA       0.9        1.0          NLDM           leakage,timing      A
INV         VDDC           0.75       0.75         CCSP,NLDM      leakage             B
```

Related Commands

- report_power

power_report_missing_bulk_connectivity

```
power_report_missing_bulk_connectivity {true | false}
```

Default: `false`

Data_type: bool

Specifies to report missing bulk pins in the missing input report (`power_report_missing_input`).

Related Commands

- report_power

power_report_missing_input

```
power_report_missing_input {true | false}
```

Default: `false`

Data_type: bool

Specifies to report missing netlist information in input files, such as library, LEF/DEF, PGV, SPEF, TWF, and missing logical connectivity for a cell instance (PGNET).

The name of the report file is: `<prefix>_missingdata.<spef|lefdef|lib|pgv|twf|pgnet>`

Related Commands

- report_power

power_report_missing_nets

```
power_report_missing_nets {true | false}
```

Default: `false`

Data_type: bool

Controls reporting of missing nets in both static and dynamic power analysis.

This attribute controls reporting for TWF and activity files in static analysis, and controls reporting for TWF/SDC/SPEF and activity files in dynamic analysis.

Related Commands

- report_power

power_report_scan_chain_statistics

```
power_report_scan_chain_statistics {true | false}
```

Default: `false`

Data_type: bool

Specifies to generate a report file called `voltus_power.scanchain.stat` during scan mode analysis that contains scan chain statistics.

The report has 2 parts:

- **Global Statistics**: this section has the cumulative statistics of all scan chains in the design
- **Chain Statistics**: this section has the statistics for each scan chain in the design

The Global and Chain Statistics sections have the following information:

- `Total`: total instances specified in the control file or in a scan chain
- `AssignedFF`: flip-flops defined in the scan control file which exist in the design
- `SwitchedFF`: flip-flops that have switching event at the output
- `Non-ScanFF`: flip-flops that have no scan-out pin
- `DuplicatedFF`: flip-flops that are specified in multiple chains
- `StateConflictFF`: flip-flops that have conflicting state assignment

Related Commands

- `report_power`

power_report_statistics

```
power_report_statistics {true | false}
```

Default: `false`

Data_type: bool

Reports a set of statistics on the instance power, instance power density, clock power, or transition density. This attribute is useful in viewing and debugging user defined activity factors.

Related Commands

- `report_power`

power_report_time_display_fraction_digits

```
power_report_time_display_fraction_digits value
```

Default: `-1`

Data_type: int

Sets the number of fractional digits or decimal places displayed for the instance switching time values in the `voltus_power.stateprop.switchinst` file. This attribute displays fractional digits that show the exact time difference if there are two events (rise/fall) of an instance switching at the same time.

Related Commands

- `report_power`

power_report_twf_attributes

```
power_report_twf_attributes {summary| detailed}
```

Default:`""`

Data_type: string

Controls the generation of the TWF attribute report based on the TWF attributes that are specified using the `set_twf_attribute` command.

The possible arguments are:

- `summary` - generates a summarized static timing analysis report "`voltus_power.twf_attribute.summary`" that displays the number of user-defined TWF attributes (delay, slew, and slack values for both the rise and fall transitions) and the number of annotated TWF attributes for dynamic power analysis. The following is a snippet of the report:

```
STATISTICS:
                    User Defined            Annotated               Annotated/Total(%)
shift_arrival_time   5                       4                       80
rise_slew            2                       2                       100
fall_slew            2                       2                       100
rise_delay           5                       4                       80
fall_delay           5                       4                       80
rise_slack           2                       2                       100
fall_slack           2                       2                       100
```

- `detailed` - generates a detailed static timing analysis report " `voltus_power.twf_attribute.detailed`" that includes the summary report, and a detailed report of the rise and fall transitions for the TWF attributes of each annotated instance/pin. It also includes the shift arrival time report.

  This argument also allows you to generate a report `voltus_power.twf.rpt` containing the TWF statistics to highlight clock-frequency and delay used for the static and dynamic power calculation.

  The TWF statistics report is generated only if:

  - the `read_twf` command is specified before specifying the `power` category attributes.
  - the `power_method static power_static_netlist def` or `power_method dynamic_vectorless | dynamic_vectorbased` command is specified.

  The format of the `voltus_power.twf.rpt` report is:

```
# Voltus TWF Statistics
# Units: Freq (Hz), Delay (second), Slew (second)
# TWF File List:
#     TWF_file1
#     TWF_fileN

USER DEFINED TWF ATTRIBUTE STATISTICS
<Clock Freq> <Min Rise_Delay> <Rise Delay> <Max Rise Delay> <Min Fall Delay> <Fall Delay> <Max Fall Delay> <Net>
```

  The `USER DEFINED TWF ATTRIBUTE STATISTICS` section is included in the report only if the TWF attributes are defined using the `set_twf_attribute` command.

Example :

#check all instances of inst_C1 get shifted by 3ns

```
set_twf_attribute -pin inst_C1 -shift_arrival_time 3
```

#check all instances of inst_D1 get shifted by 3ns

```
set_twf_attribute -net inst_D1 -shift_arrival_time 3

set_db power_method dynamic_vectorless ; set_db power_write_db false ; set_db power_disable_static false ; set_db
power_enable_state_propagation true; set_db power_current_generation_method peak ; set_db power_grid_libraries /../library_pv.cl ; set_db
power_report_twf_attributes summary
```

Related Commands

- `report_power`

power_reuse_flop_ranking_data

```
power_reuse_flop_ranking_data directoryname
```

Default: `""`

Data_type: string

Specifies the name of the directory where the flop ranking data to be reused is placed.

Related Commands

- `report_power`

power_reuse_flop_ranking_data_hier

```
power_reuse_flop_ranking_data_hier blockname
```

Default: `""`

Data_type: string

Allows you to choose the block/hierarchy whose ranking data is to be used for the block-level analysis. This attribute is used when there are multiple instantiations of the same DEF block.

Related Commands

- report_power

power_scale_to_sdc_clock_frequency

```
power_scale_to_sdc_clock_frequency {true | false}
```

Default: false

Data_type: bool

Specifies to enable the VCD clock frequency to be scaled up to the SDC clock frequency. This allows you to match the VCD clock to the SDC clock to run analysis. By default, the clock frequency is scaled based on the activity file. When you set the power_scale_to_sdc_clock_frequency attribute to true, the power report and current waveforms apply the after-scaled clock frequency.

The default behavior for clock frequency scaling in the RTL and Gate level VCD flows is different, as described below:

- **RTL VCD** - By default, the clock frequency is scaled to the SDC clock frequency (power_scale_to_sdc_clock_frequency true) when the RTL VCD flow is enabled (power_enable_rtl_dynamic_vector_based true).
  You can disable clock frequency scaling by setting the power_scale_to_sdc_clock_frequency attribute to false.
- **Gate VCD** - By default, scaling of the clock frequency is disabled (power_scale_to_sdc_clock_frequency false) .
  You can enable the VCD clock frequency to be scaled up to the SDC clock frequency by setting the power_scale_to_sdc_clock_frequency attribute to true. This works only when power_use_zero_delay_vector_file is set to true, which means that the gate VCD is a zero-delay gate VCD.

Related Commands

- report_power

power_scan_chain_activity

```
power_scan_chain_activity {design_name  chain_name  activity_number} | {vectorless  activity_number}
```

Default: ""

Data_type: string

Specifies to either provide vectorless activity for all scan chains or provide a specific activity for a specific chain. This attribute allows you to specify vectorless or user-defined activity to scan chains.

The following are the two use models:

- Generate the scan control file for a specific chain:
  ```
  set_db power_scan_chain_activity {design_name  chain_name  activity_number}
  ```
- Generate the scan control file for all scan chains:
  ```
  set_db power_scan_chain_activity {vectorless  activity_number}
  ```

The power_scan_chain_activity attribute is supported only in the XP mode.

Related Commands

- report_power

power_scan_chain_name_pattern

```
power_scan_chain_name_pattern {design_name  chain_name  pattern}
```

Default: ""

Data_type: string

Specifies to automatically generate a scan-chain control file from a scan-chain based DEF file for the shift mode scan-chain analysis. This attribute allows you to create a control file for a large-sized DEF containing long chains or for multiple-DEF files. The generated scan-chain control file is saved in the power output directory.

The use model of the attribute is:

- power_scan_chain_name_pattern {all pattern} - generate scan control file for all scan chains.

Example: `power_scan_chain_name_pattern {all 11010}`

- `power_scan_chain_name_pattern {design_name chain_name pattern}` - generate scan control file for a specific chain.
  Example: `power_scan_chain_name_pattern {counter AutoChain_1_seg1_clk_rising 10010}`

Using this attribute, you can generate the control file for both flat and hierarchical DEFs. For more information, refer to Scan Control File Format.

Related Commands

- `report_power`

power_scan_control_file

`power_scan_control_file` *`filename`*

Default: `""`

Data_type: string

Specifies the scan control file name required to run the Scan Mode Analysis flow.

The scan control file contains details about the scan analysis mode used for testing. For more information, refer to Scan Control File Format.

Related Commands

- `report_power`

power_scan_multi_bit_flop_chain_type

`power_scan_multi_bit_flop_chain_type` *`type`*

Default: `liberty`

Data_type: string

Specifies the type of multi-bit scan flip-flop.

- `liberty` - specifies to use the syntax in Liberty to decide the multi-bit flip-flop type.
- `serial` - specifies to pick the first flop as the starting flop, and treat the scan chain as serial, regardless of .lib.
- `parallel` - specifies to treat the scan chain as parallel, regardless of .lib.

Related Commands

- `report_power`

power_settling_buffer

`power_settling_buffer` *`value`*

Default: `-1.0`

Data_type: string

Specifies the settling buffer time (in ps unit) between multiple windows of a VCD file. This attribute is used when you specify multiple pairs of the start time and end time for the non-overlapping multiple windows specified in an activity file (using the `read_activity_file` command).

Multiple current waveforms representing multiple VCD windows are merged into a single continuous current waveform. To capture the waveform for signals at the edge of user windows, a buffer time is added between the windows being stitched. This buffer time ensures that the stitched waveform is contiguous. The generated waveform hence has the duration of user windows and the intervening settling buffers. The default settling buffer period is 400ps. You must specify the buffer value without unit.

Related Commands

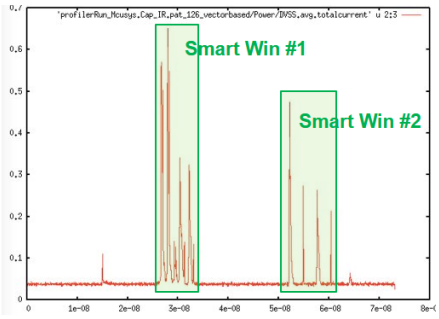
- `report_power`

power_smart_window

```
power_smart_window {true | false}
```

Default: `false`

Specifies to enable the smart window feature to extract peak power scenarios from a vector-based activity file. A smart window is a variable size window to capture maximum regions of high power dissipation. An activity file can have multiple variable-sized regions that are ranked in the descending order of power metric.



The use model of the `power_smart_window` attribute is:

```
set_db power_smart_window true
set_db power_worst_step_size value
set_db power_worst_window_type [ power | activity | delta_power | delta_activity | ir | critical_inst_power ]
```

Related Commands

- `report_power`

power_split_bus_power

```
power_split_bus_power {true | false}
```

Default: `false`

Data_type: bool

A value of `false` applies the internal power number to each individual bit.

A value of `true` divides the internal power number by bus width, before applying it to the bus bit.

Related Commands

- `report_power`

power_start_time_alignment

```
power_start_time_alignment {true | false}
```

Default: `true`

Data_type: bool

Specifies to align all the signals of the activity file at time zero. When set to `true`, the simulation period is `max(endtime - starttime)`. When it is `false`, the simulation period is `max(endtime)- min(startime)`.

Note: This attribute is not supported in the vector profiling flow. In the vector profiling flow, the start time will always be the `min(starttime)` and the end time will always be `max(endtime)`

Related Commands

- `report_power`

power_state_dependent_leakage

```
power_state_dependent_leakage {true | false}
```

Default: `true`

Data_type: bool

When set to false, power analysis performs state independent leakage power calculation.

Related Commands

- report_power

power_stateprop_ignore_unannot_pins

```
power_stateprop_ignore_unannot_pins {true | false}
```

Default: `false`

Data_type: bool

Specifies to ignore unannotated pins in the functional logic of output pins for the RTL propagation flow. This attribute is set to `true` if there are unannotated input pins for instances and such pins are used in the functional logic of output pins that are propagated. For example output pin Q is propagated with functional logic A & B where A is unannotated and might cause wrong propagation for the Q pin.

Related Commands

- report_power

power_static_multi_mode_scenario_file

```
power_static_multi_mode_scenario_file  filename
```

Default: `""`

Data_type: string

Specifies a file with information on instance scaling scenario for the static multi-mode IR analysis flow. When this parameter is specified, Power Analysis creates the multi-mode static current file that is used during rail analysis. The format of the input file is:

```
INST_NAME       PIN_NAME        SCALE_FACTOR_1       …..   SCALE_FACTOR_N
```

Here, the first column indicates the macro instance name, the second column indicates the pin name, followed by multiple current scaling factors. Each column of the scaling factor is referred to as a scenario. You must specify positive values only for scale factors.

The following is a snippet from the specified input file:

```
top/macroA     VDD     1     0.5     0.5     1
top/macroA     VDDM    0.5   0.5     0.5     1
top/macroB     VDD     0.5   1       0.5     0.5
```

If scale factors are not specified for certain scenarios, the tool will automatically use the instance's last stored scale factor value to complete current file generation.

In the following example, scale factor value `0.45` will be used in the 3rd and 4th scenario for instanceC, and scale factor value `0.35` will be used in the 4th scenario for instanceD:

```
instanceA VDD 0.45 0.55 0.65 0.31
instanceB VDD 0.31 0.5 0.67 0.21
instanceC VDD 0.25 0.45
instanceD VDD 0.31 0.25 0.35
```

Related Commands

- report_power

power_static_netlist

```
power_static_netlist  {verilog | def}
```

Default: `verilog`

Data_type: string

Specifies to perform static power analysis using a Verilog or DEF only neltist.

By default, the static power analysis is performed using the Verilog netlist as the primary netlist. Using this attribute, you can specify DEF when a DEF netlist with logical connectivity is available, and use it as primary and not consider the Verilog netlist.

This attribute is also enabled when `set_rail_analysis_config -report_power_in_parallel` is `true` for static power computation.

Related Commands

- `report_power`

power_switching_power_on_rise_only

```
power_switching_power_on_rise_only {true | false}
```

Default: `false`

Data_type: bool

Specifies to perform switching power analysis only for rise toggles.

Related Commands

- `report_power`

power_thermal_input_file

```
power_thermal_input_file  file
```

Default: `""`

Data_type: string

Specifies to read a power map file to perform thermal analysis. Thermal input file contains die area divided into tiles, and temperature value for each tile. This temperature of each tile is used to calculate power of all the instances that fall in that tile's bounding box.

The format of the thermal input file is:

```
DIE_TEMPERATURE_MAP
DIE_AREA   xmin(um) ymin(um) xmax(um) ymax(um) nx(int) ny(int)

NUMBER_OF_LAYERS    nLayers(int)
LAYER    layer_name(string)
TEMPERATURE

XCOOR    x0(0)    x0(1)    x0(2)... ...x0(nx-1)
YCOOR    y0(0)    y0(1)    y0(2)... ...y0(ny-1)

T0(0,0)    T0(1,0)    ...    T0(nx-1,0)
T0(0,1)    T0(1,1)    ...    T0(nx-1,1)

:
T0(0,ny-1)    T0(1,ny-1)          T0(nx-1,ny-1)
END_TEMPERATURE
END_LAYER
END_DIE_TEMPERATURE_MAP
```

where,

- `DIE_AREA` specifies the coordinates of the four points of die outline as well as the tile number in X and Y direction.
- `NUMBER_OF_LAYERS` is the number of layers in each die instance
- `LAYER` specifies the LEF layer name
- XCOOR and YCOOR are the coordinates of each tile
- `T0(0,0)` …. is the temperature value assigned to a tile at a specific coordinate

Related Commands

- report_power

power_thermal_leakage_temperature_scale_table_file

```
power_thermal_leakage_temperature_scale_table_file file
```

Default: ""

Specifies a file containing the user-defined temperature values and temperature scale factors for each instance. This attribute allows you to use the current file (.ptiavg) with re-adjusted leakage power values to perform thermal-aware IR drop analysis. The power_thermal_leakage_temperature_scale_table_file attribute must be specified with the power_thermal_input_file attribute to import the temperature map file generated by Celsius.

When the new attribute is specified, the generated power will include the scaled leakage power values.

The following is the format of the temperature-aware leakage scaling table:

```
#Type    Instance_Name        temp1             temp2              temp3              temp4
(Type: Lib/Cell/inst)

inst     inst_name1     scalefactor@temp1   scalefactor@temp2  scalefactor@temp3   scalefactor@temp4
inst     inst_name2     scalefactor@temp1   scalefactor@temp2  scalefactor@temp3   scalefactor@temp4
```

File Format Example:

```
#Type     Name        25    50    125    150

inst     ring/b213    1     2     5      10
inst     ring/b212    1     2     5      10
inst     ring/b211    1     2     5      10
inst     ring/b210    1     2     5      10
```

Related Commands

- report_power

power_to_x_transition_factor

```
power_to_x_transition_factor value
```

Default: 0.5

Data_type: double

Specifies how 0/1 to X transitions are counted.

Related Commands

- set_power

power_to_z_transition_factor

```
power_to_z_transition_factor value
```

Default: 0.25

Data_type: double

Specifies how 0/1 to Z transitions are counted.

Related Commands

- set_power

power_transition_factor_based_duty

```
power_transition_factor_based_duty {true | false}
```

Default: `false`

Data_type: bool

Specifies that duty for X and Z toggles is calculated using the X and Z transition factor of toggle specified using the following attributes:

- `power_from_x_transition_factor`
- `power_from_z_transition_factor`
- `power_to_x_transition_factor`
- `power_to_z_transition_factor`

The default value of `false` specifies to use the duty value given with the `set_default_switching_activity`/`set_switching_activity -duty` parameter.

Related Commands

- `report_power`

power_transition_time_method

```
power_transition_time_method  {min | avg | max}
```

Default: The default value is:

- `min` for static power analysis using the Verilog netlist (`-static_netlist verilog`).
- `avg` for static power analysis using the DEF netlist (`-static_netlist def`) and dynamic power analysis.

Data_type: string

Specifies the minimum, maximum, or average transition time method that will be used with the integrated timer or the external TWF.

Related Commands

- `report_power`

power_twf_delay_annotation

```
power_twf_delay_annotation {min | avg | max}
```

Default: `avg`

Data_type: string

Allows you to choose between min, max, or avg arrival times from the timing window file (TWF). The arrival time is annotated to the vectors processed from the RTL VCD/FSDB Zero-Delay flows.

Related Commands

- `report_power`

power_twf_load_cap

```
power_twf_load_cap {min | avg | max}
```

Default: `max`

Data_type: string

Allows you to select minimum, maximum, or average value of TWF external load or capacitance for power calculation.

Related Commands

- `report_power`

power_use_cell_leakage_power_density

```
power_use_cell_leakage_power_density {true | false}
```

Default: `true`

Data_type: bool

Specifies to use library leakage density times area (`default_leakage_power_density`), if defined, instead of the library's default cell leakage power (`default_cell_leakage_power`). This is used when leakage power for cells are missing or not defined.

Related Commands

- `report_power`

power_use_fastest_clock_for_dynamic_scheduling

```
power_use_fastest_clock_for_dynamic_scheduling {true | false}
```

Default: `false`

Data_type: bool

Specifies to use only the respective fastest clock associated with each net or pin to schedule events for a given simulation period.

Related Commands

- `report_power`

power_use_lef_for_missing_cells

```
power_use_lef_for_missing_cells {true | false}
```

Default: `false`

Data_type: bool

Allows a combination of LEF and PGV in the dynamic analysis flow. If there are cells that are common to LEF and PGV, the PGV cell will get the precedence.

Related Commands

- `report_power`

power_use_physical_partition

```
power_use_physical_partition {true | false}
```

Default: `false`

Data_type: bool

Enables tile or area-based partitioning of a design for distributed processing. When this attribute is specified, the top-level design is divided into physical tiles, which are then grouped to ensure that each group or partition has the same instance count. Each partition is considered and processed as a separate job.

This attribute is only applicable to the event-based power analysis flow (`power_method event_based`) in the XP mode. The `power_use_physical_partition` attribute must be specified with the `power_partition_count` attribute.

Example:

The following command specifies to enable area-based partitioning, and distribute the event-based analysis into four jobs:

```
set_db power_method event_based power_enable_xp true power_use_physical_partition true power_partition_count 4
report_power -distribute
```

Related Commands

- `report_power`

power_worst_case_vector_activity

```
power_worst_case_vector_activity {true | false}
```

Default: `false`

Data_type: bool

Specifies to use the worst activity value when multiple vectors are specified in the static power calculation flow.

Related Commands

- `report_power`

power_worst_step_size

```
power_worst_step_size value
```

Default: `Total simulation duration/100`

Data_type: string

Specifies the step size or resolution for vector profiling. Activity/ Power profiling is carried out for every step size that you specify.

When this attribute is used with `power_worst_window_size`, the specified step size is the resolution at which window sliding is performed. The supported time units are s, ms, us, ns, and ps. If no explicit time unit is specified, the default ns will be applied.

Related Commands

- `report_power`

power_worst_window_count

```
power_worst_window_count value
```

Default: 1 (implements single worst window)

Data_type: integer

Specifies the number of worst windows from the last vector profile run to be used for dynamic power analysis. It provides n top windows with maximum activity/power/IR. This attribute is used when you need to combine dynamic power analysis and vector profiling for multiple worst-case windows in a single run.

Related Commands

- `report_power`

power_worst_window_coverage

```
power_worst_window_coverage { top | tile }
```

Default: `top`

Specifies how the worst window type is applied for multi-window analysis in the vector profiling flow. The following are the possible options of this attribute:

- `top`: worst window selection for the full design
- `tile`: interval selection as per the worst tile power

Use Model:

```
set_db power_method event_based power_worst_window_coverage tile
report_power -out_file power.rpt -power_density_tiles 100
```

This flow should be run with `power_method event_based`.

When the `power_worst_window_coverage tile` attribute is specified, you should include any one of the following parameters to specify the total number of tiles:

- `report_power -power_density_tiles_size " 15 15 "`
- `report_power -power_density_tiles_row_column " 2 2 "`
- `report_power -power_density_tiles 100`

The software generates the `power.rpt.density` report that has the power density tiles profile report with an additional section "Intervals covering unique tiles having worst power density".

Related Commands

- `report_power`

power_worst_window_reports

```
power_worst_window_reports {full | worst | both}
```

Default: `full`

Data_type: string

Specifies to generate static power analysis reports for the specified worst window type. The possible arguments are:

- `full`: creates the static power report for the full simulation window specified with the `-start`/`-end` parameters of the `read_activity_file` command.
- `worst`: creates the static power report for the worst window only.
- `both`: creates the static power report for both the full simulation and worst windows.

The worst window report is created with '**.1**' added in the file name, as shown below:

- Static reports for full simulation: `power.rpt.avgpwr`, `power.rpt.instpwr`
- Static reports for worst window: `power.rpt.1.avgpwr`, `power.rpt.1.instpwr`

Related Commands

- `report_power`

power_worst_window_size

```
power_worst_window_size value
```

Default: `""`

Data_type: string

Specifies the duration of dynamic analysis. This attribute is used for sliding window vector profiling that involves sliding the profiling windows by using a very small resolution value to get the window with the worst current profile. `power_worst_window_size` must be specified with `power_worst_step_size`.

The supported time units are s, ms, us, ns, and ps. If no explicit time unit is specified, the default ns will be applied.

Related Commands

- `report_power`

power_worst_window_type

```
power_worst_window_type  {power | activity | delta_power | delta_activity | ir | critical_inst_power}
```

Default: `power`

Data_type: string

Specifies the window type to be used for multi-window analysis. The possible arguments are:

- `power` - worst instance power
- `activity` - worst instance activity
- `delta_power` - worst dp/dt (rate of change of power)
- `delta_activity` - worst da/dt (rate of change of activity)
- `ir` - worst IR
- `critical_inst_power` - worst power for critical/IR-sensitive instance (worst timing and IR)

Related Commands

- report_power

power_use_zero_delay_vector_file

```
power_use_zero_delay_vector_file {true | false}
```

Default: false

Data_type: bool

Enables zero delay mode in vector-based dynamic analysis to avoid pessimism in current estimation. When set to true, the software reads the cycle accurate (zero delay) VCD/FSDB file and adds the timing/delay information from the Timing Analyzer or external TWF file to the VCD/FSDB file.

Related Commands

- report_power

power_vector_based_multithread

```
power_vector_based_multithread {true | false}
```

Default: true

Data_type: bool

Specifies to enable multi-threading for the VCD/FSDB based dynamic vector-based flows.

To enable multi-threading in the vector-based flows, set this attribute to true.

Related Commands

- report_power

power_vector_profile_mode

```
power_vector_profile_mode {activity | event_based | power_density | transient}
```

Default: event_based

Data_type: string

Specifies the method used to perform vector profiling. The possible arguments are:

- activity - performs activity profiling. This parameter generates only the worst activity report, and does not generate the average power report. The name of the file is as specified using the report_power -out_file parameter.
- event_based - generates the average power report. This is the average power of all events in the user-specified window. This report includes a summary based on the power components, cell type, power rail, and clock network. The worst window report is captured in a file specified with the report_power -out_file parameter, and the report is suffixed by '.avgpower'. When -out_file is not specified, the vectorprofile.report.avgpower report file is created.
- power_density - performs area or power density profiling. For this method, power is reported for each tile of the design, where design can be considered to be physically divided into equal area tiles. By default, a design is divided in 10x10 tiles.
- transient - generates the event-based average power report and current files for the worst power window.

Related Commands

- report_power

power_write_bbox

```
power_write_bbox  {true | false}
```

Default: false

Data_type: bool

Specifies to save the boundary box of each instance, its placement, and rotation at the top level. When set to `true`, generates the power database with each instance boundary box, placement, and rotation information at the top level.

Related Commands

- `report_power`

power_write_db

```
power_write_db {true | false}
```

Default: `false`

Data_type: bool

A value of `true` creates a binary database of power results.

Related Commands

- `report_power`

power_write_default_pti_files

```
power_write_default_pti_files {true | false}
```

Default: `true`

Data_type: bool

For instances that are not hooked to any power/ground rail, the current for these instances are reflected in the default static current files:

- `static_default_ground_rail.ptiavg`
- `static_default_power_rail.ptiavg`

Related Commands

- `report_power`

power_write_dynamic_currents

```
power_write_dynamic_currents {true | false}
```

Default: `false`

Data_type: bool

Specifies to create dynamic current files either for full simulation duration or for user-specified duration. This attribute is only applicable to the event-based power analysis flow (`power_method event_based`).

Example:

```
set_db power_method event_based power_write_dynamic_currents true power_enable_state_propagation true
read_activity_file sim.vcd -format vcd
report_power -out_file power.rpt
```

Related Commands

- `report_power`

power_write_gui_db

```
power_write_gui_db {true | false}
```

Default: `false`

Data_type: bool

Specifies to create a binary database of power results in the XP mode. When set to `true`, the tool creates sliced power database file for each rail partition and saves it to the `gui.db` sub-directory under the power output directory (example: `power_dir/part_*/gui.db/rail_part_*/power.x.db` (x = 1, 2, ..., 14). The generated power database allows you to perform GUI interactive debugging using the *Power & Rail Plots* and *Power Debug* forms.

Related Commands

- `report_power`

power_write_profiling_db

```
power_write_profiling_db {true | false}
```

Default: `false`

Data_type: bool

Writes out profiling databases which can later be viewed as histograms using the SimVision interface. You can specify this parameter during both the activity and power vector profiling. The profiling databases support instance level and power/ground net histograms. It creates an output file name with the `*.trn` extension.

Related Commands

- `report_power`

power_write_simulation_db

```
power_write_simulation_db  {true | false}
```

Default: `false`

Data_type: bool

Specifies to save functional waveforms for each instance when parsing an activity file. When set to `true`, creates SimVision waveform database (SHM database) for toggle simulation used during power analysis, which can later be viewed as histograms using the SimVision interface.

The simulation database (`shmdb.trn`) is generated in the power analysis output directory.

Related Commands

- `report_power`

power_write_static_currents

```
power_write_static_currents {true | false}
```

Default: `false`

Data_type: bool

A value of `true` generates the current data files per net.

Note: When you perform static power calculation in the dynamic power analysis flow, you can use either the `power_disable_static` or `power_write_static_currents` attribute to enable static power calculation and write static current file. If only `power_disable_static` is set to `false` and `power_write_static_currents` is not set, the tool automatically sets `power_write_static_currents` to `true`. Similarly, if `power_write_static_currents` is set to `true`, and `power_disable_static` is not set, the tool automatically sets `power_disable_static` to `false`.

Related Commands

- `report_power`

power_x_count_transition_using_3_states

```
power_x_count_transition_using_3_states {true | false}
```

Default: `false`

Data_type: bool

Specifies to calculate the toggle rate using 3 states, pre-previous, previous and current states.

Related Commands

- `report_power`

power_x_transition_factor

```
power_x_transition_factor value
```

Default: `0.5`

Data_type: double

When using VCD/FSDB, one can specify how transitions to and from X are counted. These transitions are defined as shown in Table 1 below. Transitions to and from the X state will be treated as full transitions multiplied by the specified factor.

Note: 0 -> X -> 1 or 1 -> X -> 0 count as full transitions and they are not controlled by the attribute.

Related Commands

- `report_power`

power_z_transition_factor

```
power_z_transition_factor value
```

Default: `0.25`

Data_type: double

When using VCD/FSDB, one can specify how transitions to and from Z are counted. These transitions are defined as shown in Table 1 below. Transitions to and from the Z state will be treated as full transitions multiplied by the specified factor.

Note: 0 -> XZ-> 1 or 1 -> Z-> 0 count as full transitions and they are not controlled by the `attribute`.

Related Commands

- `report_power`

Table **1: Transitions from/to X and Z values and**

Transition	Definition	Default
to/from X	[0 or 1 or Z] <-> X	0.5
to/from Z	[0 or 1] <-> Z	0.25

power_zero_delay_vector_toggle_shift

```
power_zero_delay_vector_toggle_shift value
```

Default: `0`

Data_type: string

Specifies to shift the current waveform in the zero-delay VCD flow. This attribute is useful in removing the idle period for the current waveform result with a long idle period (small flat current) before the first high current peak because of delay annotation. The attribute allows to offset the idle period from the delay values.

The default value is 0ns. The supported time units are s, ms, us, ns, and ps. The default unit is ns. You can specify a negative or a positive value. A positive value means right shift in the timeline or add more delay to the original arrival time, and a negative value means left shift in the timeline or trim the unwanted idle period.

The `power_zero_delay_vector_toggle_shift` attribute enables you to make a more realistic current waveform that can be easily aligned with the other current waveforms.

Note: This attribute is similar to the `set_twf_attribute -shift_arrival_time` parameter, with the only difference that `power_zero_delay_vector_toggle_shift` supports both positive and negative values while `-shift_arrival_time` supports only a positive value.

Related Commands

- `report_power`

Scan Control File Format

The use model for the Scan Mode Analysis flow is:

```
set_db power_method dynamic_vectorbased power_scan_control_file filename
```

The format of the scan control file is:

```
MODE = [ SHIFT | VECTORLESS]
VECTORLESS_GLOBAL_ACTIVITY = <factor> [Between 0 - 1]
<chain_name> <flop_inst> <initial_state> <master_cell_name> <scale> <mode> <scan_in_pin> <scan_out_pin> <scan_en_pin>
```

Note that <`chain_name`> is optional, <`initial_state`> is optional in vector-less mode, and <`master_cell_name`>, <`scale`>, <`mode`>, <`scan_in_pin`>, <`scan_out_pin`>, <`scan_en_pin`> are optional and only needed for the first internal scan flop inside one macro.

Where,

- `Mode` specifies the mode used for scan design analysis. The two modes are: `SHIFT` and `VECTORLESS`.
- `VECTORLESS_GLOBAL_ACTIVITY` specifies the activity specification used in the `VECTORLESS` mode.
- `chain_name` is the name of the scan chain.
- `initial_state` is the initial state of all scan flops.
- `master_cell_name` is the name of the macro.
- `scale` is the scaling factor applied to the current.
- `mode` is mode name of the scan mode in the PGV view.
- `scan_in_pin` is the macro's scan_in pin name.
- `scan_out_pin` is the macro's scan_out pin name.
- `scan_en_pin` is the macro's scan_enable pin name.

propagate_activity

```
propagate_activity
[-set_net_frequency {true | false}]
```

Propagates the activity file in the database after it is read in using the `read_activity_file` command. This command propagates the activity for all primary

inputs, nets, and other devices in the design whose activity has not been previously defined through user attributes.

`propagate_activity` can be used to propagate activities in the design and check for activity annotation before running power calculation. This is not a mandatory step as execution of `report_power` will also do the same and then do power calculation based on the propagated activities.

Parameters

`-set_net_frequency {true | false}`
Specifies that activity from the generated TCF file needs to be used to capture net frequency for signal EM analysis. When this parameter is set, you do not have to read the TCF file to set net frequency. *Data_type*: enum, optional

Example

- The following commands read and propagate the activity file in the database:

  ```
  read_activity_file
  propagate_activity
  ```

Related Information

- `read_activity_file`
- "Dynamic Power and IRDrop Analysis" in the *Voltus Stylus Common UI User Guide*

query_power_data

```
query_power_data
[-help]
[<pti_files <file1[file2] ...>>]
[-average_current]
[-clock_average]
[-write_pwl]
[-frame <string>]
[-insts <inst_list>]
[-inst_list_file filename]
[-list]
[-out_dir <string>]
[-peak_current]
[-peak_time]
[-pin]
[-time_steps]
[-verbose]
[-total_current <input_current_file> ]
[-output_tap_name <tap_name>]
```

The `query_power_data` command allows you to query the binary current files (.ptiavg/.ptipeak) that Power Calculation/Rail Analysis creates. It reads the tap current data in the current files and reports various information for debugging.

Parameters

`-help`	Outputs the command usage and a brief description about the command parameters.
`<pti_files <file1[file2] ...>>`	
	Specifies the names of the VDD and VSS instance voltage pti files. *Data_type*: string, optional
`-average_current`	
	Specifies to write the average current of all instances. *Data_type*: bool, optional
`-clock_average`	
	Specifies to write the clock based current report. *Data_type*: bool, optional
`-write_pwl`	
	Specifies to write the tap current in the PWL format. You can use this parameter to view the contents of the binary data file. *Data_type*: bool, optional
`-frame <string>`	
	Specifies intervals for the clock_average report. *Data_type*: string, optional
`-insts <inst_list>`	

	Specify the list of instances to be dumped in the ASCII format, one instance per line. If not specified, it prints all instances. The `-insts` parameter is specified with the `-write_pwl`, `-peak_current`, `-peak_time`, and`-average_current` parameters. *Data_type*: string, optional
`-inst_list_file` *filename*	
	Specifies a file with the list of instances to be dumped in the ASCII format. *Data_type*: string, optional
`-list`	
	Specifies to write the tap names from the input file. *Data_type*: bool, optional
`-out_dir` <*string*>	
	Specifies the name of the output file. *Data_type*: string, optional
`-output_tap_name` <*tap_name*>	
	Specifies the name of the output tap in the new current file, which is created using the `-total_current` parameter. *Data_type*: string, optional
`-peak_current`	
	Specifies to write the peak current of all instances. *Data_type*: bool, optional
`-peak_time`	
	Specifies to write the peak current time of all instances. *Data_type*: bool, optional
`-pin`	
	Specifies to print the pin names with the instance names. The `-pin` parameter is specified with the `-write_pwl` and `-list` parameters. *Data_type*: bool, optional
`-verbose`	
	Specifies to print the report to standard output. *Data_type*: bool, optional
`-time_steps`	
	Specifies to summarize the minimum current, maximum current, average current, and total current for each interval in the data file. You can use this data to estimate which interval in a transient response might contain the worst-case data. *Data_type*: bool, optional
`-total_current` <*input_current_file*> <*output_total_current_file*>	

	Specifies to create a new current (.ptiavg) file containing the total current for all taps of a net. This parameter can be used if you have a very large current file generated by the Power Calculation engine and want to see only a total current waveform in the SimVision waveform viewer. *input_current_file* is the current file that will be read in (output from the Power Calculation engine). Use the following syntax to create a total current file: `query_power_data -total_current <input_current_file> -out_dir <output_total_current_file>` `-out_dir` is used to specify a user-defined output current filename, and is not a mandatory parameter. If not specified, the output file will be generated automatically with the name of the input file suffixed with `.ptiavg`. *Data_type*: bool, optional

Example

- The following command creates a total current waveform file `VDD` from the input file `dynamic_VDD.ptiavg`:
  ```
  query_power_data -output_tap_name vdd_tap -total_current dynamic_VDD.ptiavg -out_dir VDD
  ```

Related Information

read_activity_file

```
read_activity_file activity_file
[-end { time1 time2 ...timen } ]
[-format {vcd | tcf | saif | fsdb | phy | shm}]
[-hierarchy_separator separator ]
[-reset]
[-start { time1 time2 ...timen } ]
[-write_net_freq {true | false}]
[-block block_name ]
[-scope scope_name ]
[-scale_time scalefactor ]
[-start_time_shift value ]
[-rtl {true|false}]
[-name_mapping_rule file]
[-weight value]
[-zero_delay {true|false}]
[-cell cell_name ]
```

Specifies the name and type of activity file to be used as input. This command must be used when specifying activity files for static or dynamic power calculation.

Parameters

`-block block_name`	
	Specifies the name of the FSDB/SAIF/TCF/VCD block to map a sub-block activity file with a top level Verilog file. Provides the ability to su files based upon block instance names. The block argument is added to the FSDB/SAIF/TCF/VCD name before comparing it to the Verilo *Data_type*: string, optional
`-cell cell_name`	

	Specifies the master cell name for the activity file. This parameter allows you to support master-cell-based activity specification. That is, yo the master cell name for the activity file, instead of specifying all the instances that were instantiated from a master cell.
	Example
	Let us consider a design that has a cell named "super_filter" with four block instances "super_filter1", "super_filter2", "super_filter3",and "s
	Instance-Based Use Model:
	`read_activity_file -format VCD -block super_filter1`
	`read_activity_file -format VCD -block super_filter2`
	`read_activity_file -format VCD -block super_filter3`
	`read_activity_file -format VCD -block super_filter4`
	Master-Cell-Based Use Model:
	`read_activity_file -format VCD -cell super_filter`

`-end { time1 time2 ...timen }`	

When you use the vector-driven method of performing dynamic instance-based power-consumption calculation, you can specify the part o which you want power analysis to use for the power calculation. This option specifies the end time of this range and is used in conjunctio option.

Specifies the end time as time-value pairs to report the average power across non-overlapping multiple windows specified in the activity f hierarchy, or other part of the design that you want to analyze. Units are in seconds (`s`), milliseconds (`ms`), microseconds (`us`), nanosecond (`ps`).

Default: The time unit is defined in the first `.lib` file read during design import.

You can specify the `$worst_power_window_end` variable with the `-end` parameter to take the worst case end time from the last vector profile TCF and SAIF.

Note: You can read multiple windows in a single VCD file by specifying multiple pairs of the start time and end time for the non-overlappir specified in the activity file. The use model for reading multiple windows is:

```
read_activity_file -format VCD design.vcd -start {start1 start2 start3} -end {end1 end2 end3}
```

The *start1/2/3* and *end1/2/3* values should be in the ascending order.

Multiple current waveforms representing multiple VCD windows are merged into a single continuous current waveform. To capture the wa the edge of user windows, a buffer time is added between the windows being stitched using the `set_power_analysis_mode -settling_bu` buffer time ensures that the stitched waveform is contiguous. The generated waveform hence has the duration of user windows and the in buffers. The default settling buffer period is 400ps.

Data_type: string, optional

`-format {vcd | tcf | saif | fsdb | phy | shm}`

Specifies the net activity of the design using an activity file in the VCD, TCF, FSDB, SAIF, PHY, or SHM format. The arguments specified parameter are case-sensitive.

- The VCD file format uses the toggle count information as the basis for the power consumption calculation. These files can be in compr using the .gz extension.
- The TCF file format contains data on the switching activity of the nets in the design. The switching activity includes the toggle count inf probability of the net or pin being in the logic 1 state.
  These files can be in compressed (zipped) format using the .gz extension.

  Supports extended TCF which contains transition density for X and Z as shown in the following extended TCF example:

  "out" :"0.0 0" "0.005000 2" "0.0 0"

  The fields are defined as follows:

  Field 1: net or pin name
  Field 2: duty and transition density for transition of 0-1
  Field 3: duty and transition density for transition of X(0-X-1)
  Field 4: duty and transition density for transition of Z(0-Z-1)
- The SAIF file format contains aggregate switching activity information on the nets and/or ports in the design. It does not contain time-ba file format is used for quick average power analysis of the design.
- The FSDB file format specifies the net activity of the design using an activity file in FSDB format. Innovus supports the FSDB version u
  Use Model

  ```
  read_activity_file -format fsdb fsdbfile
  report_power
  ```

  (or)

  ```
  report_vector_profile
  ```

  Example

  ```
  read_activity_file -format fsdb test.fsdb -scope top
  ```
- The PHY (Palladium database format generated in the Palladium environment) format contains the simulation activity data generated simulation. The PHY format can be used in all vector-based power analysis flows (vector profiler, static power analysis and dynamic v analysis).
  Use Model

  ```
  read_activity_file-format phy <path to PHY database directory>
  ```

  Example

```
read_activity_file -format phy ./phy2/trace.phy -scope test
```

Notes:

- The xeDebug software must be present in the `PATH` environment. Add xeDebug in the path using the following command:
  ```
  set path = (<install_dir>/bin $path)
  ```
  The xeDebug software version should be the same as the one using which the PHY database is generated.
- The PHY database generated from the following UXE/VXE version is supported:
  ```
  UXE18.6.0 onwards
  VXE18.6.0 onwards
  ```
- When reading a PHY format activity file, you require a DPA (DPA_ToggleCountFormat) license.
- For information on error messages displayed while reading the PHY database, refer to the `xe.msg` file in the PHY database directory
- Make sure that the PHY database is not locked before invoking the Voltus software.
- Make sure that the xeDebug software is not already running on the machine.
- Ensure that the following directories are present in the top-level PHY database directory: `*.phy`, `PDB`, `cellList`, `QTDB`, `dbFiles`, and
- It is recommended that the write permission is assigned on the entire PHY database. In case the write permission cannot be grante `SWFV_FREEZE_PHY` environment variable to `1`.
- If you want to run parallel Voltus executables on the same top-level PHY directory with multiple `*.phy` databases, it is suggested to the multiple top-level directories, with links to the original PHY database. This will allow local copies of the PHY database to acquir

- The Simulation History Manager (SHM) database format is a record of the data signal changes that occur during design simulation. Th consists of a directory, typically with the "`.shm`" suffix. The directory contains two disk files, namely `*.trn` and `*.dsn`. For more informati format, refer to the *SimVision Analysis Environment* manual available on the Cadence Online Support (COS) website.
  Example
  ```
  read_activity_file -format shm  /../shm/ADDER.trn -scope adder_e/u1 -start 0ns -end 60ns
  ```

Data_type: string, optional

`-hierarchy_separator` *separator*

Specifies the separator character in the hierarchical net names, bus names, and pin names for the block or other part of the design that yo must be the same as the separator character in the design netlist.

Default: slash (/)

Data_type: string, optional

`-name_mapping_rule` *file*

Specifies to enable rule-based mapping to map RTL vectors to gate-level netlist. This parameter helps in resolving name mismatch betwe netlists.

The name mapping rule file format is:

```
Name_Mapping_Rule_file
# RTL        # Gate
<rtlstring> <gatestring>
```

where, each line is a rule. The string in the first column(RTL) is what we want to replace with the string in the second column(Gate). The r added onto the previous rules.

For example, to replace all the square `[]` brackets with under score _ for RTL-to-Gate matching, the rule file will be:

```
#RTL    #GATE

[         _

]         _
```

Note: `-name_mapping_rule` is not supported when the `power_comprehensive_automapping` attribute is set to `true`.

Data_type: string, optional

`-reset`

If `-reset` is specified, all previous activity files specified using the `read_activity_file` command will be reset and ignored.

Default: All the previous activity files specified using the `read_activity_file` command are loaded and used (They are additive).

Data_type: bool, optional

`-rtl {true|false}`

	Specifies to process the vector as an RTL vector and perform state propagation. The propagation behavior is global and the full design is vectors are zero-delay vectors so delay annotation is always done for signals from this vector file. *Default*: `false`
`-scale_time` *scalefactor*	
	Scales the FSDB/SAIF/TCF/VCD duration value by the specified scale factor. For example, an FSDB scale of 2 will double the FSDB du **Note:** The `-start` and `-end` parameters of the `read_activity_file` command are post scaled. *Data_type*: string, optional
`-scope` *scope_name*	

	Specifies the FSDB/SAIF/TCF/VCD scope, that is, the name of the module within the activity file associated with the block or other part of want to analyze.
	The scope argument is removed from the FSDB/SAIF/TCF/VCD name before comparing it to the Verilog file.
	⚠ If the scope value has backslash '\' or square brackets '[]', you must specify the scope within curly brackets {{…..}} to ensure that '\' o processed by the Tcl Interpreter. In the following example, the scope value is specified within curly brackets as it contains '\' and '[]':
	`read_activity_file -scope {{reg_based_buffer.reg_inst\/sv_xpol_trans_q_reg[0][14][7][sv_re][4]}}`
	If '\' and '[]' are not there, curly brackets are not required.
	Example
	The following command specifies the u1 module within the VCD file as the module associated with the part of the design being analyzed, `dut_5buf_full_chip` block instance as the block to map:
	`read_activity_file \`
	`-format VCD \`
	`-scope adder/u1 \`
	`-start {0ps 2000ps} \`
	`-end {1100ps 3100ps} \`
	`-block ../vcd/dut_5buf_full_chip`
	Data_type: string, optional

`-write_net_freq {true | false}`	

	This option should be set when an activity from a TCF or VCD file needs to be used to capture net frequency for signal EM analysis (`chec` addition, you must use the `check_ac_limits -use_db_freq` option to read the toggle rates from the activity file.
	Default: `false`
	Example
	The following example reads a TCF file which is used to capture net frequency for signal EM analysis:
	`read_activity_file -format tcf -write_net_freq true design.tcf`
	`check_ac_limits -use_db_freq -report signal_em.rpt`
	Data_type: enum, optional

`-start {` *time1 time2 ... timen* `}`	

	When you use the vector-driven method of performing dynamic instance-based power-consumption calculation, you can specify the part o which you want power analysis to use for the power calculation. This option specifies the start time of this range and is used in conjunctio Specifies the start time as time-value pairs to report the average power across non-overlapping multiple windows specified in the VCD file hierarchy, or other part of the design that you want to analyze. Units are in seconds (`s`), milliseconds (`ms`), microseconds (`us`), nanosecond (`ps`). *Default*: The time unit is defined in the first `.lib` file read during design import. You can specify the `$worst_power_window_start` variable with the `-start` parameter to take the worst case start time from the last vector p required for TCF and SAIF. **Note**: You can read multiple windows in a single VCD file by specifying multiple pairs of the start time and end time for the non-overlappir specified in the activity file. The use model for reading multiple windows is: `read_activity_file -format VCD design.vcd -start {start1 start2 start3} -end {end1 end2 end3}` The *start1/2/3* and *end1/2/3* values should be in the ascending order. Multiple current waveforms representing multiple VCD windows are merged into a single continuous current waveform. To capture the wa the edge of user windows, a buffer time is added between the windows being stitched using the `set_power_analysis_mode -settling_bu` buffer time ensures that the stitched waveform is contiguous. The generated waveform hence has the duration of user windows and the in buffers. The default settling buffer period is 400ps. *Data_type*: string, optional
`-start_time_shift` *value*	
	Specifies to shift the start time of the specified activity files. When you specify the `-scale_time` parameter with the `-start_time_shift` parameter, it scales the start time shift along with the start/end *Data_type*: string, optional
activity_file	The name of the activity file. *Data_type*: string, optional
`-weight` *value*	

	Specifies the weight number of the TCF file. `1.0` is the default value. The value should be a floating number that is smaller than `1.0`. This p to merge multiple TCF files at different function modes for static power estimation of a design.
	
	In the following example, TCF *file1*, *file2*, and *file3* has the weight numbers 0.3, 0.2, and 0.4, respectively.
	`read_activity_file -format TCF file1 -weight 0.3`
	`read_activity_file -format TCF file2 -weight 0.2`
	`read_activity_file -format TCF file3 -weight 0.4`
	Here, *file1*, *file2*, and *file3* will be merged together to represent the toggle and duty for the nets/pins in the design. The relative weight of 0. 0.4/0.9 would be used for static power calculation. In this example, 0.9 is the sum of weights.
	
	Data_type: string, optional

`-zero_delay {true|false}`	
	Specifies to process the vector as a zero-delay vector and perform delay annotation. *Default* : `false`

Activity Precedence

The following commands can define activity:

```
read_activity_file file
     [-format {vcd | tcf | saif} ]
     [-hierarchy_separator separator ]
     [-start time ]
     [-end time ]
     [-reset]
     [-scope scope_name ]
     [-block block_name ]

set_default_switching_activity
    [-input_activity factor ]
```

```
    [-sequential_activity factor ]
    [-period value ]
    [-duty value ]
    [-global_activity factor ]
    [-hierarchy hierarchy _name]

set_switching_activity
    [-reset]
    [-clock clock_name]
    [-period value ]
    [-activity factor | -transition_density ]
    [-net net_name | -port port_name | -pin pin_name ]
    [-duty value ]
    [-instance]
```

The precedence of activity is as follows:

1. User-Defined: Activities applied to specific nets/pins/ports
2. Activity File: Activity specification through a VCD/FSDB/SAIF/TCF format
3. Clock Gates Output Activity: Activity specification to the output of all clock gates
4. SDC/TWF constants: Set constants to a list of pins or ports for use by the timing engine (timing analysis)
5. Hierarchical Global Activity: Activity specification for a specific hierarchy
6. Global Activity: Activity specification for all instances that are part of the data network.
7. Sequential Element Activity: Activity specification applied to the output of all sequential elements.
8. Primary Input Activity: Activity specification for all primary inputs

If you specify multiple activity data for the same items, the power engine will use the one with the higher precedence.

Examples

- The following command reads the compressed ap_wait_test_pll1_mod.vcd.gz VCD file that contains the toggle count information for the power consumption calculations, specifies the crm_ap module within the VCD file as the module associated with the part of the design being analyzed, specifies the slash character (/) as the hierarchical separator for hierarchical net names, bus names, and pin names for the part of the design being analyzed, and specifies the start (180002ns) and end (189802ns) times from the VCD file for the part of the design being analyzed:

  ```
  read_activity_file -format vcd \
  -scope testbench/top/ap/mcu_platform/crm_ap \
  -hierarchy_separator \
  -start 180002ns \
  -end 189802ns \
  ap_wait_test_pll1_mod.vcd.gz
  ```

- The following command reads the compressed A.vcd.gz VCD file that contains the toggle count information for the power consumption calculations, specifies A1 as the block to map a sub-block VCD file with a block instance at the top-level, and specifies the start (180002ns) and end (189802ns) times from the VCD file for the part of the design being analyzed:

  ```
  read_activity_file -format vcd \
  -block ap/A1 \
  -start 180002ns \
  -end 189802ns \
  A.vcd.gz
  ```

- The next example specifies a VCD activity file called dmac_mac.vcd for the scope top/dma_dut.

  ```
  read_activity_file -format vcd -start 10ns -end 20ns \
  -scope top/dma_dut dmac_mac.vcd
  ```

- The following command specifies multiple pairs of the start time and end time for the multiple windows in the VCD file：

  ```
  read_activity_file \
  -format  VCD \
  -scope  adder/u1 \
  -start  {0ps 2000ps} \
  -end    {1100ps 3100ps} \
  ```

```
-block  ../vcd/dut_5buf_full_chip.vcd
```

- The following command specifies to read the RTL-level VCD activity file:

```
read_activity_file -format VCD -scope scope_top -start 300ns -end 700ns /DesignData/VCD/rtl.vcd -block inst_C1 -rtl true
set_db power_method vector_profile power_vector_profile_mode transient power_worst_window_type full power_grid_libraries
/DesignData/PGV/library_pv.cl
```

Related Information

- set_default_switching_activity
- set_switching_activity
- "Static Power, IRdrop and EM Analysis" in the *Voltus Stylus Common UI User Guide*

read_activity_map_file

```
read_activity_map_file
[-help]
[-golden {rtl | gate}]
[-gate_block block_name]
[-reset]
[-rtl_block block_name]
[-rtl_to_gate mapping_file ]
-two_column_mapping_file mapping_file
```

Specifies instance name mapping between RTL netlist and GATE level netlist. Power analysis uses this instance name mapping to annotate the output nets of this instance from the pin-based RTL VCD or TCF. The mapping file used for instance name mapping is generated by Conformal.

You must specify this command before `report_power`.

Parameters

`-gate_block block_name`	
	Specifies the GATE activity block name to map the block-level RTL mapping files to the top-level RTL activity files. The GATE block name is appended before the GATE level entries in the mapping file to match the entries in the top-level RTL activity file. *Data_type*: string, optional
`-golden {rtl | gate}`	
	Specifies whether RTL or Gate is Golden. The one not specified as golden will be considered as Revised. Currently the Conformal MatchPoint file does not specify this. *Default*: `rtl` *Data_type*: string, optional
`-help`	Outputs a brief description that includes the type and default information for each `read_activity_map_file` parameter. For a detailed description of the command and all of its parameters, use the man command `man read_activity_map_file`.
`-reset`	Specifies to reset and ignore all the previous mapping files specified using the `read_activity_map_file` command. *Default* : All the previous mapping files specified using the `read_activity_map_file` command are loaded and used. *Data_type*: bool, optional
`-rtl_to_gate mapping_file`	
	Specifies instance name mapping between RTL netlist and GATE level netlist. RTL level VCD or TCF are obtained from simulation on RTL Verilog netlist. Power analysis uses this instance name mapping to annotate the output nets of this instance from the pin based RTL VCD or TCF. The mapping file used for instance name mapping is generated by Conformal. *Data_type*: string, optional
`-rtl_block block_name`	
	Specifies the RTL activity block name to map the block-level RTL mapping files to the top-level RTL activity files. The RTL block name is appended before the RTL level entries in the mapping file to match the entries in the top-level RTL activity file. *Data_type*: string, optional
`-two_column_mapping_file mapping_file`	

	Specifies a file that contains the instance name mapping between the RTL netlist and GATE level netlist.
	This parameter can be used to specify a mapping file instead of the LEC generated mapping file (`-rtl_to_gate mapping_file`) to map points from RTL to Gate netlist. The format of the two column mapping file is:
	`#Gate name =>  # RTL name`
	`gate_inst_name1  => rtl_inst_name1`
	`...`
	Here, the first column corresponds to the gate name and the second column corresponds to the RTL name.
	Data_type: string, required

Example

- The following command specifies a mapping file rtl_map:
  ```
  read_activity_map_file -rtl_to_gate rtl_map
  ```
- The following command performs instance name mapping between RTL netlist and GATE level netlist, wherein the GATE level netlist is Golden and the RTL netlist is Revised; it specifies the mapping file MapFile.alt
  ```
  read_activity_map_file -rtl_to_gate MapFile.alt -golden gate
  ```
- The following commands appends the RTL block name and GATE block name before the RTL and GATE level entries in the mapping file to match the entries in the top-level RTL activity file:
  ```
  read_activity_map_file -rtl_to_gate LEC.top \
  -rtl_block  "core/block_top" \
  -gate_block "core/block_top"
  ```
- The following commands specify to ignore the previous mapping file (`old.map`), and use the modified mapping file (`updated.map`):
  ```
  read_activity_map_file -rtl_to_gate old.map
  read_activity_map_file -reset
  read_activity_map_file -rtl_to_gate updated.map
  ```

An example of the mapping file output from Conformal is described as follows:

```
Mapped points: SYSTEM class
1-th mapped points:
 (G) + 1 PI /x_ick
 (R) + 595 PI /x_ick
2-th mapped points:
 (G) + 2 PI /x_jreset_cp_p
 (R) + 594 PI /x_jreset_cp_p
3-th mapped points:
 (G) + 3 PI /x_mreset_cp_p
 (R) + 593 PI /x_mreset_cp_p
........
60-th mapped points:
 (G) + 4582 DFF /cpexec0/cpddecls0/gi_opls/q_reg_reg[35]
 (R) + 3856 DFF /cpexec0/cpddecls0/gi_opls/q_reg_reg_35_

61-th mapped points:
 (G) + 4583 DFF /cpexec0/cpddecls0/gi_opls/q_reg_reg[34]
 (R) + 3855 DFF /cpexec0/cpddecls0/gi_opls/q_reg_reg_34_

62-th mapped points:
 (G) + 4633 DFF /cpexec0/cpddecex0/gi_opex/q_reg_reg[21]
 (R) + 3805 DFF /cpexec0/cpddecex0/gi_opex/q_reg_reg_21_

63-th mapped points:
 (G) + 4634 DFF /cpexec0/cpddecex0/gi_opex/q_reg_reg[20]
 (R) + 3804 DFF /cpexec0/cpddecex0/gi_opex/q_reg_reg_20_

64-th mapped points:
 (G) + 4635 DFF /cpexec0/cpddecex0/gi_opex/q_reg_reg[19]
 (R) + 3803 DFF /cpexec0/cpddecex0/gi_opex/q_reg_reg_19_

65-th mapped points:
 (G) + 4636 DFF /cpexec0/cpddecex0/gi_opex/q_reg_reg[18]
 (R) + 3802 DFF /cpexec0/cpddecex0/gi_opex/q_reg_reg_18_
```

where, `G` refers to the Golden netlist name and `R` refers to the Revised netlist name.

By default, the tool assumes that the Golden netlist name refers to the RTL net name and Revised netlist refers to the GATE level net name.

Related Information

- `report_power`
- `read_activity_file`
- "RTL Activity File Flow in Static Power Calculation" in the *Voltus Stylus Common UI User Guide*

read_power_db

```
read_power_db
[-help]
-in_file {file1 file2 file3 ...}
[-hierarchy {prefix1 prefix2 prefix3 ...}]
[-hierarchy_separator "/"]
```

Restores any `power.db` file in the Voltus/Innovus session. This command can be used after restoration of a design to view the static power results or incremental report generation without having to do power analysis again.

Note: You will be able to restore the power database that you created previously, only if you created the power database using the `power_write_db` attribute. Also, the command loads power databases created in the 9.1 release only, and not in the older releases.

- The command can map a hierarchical instance to a flat netlist.
- It can restore multiple power dbs for blocks and top level, that are generated separately.
- When the information for a net or an instance is present in multiple power dbs, the last one will overwrite.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `read_power_db` parameter. For a detailed description of the command and all of its parameters, use the man command `man read_power_db`.
`-in_file {file1 file2 file3 ...}`	
	Specifies the name of the power database file. *Data_type*: string, required
`-hierarchy {prefix1 prefix2 prefix3 ...}`	
	Specifies to map each instance in the file with a prefixN/instance (for example, prefixA/inst) in the flat netlist, where '/' is the hierarchy separator. This is an optional parameter. *Default*: `all` *Data_type*: string, optional
`-hierarchy_separator "/"`	
	Specifies the separator character in the hierarchical net names, bus names, and pin names for the block or other part of the design that you want to analyze. It must be the same as the separator character in the design netlist. This is an optional parameter. *Default*: slash (`/`) *Data_type*: string, optional

Use Model

```
read_db / read_design
read_power_db -in_file power.db
report_power # for text based power reports
```

Example

For each instance in file 'file2' a prefix "A" is added to instance name such as instC, A/instC. No prefix is added to `file1' since prefix1 is none for file1.

```
read_power_db -in_file {file1 file2} -hierarchy {none A}
```

report_inst_power

```
report_inst_power
[-help] instance [-out_file filename]
```

Generates a text based report for the specified instance. This command enables you to determine how the different components of static power are calculated. You can use the report to debug static power numbers after performing power analysis (`report_power`).

This command is available through both the static and dynamic power engines.

Note: For dynamic power engine, the `report_inst_power` command does not generate text reports incrementally. If the dynamic run has been performed and you need the debug information for a static power number, you should re-run power analysis.

Parameters

`-out_file` *filename*	Writes out the static power analysis report into the file that you specify. *Data_type*: string, optional
`-help`	Outputs the command usage and a brief description about the command parameters.
instance	Specifies the instances to include in the instance power report. *Data_type*: string, required

Example

- The following command specifies an instance power report file `debug.rep` for the instance `top/i_1`:
  ```
  report_inst_power -out_file debug.rep top/i_1
  ```

```

Reports global as well as specific instance power, clock network power, clock domain power, and net switching power. It also reports the power for power domains and specific power nets. Units are reported in milliwatts.

This command starts the execution of power analysis (both static and dynamic). The `report_power` command has a character limit of 1015.

> The parameters of the `report_power` command, except `-cap`, are not supported in the dynamic only mode (specified using the `power_disable_static` attribute). These parameters are only supported in the static mode. However, `-clock_gating_efficiency`, `-register_gating_efficiency`, and `-power_domain` parameters are not supported even if the static power mode is enabled.

The `report_power` command allows generation of multiple power reports with a single `report_power` command. This allows you to generate all the static reports during dynamic analysis, and removes the need to run incremental `report_power` in static power analysis using a Verilog netlist. By default, a detailed power summary report, and a short summary will be printed at the beginning of all reports. To enable this flow, you need to specify the following parameters:

- `-out_dir`
- `-report_prefix`

The following `report_power` command parameters are supported by the multi-report flow, both in static and dynamic power analysis:

- `-cell`
- `-clock_gating_efficiency`
- `-register_gating_efficiency`
- `-cluster_gating_efficiency`
- `-net`
- `-insts`
- `-pg_net`
- `-clock_network`
- `-hierarchy`

The following parameters are not supported in the multi-report flow:

- `-cell_type`
- `-power_domain`
- `-clock_domain`
- `-clock_gating_efficiency` and `-clock_network` in the same run

> In the static power analysis flow, you can run the `report_power` command after the `read_power_db` command without loading the design. The following command is an example of the use model:
>
> ```
> read_power_db -in_file power.db
> report_power -out_dir same -report_prefix report -clock_network {all} -instances {*}
> ```
>
> The following parameters of the `report_power` command are supported without design loading:
>
> - `-cell`
> - `-cell_type`
> - `-insts`
> - `-clock_network`
> - `-clock_domain`
> - `-pg_net`
> - `-pg_net -format detailed`
> - `-hierarchy`
> - `-hierarchical_instances`

Parameters

`-cap`	Dumps out the list of net, pin, and total capacitances in three different columns. *Data_type*: bool, optional
`-cap_unit` *unit*	
	Sets the capacitance unit to be used for power report generation. The default unit is pF (picoFarads). *Data_type*: string, optional
`-cell` {*cell_list*}	
	Specifies the cells to include in the power report. Accepts wildcards (*). *Data_type*: string, optional
`-cell_list_file` *filename*	
	Specifies a file containing a list of cells that are to be included in the power reports. *Data_type*: string, optional
`-cell_type {all | {macro io combinational sequential clock_combinational clock_sequential}}`	
	Specifies the cell type to include in the power report. *Default*: `all` When you specify the cell types, `-cell_type combinational` or `sequential`, the power report now does not show the clock combinational or cl *Data_type*: string, optional
`-clock_domain` *names*	
	Specify clock domains in power reports. **Usage** `report_power -clock_domain` *name* `-out_file` *filename*
`-clock_gating_efficiency`	

	Generates a report that includes the Clock Gating Efficiency (CGE) for all clock gating instances as well as different hierarchies in the design different hierarchies is also reported.
	Clock Gating Efficiency is calculated as:
	`CGE = (toggles at clock gate output/toggles at clock gate input)`
	`Average CGE = (avg of all CGEs above)`
	When you generate a CGE report using the command `report_power -clock_gating_efficiency -out_file` *cge.rpt*, the following informatic
	• **Clock-gating Efficiency Report** - for each clock domain, it includes the toggle rate, number of registers, number of clock gates, average c registers, average toggle savings at registers, and average toggle savings histogram.
	• **Hierarchical View of Average Toggle Savings** - number of clock gates and average toggle savings for each hierarchical module in the c
	Data_type: bool, optional

`-clock_network` {`all` | {*clock_list*}}	
	Reports the power consumption of the clock network, including the power for generated clocks. Use `clock_list` to report the power consumed by specific clocks. *Default*: `all` *Data_type*: string, optional
`-cluster_gating_efficiency`	

	Specifies to generate the cluster efficiency report in the RGE report. This report gives the CGE/RGE metrics for the registers at the fanout of e instance in the design. *Data_type*: bool, optional
`-combinational_sequential_power_distribution`	
	Specifies to generate a report that gives the ratio of combinational versus sequential power for all modules of a given hierarchy. You must spe with the `-insts` parameter. *Data_type*: bool, optional
`-compress` *compression_ratio*	
	Specifies to compress the power analysis report files in the GNU Zip format. The compressed files will have the suffix `.gz`. *compression_ratio* is from 0-9. `0` indicates that the report files are not to be compressed. The compression levels vary from `1` to `9`. `1` provides f compression speed but at a lower ratio, so the file size will be larger. `9` provides the highest compression ratio but at a lower speed. *Default*: 0 *Data_type*: int, optional
`-distribute`	Enables standalone distributed power analysis. This parameter allows you to perform dynamic power analysis in the multi-CPU mode withou *Data_type*: bool, optional
`-exclude_cells {`*cell_list*`}`	
	Specifies a list of cells that should be excluded from power analysis. *Data_type*: string, optional
`-exclude_cells_file` *filename*	
	Specifies a file containing a list of cells (one per line) which should be excluded from power analysis. *Data_type*: string, optional
`-exclude_insts {`*instance_list*`}`	
	Specifies a list of instances that should be excluded from power analysis. *Data_type*: string, optional
`-exclude_instances_file` *filename*	
	Specifies a file containing a list of instances (one per line) which should be excluded from power analysis. *Data_type*: string, optional
`-float_precision` *value*	
	Sets the precision value to be used for power report generation. The default value is 4. *Data_type*: float, optional
`-format { simple | detailed }`	
	Specifies the type of report summary required for static power reporting. The possible arguments of this parameter are: • `simple` - reports the amount of power consumed by all power nets in a condensed format, breaking down power based on the switching/in components. • `detailed` - reports the amount of power consumed by all power nets in a detailed format. The detailed format includes additional informatic capacitance (`Cpin Sum`), output net capacitance (`Cnet Sum`), Total Load Capacitance (`Cpin Sum` + `Cnet Sum` = `Total Load_Cap`), maximum f and output pins (`Max_Clk_Freq`), maximum activity factor at the input and output pins (`Max_Activity`), cell name of the instance (`Cell Name`) (`C/D`), and library used in power analysis for the specific cell (`Lib`). The libraries are numbered in the header section. The name of the generated report file is `report.*.detailed.rpt`. Currently, the `-format` detailed report is only available for the `-pg_net` report *Data_type*: string, optional
`-include_sequential_in_clock`	

	Includes the leaf flip-flop power in the clock network power report. *Default*: The leaf flip-flop power will not be included in the clock network power report. *Data_type*: bool, optional
`-hierarchical_instances {`*`inst1 inst2 inst3 …`*`}`	
	Specifies to report all the power content for the specified hierarchical instances/ blocks. It reports the `Total Power` (a breakup of power compo breakup of power by cell type) of the specified block at each hierarchy. To generate a complete hierarchical instance power report, it is recommended to specify `-hierarchical_instances` with `-report_prefix`. The specified output directory. If you specify `-outfile` instead of `-report_prefix`, an instance file is output without hierarchy-level details. `-report_prefix` generates the following 3 reports: • `<`*`prefix`*`>.rpt` - reports power details for all instances in the design. • `<`*`prefix`*`>.hierpwr.rpt` - reports hierarchical power, that is, power summary, internal, switching, leakage, and total power for all hierarchica • `<`*`prefix`*`>.hierinstpwr.rpt` - reports power details for the requested block instances. **Note**: `-hierarchical_instances` must be specified with `-hierarchy` to include hierarchy-level power report. When `-hierarchical_instances hierarchy`, only top-level summary of the power consumption is written. *Data_type*: string, optional
`-hierarchy {all |` *`hierarchy_level`*`}`	
	Specifies the hierarchy level that is included in the power report. You can specify the *`hierarchy_level`* as a number that corresponds to a spe the design. A *`hierarchy_level`* of 0 specifies the top level. *Default*: `all` *Data_type*: string, optional
`-insts {`*`instance_list`*`}`	
	Specifies the instances to include in the power report. The power report provides the amount of power consumed by a specified list of hierarc instances. *`instance_list`* accepts wildcards (*) for leaf-level instances only. An instance with 0 power will not be listed in the power report. *Data_type*: string, optional
`-inst_list_file` *`filename`*	
	Specifies a file containing a list of instances that are to be included in the power reports. *Data_type*: string, optional
`-leakage`	Reports only leakage power of the design. *Data_type*: bool, optional
`-net`	Reports the net switching power, as well as the load capacitance, toggle rate, and switching values for each net in the design. *Data_type*: bool, optional

`-no_wrap`	Displays the `report_power -cell_type all` output on a single line in the report output file.
	Example
	`Instance Toggle Internal Switching Leakage Total Percentage Cell`
	`Power Power Power Power (%) Name`
	`----------`
	`dma_dut/dmamaster_dut/internal_memory/RAM4096x32/ram0 7.102e+08 5.58 0.002307 0.02424 5.607 18.19`
	`TSDN65ethernet_mac_1/rx_fifo_module_to_dma/data/dual_port_ram_4_tx_fifo/ram2P1024x32/ram`
	Data_type: bool, optional

`-nworst` *`number_of_nets`*	

	Reports the number of nets with the highest net switching power. **Note:** You must use the `-nworst` parameter in conjunction with the `-net` parameter. *Data_type*: string, optional
`-out_file` *filename*	
	Specifies the name of the report file in which the top-level summary of the power consumption information is written. You can include the dire You can convert a power report file to the gzip file format by specifying `-out_file` *filename.gz*. **Note:** If you do not specify this parameter, the software directs the power report to the command line, as well as the log file, and no power rep separate file. *Data_type*: string, optional
`-out_dir` *directory*	
	Specifies the name of the power analysis output directory that saves the power reports. The default is the current working directory. *Data_type*: string, optional
`-pg_net` {`all` | *pg_net_name_list*}	
	When set to `all`, reports the amount of power consumed by all power nets. If you specify a list, reports the power consumed by each instance that is connected to the specified list of power nets. **Note:** When using this parameter, the static power calculation engine always performs propagation and power calculation. *Default*: `all` *Data_type*: string, optional
`-pg_pin`	
	Reports power consumed by all PG pins in a design. *Data_type*: bool, optional
`-power_db_directory` *directory*	
	Specifies the location of the power database that the Power Calculation engine uses for generating standalone power reports. *Data_type*: string, optional
`-power_domain` {`all` | {*power_domain_list*}}	
	Specifies all power domains or lists power domains to be included in the report. It prints a summary of power break down for each domain be each instance in the domain. *Data_type*: string, optional
`-power_density_tiles` *value*	
	Specifies the number of tiles used for power density calculation. *Default*: `100` *Data_type*: string, optional
`-power_density_tiles_row_column` {*value1 value2*}	

Defines the number of tiles by rows * columns. *value1* is the number of tile rows and *value2* is the number of tile columns.

The following example specifies to perform power density aware vector profiling using 2 tile rows and 2 column rows:

```
set_db power_method vector_profile power_vector_profile_mode power_density power_worst_step_size 10ns
report_power  -power_density_tiles_row_column  {2 2} -time_based_report -out_file tiling1.rpt
```

The following is the vector profile report for this command:

```
Tile 0_0_0 5.06 5.33 14.95 14.555
Tile 1_0_1 14.95 5.33 24.84 14.555
Tile 2_1_0 5.06 14.555 14.95 23.78
Tile 3_1_1 14.95 14.555 24.84 23.78
...
...
```

Data_type: string, optional

`-power_density_tiles_size {value1 value2}`

Defines the absolute tile size. *value1* is the horizontal width of a tile (in micron) and *value2* is the vertical height of a tile (in micron).

Data_type: string, optional

`-power_unit unit`

Sets the power unit to be used for power report generation. The default unit is mW (miliAmps).

Data_type: string, optional

`-print_memory_power`

Specifies to report power values for the memory and macro cells under separate groups (`Memory` and `Macro`).

The following is a snapshot of the power report showing separate groups for memory and macro cells:

Group	Internal Power	Switching Power	Leakage Power	Total Power	Percentage (%)
Sequential	0.4031	0.1283	0.006583	0.538	18.38
Memory	0.1624	0.004345	0.011	0.1778	6.074
IO	0	0	0	0	0
Physical-Only	0	0	2.91e-06	2.91e-06	9.945e-05
Combinational	0.8711	1.05	0.01579	1.937	66.2
Clock (Combinational)	0.002302	0.01018	7.654e-05	0.01255	0.429
Clock (Sequential)	0.01177	0.008387	0.000347	0.0205	0.7005
Macro (non-mem)	0.2317	0.007259	0.001234	0.2402	8.208
Total	1.682	1.209	0.03503	2.926	100

Data_type: bool, optional

`-group_type user_defined_group_name`

Specifies to report power (internal/switching/leakage/total) for a user-defined collection of cells that are stated under a power group in the pov
You can use the following Tempus commands to create power groups:

- `define_property` - define a property.
- `set_property` - assign the defined property (group type) and its value (power group) to a list of cells.

The use model of the `-group_type` parameter is:
`report_power -group_type user_defined_group_type`

Here, *`user_defined_group_type`* is the user-defined power group type applied to a list of cells in a design. When the `-group_type` parameter i
command reports power for the power groups associated with the specified group type in the power summary report.

Example:

The following command defines the `poly_bias` property (group type) on library cells:
`define_property poly_bias -obj_type lib_cell -type string`

The following commands apply the property `poly_bias` with the group name `P0` and `P10` to the collection of cells:
`set_property [get_lib_cells -of_objects [get_cells -hierarchical * -filter {ref_name=~*PB0*}]] poly_bias  P0`
`set_property [get_lib_cells -of_objects [get_cells -hierarchical * -filter {ref_name=~*PB10*}]] poly_bias  P10`

The following command reports power for the user-defined power groups that are associated with the property `poly_bias`:
`report_power -out_file basic_group_type.rpt -group_type poly_bias`

The following is a snippet of the power report that shows the user-defined power groups `P0` and `P10` that are associated with the property `poly`
the existing groups (sequential, macro, IO, and so on):

```
User Group                      Internal   Switching     Leakage       Total  Percentage
                                Power      Power         Power         Power  (%)
-------------------------------------------------------------------------------------
P0                               0.01498   0.0002017     0.01765     0.03283       15.63%
P10                               0.1268     0.04026     0.01011      0.1772       84.37%
-------------------------------------------------------------------------------------
Total                            0.1418     0.04047     0.02776        0.21         100%
-------------------------------------------------------------------------------------
```

```

-------------------------------------------------------------------------------------
```

Data_type: string, optional

`-register_gating_efficiency`

Generates a report that includes the Register Gating Efficiency (RGE) and Data Aware Gating Efficiency (DAGE) for all sequential cell instan
hierarchies in the design. Average RGE and DAGE for different hierarchies is reported. It also displays a section on ICG cluster information, t
about registers at the fanout of each ICG instance along with their RGE metrics.

Register Gating Efficiency is calculated as:

```
RGE = 1 - (toggles at register clock pin/root clock toggles)
```

When you generate an RGE report using the command `report_power -register_gating_efficiency -out_file rge.rpt`, the following infor
displayed:

- **Register-gating Efficiency Report** - for each clock domain, it includes the toggle rate, number of registers, number of clock gates, averag
registers, average toggle savings at registers, and average toggle savings histogram.
- **Register Gating Opportunities Report** - this report is sorted based on the Q/CLK toggle ratio. When a register's Q/CLK ratio is greater tha
every other clock cycle. However, when it is less than 25%, there is a gating opportunity to reduce power.

Data Aware Gating Efficiency is calculated as:

```
DAGE = 1 - ((toggles at clock pin - 2*toggles at Q pin)/(root clock toggles))
```

Data_type: bool, optional

`-report_prefix prefix`

Specifies a prefix for the report in which the top-level summary of the power consumption information is written. All the new report names will the detailed summary will be *prefix*.rpt.

Data_type: string, optional

-sort {internal | switching | leakage | total}

Sorts the instance-based power consumption data by internal, switching, leakage, or total power.

Default: total

Data_type: string, optional

-thermal_conductivity_inputs *file_name*

Specifies a file containing the thermal conductivity value for layers. You can use this parameter to include the thermal conductivity value of th the power map file:

- Silicon
- Metal
- Dielectric
- Micro Bump (optional for 3DIC design)
- Fill material in micro bump layer (optional for 3DIC design)

The thermal conductivity file format is:
Section 1 (layer type based thermal conductivity value)

```
#default
$layer_type1 $thermal_conductivity_parameter1
$layer_type2 $thermal_conductivity_parameter2
...
```

Section 2 (layer name based thermal conductivity value)

```
#perlayer
$layer1_name $thermal_conductivity_parameter1 $dielectric_thermal_conductivity_1
$layer2_name $thermal_conductivity_parameter2 $dielectric_thermal_conductivity_2
...
```

Here,

- You can either specify both Section 1 (layer type based) and Section 2 (layer name based), or specify one of the two sections. If both secti layer name based section takes precedence over layer type based section.
- The layer name based section has thermal conductivity value and its dielectric layer's thermal conductivity value for each metal/via layer.
- If section 2 has no parameters defined, the software will use the default parameters defined in the section 1.

Example:
###default

```
Metal      430
Silicon    250
Dielectric 0.6
```

###Perlayer

```
Metal1    430    0.4
Via1      410    0.5
Metal2    390    0.5
Via2      410    0.5
...
```

For information on the thermal conductivity input file and power map file, refer to the "Static Power, IRdrop and EM Analysis" chapter in *Voltu*

Data_type: string, optional

-thermal_leakage_temperature {*temp1 temp2 temp3 …*}

Defines the temperature to calculate leakage for the power map file.

Data_type: string, optional

-thermal_leakage_temperature_scale_table {*$temp1 $scalefactor1 $temp2 $scalefactor2 $temp3 $scalefactor3 .....*}

Specifies the global scale factor for a temperature value to enable scaling of the leakage power values coming from the input dotlib file. This p to scale the power values only at certain specific temperatures.

This parameter allows you to generate a multi-temperature leakage power map table from a single input dotlib file in the power map generatio `thermal_leakage_temperature_scale_table` and `-thermal_leakage_temperature_scale_table_file` are mutually exclusive.

Data_type: string, optional

`-thermal_leakage_temperature_scale_table_file` *filename*

Specifies a file containing the user-defined temperature values and the corresponding scale factors for each library, cell, or instance. The form

```
#Type Name temp1 temp2 temp3 temp4
Lib    library_name   scalefactor@temp1   scalefactor@temp2  scalefactor@temp3   scalefactor@temp4
Cell   cell_name      scalefactor@temp1   scalefactor@temp2  scalefactor@temp3   scalefactor@temp4
inst   instance_name  scalefactor@temp1   scalefactor@temp2  scalefactor@temp3   scalefactor@temp4
```

This parameter allows you to generate a multi-temperature leakage power map table from a single input dotlib file in the power map generatio `thermal_leakage_temperature_scale_table` and `-thermal_leakage_temperature_scale_table_file` are mutually exclusive.

File Format Example for the Type Lib:

```
#Type Name          25 50 125 150
Lib   fast          1 2 10 100
Lib   bufao         1 2 10 100
Lib   header        1 2 10 100
Lib   pso_ring_wc   1 2 10 100
```

Data_type: string, optional

`-thermal_material_file` *filename*

Specifies the name of a file containing the user-specified substrate layer thickness. The layer thickness value for the power map generation fl user-specified value or derived from the technology file. If both the values are available, the user-specified value takes precedence.

Data_type: string, optional

`-thermal_power_map_bottom_layer` *layer_name*

Writes zero metal density tables for layers lower than the user-specified layer in the power map file. This parameter prevents duplication of m when merging the top and block thermal power map files.

Data_type: string, optional

`-thermal_power_map_density_table_tiles {`*Xint Yint*`}`

Specifies the number of tiles in the X and Y directions for the metal density table.

Data_type: string, optional

`-thermal_power_map_file` *file_name*

Generates the power map file with the specified name in the output directory.

Data_type: string, optional

`-thermal_power_map_format {simple | stack }`

Generates a tile-based power map file in the simple or stack format to perform accurate thermal analysis. You must use the stack format to su package for thermal analysis.

Data_type: string, optional

`-thermal_power_map_format_version {new|default}`

	Determines whether to generate the default or the new power map file format. When set to `new`, the power map file format with non-uniform tile power (`-thermal_power_map_power_table_tiles`) and metal density tables (`-thermal_power_map_density_table_tiles`) can be generated. The following are the features of the new report format: • version number added to the header "Version : 2020.0" • nx/ny under the "DIE_AREA" section has been removed • XCOR/YCOR for each layer has been removed • nx/ny has been added for the POWER and METAL_DENSITY sections *Data_type*: string, optional
`-thermal_power_map_header_include_file` *filename*	
	Specifies a file that contains comments or additional information to be included in the header section of the power map file. *Data_type*: string, optional
`-thermal_power_map_power_table_tiles {`*Xint Yint*`}`	
	Specifies the number of tiles in the X and Y directions for the power table. *Data_type*: string, optional
`-thermal_power_map_si_unit {true | false}`	
	Specifies to change chip thermal power map units to SI in the thermal power map file. This parameter was introduced to support the thermal p used by foundry. When this parameter is set to `true`, the values for all the power map parameters (length, power, and thermal conductivity) w units. • **Length Unit:** default is `um` and SI is `m` • **Power Unit**: default is `mW` and SI is `W` • **Metal/Silicon Thermal Conductivity Unit**: default is `mW/(um * C)` and SI is `W/(m * C)` *Default* : `true` *Data_type*: string, optional
`-thermal_power_map_tiles {`*xint yint*`}`	
	Defines the tile number in the X and Y direction. By default 10*10 will be used. *Data_type*: string, optional
`-thermal_power_map_top_layer` *layer_name*	
	Writes zero metal density tables for layers higher than the user-specified layer in the power map file. This parameter prevents duplication of m when merging the top and block thermal power map files. *Data_type*: string, optional
`-threshold` *value*	
	Filters out the instances whose total power dissipation is more than the specified value. Units are in milliwatts. *Default*: `0` *Data_type*: string, optional
`-threshold_voltage_group { all |` *group_name*`}`	
	Reports leakage by voltage threshold group in the power report. This parameter supports the argument `all` (default value) or any other string, *Default*: `all` *Data_type*: string, optional
`-time_based_report`	
	Writes out a detailed VCD profiling report into the file that you specify. *Data_type*: bool, optional

`-time_unit` *unit*	
	Sets the time unit to be used for power report generation. The default unit is ns (nanoseconds). *Data_type*: string, optional
`-toggle_rate`	
	Specifies to dump out instance-based activity to the outfile. The toggle rate for each instance is based on the clock frequency to which it belo are reaching the instance, then the fastest clock is used as a reference. *Data_type*: bool, optional
`-use_geometry_cell_size {true | false}`	
	Specifies whether to use the actual geometry or placement bounding box for macro PGV cell size during generation of tile-based power map used when a macro's power is distributed across multiple tiles. When this parameter is set to `true`, the geometry-based bounding box will be generation and power will be distributed evenly across tiles. *Data_type*: bool, optional
`-view` *view_name*	
	Specifies the active timing view that was created using the multi-mode multi-corner (MMMC) `set_analysis_view -setup|-hold` command. Po performed for the specified view. The command prints the `MMMC` view name in the output file even if you do not specify the `-view` parameter. If `report_power -view` *view_name* is set, it will override the view set in the `power_view` attribute. However, if you specify the `set_analysis_vie leakage` parameters, then the view set using these `set_analysis_view` command parameters has higher priority over the `report_power -view` *Default*: Uses current view in Innovus. *Data_type*: string, optional

Examples

- The following command reports the amount of power consumed by the clock nets clk and test_clk (including leaf flip-flop power) and writes the output information to a power report file named clk_pwr.rep:
  ```
  report_power -clock_network{clk test_clk} \
  -include_sequential_in_clock -out_file clk_pwr.rep
  ```
- The following command reports the amount of power consumed down to hierarchy level 3 from the top and writes the output information to a power report file named hier.rep:
  ```
  report_power -hierarchy 3 -out_file hier.rep
  ```
- The following command compresses the power report file pg_net.rep with gzip:
  ```
  report_power -out_file pg_net.rep.gz
  ```
- The following command reports the amount of power consumed by leaf-level instances that match ECO* and writes the output information to a power report file named inst.rep:
  ```
  report_power -insts ECO* -out_file inst.rep
  ```
- The following command reports the amount of power consumed by all cells that match buf*6 and writes the output information to a power report file named cell.rep:
  ```
  report_power -cell buf*6 -out_file cell.rep
  ```
- The following command reports the amount of power consumed by all I/O and sequential cells and writes the output information to a power report file named cell_type.rep:
  ```
  report_power -cell_type {io sequential} -out_file cell_type.rep
  ```
- The following command sorts the instance-based power consumption data by leakage power and writes the output information to a power report file named sort.rep:
  ```
  report_power -sort leakage -out_file sort.rep
  ```
- The following command reports the total power of all instances whose total power dissipation is less than 1 milliwatt and writes the output information to a power report file named threshold.rep:
  ```
  report_power -threshold 1 -out_file threshold.rep
  ```
- The following command reports the net switching power, load capacitance, toggle rate, and switching values for each net in the design, reports the top 100 nets with the highest net switching power, and writes the output information to a power report file named net.rep:
  ```
  report_power -net -nworst 100 -out_file net.rep
  ```

- The following command reports the amount of power consumed by each power domain and writes the output information to a power report file named pd_all.rep:
  ```
  report_power -power_domain all -out_file pd_all.rep
  ```
- The following command reports the amount of power consumed by each power domain PD2 and writes the output information to a power report file named pd.rep:
  ```
  report_power -power_domain PD2 -out_file pd.rep
  ```
- The following command reports the amount of power consumed by view view_max-hp-max-lp1 and writes the output information to a power report file named view.rep:
  ```
  report_power -view view_max-hp-max-lp1 -out_file view.rep
  ```
- The following command reports the amount of power consumed by each instance connected to power nets vdd and vdd1 and writes the output information to a power report file named pg_net.rep:
  ```
  report_power -pg_net {vdd vddl} -out_file pg_net.rep
  ```
- The following command reports the leakage for the threshold voltage group HVT:
  ```
  report_power -leakage -threshold_voltage_group { HVT }
  ```
- The following command writes out a detailed vector profiling report for the combinational and macro cell types in the `vectorprofile.rpt` file:
  ```
  report_power -time_based_report -out_file vectorprofile.rpt -cell_type {combinational macro}
  ```
- The following command is an example of generating multiple reports at the same time:
  ```
  report_power -out_dir static_power -report_prefix design -net {name1} -insts {inst_name}
  ```
  The following reports will be generated:
  ```
  static_power/design.rpt
  static_power/design.netpwr.rpt
  static_power/design.instpwr.rpt
  ```
- The following command generates a power map file in the simple format for the specified tile:
  ```
  report_power -out_file powermeter.txt -thermal_power_map_file powermap.txt -thermal_power_map_tiles { 4 6 } -thermal_power_map_format simple
  ```
- The following command specifies to report the power content for the `inst1` hierarchical instance in the `report.hierinstpwr.rpt` report:
  ```
  report_power -output static -report_prefix report -clock_network {all} -instances * -no_wrap -hierarchy {all} -hierarchical_instances inst1 -cell_type {all}
  ```
- Example of the output of the power report.
  ```

report_unannotated_nets

```
report_unannotated_nets
[-help]
[-file filename]
-type annotationType
```

Shows the percentage of nets annotated by a specific type and also prints the names of all nets that are not annotated by that type. Annotation information is stored on a per-file basis for activity, VCD, TCF, and user commands to provide detailed annotation reports when requested.

`report_unannotated_nets` can be invoked multiple times with different report types (`-type`). You must specify this command before `report_power`.

Parameters

`-file filename`	Specifies the text file name that includes the annotation report information. If no file is specified, the report will be written to the default output file `annotation_type.log`, where *type* is taken from the `-type` argument specified. *Data_type*: string, optional
`-help`	Outputs the command usage and a brief description about the command parameters.
`-type annotationType`	The type can be any of the following: • `all` Shows annotation reports for all types. • `activity` Shows annotation data for all types of activity specifications including TCF, VCD, SDC, TWF, and user commands that set activity. • `cap` Shows annotations from the SPEF files. • `fsdb` Shows annotations from the FSDB files. • `saif` Shows annotations from the SAIF files. • `tcf` Shows annotations from the TCF files. • `timing` Shows annotations from the TWF files. This type is applicable only to the dynamic power analysis flow. • `vcd` Shows annotation from the VCD files. *Data_type*: string, optional

Example

- The following command dumps the nets in the netlist that are missing in the vcd file:
  ```
  report_unannotated_nets -type vcd -file vcd.log
  ```
  The net names are written in the file `vcd`.log.
- The following command dumps the nets in the netlist which do not have an activity annotated from any source (VCD/TCF/SDC/TWF/user defined) and writes the net names in the file `unannotatednets.log`:

```
report_unannotated_nets -type all -file unannotatednets.log
```

Related Information

reset_power_activity

`reset_power_activity`

Resets all activity in the database. You can specify this command to reset all activity and power information in a given session.

> You can reset activity from an activity file using `read_activity_file -reset`, reset activity for nets, pins, and ports using `set_switching_activity -reset`, and reset the default switching activities using `set_default_switching_activity -reset`.

Parameters

None

Related Information

- `read_activity_file`
- `set_default_switching_activity`
- `set_switching_activity`
- "Dynamic Power and IRDrop Analysis" in the *Voltus Stylus Common UI User Guide*

set_default_switching_activity

```
set_default_switching_activity
[-black_box_density value]
[-black_box_duty value]
[-duty value]
[-global_activity factor]
[-hierarchy hierarchy_name]
[-input_activity factor]
[-period value]
[-sequential_activity factor]
[-reset]
[-reset_type { global_activity | seq_activity ... }]
[-clock_gates_enable {activity_factor}]
[-integrated_clock_gate_ratio num]
[-combinational_clock_gate_ratio num]
[-clock_gates_output_ratio num]
[-clip_activity_to_domain_freq {true | false}]
[-clock_gates_output {activity_factor}]
[-name activity_name]
[-macro_activity factor]
```

Specifies the switching activity for all primary inputs, nets, and other devices in the design whose activity has not been previously defined through user attributes, the toggle count format (TCF) file, the value change dump (VCD) file, or the tracing of the clock network.

You can use this command to specify user-defined activities at the design level.

Parameters

`-black_box_density value`	
	Specifies to set the default transition density on all the output pins of all blackboxes in the design. The `-black_box_density` and `-black_box_duty` parameters must be used together. If one or both of these parameters are not specified, then the average transition density from all the input pins of the blackboxes.
`-black_box_duty value`	
	Specifies to set the default duty on all the output pins of all blackboxes in the design. The `-black_box_density` and `-black_box_duty` parameters must be used together. If one or both of these parameters are not specified, then the average transition density from all the input pins of the blackboxes.
`-clip_activity_to_domain_freq {true | false}`	
	Specifies to perform domain-based activity clipping. This parameter clips data paths to 1x frequency whereas the clock networks are still at 2x f allows you to have more control to determine the rate of clipping with respect to frequency. *Data_type*: string, optional
`-clock_gates_enable {activity_factor}`	
	Specifies the activity at the enable pin(s) of the clock gating cells. *Data_type*: string, optional
`-clock_gates_output {activity_factor}`	

	Specifies the activity at the output pin(s) of the clock gating cells. This works for both ICGs as well as combinational clock gating cells. **Example**: `set_default_switching_activity -global_activity 0.02 -clock_gates_output 2.0` (clock is transparent) transition_density of clock gate output is calculated by: `(1/clock_domain_frequency) * clockgateOutputsActivity = 1/(0.431*e-9) * activity_factor` In this case, transition_density = `clock_domain_frequency * clockgateOutputsActivity` = 1e9/0.431 * 2 = 4,640,371,200 *Data_type*: string, optional
`-clock_gates_output_ratio` *num*	

	Specifies to control transition density at the output pin(s) of the integrated and combinational clock gating cells. This parameter is equivalent to `-integrated_clock_gate_ratio` and `-combinational_clock_gate_ratio` together with the same value.
	For example, the `set_default_switching_activity -clock_gates_output_ratio 0.6` is equivalent to `set_default_switching_activity -inte 0.6 -combinational_clock_gate_ratio 0.6`.
	Note: This parameter has a cascading effect when there are multiple levels of ICG cells on the clock path. For example, when `-clock_gates_ou` the first level ICG cell will have 0.5 ratio of the root clock's toggle density, the second level ICG cell will have 0.5*0.5=`0.25` ratio of the root clock third level ICG cell will have 0.5*0.5*0.5=`0.125` ratio of the root clock's toggle density, and so on.
	Note: For dynamic power analysis, fastest clock on the path is used for calculating output toggle density. However, for static power analysis, w toggle densities is used.
	Example for static power analysis:
	`set_default_switching_activity -global_activity 0.02 -clock_gates_output_ratio 1.0`
	Transition density for either a combinational or an integrated clock gating cell with 'N' inputs is calculated by:
	`output_pin_transition_density = (summation) weighted_input_transition_density = clock_gates_output_ratio * [(duty_input_pin1 (duty_input_pin2 * Td_input_pin2) + ... + (duty_input_pinN * Td_input_pinN)]`
	Given a 2:1 clock Mux and assuming duty of 0.5 for all input pins:
	Td is the toggle density for each input pin of the instance `(Td_pinSel , Td_pinI0 , Td_pinI1).`
	`output_pin_transition_density = 1.0 * [0.5 * Td_pinSel + 0.5 * Td_pinI0 + 0.5 * Td_pinI1]`
	Data_type: string, optional

`-combinational_clock_gate_ratio` *num*	
	Specifies to set the propagation ratio for combinational clock gate cell outputs. When specified, this parameter sets the output activity of any ins combinational clock gating cell to *num* times the fastest transition density arriving on the instance's clock inputs. This parameter cannot be spec parameter. **Notes:** • This parameter does not apply to combinational clockgates with a constant data input, that is, a select pin tied low. • For dynamic power analysis, fastest clock on the path is used for calculating output toggle density. However, for static power analysis, weig toggle densities is used. For a detailed static power analysis example, refer to '`-clock_gates_output_ratio`', limiting calculations only to co
`-duty` *value*	Specifies the duty cycle, which is the probability that the signal is a logical 1. **Note:** You must specify the `-period` parameter when assigning a duty. *Default*: `0.5` (equivalent to a 50 percent duty cycle) *Data_type*: string, optional
`-global_activity` *factor*	
	Specifies the average number of times that all unset nodes switch in a clock cycle. If not specified the fastest domain frequency will be used un domains. **Note**: Due to activity precedence, the `-global_activity` and `-sequential_activity` parameters of the `set_default_switching_activity` comn exclusive. If both the parameters are specified, `-global_activity` takes precedence. *Data_type*: string, optional
`-hierarchy` *hierarchy_name*	
	A hierarchical name that the global activity is being assigned to. If not provided, the whole design is assumed. *Data_type*: string, optional

`-integrated_clock_gate_ratio` *num*	
	Specifies to set the propagation ratio for integrated clock gate (ICG) cell outputs. When specified, this parameter sets the output pin of all identif times the fastest transition density arriving on clock inputs of the instance. *Data_type*: string, optional This parameter cannot be specified with the `-hierarchy` parameter.
`-input_activity` *factor*	
	Specifies the average number of times that a primary input switches in a clock cycle. It can be any positive number. *Default*: `0.2` (Switches once every five clock cycles.) *Data_type*: string, optional
`-macro_activity` *factor*	
	Specifies the activity factor for macros in a design. The allowed values for this parameter are between `0` to `1`. If you set the macro activity to `.30`, 30% of macros in the design would be selected for switching in a given cycle during dynamic simulation. Wh specified for the static power analysis, all output pins of the macros are assigned the specified activity. *Default*: `0.2` *Data_type*: string, optional
`-name` *activity_name*	

	Allows you to set the activity level for the specified jitter activity name. You can define a low/high activity level for jitter analysis.
	Examples:
	`set_default_switching_activity -name low -clock_gates_output 0 -global_activity 0.01`
	`set_default_switching_activity -name high -clock_gates_output 2 -global_activity 0.2`
	Data_type: string, optional

`-period` *value*	Specifies the default operating period (1/frequency). It is the period that the activity is referenced to. If not specified, the software uses the *domi* The specified period will only be applied to nets that do not have reference clock (ref_clock) associated with the net. If no clock is specified, the software generates an error and prompts you to enter one. Units in seconds (`s`), milliseconds (`ms`), microseconds (`us`) picoseconds (`ps`). **Note:** If you enter the period as a negative number, the software reverts back to using the default frequency. *Default*: The time unit is defined in the first `.lib` file read during design import. *Data_type*: string, optional
`-sequential_activity` *factor*	
	Specifies the activity of outputs of the sequential logic. This value will be used at the output ports of flops for propagating activity. If the sequential activity is not specified, propagation will be done for the full design starting from the input ports. *Data_type*: string, optional
`-reset`	Resets all specified options back to default values. *Data_type*: bool, optional
`-reset_type { global_activity | seq_activity ... }`	
	Specifies to selectively reset the global specifications. **Note:** You must use the `-reset_type` parameter in conjunction with the `-reset` parameter. *Data_type*: string, optional

Activity Precedence

See "Activity Precedence" in `read_activity_file`.

Examples

- The following command specifies that the primary inputs in the design will switch once every ten clock cycles, with a clock period of 7520 ns and a duty cycle of 50 percent:
  ```
  set_default_switching_activity -input_activity 0.10 -period 7520ns -duty .5
  ```
- The following command specifies that all unswitched nodes in the design will switch once every ten clock cycles, with a clock period of 7520 ns and a duty cycle of 50 percent:
  ```
  set_default_switching_activity -global_activity 0.10 -period 7520ns -duty .5
  ```
- The next example defines the switching activity, sequential activity, and the period:
  ```
  set_default_switching_activity -input_activity 0.2 -period 10 \
      -sequential_activity 0.1
  ```
- The next example sets the default global activity to 0.5 for the hierarchy dma_dut:
  ```
  set_default_switching_activity -global_activity 0.5 -hierarchy dma_dut
  ```
- The following command resets the sequential and global activity specification:
  ```
  set_default_switching_activity -reset -reset_type
  {sequential_activity,global_activity}
  ```

set_dynamic_power_simulation

```
set_dynamic_power_simulation
[-period value]
[-resolution value]
[-reset]
[-activity_pattern {time1 activity_name1 time2 activity_name2 .... }]
```

Specifies the period and resolution for a dynamic power simulation. This command is used to specify the simulation period in the dynamic vectorbased/vectorless and power-up flows.

Parameters

-activity_pattern {*time1 activity_name1 time2 activity_name2 .... }*	
	Divides the total simulation time based on the windows given in the `activity_pattern` parameter. For a particular window, it uses the defined activity specified with the `set_default_switching_activity` command. When the user-defined low cycle and high cycle time is specified for the input/sequential activity, all the clocks will be in the low or high cycle until completely past the cycle transition time. Following is the use model of this parameter: • `set_default_switching_activity` **`-name low -input_activity 0.05 -sequential_activity 0.1`** `-clock_gates_output 0.2` • `set_default_switching_activity` **`-name high -input_activity 0.1 -sequential_activity 0.2`** `-clock_gates_output 2.0` • `set_dynamic_power_simulation -period 15ns -resolution 50ps` **`-activity_pattern {0 high 5ns low 10ns high}`** Here, high activity is used for 0ns to 5ns, low activity is used for 5ns to 10ns, and high activity is used for 10ns to 15ns. *Data_type*: string, optional
`-period` *value*	Specifies the simulation period that dynamic power analysis will use. The supported time units are `s`, `ms`, `us`, `ns`, and `ps`. If no explicit time unit is specified, the default `ns` (nanosecond) will be applied. *Data_type*: string, optional
`-reset`	Resets all specified options back to default values. *Data_type*: bool, optional
`-resolution` *value*	Specifies the transient time step size or resolution. The supported time units are `s`, `ms`, `us`, `ns`, and `ps`. If no explicit time unit is specified, the default `ps` (picosecond) will be applied. *Data_type*: string, optional

Examples

- The following command sets up the period and resolution for a dynamic simulation:
  ```
  set_dynamic_power_simulation -period 5ns -resolution 100ps
  ```

set_instance_temperature_file

```
set_instance_temperature_file
file
[-reset]
```

Specifies the instance temperature file to support thermal-aware leakage. You can use this command to do thermal-aware power calculation. Based on the temperature specified in the file, the software will calculate temperature and leakage power.

In the presence of a trilib set, the internal and leakage power will be interpolated as the per the given temperature specification.

Parameters

file	Specifies the name of the instance temperature file. *Data_type*: string, optional
-reset	Resets the temperature file. *Data_type*: bool, optional

```

Specifies the amount of power for all or part of the design. This command is used to define user-specified power on cells and instances. You must specify this command before `report_power`.

The `set_power` command can accept a cell/instance list using the `get_cells`/`get_lib_cells` commands. You can use the `get*` commands to create a collection of cells/instances whose name matches the supplied pattern list. Therefore, providing you with the flexibility in providing lists through use of regular filter patterns. This feature is supported in both static and dynamic analysis engines.

Parameters

`-ascii_power_file` *filename*	
	Specifies the name of an instance list file. This file contains the list of instances in the following format: *instance_name power_value <pin_name>* Here, • *instance_name* is the instance name to which power is to be distributed. • *power_value* is the power value for the instance in watts. • *pin_name* is an optional argument to specify the pin name. When specified, allows you to assign power to the specific pin • The three fields should be in one line, and each instance should be in a new line. *Data_type*: string, optional
`-base_cells` *cell_name value*	

	Specifies the cell name. If the cell or instance name is not specified, the power will be distributed to all rails. If you want to specify power for a group of cells/instances, use the `get_cells`/`get_lib_cells` commands. The `-base_cells` p commands to create a collection of cells/instances whose name matches the supplied pattern list. For example, `-base_cell 2mw` *Data_type*: string, optional
`-cap value`	
	Specifies the capacitance value to all instances with nets more than or equal to the fanout limit (`-fanout_limit`). *Data_type*: string, optional
`-clocks {all|clock_name}`	
	Specifies the power value for clock networks. You can specify the power value for a specific clock network or the clock netw whole design. **Note:** This parameter cannot be used with the `-base_cells`, `-insts` and `-pg_net` parameters. *Data_type*: string, optional
`-custom_macro_pwl_waveform filename`	
	Specifies to use a custom trigger file to apply instance or cell PWL waveforms. Given one master cell PWL waveform, the so generate scaled PWL waveforms of the other companion cells defined in the trigger file proportional to the cell internal powe **Note**: This parameter must be used with `set_power -dynamic_switch_pattern` in the vectorless flow. For more information on the trigger file format, see Trigger File Format. *Data_type*: string, optional
`-default_dynamic_pgv_mode { mode_name }`	
	Specifies the current characterization mode to be used during dynamic power and jitter analyses. This parameter can be sp with multiple functional modes. When this parameter is specified, the Power Calculation engine uses this preferred mode in scheduling the switching event saves these events in the trigger file. The use model of this parameter is: `set_power -base_cells {} | -insts {} -default_dynamic_pgv_mode { mode_name }` This parameter is mutually exclusive to the `-dynamic_switch_pattern` parameter. If a cell or instance has both the `-dynamic_ preferred_ddv_mode` parameters defined in the same Tcl script, `-dynamic_switch_pattern` takes higher priority. *Data_type*: string, optional
`-dynamic_switch_event { switching_events }`	
	Specifies the switching events for cells, instances, and pins along with their rise and fall time. `switching_events` is a string "r" or "f", where "r" is for rise toggle and "f" is for fall toggle. The `-dynamic_switch_event` parameter should not be specified w
`-dynamic_async_mode { mode_name }`	

	Specifies to trigger asynchronous macros based on the length of the PWL waveform to create a single continuous waveform you to specify the asynchronous mode for an instance or a cell. The start and end of the PWL saved in the PGV must have s order to avoid sudden jump in the current.
	Use model:
	`set_power -dynamic_async_mode {mode} [-insts {name} | -base_cells {name}]`
	Example:
	`set_power -base_cells pll -dynamic_asynchronous_mode {READ_C}`
	Here, power analysis will trigger the `READ_C` mode and automatically splice the waveform based on its length.

`-dynamic_switch_pattern pattern`	

	Specifies stimulus pattern on the pins of an instance and cell. Specify this parameter only in the dynamic mode for the type : The *pattern* is applied to all pins (input and output) on the instance/cell. It is a string. *pattern* specifies the switching pattern. If there is more than one clock domain with timing windows on a pin, only the windo be used, and the pattern will be applied to that clock period. It is a string of 0, 1, r, and f values. 0 for cycles not to switch and for rise only and f for fall only. The pattern string should include enough digits to cover all of the clock cycles in the simulation period. If there are not enou padded with 0 values at the end. If there are too many, the pattern will be truncated to the number of applicable cycles. Tran the center of each applicable timing window. **Notes** • 0 and 1 is supported only in the probability-based vectorless flow. It is not supported in the state-propagation-based vecto based flow. • In case of macros, you can specify the mode names, that is, which mode switches in which clock cycle -dynamic_switch_ - }. You can specify "-" to indicate that instances will not switch in a particular clock cycle. If "-" is the first value in the string of v you must insert a space before "-", as shown below: • no switching: -dynamic_switch_pattern { - - } • no switching in the 1st clock period: -dynamic_switch_pattern { - r } Examples: In the following example, instance will not switch in the 4th clock cycle: set_power -dynamic_switch_pattern { f r f - r } In the following example, the mode write will switch in the 1st clock cycle, the mode read will switch in the 2nd and 4th cloc modes will switch in the 3rd clock cycle: set_power -dynamic_switch_pattern { write read - read } **Note**: Wildcards are supported only for -dynamic_switch_pattern with -pin. When -dynamic_switch_pattern is applied for without the -pin parameter, wildcards are not supported. *Data_type*: string, optional
-exclude_clocks	Excludes clock networks when specifying a scale factor or power specification for the whole design. This parameter cannot be used with the -base_cells, -insts and -pg_net parameters. *Data_type*: string, optional
-exclude_ddv_modes {*pattern_list*}	
	Excludes the current characterization (or Dynamic Detailed View) modes that match with the specified patterns. This param the modes to be switched, instead of switching all the current characterization modes defined in the power-grid view. **Use Model** set_power -insts|-base_cells *name* -include_ddv_modes {*pattern_list*} Here: • *pattern_list* is a list of mode names, separated by space or comma • the instance, cell, and pattern names can contain wildcard characters *Data_type*: string, optional
-fanout_limit *value*	
	Specifies the fanout limit for nets. If an instance has nets more than or equal to the fanout limit, its switching/internal/leakage When this parameter is specified, the user-defined power value is applied to all the driver instances that have nets more tha limit. *Data_type*: string, optional
-force	

	Specifies to apply the `set_power` command even if there are Verilog mismatches. For dynamic or DEF-based static analysis to apply `set_power` to the DEF instances that do not exist in Verilog. *Data_type*: bool, optional
`-help`	Outputs the command usage.
`-include_ddv_modes {`*`pattern_list`*`}`	
	Includes only the current characterization (or DDV) modes that match with the specified patterns. This parameter allows you switched, instead of switching all the current characterization modes defined in the power-grid view. **Use Model** `set_power -insts|-base_cells` *`name`* `-include_ddv_modes {`*`pattern_list`*`}` Here: • *`pattern_list`* is a list of mode names, separated by space or comma • the instance, cell, and pattern names can contain wildcard characters *Data_type*: string, optional
`-internal`	Specifies the target internal power of the design, cell, or instance. To specify internal power for cells and instances, you can parameter in conjunction with the `-base_cells` or `-insts` parameter. *Data_type*: bool, optional
`-insts` *`inst_listvalue`*	
	Specifies the instance name. If the cell or instance name is not specified, the power will be distributed to all rails. *Data_type*: string, optional
`-leakage`	Specifies the target leakage power of the design, cell, instance, or power net. To specify leakage power for cells and instances you can use `-leakage` option in conjunction with `-base_cells` or `-insts` op To specify leakage power of a certain power net in the design you can use `-pg_net` option along with `-leakage` option. *Data_type*: bool, optional
`-no_propagation`	
	Specifies that the user-defined switch pattern is applied only after state-propagation is complete. The use model of the comm `set_power -dynamic_switch_pattern {`*`pattern`*`} -no_propagation` The `-no_propagation` parameter must be specified with the `-dynamic_switch_pattern` parameter. When the `-no_propagati` the dynamic power engine performs state-propagation first, and then overrides the single instance switching event by the us pattern without any further propagation. *Data_type*: bool, optional
`-pg_net` *`railname`*	
	Optional. The specified power or pwl for the cell, instance or design is applied to the specified rail. When not specified, the p all the rails associated with the instance. This option is generally used for MSMV cells. When this option is not specified the behavior is different for pwl and power options. When not specified and power option is applied for the whole design, cell, or instance. When not specified and pwl option is used, the pwl is applied to every rail of *Data_type*: string, optional
`-pg_pin {`*`pg_pin`*`}`	
	Specifies the switch pattern for a specific PG pin of an instance. This parameter must be specified with the `-dynamic_switch` *Data_type*: string, optional
`-pin` *`pin_name pin_power`*	

	Specifies pin-wise power numbers for a specific instance. This parameter allows you to control the power assigned to powe instance. Following is the use model of this parameter:
	`set_power -insts <inst_name> -pin <VDDA> <pin_power>`
	`set_power -insts <inst_name> -pin <VDDB> <pin_power>`
	Data_type: string, optional

`-pwl_waveform`	Specifies that power argument (`power | pwl`) is a waveform rather than a power number. *Data_type*: bool, optional
`-repeat`	Repeats dynamic switch pattern of all the clock cycles in the simulation period. *Data_type*: bool, optional
`-reset`	This parameter causes all previous `set_power` commands to be ignored. Note: You can selectively reset the instance/cell specifications. In addition, you can also selectively reset the cell and instar of objects through the `get_cells` and `get_lib_cells` commands. *Data_type*: bool, optional
`-scale_factor value`	

	Scales the power value by the specified scale factor. This parameter allows you to set a user-defined scale factor in the trig dynamic current of the PGV.
	To modify the scale factor, use the `-reset` parameter with the `-scale_factor` parameter.
	Example:
	`set_power -leakage -reset  -scale_factor 5 -instance A`
	You can use the following power scaling commands in the power-driven optimization flow when running Voltus within the Ir
	• `set_power -scale_factor <value> -leakage` => scale the leakage power value by the specified scale factor
	• `set_power -scale_factor <value> -internal` => scale the internal power value by the specified scale factor
	• `set_power -scale_factor <value> -switching` => scale the switching power value by the specified scale factor
	• `set_power -scale_factor <value>` => scale the leakage, internal, and switching power values by the specified scale fac
	When specifying these commands in the optimization flow, you must not specify any other parameter of the `set_power` comn
	Optimization Flow Example:
	`set_db opt_power_effort high`
	`set_db opt_leakage_to_dynamic_ratio 0.5`
	`set_power -scale_factor 15 -internal`
	`set_power -scale_factor 20 -switching`
	`report_power`
	Data_type: string, optional

`-signal_net netname`	
	Specifies the signal net name for power assignment. When this parameter is specified, the driver instances connected to the assigned the user-defined power value. *Data_type*: string, optional
`-slew value`	
	Specifies the slew value to all instances with nets more than or equal to the fanout limit (`-fanout_limit`). *Data_type*: string, optional
`-static_mode { custom_label_name | mode_name }`	

	Specifies the mode name or the custom label name associated with a cell or instance for computing instance current from P voltage multi-frequency (MvMf) modes. This current is used to compute the instance's internal power, and its switching and components would be set to zero. The use model of this parameter is given below: `set_power -insts -static_mode READ` If you specify custom label of a static MvMf mode, currents would be taken from it directly. Alternatively, if only mode name is cell/instance, the software snaps to the nearest custom label defined within this mode, based on the instance's voltage and currents. *Data_type*: string, optional
`-sticky`	Applies the simulation based PWL waveform as is, to the specified cell/instance for dynamic power analysis. Use this option only if you have specified `-pwl_waveform`. *Data_type*: bool, optional
`-switching` *value*	
	Specifies the target switching power of the design, cell, or instance. To specify switching power for cells and instances, you parameter in conjunction with the `-base_cells` or `-insts` parameter. *Data_type*: bool, optional
`-trigger_time_adjustment` *time*	
	Specifies to adjust the trigger time of the current waveforms for the various functional modes (read/write/idle) of the custom r allows you to start the waveform before the trigger time (negative time support), as shown below:  The specified time will be applied to the computed trigger time for each mode in the trigger files generated by power analysi trigger time (from timing window/vector) is computed as 1ns, 2ns, and 3ns, and if you specify `set_power -trigger_time_adj` software will adjust the trigger time to .9ns, 1.9ns, and 2.9ns. *Data_type*: string, optional

value	Specifies power in milliwatts during static power calculation or piecewise linear (`-pwl`) current waveform, during dynamic pc instance. The command accepts a unit specification (e.g. 10w).
	The format of the PWL waveform is:
	`{time1 current1 time2 current2 ...time_n current_n}`
	Time is in ns and current in mA.
	Example:
	`set_power -pwl_waveform -pg_net {} -base_cells BUFX2MTL {0 0 10 0 10.1 5 10.5 0}`
	Here, at `0ns` its value is `0mA`, at `10ns` its value is `0mA`, at `10.1ns` its value is `5mA`, and so on.
	Data_type: string, optional

Examples

- The following command sets power for vdd rail to 10 milliwatts:
  ```
  set_power -pg_net vdd 10mw
  ```

- The following command sets a power value of .005 milliwatts on power net vdd for instance clkin_neg_L14_I1:
  ```
  set_power -pg_net vdd -insts Top/A/clkin_neg_L14_I1 .005
  ```
- The following command sets a power value of .005 milliwatts for any cell named INVX2 in the design:
  ```
  set_power -base_cells INVX2 .005mw
  ```
- The following command defines a piecewise linear waveform of {0 0 10 0 10.1 5 10.5 0} for the cell of type BUFX2MTL for all power rails.
  ```
  set_power -pwl_waveform -pg_net {} -base_cells BUFX2MTL {0 0 10 0 10.1 5 10.5 0}
  ```
- The following command specifies the leakage power for the cell DFFRX1.
  ```
  set_power -leakage -base_cells DFFRX1 10mw
  ```
- The following commands specify the target leakage power for power nets VDD1 and VDD2.
  ```
  set_power -leakage -pg_net VDD1 100mw
  set_power -leakage -pg_net VDD2 200mw
  ```
- The following command specifies the PWL description of current for the instance SEHD130_1024X32X1CM8. The -sticky option tells the software to use the specified PWL simulation based waveforms as is.
  ```
  set_power -pwl_waveform -insts SEHD130_1024X32X1CM8 -sticky {0 0 1 1 2 2 7 0}
  ```
- The following command scales the total power of the instance i_1 by a scale factor of 2:
  ```
  set_power -scale_factor 2 -insts i_1
  ```
- The following command sets the total power of the design to 20mw while keeping the clock network power the same:
  ```
  set_power 20mw -exclude_clocks {all}
  ```
- The following command assigns a switching power of 3mw to all instances of the cell AND1:
  ```
  set_power -base_cells AND1 -switching 3mw
  ```
- The following command assigns 2mw power to all cells that match the specified pattern:
  ```
  set_power -base_cells[get_lib_cells NAND*] 2mw
  ```
- The following command specifies that mode1 switches in the first cycle, mode2 switches in the third cycle and no switching in others:
  ```
  set_power -dynamic_switch_pattern { mode1 0 mode2 0 }
  ```
- The following command resets power of all cells that match the specified pattern:
  ```
  set_power -reset -base_cells[get_cells A/*]
  ```
- The following command does not schedule DDV mode `scan*`:
  ```
  set_power -base_cells { * } -exclude_ddv_modes { scan* }
  ```
- The following command does not schedule DDV mode `scan*` for instance "`A1`":
  ```
  set_power -insts { A1 } -exclude_ddv_modes { scan* }
  ```
- The following command only schedules DDV mode names with the `*read*` and `*write*` pattern:
  ```
  set_power -base_cells { * } -include_ddv_modes { *read*, *write* }
  ```
- The following commands specify the toggle time for the pin names Q7 and Q6:
  ```
  set_power -dynamic_switch_event { 1.1ns r 5.5ns f } -insts clk_b_i2 -pin Q7
  set_power -dynamic_switch_event { 2.2ns r 6.6ns f } -insts clk_b_i2 -pin Q6
  ```

Trigger File Format

For specifying a custom trigger file, you must use the `-custom_macro_pwl_waveform` parameter. The format of the trigger file is:

Trigger File Format	Description
#Cell names	
`MASTER CELL <cellname1>`	Name of the reference cell.
`COMPANION_CELLS <cellname1 cellname2 … >`	Name of the cells that will use scaled PWL from the master cell.
#Mode and conditional details for trigger	

MODE_NAME <*mode1*> CONDITIONAL_INPUT <conditional input statement for cellname1>	Mode name and conditional input statement for the cell. Conditional input of current for the given mode.
CONDITIONAL_PIN <pin_name> (rise|fall|both)	Conditional pin statement for the cell. Signal pin for which the tool should rise or fall.
CONDITIONAL_STIMULUS_FILE <usim1.txt>	Simulation vector detail in the given mode.
USER_PWL_FILE <pwl1.txt>	User-specified PWL file that contains information about the PWL waveforms (power/ground currents). For an example of a PWL file, see PWL Format Example.
END_MODE	End mode section
#End cell section	
END	End cell section

Example of a Custom Macro Power Trigger File

```
MASTER_CELL        SRAM_A1
COMPANION_CELLS    { SRAM_A2, SRAM_A3, SRAM_A4, SRAM_A5 }
      MODE_NAME WRITE
               CONDITIONAL_INPUT = ( !SD & !SLP & !CEB & !WEB )
               CONDITIONAL_PIN = CLK { RISE }
               USER_PWL_FILE write_rise.txt
       END_MODE
      MODE_NAME READ
               CONDITIONAL_INPUT = ( !SD & !SLP & !CEB & WEB )
               CONDITIONAL_PIN = CLK { RISE }
               USER_PWL_FILE read_rise.txt
       END_MODE
      ...
END
```

Example of "USER_PWL_FILE" (Multiple regions)

```
UNIT CURRENT mA
UNIT TIME ns
       NET VSS
               REGION { 0 0 0.1 -1 0.2 -2 0.3 -3 0.4 -10 0.5 -50 0.6 -40 0.7 -30 0.8 -20 1 0 2 0 3 0 3.9 0 4 -0.1 4.5 -0.2 5 -4 5.5 -3 6 -2
7 0 }
       NET VDD
               REGION { 0 0 0.1 1 0.2 2 0.3 3 0.4 10 0.5 50 0.6 40 0.7 30 0.8 20 1 0 2 0 3 0 3.9 0 4 0.1 4.5 0.2 5 4 5.5 3 6 2 7 0 }
       NET VDDM
               REGION { 0 0 0.1 1 0.2 2 0.3 3 0.4 10 0.5 50 0.6 40 0.7 30 0.8 20 1 0 2 0 3 0 3.9 0 4 0.1 4.5 0.2 5 4 5.5 3 6 2 7 0 }
```

set_power_calculation_temperature

```
set_power_calculation_temperature
temperature
```

Sets the temperature for static power calculation.

In the presence of a trilib set, the internal and leakage power will be interpolated as the per the given temperature specification.

Parameters

temperature	Specifies the temperature for static power calculation. **Note:** The static power calculation software gets the temperature value of each instance from the following sources (in order of precedence): • Instance temperature file • `set_power_calculation_temperature` command • The current operating condition temperature

Related Information

- power Category Attributes
- "Static Power, IRdrop and EM Analysis" in the *Voltus Stylus Common UI User Guide*

set_power_include_file

```
set_power_include_file
file
[-reset]
```

Specifies a power analysis include file. You can use the `set_power_include_file` command to specify certain commands of the dynamic engine which do not have a Voltus equivalent. For more information on these commands, refer to the Power Analysis Options chapter.

The `set_power_include_file` command is required only if the `power_static_netlist` attribute is set to `def`.

Note: The `set_power_include_file` command is used to pass the legacy power analysis commands and `report_power` command options only in the dynamic mode (vectorbased and vectorless). If the `power_method` attribute is set to `static`, the `set_power_include_file` command is ignored.

Parameters

file	Name of the include file. This file will include all commands that can not be translated to Voltus commands. In addition, you can also include the `report_power` command options to generate different power reports. *Data_type*: string, optional
`-reset`	Resets all options back to default values. *Data_type*: bool, optional

Examples

- The following command specifies a power include file of `power.inc`:
  ```
  set_power_include_file power.inc
  ```
- The following example shows the contents of the `power.inc` file.
  # power.inc file must use the pre-defined design and power objects as "design" # and "ChipPwr" respectively. The power output object is not supported.
  ```
  design calCellsToIgnore BUFX1
  ChipPwr calRailVoltage VDD 1.2

  report_power -net -outfile Net.rep
  report_power -cell {INV*} -outfile Invpower.rep
  ```

Related Information

- power Category Attributes
- "Dynamic Power and IRDrop Analysis" in the *Voltus Stylus Common UI User Guide*

set_power_output_dir

```
set_power_output_dir dir
[-reset]
```

Specifies the name of the directory that power information will be output to.

Parameters

dir	Specifies the name of the directory in which power analysis output information is written. *Data_type*: string, optional
-reset	Resets all options back to default values. *Data_type*: bool, optional

Examples

- The following command specifies the output directory called `static_power_AvallOn` in which the power information is written.
  ```
  set_power_output_dir static_power_AVallOn
  ```

Related Information

- power Category Attributes

set_switching_activity

```
set_switching_activity
[-reset]
[-activity factor | -transition_density transition_density ]
[-clock clock_name]
[-duty value]
[-inst instance_name]
[-net net_name | -port port_name | -pin pin_name | -input_port port_name |-output_port port_name | -bidir_port port_name]
[-period value]
[-integrated_clock_gate_ratio num]
[-combinational_clock_gate_ratio num]
[-hierarchy hierarchy_name]
[-scale value]
[-cell cell_name]
[-force]
[-quiet]
[-unclocked]
```

Specifies activity for nets, pins, and ports. This command is used to specify user-defined activities at specific pins/nets/ports. You must specify this command before `report_power`.

The `set_switching_activity` command can accept a net/pin/port list using the `get_pins`/`get_ports`/`get_nets` commands. You can use the `get*` commands to create a collection of nets/pins/ports whose name matches the supplied pattern list. Therefore, providing you with the flexibility in providing lists through use of regular filter patterns. This feature is supported in both static and dynamic analysis engines.

Parameters

`-activity` *factor*	
	Specifies the activity for a net, pin, or top-level port. The *activity_factor* specifies the number of times the net, pin, or port switches in a clock cycle. Enter any positive number. If if the activity is set to 0.5, the activity happens once for every two clock cycles. If the activity is set to 2.0, the activity happens two times per clock cycle. There is no default value. *Data_type*: string, optional
`-bidir_port` *port_name*	
	Specifies the name of the bidirectional port. The port names are in the following format: bidirectional*-port*. This parameter supports wildcards (*). *Data_type*: string, optional
`-cell` *cell_name*	
	Specifies the activity on all output pins for all instances of the specified cell. *Data_type*: string, optional
`-clock` *clock_name*	
	Assigns global activity factor to all nets in domain of *clock_name* if and only if *clock_name* is the fastest clock in the domain set. To use this option, `-clock` and `-activity` must be used without any other options. *Data_type*: string, optional
`-combinational_clock_gate_ratio` *num*	
	Specifies to set the propagation ratio for combinational clock gate cell outputs. When specified, this parameter sets the output activity of any instance that is identified as a combinational clock gating cell to *num* times the fastest transition density arriving on the instance's clock inputs. You can specify this ratio for a net, pin, port, or clock. This parameter cannot be specified with the `-hierarchy` parameter. *Data_type*: string, optional
`-force`	

	Specifies to apply user-defined activities for specific nets, pins, and ports, without having to load a verilog netlist. When a verilog netlist is not specified, the `set_switching_activity` command does not support the `-cell` parameter, and the net/pin/port list using the `get_pins/get_ports/get_nets` commands. *Data_type*: bool, optional
`-transition_density` *transition_density*	
	Specifies the transition density for a specific net, pin, or top-level port. Transition density specifies the number of transitions per second. it can be any positive number. There is no default value. **Note:** If you specify the `-transition_density` parameter in conjunction with the `-period` parameter, the software issues a warning and the `-period` parameter is ignored. *Data_type*: string, optional
`-duty` *value*	
	Specifies the duty cycle, which is the probability that the signal is a logical 1. The `-period` parameter must be specified to add a duty. If not specified, the `set_switcing_activity` command picks this value from the external TWF or SDC through the Common Timing Engine (CTE). *Default*: Uses the duty specified by the `set_default_switching_activity` command if the `-duty` parameter is not specified. *Data_type*: string, optional
`-hierarchy` *hierarchy_name*	
	A hierarchical name that an activity is being assigned to. *Data_type*: string, optional
`-integrated_clock_gate_ratio` *num*	
	Specifies to set the propagation ratio for integrated clock gate (ICG) cell outputs. When specified, this parameter sets the output pin of all identified ICG instances to *num* times the fastest transition density arriving on clock inputs of the instance. You can specify this ratio for a net, pin, port, or clock. This parameter cannot be specified with the `-hierarchy` parameter. *Data_type*: string, optional
`-input_port` *port_name*	
	Specifies the name of the input port. The port names are in the following format: *input-port*. This parameter supports wildcards (*) *Data_type*: string, optional
`-inst` *instance_name*	
	Specifies the activity on a specific instance. *Data_type*: string, optional
`-net` *net_name*	
	Specifies the name of the net. This parameter supports wildcards (*). *Data_type*: string, optional
`-output_port` *port_name*	
	Specifies the name of the output port. The port names are in the following format: *output-port*. This parameter supports wildcards (*) *Data_type*: string, optional
`-period` *value*	

	Specifies the period that the activity is referenced to. If not specified, a default frequency is used. If a negative number is specified, the static power calculation engine reverts back to the default frequency. Units in seconds (`s`), milliseconds (`ms`), microseconds (`us`), nanoseconds (`ns`), or picoseconds (`ps`). **Note:** If you specify the `-period` parameter in conjunction with the `-transition_density` parameter, the software issues a warning and the `-period` parameter is ignored. *Default*: The time unit is defined in the first `.lib` file read during design import. If the time unit is not defined, the period specified in the `set_default_switching_activity` command is used. *Data_type*: string, optional
`-pin` *pin_name*	
	Specifies the name of a pin. The pin names are in the following format: *instance-name + default-hierarchyarchy-separator + pin*. This parameter supports wildcards (`*`) *Data_type*: string, optional
`-port` *port_name*	
	Specifies the name of a top-level port. The port names are in the following format: *top-level-port*. This parameter supports wildcards (`*`) *Data_type*: string, optional
`-quiet`	Suppresses all error and warning messages generated when the `set_switching_activity` command is run. *Data_type*: bool, optional
`-reset`	Resets all specified options back to default values. The reset option should be the first option specified, otherwise all options set prior to this will be reset. **Note:** You can selectively reset the pin/port/net specifications. In addition, you can also selectively reset the pin/port/net specifications of a list of objects through the `get_pins`/`get_ports`/`get_nets` commands. *Data_type*: bool, optional
`-scale` *value*	
	Specifies to scale frequencies of the specified clock domains. This parameter allows you to scale transition densities of all instances associated with the clock domain by the specified scale factor to compute internal and switching power. This parameter must be specified with the `-clock` parameter. The `-scale` parameter is only applicable to static power and dynamic vectorless power analysis. *Data_type*: string, optional
`-unclocked`	Applies *activity* (with reference *period*) to all nets that have no clock domain (`-unclocked`). To use this option, `-unclocked` must be used with `-activity` and `-period` with no other options. *Data_type*: bool, optional

Activity Precedence

See "Activity Precedence".

Examples

- The following command specifies that net `n189` will switch once every ten clock cycles, with a clock period of `7520ns` and a duty cycle of 50 percent:
  ```
  set_switching_activity -net n189 -activity 0.10 -period 7520ns -duty .5
  ```
- The following command sets the transition density of port `out_cpu_top` to `20000` transitions per second:
  ```
  set_switching_activity -port out_cpu_top -transition_density 20000
  ```
- The following command applies a transition density of `1e+06` to all input ports that match the specified pattern:
  ```
  set_switching_activity -port[get_ports "mode*" -filter {port_direction==in}] -transition_density 1e+06
  ```
- The following command resets the previously defined activity on all nets that match the specified pattern:
  ```
  set_switching_activity -reset -net[get_nets n23*]
  ```
- The following command specifies the clock gate ratio for the clock domain `sys_clk`:

```
set_switching_activity -clock sys_clk -integrated_clock_gate_ratio 0.8 -combinational_clock_gate_ratio 0.5
```

- The following command specifies to set the default switching activity for all other clock domains of the design:
  ```
  set_default_switching_activity -integrated_clock_gate_ratio 1.0 -combinational_clock_gate_ratio 1.0
  ```

set_twf_attribute

```
set_twf_attribute
[-help]
[-clock clock_name]
[-clock_edge {rise | fall}]
[-clock_frequency value]
[-fall_delay {min:max or single_value}]
[-fall_slack {min:max or single_value}]
[-fall_slew {min:max or single_value}]
[-net net_name]
[-pin pin_name]
[-reset]
[-rise_delay {min:max or single_value}]
[-rise_slack {min:max or single_value}]
[-rise_slew {min:max or single_value}]
[-type {data | clock}]
[-shift_arrival_time time]
[-clear_twf_attribute]
```

Specifies static timing analysis information. The command allows you to override timing parameters, such as slew and clock, on desired pins/nets from an existing timing windows file (TWF).

Parameters

`-clear_twf_attribute`	
	Specifies to reset the TWF file values for a specific pin or net. The use model of this parameter is: `set_twf_attribute -clear_twf_attribute -pin/-net <name>` *Data_type*: bool, optional
`-clock clock_name`	
	Specifies the clock name. This indicates that the nets and pins that are timing constrained have arrival times (timing windows) caused by this clock. *Data_type*: string, optional
`-clock_edge {rise | fall}`	
	Specifies the capturing clock edge direction: rise or fall. *Data_type*: string, optional
`-clock_frequency value`	
	Specifies the clock frequency. You must specify the `-clock` parameter along with the `-clock_frequency` parameter to assign the clock for which the frequency needs to be updated. *Data_type*: string, optional
`-fall_delay {min:max` or `single_value}`	
	Specifies the fall delay for the pin. This parameter is not supported in the static power analysis flow. *Data_type*: string, optional
`-fall_slack {min:max or single_value}`	
	Specifies the fall slack for the pin. *Data_type*: string, optional

`-fall_slew {min:max or single_value}`	
	Specifies the fall slew for the pin. *Data_type*: string, optional
`-net net_name`	
	Specifies the net name. The `-net` and `-pin` parameters are mutually exclusive. *Data_type*: string, optional
`-pin pin_name`	
	Specifies the pin name. The `-net` and `-pin` parameters are mutually exclusive. *Data_type*: string, optional
`-reset`	Resets all specified options back to default values. *Data_type*: bool, optional
`-rise_delay {min:max or single_value}`	
	Specifies the rise delay for the pin. This parameter is not supported in the static power analysis flow. *Data_type*: string, optional
`-rise_slack {min:max or single_value}`	
	Specifies the rise slack for the pin. *Data_type*: string, optional
`-rise_slew {min:max or single_value}`	
	Specifies the rise slew for the pin. *Data_type*: string, optional
`-shift_arrival_time time`	

	Specifies to filter the idle period of the current waveform in the dynamic power analysis flow. This parameter is useful in removing the idle period of the current waveform result with long idle period (small current) before the 1st high current peak because of TWF delay annotation. The parameter allows to offset idle period from the TWF delay values.
	The use model is given below:
	`set_twf_attribute -shift_arrival_time 3.0ns`
	The default value is 0ns. The supported time units are s, ms, us, ns, and ps. The default unit is ns. You must specify a positive value only. A positive value means shift right in the time line or add more delay to the original arrival time.
	You can specify the `-clock` parameter to limit the changes to a clock domain. In addition, you can further add the `-pin/-net` parameter to limit the changes to a block. The following are examples of shifting different delays to different clock domains because different clocks may have different clock insertion delays at the top level:
	`set_twf_attribute -shift_arrival_time 1.2ns -clock clk_a`
	`set_twf_attribute -shift_arrival_time 2.3ns -clock clk_b`
	If a clock domain is not specified, the delay will be applied to all the specified nets/pins.
	Note: The final rise/fall delays for the annotated nets/pins after the shift has been applied are reported under the "Shift Arrival Time Report" section of the detailed TWF Attributes report. This report is generated using the `power_report_twf_attributes detailed` attribute.
	The following example illustrates a sample command and report snippet:
	Command:
	`set_twf_attribute -shift_arrival_time 3.0ns`
	Report:
	`Clock domain annotated`
	`  - CK1_1`
	`  - CK1_2`
	`  - CK2_1`
	`  - CK2_2`
	`Rise Delay  Fall Delay  Net Name`
	`1e-09  1e-09  CK1_1`
	`1e-09  1e-09  CK1_2`
	`1e-09  1e-09  CK2_1`
	`...`
	Data_type: string, optional

`-type {data | clock}`	
	Specifies whether the net or pin is part of the clock or data network. *Data_type*: string, optional

Examples

- The following command specifies to use the following TWF attributes for the net `netB1`:

  ```
  set_twf_attribute -net netB1 -rise_delay 2.1978:2.1978 -rise_slew 0.05:0.05 -rise_slack 0.2741:3.6961
  -fall_delay 2.1819:2.1819 -fall_slew 0.05:0.05 -fall_slack 0.237:3.6948 -clock CK1_1 -clock_frequency 100 -type data
  ```

- The following commands reset the TWF values for the "`DFF11/DFF/Q`" pin to default, and then sets the rise/fall delay:

  ```
  set_twf_attribute -clear_twf_attribute -pin "DFF11/DFF/Q"
  set_twf_attribute -pin "DFF11/DFF/Q" -rise_delay 0.35 -fall_delay 0.45 -clock CLK1
  ```

set_virtual_clock_network_parameters

```
set_virtual_clock_network_parameters
[-help]
[-cell cell_name]
[-clock list_of_clocks]
[-library library_name]
[-max_fanout value]
[-wire_load_model wireload_model]
[-reset]
```

Specifies to estimate power for a virtual clock tree. When the command is specified, the software reports the power of the clock network based on the buffers inserted in the clock tree. It also reports the number of buffers used for implementing the clock tree and the depth of the clock tree.

You can use this command for fast power estimation of clock network power of a pre-CTS netlist.

This command should be invoked before running the `report_power` command.

Parameters

`-help`	Outputs a brief description that includes the type and default information for `each` set_virtual_clock_network_parameters parameter. For a detailed description of the command and all of its parameters, use the man command man `set_virtual_clock_network_parameters`.
`-cell cell_name`	
	Specifies the name of the buffer or inverter cell that has to be used to build the clock tree. *Data_type*: string, optional
`-clock list_of_clocks`	
	Specifies the list of clocks for which the clock tree needs to be implemented. The default is for all the clocks. *Data_type*: string, optional
`-library library_name`	
	Specifies the name of the library which contains the cell. *Data_type*: string, optional
`-max_fanout value`	
	Specifies the maximum fanout that the buffer cell can drive. *Data_type*: int, optional
`-wire_load_model wireload_model`	
	Specifies the wire load model used to compute the wire load model for the nets in the clock network. *Data_type*: string, optional
`-reset`	Resets all specified parameters back to default values. *Data_type*: bool, optional

Example

The following command specifies to use the cell `BUFX12`, with a maximum fanout value of `2`, to build a virtual clock tree:

```
set_virtual_clock_network_parameters -cell { BUFX12 } -library typical -max_fanout 2 -wire_load_model B0X0
```

write_power_constraints

```
write_power_constraints
[-help]
[-out_file filename]
```

Writes out all the power constraints such as the power analysis mode, activity file specifications, simulation period specifications, and so on, into a file. You can use this command at any time during the session to dump out the power commands/ options specified till that point.

You can source this file into other Voltus/Tempus/Innovus session in order to use the same settings.

Parameters

`-help`	Outputs a brief description that includes the type and default information for each `write_power_constraints` parameter. For a detailed description of the command and all of its parameters, use the man command `man write_power_constraints`.
`-out_file filename`	Specifies the output file into which the power constraints are to be written. *Data_type*: string, optional

Example

```
write_power_constraints -out_file test1.tcl
```

Related Information

- power Category Attributes

write_tcf

```
write_tcf file
[-block block_name]
[-exclude_hier_insts list_of_instances]
[-primary_input]
[-sequential_output]
[-pin]
[-macro_output]
```

Writes out the propagated switching activity information to a toggle count format (TCF) file. The TCF file contains switching activity information, toggle count information, and the probability of the net or pin being in the logic1 state.

You must specify this command before `report_power`.

Parameters

`-block block_name`	
	Specifies to generate the block-level TCF from the top-level design. When specified, it writes out the block-level duty and activity in the generated TCF file. The use model of this parameter is: `write_tcf -pin -block blockname TCF_filename`
`-exclude_hier_insts list_of_instances`	
	Excludes the specified hierarchical modules or instances when writing out a pin-based TCF. This parameter allows you to ignore the activity generated for the excluded instances. The use model of this parameter is: `write_tcf -pin -exclude_hier_insts {list_of_instances}`
`-macro_output`	Specifies to generate a TCF file that includes all the activities for the macro outputs in the design. *Data_type*: bool, optional
`-pin`	Specifies to write out pin-based TCF. *Data_type*: bool, optional
`-primary_input`	Generates a TCF file that includes only the primary inputs in the design. *Data_type*: bool, optional
`-sequential_output`	
	Generates a TCF file that includes all the activities for the sequential outputs in the design. *Data_type*: bool, optional
file	Specifies the name of the output TCF file. *Data_type*: string, optional

Example

- The following command writes the propagated switching activity information to TCF file `mmm.tcf`:
  ```
  write_tcf mmm.tcf
  ```
- The following command writes a pin-based TCF for the whole design:
  ```
  write_tcf -pin pin_design.tcf
  ```
- The following command writes out a TCF which only includes activity information for the primary inputs and sequential outputs in the design:

```
write_tcf -primary_input -sequential_output Power.tcf
```

- The following command writes out a pin-based TCF that excludes the specified hierarchical instances:
```
write_tcf -pin -exclude_hier_insts {DTMF_INST/CORE_INST DTMF_INST/RAM_128x16 DTMF_INST/RESULTS_INST
```

Power-Grid Library Commands

- check_pg_library
- check_pgv
- merge_pg_library
- rename_pg_library
- set_advanced_pg_library_mode
- set_pg_library_mode
- trim_pg_library
- write_pg_library
- write_tech_pg_lib
- write_xpgv

check_pg_library

```
check_pg_library
[-help]
power_library_paths
[-cell_list_file file]
[-check_compatibility | -lef_consistency]
[-check_parameters]
[-out_dir file]
[-integrity_check]
[-list]
[-report]
[-rule_file file]
[-skip_layer_list_file filename]
[-skip_signal_net_check {true | false}]
[-summary]
[-tech_layers]
[-total_currents]
[-report_detail_multiple_voltage_cap file]
[-command_write]
[-metal_density_map]
```

Specifies to perform a comprehensive check of power-grid views (PGV) to be used in rail analysis. These checks include:

- Verify that all the PGV views exist: Early/IR/EM
- Report the dynamic PWL and static current
- Perform a compatibility check on version, layermap and resistivity parameters
- Check any missing information, such as temperature, qrcTechFile location, and so on.

Parameters

`-help`	Outputs the command usage.
power_library_path	

	Specifies the absolute path to the power library (`.cl`) file. You can run multiple power library files (.cl) at the same time. *Data_type*: string, required
`-cell_list_file` *file*	

	Specifies a file containing the list of cells for which the LEF consistency checks will be done. This parameter allows you to perform the consistency checks only for the user-defined cells.
	The format of the input file is:
	`CELL1`
	`CELL2`
	`CELL3`
	Data_type: string, optional

`-check_compatibility`	
	Checks for compatibility between the specified cell libraries. It checks whether the following parameters are the same for the libraries that are to be merged: • Time Units • Capacitance Units • Layout Scale Factor • Manufacturing Grid If one or more of these parameters are not the same, a warning message appears stating that the libraries are not compatible and cannot be merged. It also specifies the parameters that are different. Based on the above electrical/physical parameter check, a compatibility report (compatibility.report) with pass/fail is generated. Fail implies that the library is not compatible and cannot be used in Voltus rail analysis. The use model of this parameter is: `check_pg_library -check_compatibility {`*lib1 lib2*`}` *Data_type*: bool, optional
`-check_parameters`	

	Checks for the following electrical parameters of the specified cell libraries: • `CINT_MIN and CINT_MAX`: Intrinsic device capacitance • `CG_MIN and CG_MAX`: Grid capacitance • `RON_MIN and RON_MAX`: On-resistance for powergates • `IDSAT_MIN and IDSAT_MAX`: Saturation current for powergates • `ILEAK_MIN and ILEAK_MAX`: Leakage current for powergates • `IAVG_MIN and IAVG_MAX`: Static current • `IPEAK_MIN and IPEAK_MAX`: Dynamic peak current • `ESR_MIN and ESR_MAX`: Equivalent series resistance For powergates, `-check_parameters` will check the Vds-Ids table for the correct trend. It checks whether: • for a given `Vgs`, `Ids` increases with `Vds` • for a given `Vds`, `Ids` increases with `Vgs` where; `Vgs` is voltage across gate and source `Vds` is voltage across drain and source `Ids` is current from drain to source (of a transistor) *Data_type*: bool, optional
`-command_write`	
	Specifies to print the settings used during PGV characterization to a text file called `command_list.txt`. This parameter allows you to determine the user-specified or default settings used during PGV generation for the specified power library (.cl). *Data_type*: bool, optional
`-integrity_check`	
	Specifies to load all the views from a power-grid library to ensure that the library contains the required data. This parameter checks if there are any missing files or views, and that the PGV is usable in rail analysis.
`-lef_consistency`	
	Checks for LEF consistency of the cells in the specified cell libraries. It reads the LEF and PGV files, and compares the given LEF file with the LEF file used in PGV generation. *Data_type*: bool, optional

`-list`	Specifies to list the PGVs and the cells in each PGV. The parameter allows you to determine the name of the PGV library that contains a specific cell and determine whether a cell is there in multiple libraries.
	
	The format of the output file is:
	`PGV Library: <Number of PGV libraries>`
	`<Lib_1> <TOOL VERSION> <PGV VERSION> <GENERATE_DATE> <Path>`
	`<Lib_2> <TOOL VERSION> <PGV VERSION> <GENERATE_DATE> <Path>`
	`...`
	`Duplicated Cells: <Number of cells in multiple libraries>`
	`<CELLNAME> <Lib_1 Lib_2 Lib_3>`
	`Cell List: <Number of cells in a library>`
	`<CELLNAME> <LIB#>`
	
	Data_type: bool, optional

`-metal_density_map`	
	Generates the metal density map report file (`<pgvname>.metal_density`) in the PGV output directory. This file contains information about the macro size, number of tiles in the x and y direction, metal layer ID, layer name, and metal density values for each tile. This parameter is used with the `-calculate_metal_layer_density` parameter of the `set_pg_library_mode` command. *Data_type*: bool, optional
`-out_dir dir_name`	
	Specifies the name of the output directory in which the power-grid library report is created. The default is the current working directory. *Data_type*: string, optional
`-report`	Specifies to generate the power-grid library report. *Data_type*: bool, optional
`-report_detail_multiple_voltage_cap file`	
	Specifies to generate a voltage-dependent capacitance table that contains the detailed capacitance values of the given power-grid library. The capacitance table file is called `<pgvname>.cap_table`. This parameter is used with the `-enable_multi_voltage_cap_generation` parameter of the `set_pg_library_mode` command. *Data_type*: bool, optional
`-rule_file file`	

	Specifies the rule file name used for parameter checking. This file contains the list of electrical parameters to be checked.
	File Format:
	`CINT_MIN <min cap value>`
	`CINT_MAX <max cap value>`
	`RON_MIN <value>`
	`RON_MAX <value>`
	`IDSAT_MIN <value>`
	`IDSAT_MAX <value>`
	`ILEAK_MIN <value>`
	`ILEAK_MAX <value>`
	`IPEAK_MIN <value>`
	`IPEAK_MAX <value>`
	`IAVG_MIN <value>`
	`IAVG_MAX <value>`
	`ESR_MIN <value>`
	`ESR_MAX <value>`
	This parameter must be specified with the `-check_parameters` parameter.
	Data_type: string, optional

`-skip_layer_list_file` *filename*	
	Specifies the name of a file containing a list of layers to ignore while checking PGV and LEF compatibility. Its format is one layer per line. This parameter must be specified with the `-check_compatibility` parameter. *Data_type*: string, optional
`-skip_signal_net_check {true | false}`	
	Default: `false` Specifies to skip LEF consistency checks for signal nets. This forces skipping of the signal pin checks when performing a comprehensive check of power-grid views to be used in rail analysis. The `-skip_signal_net_check` parameter can be used if you want to check LEF consistency of only the power and ground pins. *Data_type*: string, optional
`-summary`	
	Specifies to generate a detailed report of the library contents for the specified cells that can be used for debugging purpose. *Data_type*: bool, optional
`-tech_layers`	
	Specifies to report technology layer information and layer mapping. *Data_type*: bool, optional
`-total_currents`	
	Specifies to report the static current for each power/ground net, and dynamic PWL for each mode. For each mode, it reports the peak and average current, and the number of points for power supply nets. When specified, the total current is reported in `<lib_name>.total_current` for each library. *Data_type*: bool, optional

Examples

- The following command creates a report for the library std_cells.cl:
  ```
  check_pg_library std_cells_fast/std_cells_fast.cl -report
  ```
- The following command checks for LEF consistency:
  ```
  read_lib -lef ddk.0.lef
  read_lib -lef ddk.1.lef
  check_pg_library -lef_consistency \
  "/../library1.cl\
  /../library2.cl"
  ```
- The following command displays the list of layers (defined in the technology file) on stdout:
  ```
  check_pg_library -tech_layers ./check_param/powergate/stdcells.cl
  ```
- The following command checks for compatibility between the specified cell libraries and generates a compatibility report (compatibility.report) in the output directory:
  ```
  check_pg_library -out_dir out -check_compatibility  {/../lib1.cl /../lib2.cl}
  ```
- The following command specifies to list the cells corresponding to the specified libraries, `pgv1.cl` and `pgv2.cl`:
  ```
  check_pg_library -list {/../pgv1.cl  /../pgv2.cl}
  ```
- The following command checks for electrical parameters of the stdcells.cl library:
  ```
  check_pg_library -out_dir OUT -check_parameters ./stdcells.cl
  ```
  The following is a sample output of this command:

  ```
            PARAM        VALUE            RANGE         PASS/FAIL

         Idsat Trend  : PASS
         Ileak Trend : PASS
  ```
- The following command reports the static current for each power/ground net:
  ```
  check_pg_library -total_currents /../pg.cl
  ```
  The following is a sample output of this command:

  ```
  Net VSS
  Static current = -0.00021181

  Net VDD
  Static current = 0.000211809

  MODE1
  Trigger Condition: ( !CEN & !WEN )
  Net VDD
      Peak = 0.0138308
      Avg = 0.000276053
      Number of points 190

  Net VSS
      Peak = -0.0166879
      Avg = -0.000300184
      Number of points 190
  ```

```
MODE2
...
```

- The following command generates a capacitance table (`powergate_stdcells.cap_table`) that contains the detailed capacitance values of the powergate_stdcells.cl library:

  ```
  check_pg_library -report_detail_multiple_voltage_cap ../powergate_stdcells.cl
  ```

  The following is a snippet of the capacitance table file (`powergate_stdcells.cap_table`):

  ```
  ================================================================================
  CellName    NetName      Voltage       Capacitance
  --------------------------------------------------------------------------------
  powercell    vccm        0.1000        4.586e-14
  powercell    vccm        0.2825        4.102e-14
  ...
  ```

- The following command specifies to output the settings used during generation of `macros_pll.cl` to a text file called `command_list.txt`:

  ```
  check_pg_library -command_write macro_pgv/macros_pll.cl
  ```

  The following is a sample snippet of the `command_list.txt` file:

  ```
  temperature 25
  spice_subckts /../spice.sp
  spice_models /../spectre_load.sp
  extraction_tech_file /../tech.tch
  gds_files /../file1.gds
  stop@via VIA_1
  spice_subckts_xyscaling 1000
  use_powergate_data_from_lib 0
  default_frequency 2e+08
  decap_frequency 1e+08
  ```

- The following command generates the power-grid library report:

  ```
  check_pg_library -out_dir report -report /../pg.cl
  ```

  The following is a sample output of this command:

  ```
  ================================================================================

[-pgv_mode_dynamic_switch_pattern pattern]
```

Specifies to validate a macro PGV. The command takes a macro PGV and Liberty file as input, and performs IR Drop based validation by running static and dynamic power and rail analysis. In this flow, Library Generation will read the input PGV and generate a dummy DEF file that has an instance of the macro (one-cell design). It will then run static/dynamic power and rail analysis on this design. You can analyze the power and rail results to check for hotspots, connectivity, and current distribution inside the PGV.

Parameters

`-help`	
	Outputs the command usage.
`-activity value`	
	Specifies the activity value for input pins. If not specified, a default activity of 0.2 is used. The activity specifies the number of times an input pin switches *Data_type*: string, optional
`-cell cell_name`	
	Specifies the name of the cell to be validated. *Data_type*: string, required
`-clock {clk1 clk2 ...}`	
	Specifies the list of clock pins. *Data_type*: string, optional

`-disable_rail_analysis {true | false}`

Specifies to disable rail analysis during macro PGV validation. The following is the behavior of `-disable_rail_analysis true` with the `-enable_xp` para

- if `-enable_xp` is set to `true`, the tool will run only power analysis in the XP mode
- if `-enable_xp` is set to `false`, the tool will enable only power analysis in the non-XP or normal mode

Default: `false`

Data_type: enum, optional

`-dynamic_analysis_duration value`

Specifies the simulation period that dynamic power analysis will use. It is the duration for which a window is selected for calculation of IR drop during pc default value is 10ns.

Data_type: string, optional

`-enable_xp {true | false}`

Specifies to validate the macro PGV in the extensively parallel (XP) mode.

Default: `false`

`-extraction_tech_file tech_file_path`

Specifies the path of the extraction technology file.

Data_type: string, optional

`-frequency value`

Specifies the clock frequency. The default value is 100Mhz.

Data_type: string, optional

`-input_pin_set_case_analysis_low {pin1 pin2 ...}`

Specifies the list of pins to be kept at a logical low. The `set_case_analysis` command in the SDC file will have the same effect as the set pin to constant described here.

Data_type: string, optional

`-input_pin_set_case_analysis_high {pin1 pin2 ...}`

Specifies the list of pins to be kept at a logical high. The `set_case_analysis` command in the SDC file will have the same effect as the set pin to constan described here.

Data_type: string, optional

`-liberty liberty_file`

Specifies the name of the Liberty file for power calculation.

This parameter is optional for the static power analysis flow, and is mandatory for the dynamic power analysis flow. In the static flow, you need to specif `set_total_power`. If both the parameters are specified, the `-set_total_power` parameter will be honored.

Data_type: string, optional

`-max_ir_drop value`

Specifies the maximum IR drop allowed. Default is 5 (in percentage).

Data_type: float, optional

`-net_capacitance value`

Specifies the value of the net capacitance. The default value is 1pF.

Data_type: string, optional

`-output output_dir`

Specifies the name of the output directory. This directory saves the power and rail reports, and the design output (such as .lef, .def, and so on).

Data_type: string, optional

`-pgv_mode_dynamic_switch_pattern` *pattern*

Specifies the switching patterns for the functional modes in the dynamic power calculation flow. The use model of this parameter is same as the `set_pow` `dynamic_switch_pattern` parameter.

In the following example, the mode `write` will switch in the 1st clock cycle, the mode `read` will switch in the 2nd and 4th clock cycles, and none of the mo 3rd clock cycle:

```
check_pgv -pgv_mode_dynamic_switch_pattern { write read - read }
```

`-pin_capacitance` *value*

Specifies the value of the pin capacitance. The default value is 1pF.

Data_type: string, optional

`-power_grid_library_path` *pgv_path*

Specifies the path of the power-grid library file.

Data_type: string, required

`-power_grid_library_view` *view_name*

Specifies the power-grid view name.

Data_type: string, optional

`-power_include_file` *filename*

Specifies a power analysis include file. This file specifies certain commands of the dynamic engine that do not have a Voltus equivalent. This parameter the dynamic power analysis flow.

Data_type: string, optional

`-power_pad_size` *value*

Specifies the distance between two adjacent DEF voltage sources. The default value is `50` (in Micron).

Data_type: float, optional

`-rail_analysis_type {static | dynamic}`

Specifies whether static or dynamic analysis will be done. The default value is `static`.

Data_type: string, optional

`-rail_include_file_begin` *filename*

Provides a file that includes additional rail options that will be run prior to the `analyze` command. This can be used for those legacy rail analysis comma Voltus equivalent.

Data_type: string, optional

`-rail_include_file_end` *filename*

Provides a file that includes additional rail options that will be run after the `analyze` command. This can be used for those legacy rail analysis command Voltus equivalent.

Data_type: string, optional

`-rail_trigger_switching_pattern` *pattern*

Default: None

Specifies a dynamic trigger file. When a Macro EM view with current signature is used in a design, it needs to be determined when this block/cell is trigg trigger file is used to determine this. The use model of this parameter is same as the `set_rail_analysis_config -dynamic_trigger_file` parameter.

Data_type: string, optional

`-sdc_file` *filename*

Specifies the name of the timing constraints file.

Data_type: string, optional

`-set_power_switching_pattern` *trigger_file*

Default: None

Specifies the stimulus pattern on the pins of an instance and cell. Specify this parameter only in the dynamic mode for the type instance and cell. The us
parameter is same as the `set_power -dynamic_switch_pattern` parameter.

Data_type: string, optional

`-set_total_power value`

Specifies the total power for the design in Watts. This power is distributed based on cell area.

Data_type: string, optional

`-step_size value`

Specifies the simulation step size, in picoseconds. The default value is 20ps. This parameter is applicable only to the dynamic power analysis flow.

Data_type: string, optional

`-supply_voltage value`

Specifies the voltage of each power supply pin. The default value is 1V.

Data_type: float, optional

`-tech_lef_file tech_lef_file_path`

Specifies the path of the technology LEF file.

Data_type: string, optional

`-temperature value`

Sets the temperature for static power calculation. The default is 125 degrees.

Data_type: string, optional

`-transition_time time`

Specifies the transition time for specific pins or instances in the design. This parameter is applicable only to the dynamic power analysis flow.

Data_type: string, optional

`-twf_path twf_location`

Specifies the location of the Timing Window File (TWF) for noise and power calculation.

Data_type: string, optional

`-user_defined_power_pin_location_file filename`

Specifies the name of a file containing net names and corresponding user-defined ploc or power pad files (.pploc). The .pploc file includes power pin or
locations for power and ground nets. The parameter gives you the flexibility to include either user-specified or tool-generated voltage sources.

The following is a sample file with the list of nets and power pad files:

```
----ploc.list----
#<NET_NAME> <Pointer to ploc file>

VDD   input/ploc/VDD.pploc
VDDA  input/ploc/VDDA.pploc
VDDF  input/ploc/VDDF.pploc
VSS   input/ploc/VSS.pploc
```

When specified, the voltage source location files (.pploc) in the given *`ploc.list`* file will be used for library generation. If the pploc file is missing for a fe
file, then library generation will automatically generate `.pploc` for those nets.

Data_type: string, optional

Examples

- The following command specifies to validate the cell `cell1` by running static power and rail analysis:
  ```
  check_pgv -cell cell1 -liberty 125c.lib -clock {CLKW CLKR} -power_grid_library_path macros_cell.cl -extraction_tech_file caps.tch -tech_lef_file tech.lef -output validate_pg_output_static -rail_analysis_type static
  ```
- The following command specifies to validate the cell `cell1` by running dynamic power and rail analysis
  ```
  check_pgv -cell cell1 -liberty 125c.lib -clock {CLKW CLKR} -power_grid_library_path macros_cell.cl -temperature 122 -extraction_tech_file caps.tch -tech_lef_file tech.lef -output validate_pg_output_dynamic -rail_analysis_type dynamic
  ```

Related Information

- `check_pg_library`
- "Power-Grid Library Generation" in the *Voltus Stylus Common UI User Guide*

merge_pg_library

```
merge_pg_library
[-help]
[-force_merge {true | false}]
-library_list_file file_name
[-library_prefix prefix]
[-merge_single_voltage_pgvs {true |false}]
[-out_dir directory_name]
[-remove_tech {true | false}]
[-validate_rail_merge {true | false}]
```

Specifies to merge power-grid libraries. Using this command, you can merge multiple same-type power-grid libraries into one consolidated power-grid library.

Parameters

`-help`	Outputs the command usage.
`-force_merge {true | false}`	
	Specifies to force merge PGVs with different resistivity and layers. It uses the technology information of the first library. If multiple tech-only PGVs are specified, it will take the first tech-only PGV definition and the first cell definition. If you are merging a tech-only PGV with other PGVs, it will keep the tech-only technology definition and the first cell definition. The default value of the parameter is `false`. *Data_type*: string, optional
`-library_list_file` *file_name*	
	Specifies the file containing the list of libraries. *Data_type*: string, required
`-library_prefix` *prefix*	
	Specifies a prefix for the generated power-grid library. *Data_type*: string, optional
`-merge_single_voltage_pgvs {true |false}`	
	Specifies to merge all the single voltage PGVs into a multi-voltage PGV for better handling of the library characterization flow. This parameter is used in a scenario when you have generated multiple PGVs for different voltages, instead of generating a single multi-voltage PGV that has voltage-dependent capacitance. The default value of the parameter is `false`. *Data_type*: string, optional
`-out_dir` *directory_name*	
	Specifies the name of the output directory in which power-grid libraries are created. The default is the current working directory. **Note**: If you specify both `-out_dir` *output_dir* and `-library_prefix` *prefix* parameters, the command generates the PGV in the *output_dir* directory with PGV name `prefix.cl`. *Data_type*: string, optional
`-remove_tech {true | false}`	
	Specifies to remove technology dependency from the specified or merged library. The newly created library will not contain the technology information. The default value of the parameter is `false`. *Data_type*: string, optional
`-validate_rail_merge {true | false}`	
	Specifies to validate the merged PGV in the same way as done when merging PGV during rail analysis. When this parameter is specified, the log file reports error, warning, and info messages if the tool finds any issues during PGV merging. The parameter allows you to check the PGV merging issues as reported during rail analysis, without having to run the full design. `-validate_rail_merge` is used only for validation purpose, and the merged PGV is not to be used for analysis. *Data_type*: string, optional

Examples

- The following command merges the power-grid libraries specified in the `merge_lib.list` file into one consolidated power-grid library:
  ```
  merge_pg_library -library_list_file "merge_lib.list" -out_dir ./ -library_prefix "new_merged"
  ```
  The content of `merge_lib.list` file is:
  library1.cl
  library2.cl
  library3.cl

rename_pg_library

```
rename_pg_library
[-help]
-cell_list_map_file filename
-merge_library_list_file filename
-out_dir directory_name
-output_library new_library_name
```

Specifies to copy and rename the specified power-grid view library. The command also allows you to rename the cells of the specified input library.

Parameters

`-help`	Outputs the command usage.
`-cell_list_map_file` *filename*	
	Specifies a file containing the list of cells to be renamed. The format of the specified file is: *<old cell name1> <new cell name1>* *<old cell name2> <new cell name2>* ... *Data_type*: string, required
`-merge_library_list_file` *filename*	
	Specifies a file containing the input library to be renamed. The format of the specified file is: *<path to the input library>* *Data_type*: string, required
`-out_dir` *directory_name*	
	Specifies the name of the output directory in which the new power-grid library is created. The default is the current working directory. *Data_type*: string, required
`-output_library` *new_library_name*	
	Specifies the new name of the specified input library. *Data_type*: string, required

Examples

- The following command specifies to rename the input library to `new_lib`:

```
rename_pg_library -merge_library_list_file new.list -cell_list_map_file cell.list -output_library new_lib -out_dir .
```

```

Specifies the advanced power-grid library generation features. If the `set_advanced_pg_library_mode` command is specified twice, the last specified command takes precedence.

Parameters

`-add_port_labels file_name`

Specifies the name of a file containing details about the label of a switched rail. Using this parameter, you can add a label for the switched rail manually in the specified port file, if the switched rail is not labeled.
The format of the port file is given below:

MACRO *macro_name*
PIN *pin_name*

Data_type: string, optional

`-assume_foreign {true | false}`

Enables the Library Characterization engine to process LEF files in which FOREIGN statements are not defined as part of the macro definition. When generating detailed power-grid views, the engine assumes that FOREIGN statements are defined as part of the macro definition in the LEF file.

When this option is set to `true`, the engine processes the LEF file by using the name defined by the MACRO statement rather than requiring a FOREIGN statement. The `-assume_foreign` parameter ensures that the FOREIGN statement is placed at 0,0. Therefore, if the MACRO statement has an offset, you must provide a FOREIGN statement that contains an offset. This option works for offsets that are 0,0 or the inverse of the origin.

Default: false

Data_type: enum, optional

`-assume_foreign_mode [1 | 0]`

Determines how the Library Characterization engine processes cells for which FOREIGN statements are assumed. If set to 0, the engine assumes that the cell for which FOREIGN statements are assumed is placed at (0,0). When you set it to 1, the engine assumes that the FOREIGN cell is placed at the inverse of the macro origin. The default is 1.

Default: 1

Data_type: enum, optional

`-cell_electrical_data_file file`

Specifies the name of a file containing data about the electrical characteristics of cells. Voltus library simulator requires this data to generate currents during power-grid view generation.

Data_type: string, optional

`-cell_per_distributed_host value`

Specifies the number of cells to be submitted per host for distributed PGV generation. The default value is 50.

Data_type: int, optional

`-cell_pin_net_map_file file`

	Specifies the mapping between the cell LEF pin names and the internal names of the net to which those pins are attached. It is used when multiple pins are attached to a single net. *Data_type:* string, optional
`-circuit_include_file` *`simulator.inc`*	
	Specifies the name of the input file for Voltus library simulator in the Library Characterization command file. *Data_type:* string, optional
`-cluster_via_rule {{`*`via_layer1 number_of_equidistant_vias`*`}...}`	
	Controls the number of vias to cluster on a layer basis. The VIA clustering rule specified using this parameter will override the default clustering rule for PGV generation. You can use this parameter when you need clustering at VIA1, or different clustering for different layers. The default cluster size for PGV generation is `64` for all via layers except VIA1. **Example**: The following command will cluster 100 equidistant VIA1 cuts, 200 equidistant VIA2 cuts, and 300 equidistant VIA7 cuts: `set_advanced_pg_library_mode -cluster_via_rule {{VIA1 100} {VIA2 200} {VIA7 300}}` *Data_type:* string, optional
`-cluster_via_size` *`value`*	
	Specifies that power-grid extraction for library cell needs to perform 64 (8x8) via clustering inside PGV for all via layers above VIA1 between Metal1 and Metal2. The default value of this parameter is `64`. The following command specifies to perform 16 (4x4) via clustering: `set_advanced_pg_library_mode -cluster_via_size 16` *Data_type:* int, optional
`-common_supply_pins{`*`net_name+`*`}`	
	Identifies the generic supply net or nets which could act as either a power or ground supply net. No wildcards are allowed for the specification of net names. Generic supply nets are used for pads or bump cells that could be connected to either a power or ground net. They will be connected to the correct power-grid based on the DEF or GDS file. *Data_type:* string, optional
`-create_static_view_from_dynamic_view {true | false}`	
	Specifies to generate static power-grid view by averaging of dynamic currents in the multi-mode characterization flow. When this parameter is specified, the software performs averaging of the dynamic currents of all the modes and saves it as static current in the power-grid view. *Default*: `false` *Data_type:* enum, optional
`-damping_decap_cells {`*`cell1cell2 ..`*`}`	
	Specifies a list of damping decap cells. *Data_type:* string, optional
`-damping_decap_frequency` *`value`*	
	Specifies the frequency of operation of the damping decap cells. The default value is 200MHz. *Data_type:* float, optional
`-decap_frequency` *`value`*	

	Specifies the decoupling capacitance frequency (in hertz) used during PGV generation. Intrinsic capacitance of cells has a significant dependency on frequency used during PGV generation. PGVs characterized with higher frequency may lead to pessimism during dynamic analysis due to less impact of intrinsic capacitance of the cells characterized with higher frequency. Using this parameter, you can specify the dominant frequency to be used for PGV generation. The default value for decoupling capacitance frequency is 1GHz. For example, the following command specifies that the decap frequency is 200 MHz: `set_advanced_pg_library_mode -decap_frequency 2e+8` *Data_type:* string, optional
`-default_frequency` *value*	
	Specifies the default frequency of signal nets in hertz (Hz); this is used to calculate the current and capacitance values during the creation of detailed power-grid views. For example, the following command specifies that the default switching frequency is 100 MHz: `set_advanced_pg_library_mode -default_frequency 100e+06` *Data_type:* string, optional
`-default_power_voltage` *value*	
	Specifies the default voltage for power nets. This parameter assigns a default value to power nets for which voltage has not been defined using the `-power_pins` parameter. *Data_type:* float, optional
`-delete_generated_fsdb_files {true|false}`	
	Specifies to delete the intermediate FSDB files generated in the Spice deck (user-specified) method of current characterization. This parameter allows you to retain or delete the huge FSDB files. *Data_type:* enum, optional
`-disable_power_switch_ramp_up_simulation {true | false}`	
	Specifies whether to run power gate ramp-up simulation during power-grid view generation. When this parameter is set to `true`, the Ids-Vds table will not be present in PGV, therefore, this PGV cannot be used for the power-up or rush current analysis flow. This parameter can be specified to reduce the run time when you require only the RON/Idsat/Ileak and Cap values in PGV. `-disable_power_switch_ramp_up_simulation` is used when power gate parameters are specified using the `set_pg_library_mode -power_switch_parameters_file` parameter. *Default*: `false`
`-distribute_current_to_switch_net {true | false}`	
	Distributes the PWL waveform, which is specified to the always-on power net, to the taps of both the always-on power net and the related switched power nets in the fine-grain memory characterization flow. By default, the current waveform is distributed only to the taps of the always-on power net when you specify the PWL to the always-on power net. *Default*: `false` *Data_type:* enum, optional
`-enable_ac_simulation_for_IO_characterization {true | false}`	
	Specifies to perform an AC analysis based coupled capacitance calculation for IO cells. When set to `false`, the software performs DC analysis based coupled capacitance calculation for IO cells. The default is `false`. *Data_type:* enum, optional
`-enable_spectre_netlist_flow {true | false}`	
	Specifies to use the Spectre simulator to read the Spice/Spectre netlist for the standard cells characterization flow. This option should be used when the netlist is in Spectre format, or when the netlist is encrypted by Spectre. *Default*: `false` *Data_type:* enum, optional

`-enable_subconductor_layers {true | false}`

Allows to control the generation of the sub-conductor layers in the PGV. When this parameter is set to `false`, the sub-conductor layers are not generated in the PGV. The default value of this parameter is `true`.

Data_type: enum, optional

`-enable_via_based_current_distribution {true | false}`

Default: `false`

Specifies to enable location-based via current modelling during GDS-based macro power-grid view generation. When set to `true`, defines the current values only on the user-defined via location. This parameter allows you to define average and peak current values for specific-location vias.

The `-enable_via_based_current_distribution` parameter must be specified with the `-via_based_current_config_file` parameter.

If the parameter is set to `false`, current is uniformly distributed across all vias in the macro PGV.

Data_type: enum, optional

`-esd_cells {cell_list}`

Specifies a list of Electrostatic Discharge (ESD) cells. You can use this parameter to characterize ESD cells. When you specify this parameter, the list of ESD cells are later used in the ESD analysis flow while loading the power-grid view library.

Data_type: string, optional

`-esd_cells_list_file filename`

Specifies a file containing a list of ESD cells that are later used in the ESD analysis flow while loading the power-grid view library.

The `-esd_cells_list_file` parameter is the same as the existing `-esd_cells` parameter of the `set_advanced_pg_library_mode` command, except that the `-esd_cells_list_file` parameter allows you to specify a list of ESD cells in a file while the `-esd_cells` parameter allows you to specify the ESD cells in the command line itself.

The following is an example of this parameter:

```
set_advanced_pg_library_mode -esd_cells_list_file {./Esd_Cell_list.txt}
```

The following is the ESD cell file format:

```
CELL_1
CELL_2
...
CELL_n
```

Data_type: string, optional

`-esd_device_list {device1 device2 ....deviceN}`

Specifies the list of ESD devices. The ESD device information is used for accurate ESD analysis as it takes into account the internal grid from the ports to the ESD devices. The followings inputs are required for ESD tagging during macro PGV generation:

- an xDSPF file
- ESD device list

Data_type: string, optional

`-esd_parameters_file filename`

Specifies resistance information for the following types of ESD cells during ESD cell characterization:

- Diodes
- RC Clamp

When this parameter is specified, the software uses these electrical parameters from the generated PGV for ESD analysis.

The format of the input file is:

```
Cell <cell name>  <Ron> <Roff> <power_pin> <ground_pin> <voltage>
Type <esd cell type> <Ron> <Roff> <power_pin> <ground_pin> <voltage>
```

Here,

- `Cell` and `Type` are keywords
- *<cell name>* specifies the ESD cell name
- *<esd cell type>* specifies the ESD cell type, such as DIODE and CLAMP
- `RON` is the resistance of the complete cell when it is switched on.
- `ROFF` is the resistance of the complete cell when it is switched off.
- *power_pin* is the name of the power pin connected to the power net
- *ground_pin* is the name of the ground pin connected to the ground net
- *voltage* is the threshold value between the power and ground pin.
- When you specify the cell name, the RON and ROFF would be applied only for that cell, and when you specify the cell type, the RON and ROFF would be applied for all the ESD cells of the particular type.

The following is a snippet of the input file:

```
Cell HEADER_SWITCH 10 5 pwr_pin gnd_pin 0.4
```

Data_type: string, optional

`-esd_pin_list {`*pin1 pin2 ....pinN*`}`

Specifies the list of ESD pins. This parameter tags the user-specified pin as the ESD pin before running the `report_esd_network` command, and ensures that the software traces only this ESD power pin to bump and extracts resistance. The ESD cell pins that are tagged using this parameter are listed in the `.report` file.

Data_type: string, optional

`-exclude_tap_region_file` *filename*

Specifies to exclude certain tap points during macro PGV generation. This parameter helps to avoid false IR-drop violations inside macros caused by inadvertently assigning evenly-distributed tap current to certain undesired tie high/low paths or shielding paths at certain via layers. The Spice netlist and models are not mandatory parameters for excluding the tap points in the macro PGV generation flow.

The format of the region file is:

```
REGION X1 Y1 X2 Y2
REGION X3 Y3 X4 Y4
```

where, `REGION` keyword specifies that the coordinates following it is a tap current region. The unit for coordinates is micron.

Data_type: string, optional

`-extraction_command_file` *file*

Specifies the file name of an extraction command file.

Data_type: string, optional

`-followpins_tap_layer {lowest_lef_pin_layer | highest_lef_pin_layer | all_lef_pin_layers}`

Specifies the LEF metal layer used to generate current taps. This parameter has two arguments:

- `lowest_lef_pin_layer`: The tool generates current taps only on the lowest LEF metal layer. For example, if both METAL1 and METAL2 metal layers exist for the power/ground pin in the cell LEF, the tool uses METAL1 layer as the tap layer.
- `highest_lef_pin_layer`: The tool generates current taps only on the highest LEF metal layer. For example, if both METAL1 and METAL2 metal layers exist for the power/ground pin in the cell LEF, the tool uses METAL2 layer as the tap layer.
- `all_lef_pin_layers`: The tool generates current taps on all LEF metal layers. For example, if both METAL1 and METAL2 metal layers exist for the power/ground pin in the cell LEF, the tool uses both METAL1 and METAL2 layers as the tap layer. This is the default value.

Data_type: enum, optional

`-followpins_interface_node_layer {lowest_lef_pin_layer | highest_lef_pin_layer | all_lef_pin_layers}`

Specifies the LEF metal layer used to generate interface nodes. This parameter has three arguments:

- `lowest_lef_pin_layer`: The tool generates interface nodes only on the lowest LEF metal layer. For example, if both METAL1 and METAL2 metal layers exist for the power/ground pin in the cell LEF, the tool will only generate the interface nodes on the METAL1 layer.
- `highest_lef_pin_layer`: The tool generates interface nodes only on the highest LEF metal layer. For example, if both METAL1 and METAL2 metal layers exist for the power/ground pin in the cell LEF, the tool will only generate the interface nodes on the METAL2 layer.
- `all_lef_pin_layers`: The tool generates interface nodes on all LEF metal layers. For example, if both METAL1 and METAL2 metal layers exist for the power/ground pin in the cell LEF, the tool generates the interface nodes on both METAL1 and METAL2 layers. This is the default value.

Data_type: enum, optional

`-generate_bulk_pin_cap_separately {true | false}`

Specifies to generate separate capacitance values for body bias pins in the library report. This parameter allows you to check the bulk pin capacitance based on the Spice simulation. The default value of this parameter is `false`. When set to `false`, the software would sum up the capacitance values for the body bias pins and power/ground pins.

The following is a snippet of the library report:

```
cell_A
            VPP(0.9350)     2.3e-16         EARLY(1 taps) EM(1 taps) IR(1 taps)
            VBB(0.0000)     2.3e-16         EARLY(1 taps) EM(1 taps) IR(1 taps)
            VDD(0.9350)     8.1e-15         EARLY(1 taps) EM(1 taps) IR(1 taps)
            VSS(0.0000)     8.1e-15         EARLY(1 taps) EM(1 taps) IR(1 taps)
Cell Type = STDCELL                    Cell_Status: PASS
```

Here, the blue-highlighted text shows the capacitance values for the `VPP` and `VBB` body bias pins.

Data_type: enum, optional

`-generate_gray_box_data {true | false}`

Controls the generation of gray box data and storage of this data in the cell library. It is recommended to set this parameter to `false` to reduce the size of the PGV significantly (from 10MB to 1MB) without loss of accuracy. The default value of this parameter is `true`.

This parameter is applicable only for macro PGV generation (`-cell_type macros`).

`-generate_interface_node_x_direction {true | false}`

When the LEF port geometry is bigger than the tap node distance (`set_advanced_pg_library_mode -tap_node_distance`), multiple interface nodes are generated. You can specify this parameter to generate the interface nodes along the X direction.

The default value is `true`. When set to `false`, interface nodes are not generated along the specified direction.

Data_type: enum, optional

`-generate_interface_node_y_direction {true | false}`

When the LEF port geometry is bigger than the tap node distance (`set_advanced_pg_library_mode -tap_node_distance`), multiple interface nodes are generated. You can specify this parameter to generate the interface nodes along the Y direction.

The default value is `true`. When set to `false`, interface nodes are not generated along the specified direction.

Data_type: enum, optional

`-generate_interface_nodes_at_via_layer {true | false}`

Specifies to generate interface nodes at via locations in scenarios where the tap current source is a VIA layer.

Data_type: enum, optional

`-ignore_pg_nets {{cellname netname}+}`

Skips the specified power or ground nets in PGV generation.

Data_type: string, optional

`-import_xdspf_list_file filename`

Specifies the name of the xDSPF (third-party netlist) parasitic file that is imported by the Library Characterization engine to create PGDB. You must also specify the mapping file using the `-xdspf_layer_map` parameter.

When you specify this parameter, the following parameters are not supported:

- `-xtc_command_file`
- `set_pg_library_mode -spice_subckts`
- `set_pg_library_mode -gds_files`
- `set_pg_library_mode -gds_layer_map`
- `-techgen_dir`

Data_type: string, optional

`-input_port_value_list {pin1 value1 pin2 value2 ....pinN valueN}`

Specifies the voltage conditions of the signal inputs during power-grid library characterization. A typical usage model of this parameter include setting the SET or RESET signal port to be the same voltage as supply or ground (tie high/low) to obtain the correct model of operation.

The following example illustrates the use model:

```
set_advanced_pg_library_mode -input_port_value_list { RESETVDD 3.3 }
```

Data_type: string, optional

`-interface_node_location_file filename`

Specifies a file containing the location of interface nodes where tap currents are to be generated. The specified file includes the cell name, net name, layer name, and location of the nodes. This parameter allows to generate current taps at user-specified locations during PGV generation.

The format of the file is:

```
CELL <cell_name>
NET <net_name>
LAYER <layer_name> (x1,y1),(x2,y2)
```

Example:

```
CELL cellA
NET VDD
LAYER M0 (0,0.15),(0.585,0.177),(0.2,0.15),(0.3,0.177)

NET VSS
LAYER M0 (0.485,0.019)

CELL cellB
NET VDD
LAYER M0 (0.49,0.008),(0.24,0.008)
```

This parameter is applicable only for technology and standard cell PGV generation (`-cell_type techonly | stdcells`).

`-lef_layer_ignore_list {lef_layername+}`

Specifies the names of the LEF layers that power-grid library generation is to ignore when it creates the cell library.

Data_type: string, optional

`-lef_layer_ignore_list_file filename`

Specifies the name of a file containing a list of the LEF layers that power-grid library generation is to ignore when it creates the cell library. Each line in the file must consist of a single LEF layer name.

The format of the file is:

```
layer1
layer2
...
layern
```

Data_type: string, optional

`-lef_pin_short {true | false}`
