

# Laser Processing of Materials

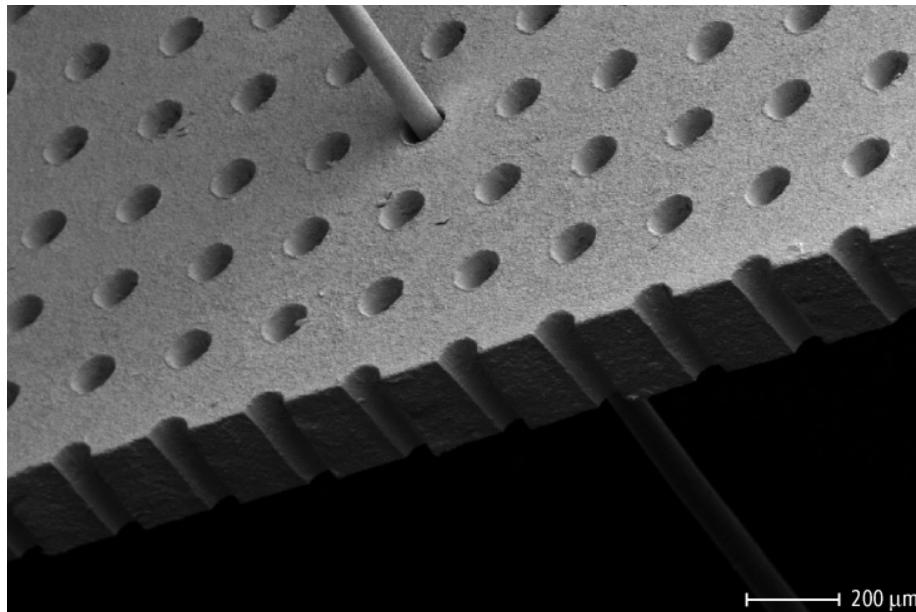

## Applications: Ultrafast Laser Ablation

---

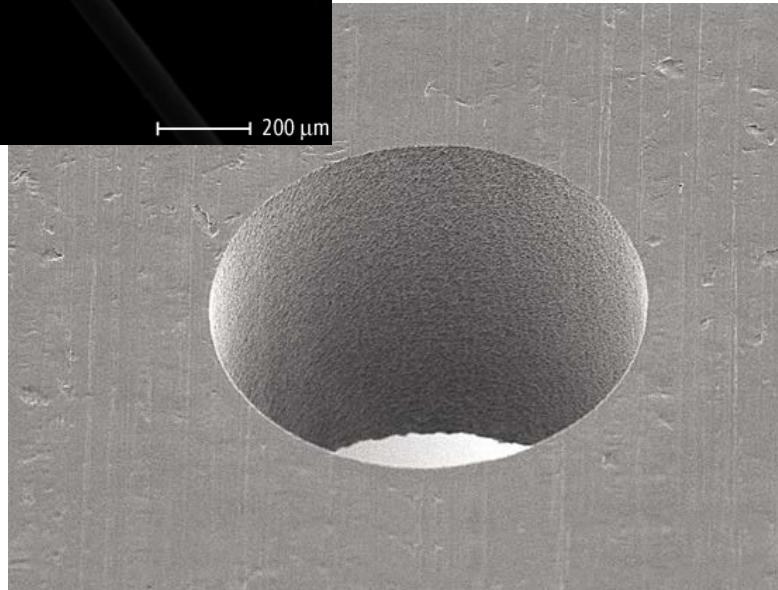

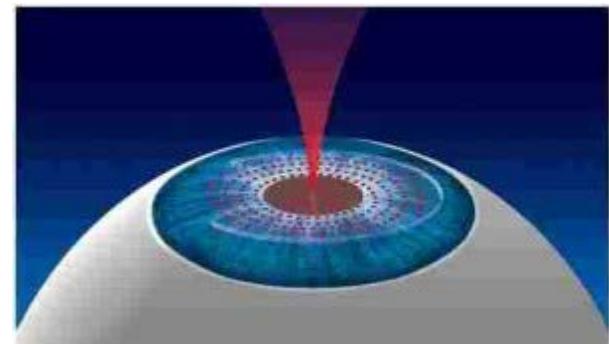

Patrik Hoffmann

# Applications: Ultrafast (modelocked) Lasers

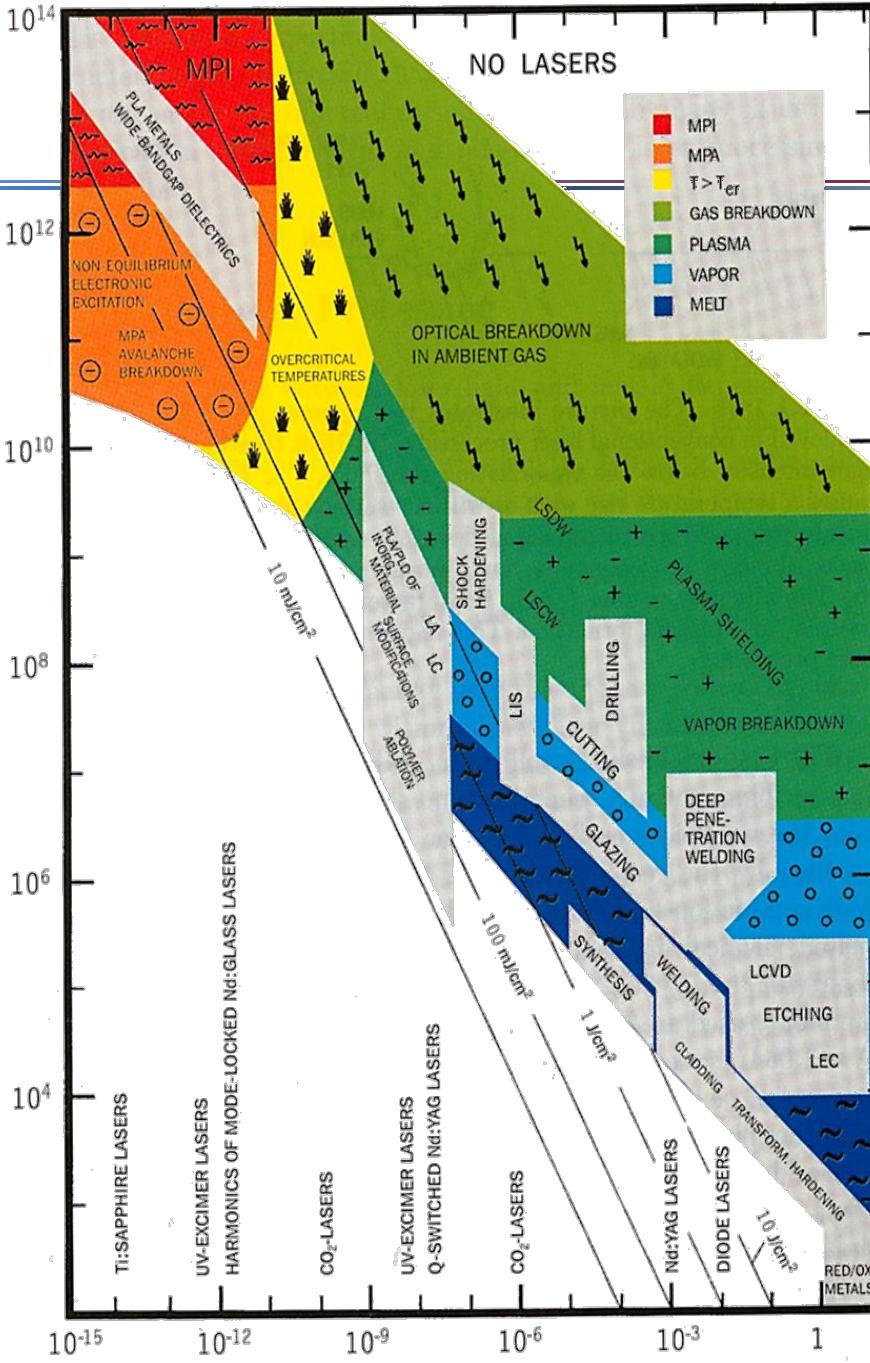

**high precision laser machining**

**no blade cut  
eye correction**

LASER LIGHT INTENSITY  $I$  [W/cm<sup>2</sup>]

# Application of lasers in materials processing: Intensity-Time Diagram

PLA/PLD – pulsed laser ablation/  
deposition

LA – laser annealing

LC – laser cleaning

LIS – laser induced isotope separation/IR –  
laser photochemistry

MPA/MPI – multiphoton absorption  
ionization

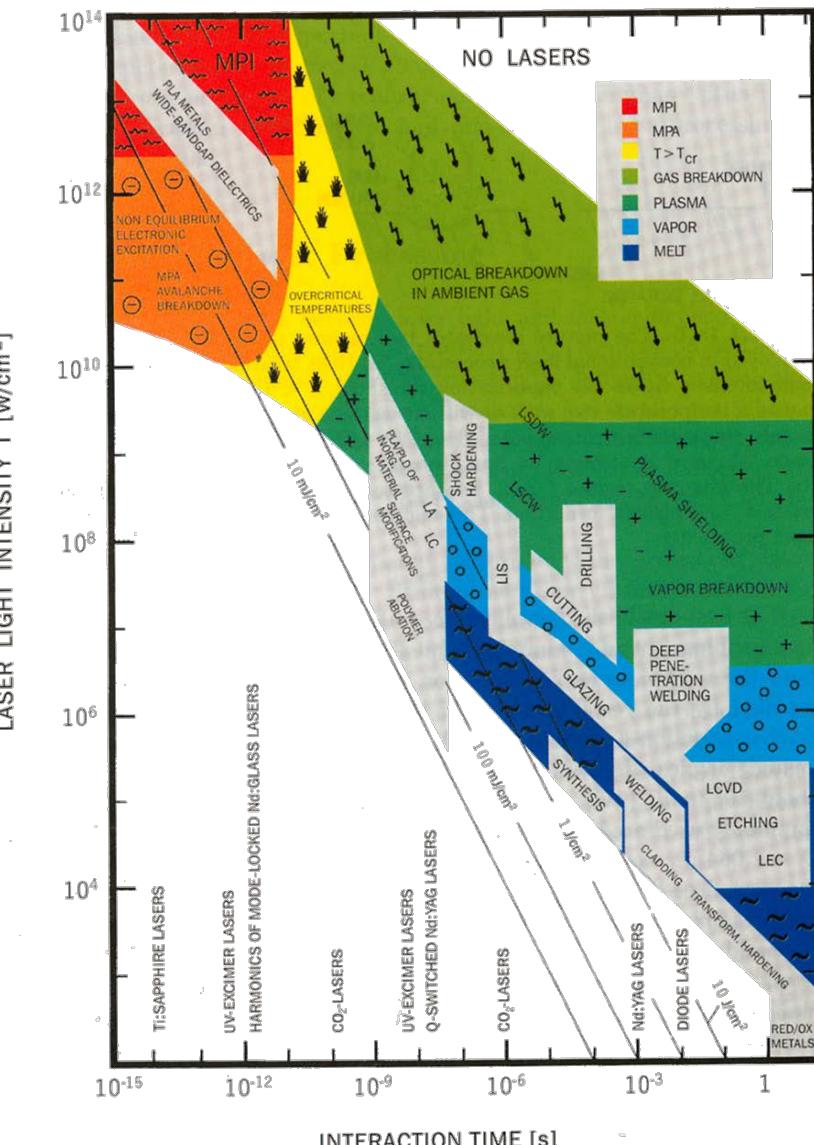

LSDW/LSCW – laser supported  
detonation/combustion waves

LCVD – laser induced chemical vapour  
deposition

LEC – laser induced electrochemical  
plating/etching

RED/OX – long pulse or cw CO<sub>2</sub>-laser  
induced reduction/oxidation

D. Bäuerle; Laser Processing and  
Chemistry, 3rd ed. Springer, Berlin,  
2000

# Laser Types: Pulsed & CW

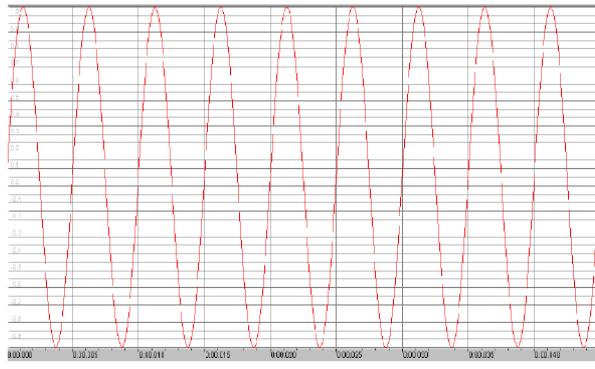

Type of laser	Pulse length determined by	Typical pulse length	Characteristic pulse peak power
Continuous wave (cw)	-	$\infty$	Ws – kWs
Free running laser	Pump pulse length (flash lamp)	100 $\mu$ s – 1ms	kWs
Q-switched laser	Time constants of active material and modulating element	1 ns – 100 ns	MWs
Mode-locked laser	Number of coupled modes, pulse compression	10 fs – 10 ps	GWs

Why do you want very short pulses?

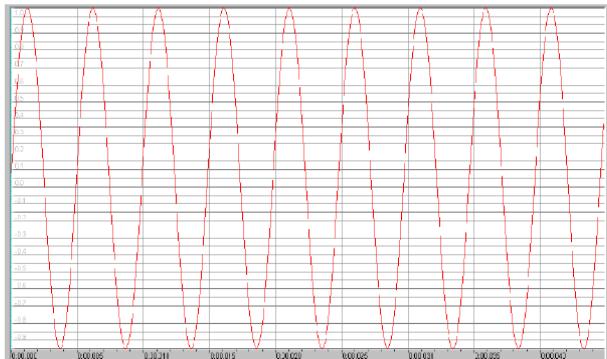

# Mode-locking regime

Mode-locked pulses – result of **intference of many „locked“ (phase/frequency related) light waves**

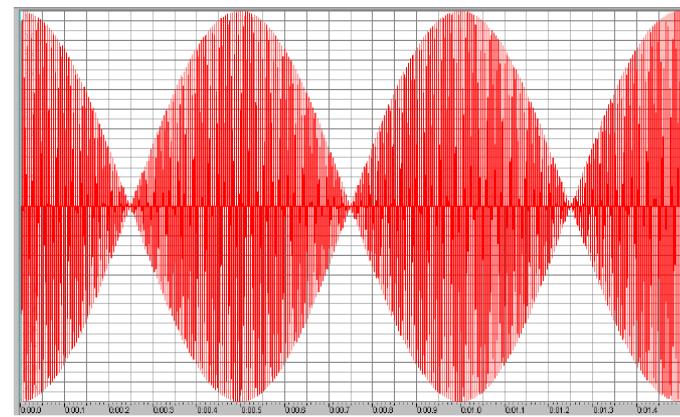

interference of waves with two different frequencies

$$A_{S2}(t) = A_1(t) + A_2(t) = \sin(2\pi\nu_1 t) + \sin(2\pi\nu_2 t)$$

$t$  [s]

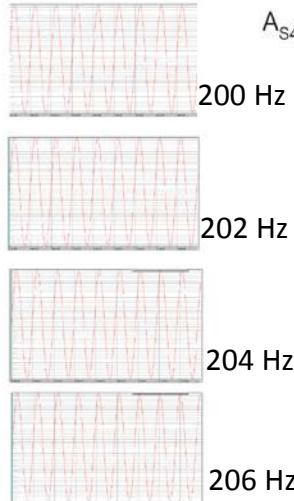

200 Hz

202 Hz

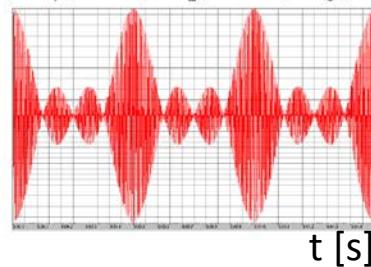

$t$  [s]

# Mode-locking regime

interference of waves  
with four equidistant frequencies

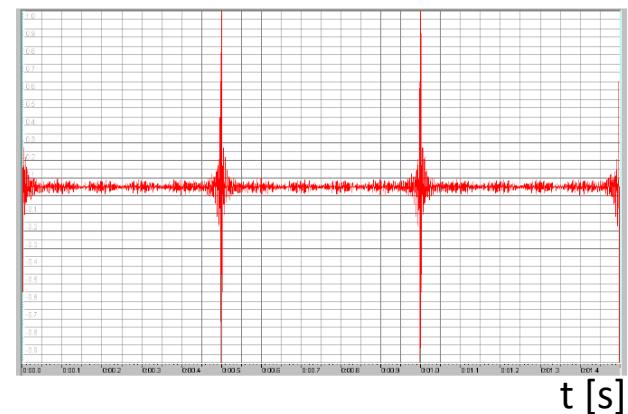

$$A_{S4}(t) = A_1(t) + A_2(t) + A_3(t) + A_4(t) \\ = \sin(2\pi\nu_1 t) + \sin(2\pi\nu_2 t) + \sin(2\pi\nu_3 t) + \sin(2\pi\nu_4 t)$$

interference of waves  
with 120 equidistant frequencies

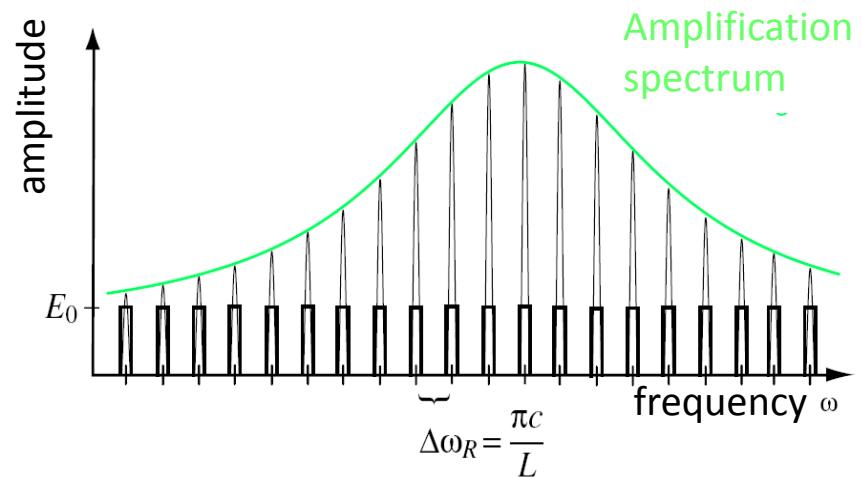

$$A_{S120}(t) = \sum_{n=0}^{120} \sin[2\pi(\nu_1 + n\Delta\nu)t]$$

$$\nu_1 = 200 \text{ Hz} \\ \Delta\nu = 2 \text{ Hz}$$

# Mode-Locking

- Different interfering light waves are **longitudinal modes** of the resonator
- more modes → shorter the pulse
- Typical mode-locked lasers have:  
ultra short pulses  $\sim 50 \text{ fs} - 1 \text{ ps}$   
very high peak power  $\sim 1 \text{ MW} - 10 \text{ GW}$

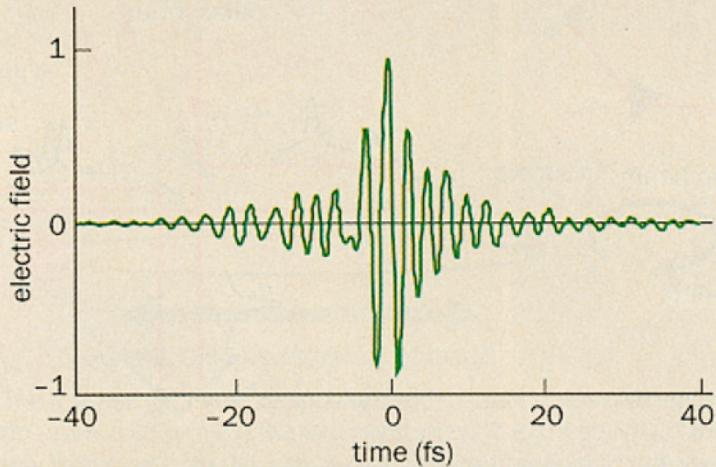

Heisenberg uncertainty principle:  $\Delta \nu \cdot \Delta \tau \geq 1$

$\Rightarrow$  very short light pulses cannot be very monochromatic  $\Rightarrow$  special active media with **broad emission spectrum** needed for very short (femtosecond) pulses

Ti:Sapphire is typical active medium for fs-lasers

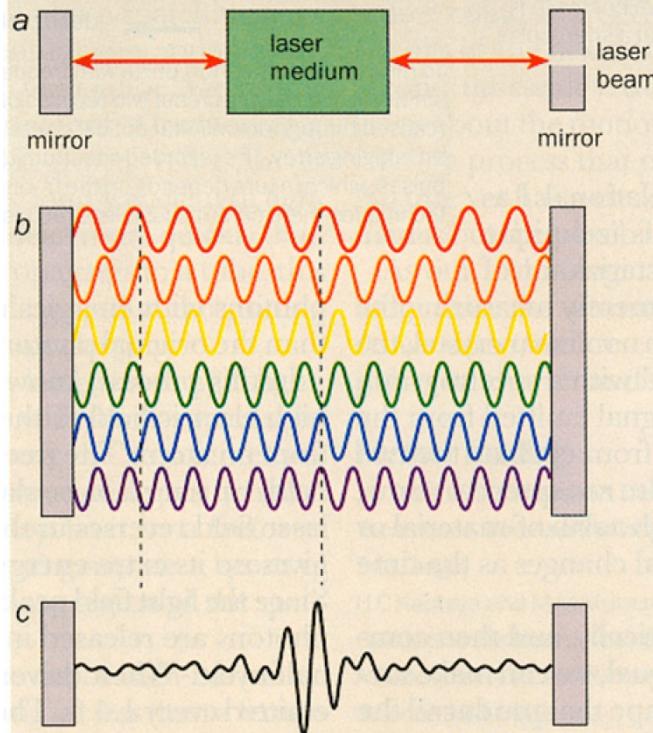

# Examples of Ultra-short pulses

## 2 Short light pulses

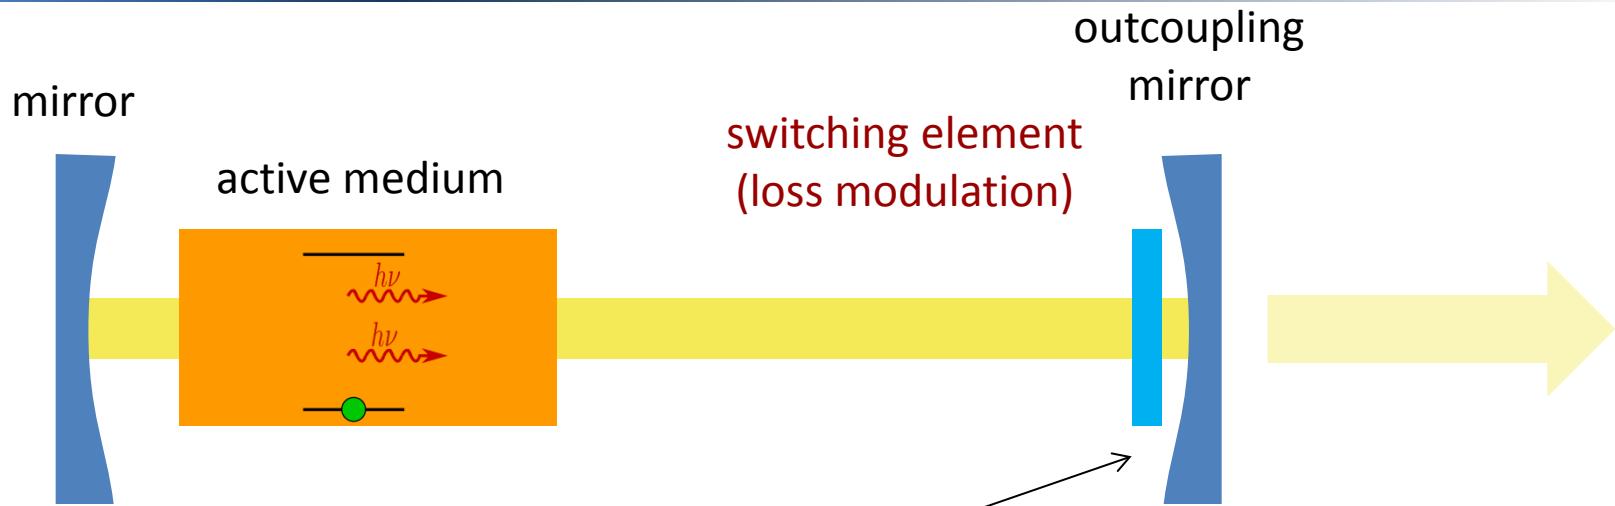

Maxim Pshenichnikov of the University of Groningen in the Netherlands has measured the electric field of a 5 fs light pulse, the shortest complete pulse measurement made to date. The output pulse consists of the two complete cycles centred around 0 fs.

## 3 Laser modes

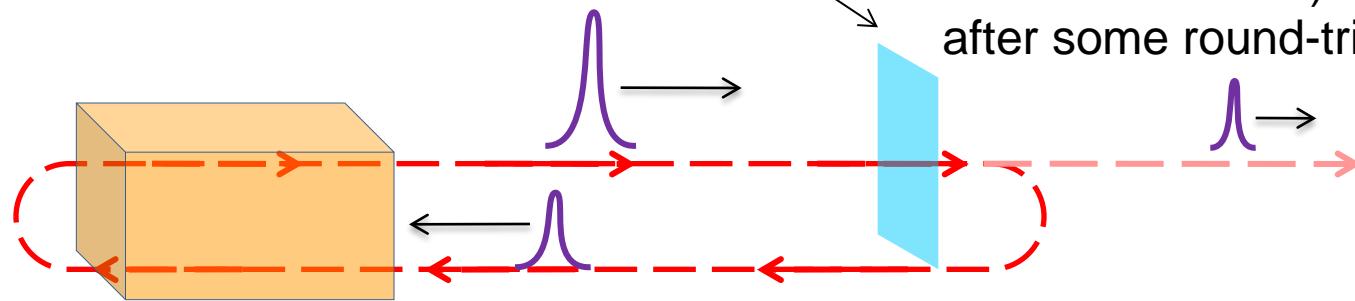

(a) A laser essentially consists of a laser medium sandwiched between two mirrors, one of which is partly transmissive. If the amplification of light by the laser medium is greater than the energy loss, light is emitted through the end mirror. (b) Many different modes can exist within the laser cavity, under the condition that the cavity length must equal an integer number of wavelengths. Each mode has a different frequency and wavelength. (c) In a mode-locked laser the electric field associated with the different modes must add constructively at one point and destructively elsewhere to create a high-intensity spike.

# Modes couplés dans la pratique

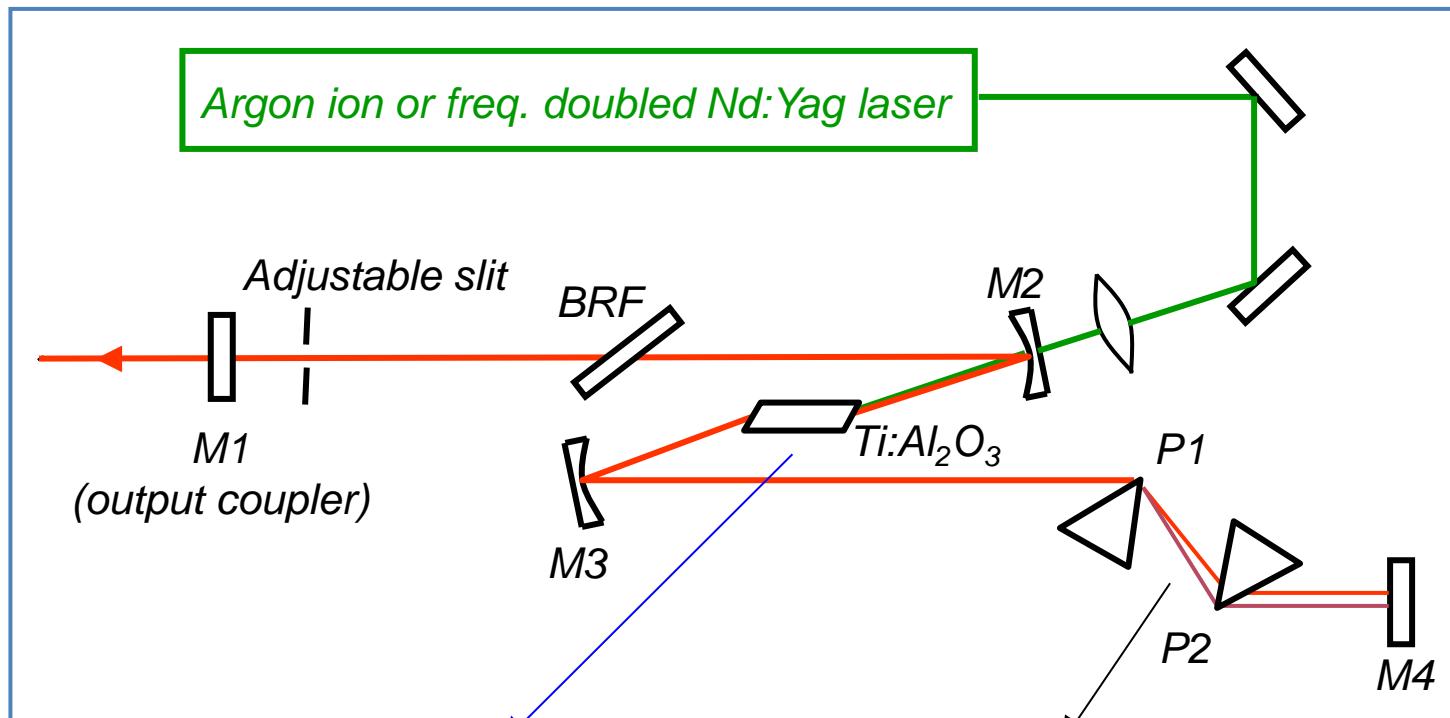

Q-modulating element (1-2%) and pulse round-trip in the resonator are synchronized: actively or passively (automatically)

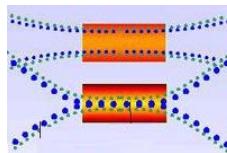

- the **synchronized** bunch of light is amplified, **out-of-phase** emission is suppressed
- a **single travelling pulse** (= mode-locked conditions) is established after some round-trips

# Schematics of a Femtosecond Laser

## Astigmatismus, dispersion and Kerr lens effect

$$\tau_{blue} > \tau_{red}$$

## Dispersion compensation

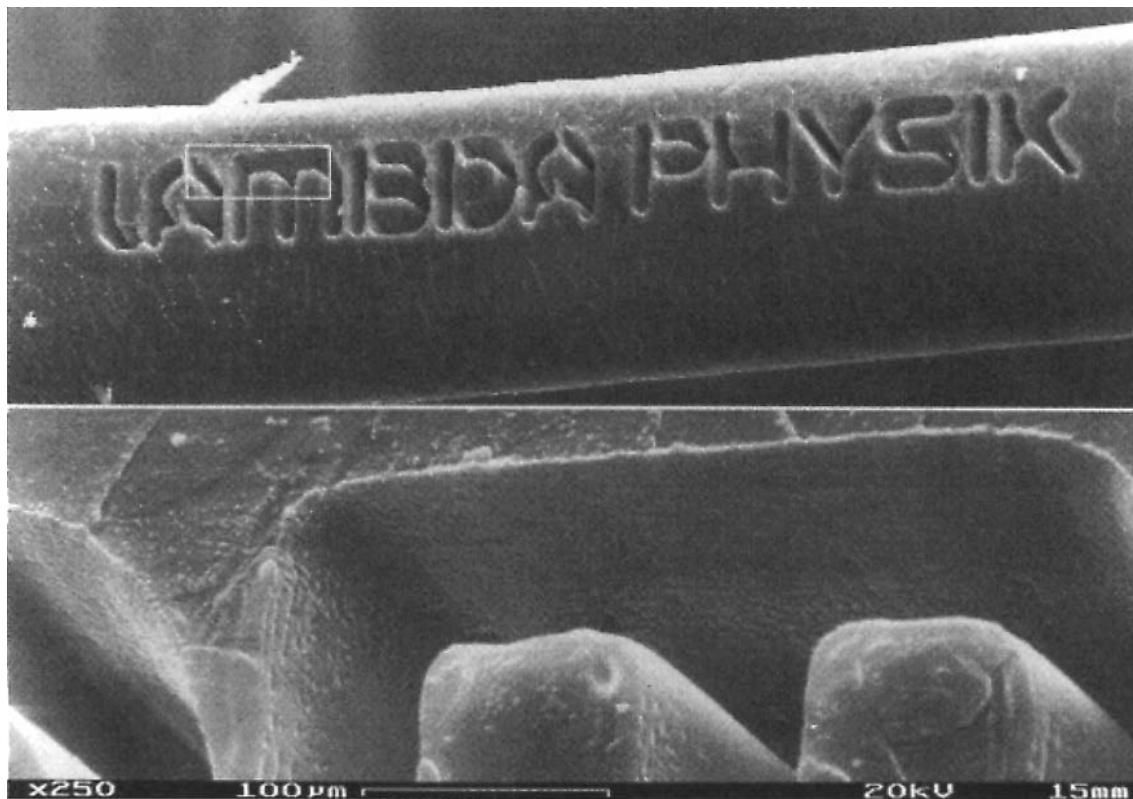

$$\tau_{red} > \tau_{blue}$$

→ minimum pulse width: ~30 fs, special thin crystal and chirped mirrors: 4-5 fs

# Example: Human Hair Marking

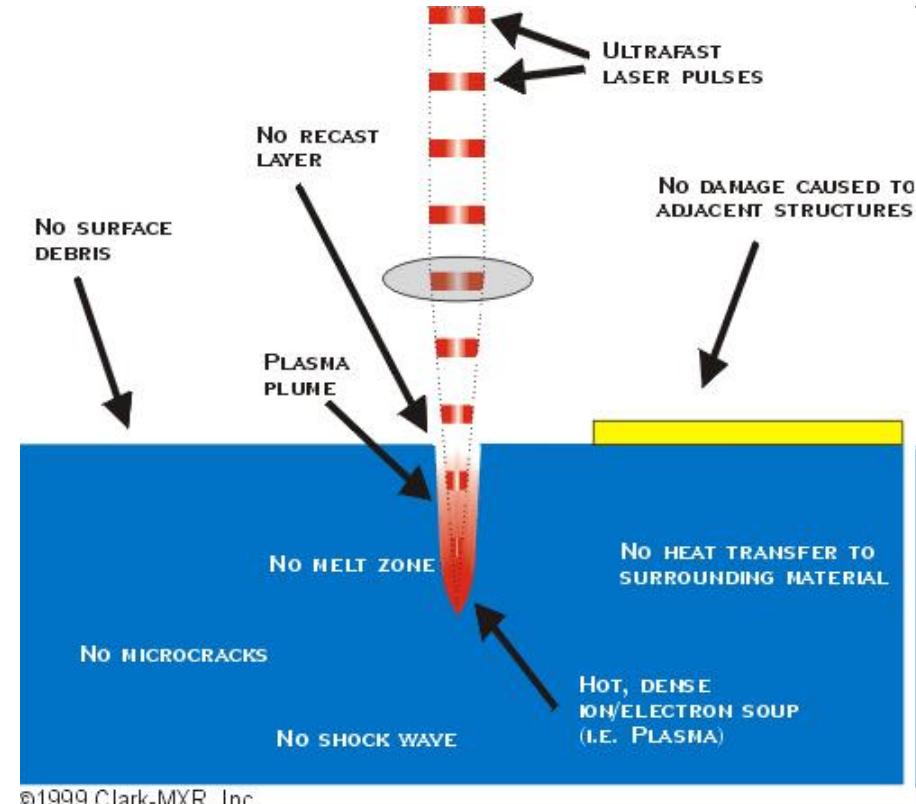

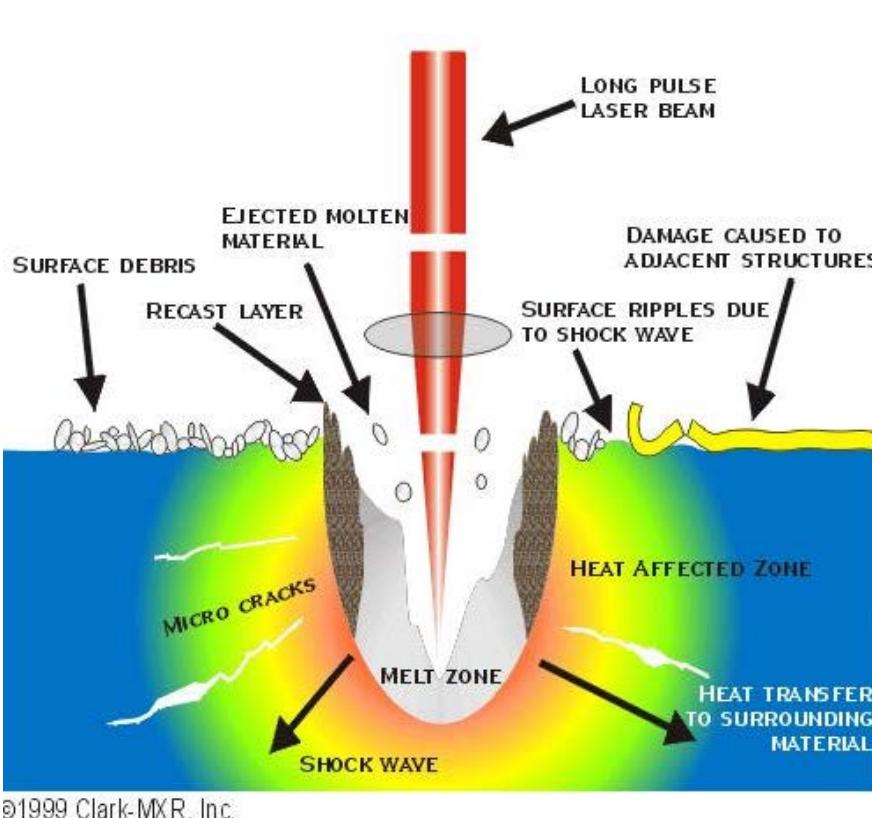

„Cold“  
ablation?

*Scanning electron micrograph showing writing by excimer laser induced ablation on a human hair*

Srinivasan, 1982, IBM Yorktown Heights;  
Cold ablation by UV photon bond scission

# ns-Machining vs. fs-Machining
