

## Exercise 06

### A cascade of repressors

Consider a cascade of three repressors:

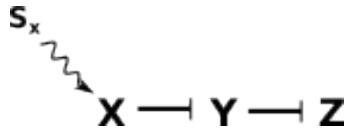

Figure 1: Cascade of three repressors. Signal  $S_x$  is keeping  $X$  in its inactive form and prevents the production of  $Y$ .

Protein  $X$  is initially present in the cell in its inactive form. Protein  $Z$  is present in the cell at its steady state concentration, and is continuously produced at rate  $\beta$ . At  $t = 0$ , the input signal of  $X$ ,  $S_x$  is removed.  $X$  is rapidly converted to its active form,  $X^*$ , and binds to the promoter of gene  $Y$ . As a result, production of protein  $Y$  begins. When  $Y$  levels increase above threshold  $K_Y$ , gene  $Z$  is repressed. All proteins have the same degradation/dilution rate  $\alpha$ .

- a)** Sketch the concentration of  $Y$  and  $Z$  as a function of time.
- b)** Show that the response time of  $Y$ , with respect to the addition of  $S_x$ , is:

$$t_{Y_{1/2}} = \frac{\ln(2)}{\alpha}$$

- c)** Show that the time at which production of  $Z$  stops,  $t_{YZ}$ , is:

$$t_{YZ} = \frac{1}{\alpha} \cdot \ln \left( \frac{Y_{st}}{Y_{st} - K_Y} \right)$$

- d)** What is the response time of  $Z$ , with respect to the addition of  $S_x$ ?
- e)** What is the effect of placing  $Z$  at the end of a cascade, as here, compared with placing  $Z$  under simple repression? Why might this effect be biologically useful?
