Advanced VLSI design How to properly size a design using Virtuoso and ADE?

1. SETTING UP THE DESIGN UNDER TEST

Here, for the example, we consider a simple chain of inverters in 65ll UMC CMOS technology.

Each inverter is composed of 1pmos and 1nmos transistor (here we use nch_mac and pch_mac). We set the nmos and pmos W parameter to Wn and Wp respectively.

The input source (IN) generates a 50% 1ns period square signal between 0 and 1.2V with a rise and fall time of 10ps. The output capacitor is 10fF, and we chain several inverters to avoid capacitive coupling with the input signal.

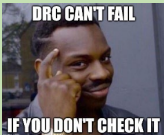

Special teacher tips: We generally advise to use “mac” devices for mos transistors as they have 4 terminal and the designer has explicit control over the bulk. In non-mac mos devices, the bulk terminal is generally connected to GND!/VSS! or VDD! using a global variable. Explicit declaration is always a good way to not make mistakes.

Create an ADE assembler view for it, set measures probes on IN, IN1, IN2, IN3 and OUT signals. Set a 10ns transient analysis. Define global variables Wn and Wp to 120n (no need to put the unit there – it’s obviously meters). Run the simulation and check that everything works properly.

Here we are particularly interested in the transmission time through the last inverter. So the delay between IN3 and OUT.

Open the calculator (tools > calculator) and use the special function delay to extract the time transmission time of the last inverter (I3) on the second rising and falling edges of OUT (here we are checking the transition at 2ns and 3ns). Call these expressions FallingOUT and RisingOUT. As we are characterizing an inverter, so one signal is falling while the second is rising (and inversely).

Special teacher tips: when measuring a timing, power or energy from a transient simulation, it is a good practice to not take the first switching. Typically a transient analysis starts from the state to which the DC analysis converged to. One has no guarantee that the resulting state is correct and that no nodes are stuck in some metastable states. Running a few cycles is never bad to reach some kind of “steady state” situation. Also, the measurement conditions one may want to reach are rarely the ones from the dc analysis.

Here is an example of expression :

```
delay(?wf1 VT("/IN3"), ?value1 0.6, ?edge1 "rising", ?nth1 2, ?td1 0.0, ?tol1 nil, ?wf2 VT("/OUT"),
?value2 0.6, ?edge2 "falling", ?nth2 2, ?tol2 nil, ?td2 nil, ?stop nil, ?multiple nil)
```

here we consider 50-50 at 0.6V

and the corresponding calculator window :

The Function Panel window displays settings for two signals, Signal1 and Signal2. Signal1 is set to `VT("/IN3")` and Signal2 is set to `VT("/OUT")`. Both signals have a Threshold Value of 0.6, Edge Number of 2, Edge Type of rising (Signal1) and falling (Signal2), Periodicity of 1, and Tolerance of nil.

Here is a few of the ADE assembler view with all the signals and expressions.

Test	Name	Type	Details	EvalType	Plot	Save
alwork_IV_param_tb_1	/OUT	signal		point	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>
alwork_IV_param_tb_1	/IN	signal		point	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>
alwork_IV_param_tb_1	/IN1	signal		point	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>
alwork_IV_param_tb_1	/IN2	signal		point	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>
alwork_IV_param_tb_1	/IN3	signal		point	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>
alwork_IV_param_tb_1	FallingOUT	expr	delay(?wf1 VT("/IN3") ?value1 0.6 ?edge1 "ri...	point	<input checked="" type="checkbox"/>	<input type="checkbox"/>
alwork_IV_param_tb_1	RisingOUT	expr	delay(?wf1 VT("/IN3") ?value1 0.6 ?edge1 "f...	point	<input checked="" type="checkbox"/>	<input type="checkbox"/>

Run the simulation and check the timing you get for the falling and rising times. With such an unbalanced sizing (120nm for both Wn and Wp), you should get a much slower rising than falling as the pmos is much weaker than the nmos. Something around 90ps for falling and 150ps for rising.

2. DEFINING TARGETS

In the FallingOUT and RisingOUT expressions, define timing targets at <50ps.

Test	Name	Type	Details	EvalType	Plot	Save	Spec	Weigh
alwork_IV_param_tb_1	/OUT	signal		point	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>		
alwork_IV_param_tb_1	/IN	signal		point	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>		
alwork_IV_param_tb_1	/IN1	signal		point	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>		
alwork_IV_param_tb_1	/IN2	signal		point	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>		
alwork_IV_param_tb_1	/IN3	signal		point	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>		
alwork_IV_param_tb_1	FallingOUT	expr	delay(?wf1 VT("/IN3") ?value1 0.6 ?edge1 "ri...	point	<input checked="" type="checkbox"/>	<input type="checkbox"/>	< 50p	
alwork_IV_param_tb_1	RisingOUT	expr	delay(?wf1 VT("/IN3") ?value1 0.6 ?edge1 "f...	point	<input checked="" type="checkbox"/>	<input type="checkbox"/>	< 50p	

Note how both of them are in red and marked as failed in the results panel after you run the simulation

alwork_IV_param...	FallingOUT	90.7p	< 50p		fail
alwork_IV_param...	RisingOUT	148.8p	< 50p		fail

3. RUNNING A PARAMETRIC ANALYSIS

Let's analysis Wn first.

To set a parametric analysis, define a parameter, and set a from/to analysis.

- In the dataview panel in the Wn global variable, click on the “...” button
- Click delete spec to remove the current 120nm sizing
- Select from/to in the dropdown menu, and select 10 step, auto, from 120n to 1u.

This will run 10 simulations with various sizes of Wn from 120nm to 1u.

In the results panel, note that the dropdown menu has a lot of options. The Detail-transpose is generally the easier to read. Here Wp is constant and Wn varies.

fail						30.09p	160.3p
fail						29.51p	161.9p

Counterintuitive remarks: Note that RisingOUT increases when Wn increases (think about it 😊). And if you can't find the answer, it's in the EDALABS material session 2.

Do the same with both Wn and Wp. Note that now virtuoso has to do 100 simulations. It's a lot. One way to go faster is to run several simulations in parallel.

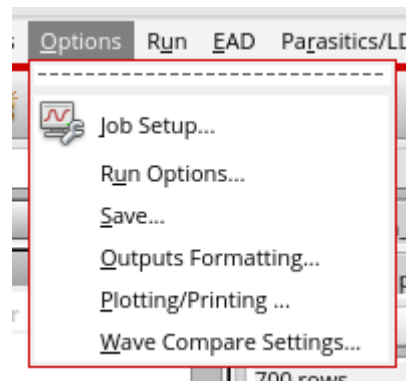

Options>Job Setup...

There you can define the number of jobs that can run simultaneously. You can put 2 in "max jobs"

Options>Run Options...

Tick "parallel"

PLEASE, be gentle with the resources. Remember that you generally work in a shared infrastructure with other users, and a limited amount of licenses.

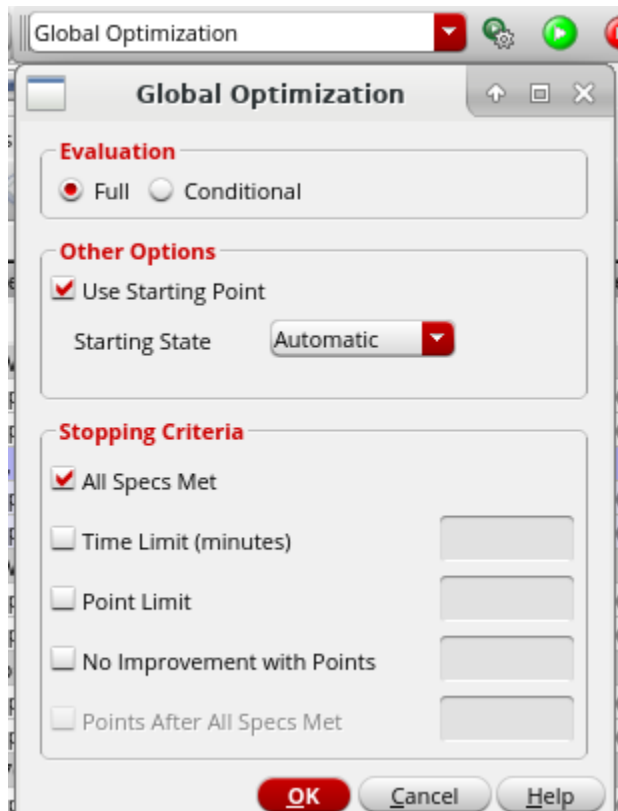

Check the result. You should find that sizes of Wn=315n and Wp=610n are good.

This highlights how design space explorations can become complex particularly when involving constraints pulling in different directions.

4. AUTOMATING PARAMETRIC ANALYSIS WITH VIRTUOSO

Virtuoso embeds an optimization tool that enables you to explore a design space faster. It does a pre-screening of the design space, identifies trends, and then try to find an optimum that matches with the defined targets. Note that you can also weight them to help it converge.

Select “Global optimization” and click on . There are many options in there, here we pick a configuration, but depending on your needs you may want :

- To change parameters
- To read about it on support.cadence.com

Selecting a starting point will force it to start from the middle of the range defined in the global variable panel (here approx. $W_p=W_n=600\text{nm}$). For the example, we updated the constraints to a range between 50p and 60ps for the target, to force the optimizer to explore the design space.

9	nom	804.4n	217.8n	fail	canceled	canceled	canceled	canceled	canceled	canceled	canceled		

It took 8 iterations to converge to an acceptable solution, relatively similar to the one we got with a complete design space exploration.

Clicking on  will show you the iterative process to converge.
