

## 1 Tension versus three-point bending

In this question, we consider square cross-section bars of a brittle material with thickness  $b$  and length  $l$  tested in uniaxial tension and three-point bending (Figure 1), and whose tensile strength obeys Weibull statistics.

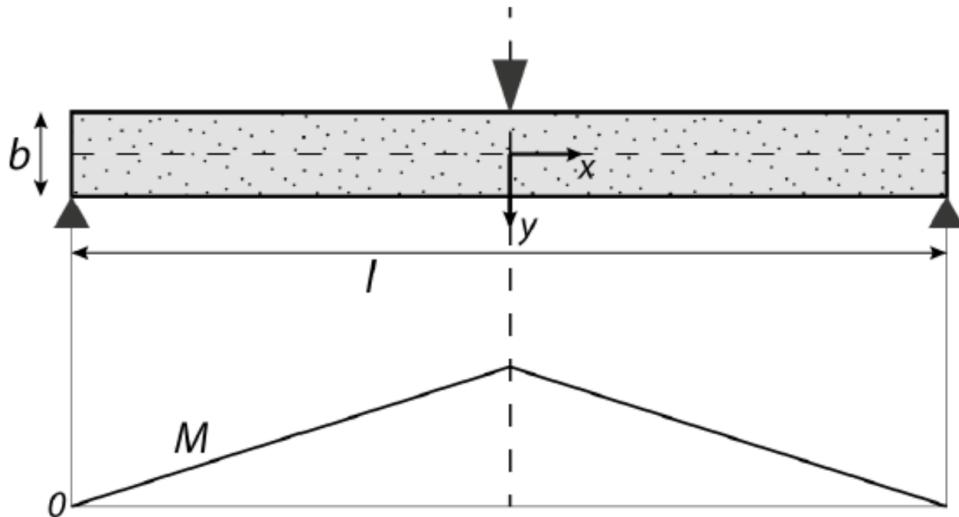

Figure 1: A three-point bend specimen along with a sketch of the variation of the bending moment  $M$  with distance  $x$  between the support points and the loading point.

### Question 1

Write down the two-parameter Weibull distribution for failure in uniaxial tension. What is the corresponding expression for a solid with an arbitrary stress profile  $\sigma(x, y)$ , where  $x$  is in the tensile direction and  $y$  is perpendicular to the tensile direction? (You may assume  $\sigma$  not to vary in the third dimension).

### Question 2

Show from simple beam analysis that in three-point bending:

$$\sigma(x, y) = \sigma_{max} \left(1 - \frac{2|x|}{l}\right) \frac{2y}{b}$$

where  $\sigma_{max}$  is the maximum stress in the specimen at any given load and you may assume from simple beam theory that  $\sigma = M(x)y/I$ , where  $y$  is the vertical distance from the neutral axis,  $I$  is the moment of inertia of the beam and  $M$  is the bending moment (for a square cross-section beam of side  $b$ ,  $I = b^4/12$ , but you don't need this result to answer the question).

### Question 3

Hence, derive the two-parameter Weibull distribution for failure in three-point bending in terms of the Weibull parameters obtained in uniaxial tension, and the expression for the correction factor  $k_m$ , namely  $k_m = \frac{1}{2(m+1)^2}$ .

## 2 Statistical failure of $\text{Si}_3\text{N}_4$ in four-point bending

Sintered silicon nitride is a very hard, high-performance ceramic used in car engines, bearings, and rocket engines, for example. It is therefore very much a structural material and must meet stringent performance requirements despite its intrinsically brittle nature.

A series of  $\text{Si}_3\text{N}_4$  bars of constant rectangular square cross-section A were tested in four-point bending with an inner span length  $L_i$  equal to a third of the outer span length  $L_o$ . The strength data from 60 samples, are given at the end of these exercises, and in an Excel file on Moodle (if you need other formats, please ask), where they have already been ranked. You are asked to analyse these data using a two-parameter Weibull distribution.

| ordered strength [Mpa] | ln(strength) | order | ordered strength [Mpa] | ln(strength) | order | ordered strength [Mpa] | ln(strength) | order |
|------------------------|--------------|-------|------------------------|--------------|-------|------------------------|--------------|-------|

Figure 2: Ordered strength values of  $\text{Si}_3\text{N}_4$  bars tested in four-point bending.

### Question 1

Determine the Weibull modulus  $m$ . What is your opinion of the quality of the bars?

### Question 2

Determine  $k_m$  for this geometry.

### Question 3

Determine the Weibull scale parameter,  $\sigma_0$ , for a sample whose reference volume  $V_0$  is the effective volume of the test bar ( $AL_i$ ).

### Question 4

What would the Weibull scale parameter for stress,  $\sigma_0$ , be if we had instead adopted as a reference volume a volume with the same length  $L_i$  but a cross-section equal to  $A/16$  ?

**Question 5**

Your boss (who is fundamentally a nice person, but is under heavy pressure to cut costs), would like to guarantee to the customers that bars of length  $L_i$  and cross-section  $A$  will not fail below some critical stress  $\sigma_c$ . However, he/she can only afford to reject 30% of production. What do you do, and what should he/she tell the customers?

### 3 The fracture of solid fats

You do a series of tests on un-notched specimens of a solid fat-based confectionary formulation and find that its behaviour may be described by a two-parameter Weibull distribution with  $m = 4$  and  $\sigma_0 = 200$  kPa, owing to the presence of internal microcracks.

**Question 1**

Suppose that your material has a surface energy  $\gamma = 3 \times 10^{-2}$  J/m<sup>2</sup>. Estimate  $G_{IC}$  by assuming the material to behave as an ideal linear elastic solid up to fracture (cf. Griffith's model for glass).

**Question 2**

If the tensile modulus of the material is 200 MPa and its Poisson's ratio  $\nu$  is 0.4, what is  $K_{IC}$ ?

**Question 3**

Based on reasonable assumption that the microcracks that give rise to the Weibull distribution are penny-shaped, estimate the microcrack size that corresponds to the observed value of  $\sigma_0$ .

**Question 4**

Suppose that you can increase the tensile modulus of the specimen independently of all the other materials parameters (it might be enough to decrease the temperature to obtain roughly this effect). Do you think its strength will increase or decrease?
