

Control and Operation of Tokamaks

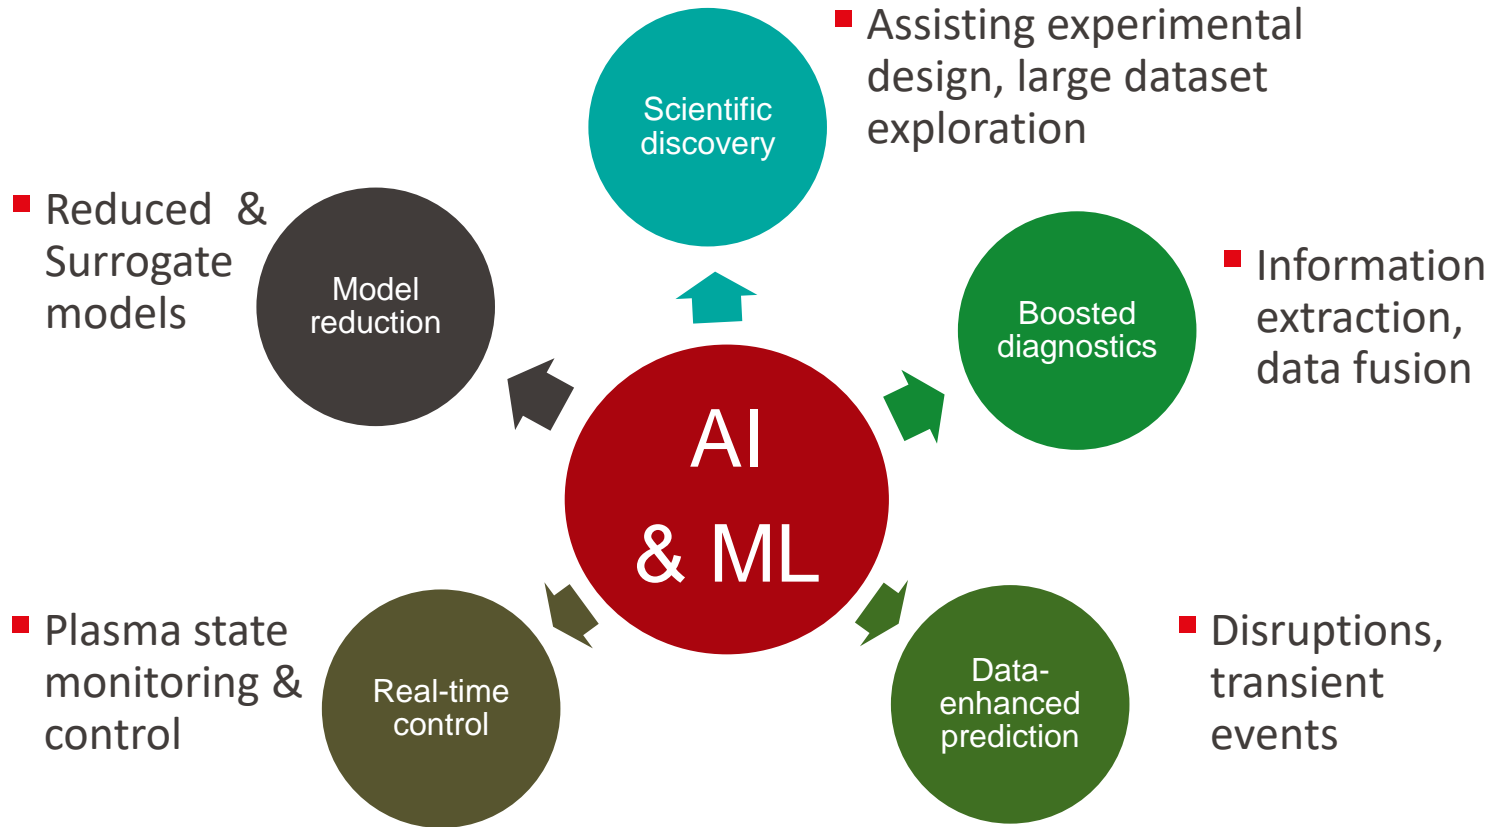

Machine Learning for plasma control

Alessandro Pau

12/02/2025, Lausanne

Advancing fusion by leveraging AI and ML

Data in fusion: a challenge in itself

- **Massive amount of data** (Big data – 2PB/day at ITER, high bandwidth diagnostics) ✓

- **Well-curated and annotated datasets:** do we have a well-defined vocabulary?

- **High-dimensional and heterogenous data** (many diagnostics measuring various plasma properties) ✓

- **Clear formulation** of the problem, and **well-defined targets?** Not always easy to translate high-level fusion research objectives in a well-defined machine learning formulation...

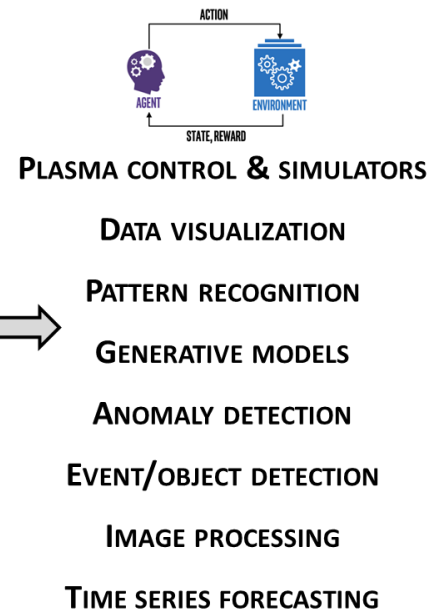

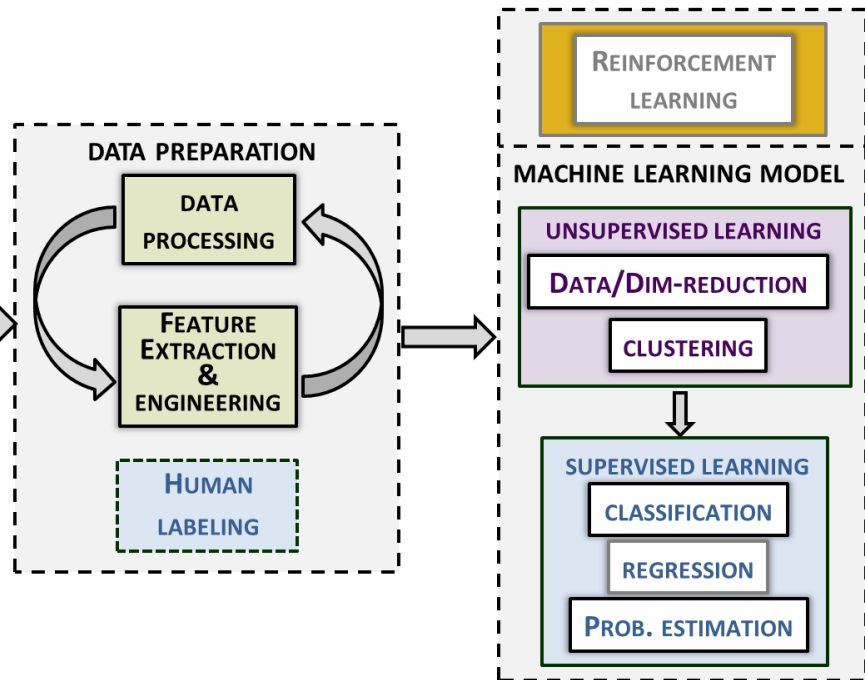

Typical Machine Learning workflow

- Massive volume of data
- High-dimensional;

- Heterogenous
- multiple timescales

...Type of learning: Supervised Learning

Training data

$$\mathcal{D}: (x_1, y_1), (x_2, y_2), \dots, (x_N, y_N)$$

Batch Learning:

- training on a **dataset entirely available** to the learning algorithm, with model's parameters being updated after each iteration through the data.
 - Typically, **more computationally efficient**, but less flexible to adapt to new data distributions.

Active learning:

- the learning algorithm is able to **interactively query** an information source to obtain the **desired outputs on new data** points (most informative data points to learn from)
 - often used when there is a limited amount of labelled data available: selecting which data points to learn from, the model can learn more effectively and efficiently.

Online Learning:

- the algorithm receives **one example at a time**, with model's parameters being updated incrementally as new data comes in.
 - Useful in case of limitations on computing and storage

...Type of learning: Reinforcement Learning

Training data

(input, output, reward/penalty)

Reinforcement learning:

- an “**agent**” learns to make decisions by continuously interacting with an environment and receiving **feedback** in the form of **rewards** or **penalties**.
 - The goal of reinforcement learning is to learn a “**policy**”, which is a **mapping from states to actions**, that maximizes the cumulative reward the agent receives over time.
-
- **Training data** consists of **sequences of states, actions, and rewards**.
 - Learning by **trial-and-error**, where the agent takes actions, receives rewards, and updates its policy based on the observed rewards until convergence to an optimal solution

...Type of learning: Unsupervised Learning

Unsupervised Learning:

- useful to discover **patterns** or **structure** in the data, with **no labelled data**. The learning algorithm task is to identify structure in the data, such as **grouping** similar examples according to a well-defined **metric**.
- Some common unsupervised learning techniques:
 - **Clustering**: grouping of similar examples into clusters,
 - **dimensionality_reduction**: projection of the data into a lower-dimensional space while preserving as much of the structure of the data as possible
 - **anomaly detection**: identification of examples that are significantly different from the majority of the data (...novelty detection).

Training data

$(x_1, \dots), (x_2, \dots), \dots, (x_N, \dots)$

Model fitting, or training:

(Training) data $\mathcal{D}: (x_1, y_1), (x_2, y_2), \dots, (x_N, y_N)$

- Learn the unknown target function describing the relation $f(x, \theta) \rightarrow y$
- find the set of parameters θ that best describe the mapping between the input and output variables in the data.
- Given the input data \mathcal{D} , solve an optimization problem in terms of minimization of an **objective** or **loss function**

Training examples

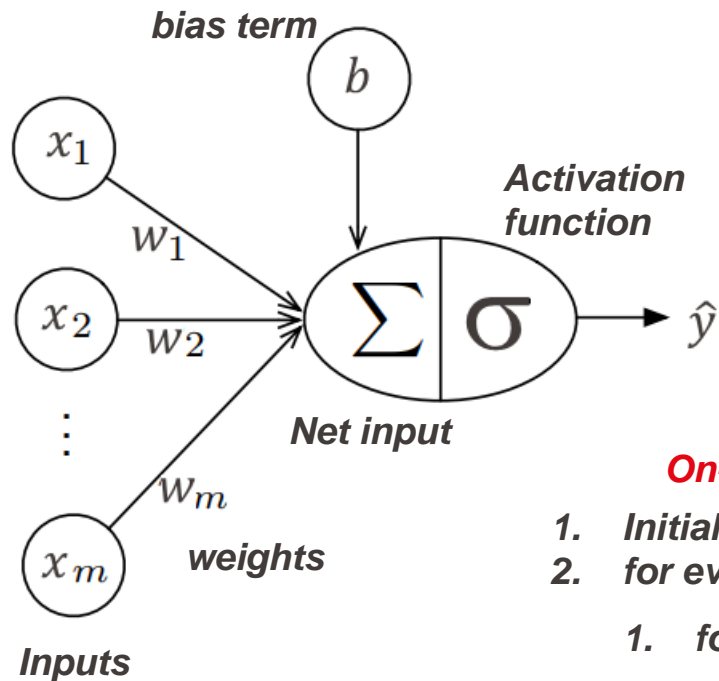

$$\mathcal{D}: x_1, x_2, \dots, x_N$$

Loss function

$$\hat{\theta} = \operatorname{argmin}_{\theta} \mathcal{L}(\mathcal{D}|\theta)$$

- What we call **inference** depends on the context: quantify the uncertainty or confidence in the estimate $\hat{\theta}$, or making prediction with a training model;
 - More in general: *process of drawing conclusions about the underlying data-generating process*

ML foundations: fitting/training a Perceptron

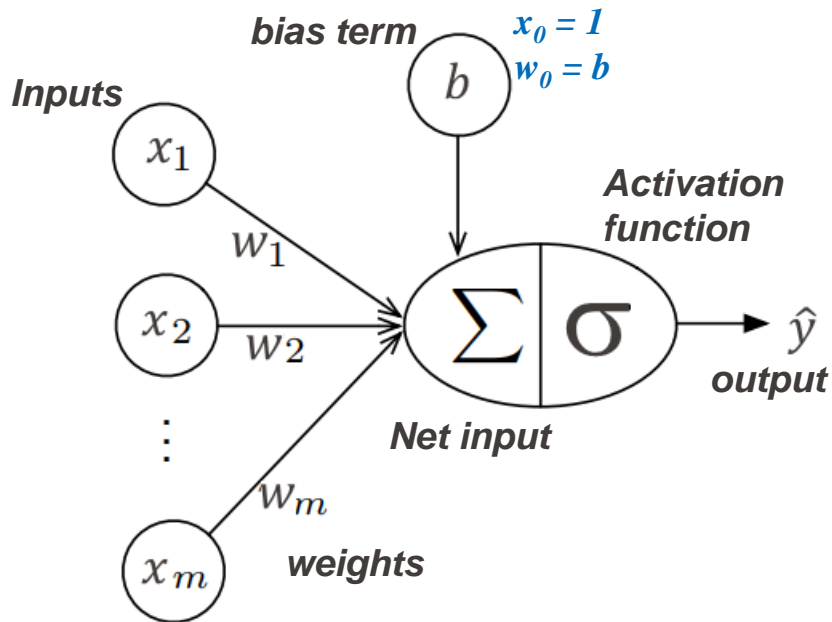

$$\hat{y} = \sigma \left(\left(\sum_{i=1}^m w_i \cdot x_i \right) + b \right) = \sigma(\mathbf{x}^T \mathbf{w} + b)$$

Given a training set:

$$\mathcal{D}: (\mathbf{x}^{[1]}, y^{[1]}), (\mathbf{x}^{[2]}, y^{[2]}), \dots, (\mathbf{x}^{[N]}, y^{[N]}) \in \mathbb{R}^m$$

On-line mode with Gradient Descent

1. Initialize w, b . (with $x^{[0]} = 1$ for b)
2. for every training epoch:
 1. for every $(x^{[j]}, y^{[j]})$ in \mathcal{D} : (or over mini-batches)
 1. $\hat{y}^{[j]} = \sigma(\mathbf{w}^T \mathbf{x}^{[j]} + b)$ compute prediction (forward)
 2. $err = (y^{[j]} - \hat{y}^{[j]})$ compute error (backward)
 3. $w, b = w, b + err \cdot x^{[j]}$ update parameters

$$\hat{y} = \sigma \left(\left(\sum_{i=1}^m w_i \cdot x_i \right) + b \right) = \sigma(\mathbf{x}^T \mathbf{w} + b)$$

$$\mathcal{D}: (\mathbf{x}^{[1]}, y^{[1]}), (\mathbf{x}^{[2]}, y^{[2]}), \dots, (\mathbf{x}^{[N]}, y^{[N]}) \in \mathcal{R}^m$$

function

$$\mathcal{L}(\mathbf{w}, b) = \sum_j (\hat{y}^{[j]} - y^{[j]})^2$$

On-line mode:

- Learning faster but noisier (shuffling each epoch) – *update after each* $(x^{[j]}, y^{[j]})$

Batch mode:

- Slower but less sensitive to noise
- *update after the entire data “batch”*

Mini-batch mode (typically used in DL)

- In between the previous two: with respect to batch settings, the update is done for each “mini-batches”.
- Advantage: **vectorization** (GPUs)
- Less noisy than online-mode & learning faster than batch

$$\hat{y} = \sigma \left(\left(\sum_{i=1}^m w_i \cdot x_i \right) + b \right) = \sigma(\mathbf{x}^T \mathbf{w} + b)$$

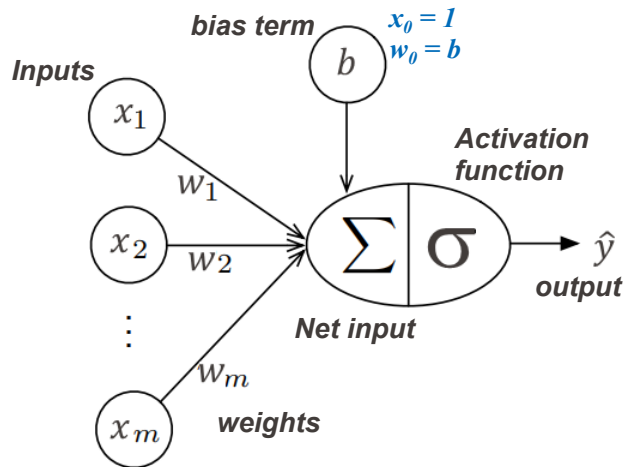

$$\mathcal{D}: (\mathbf{x}^{[1]}, y^{[1]}), (\mathbf{x}^{[2]}, y^{[2]}), \dots, (\mathbf{x}^{[N]}, y^{[N]}) \in \mathbb{R}^m$$

**Other training paradigm:**

- **Stochastic Gradient Descend** (SGD)
- **Batch Normalization** (BN)

Optimization problems with **Least-Squares**

normal equation: $\mathbf{w} = (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \mathbf{y}$

$$\hat{y} = \sigma(\mathbf{x}^T \mathbf{w} + b); \quad \sigma = I;$$

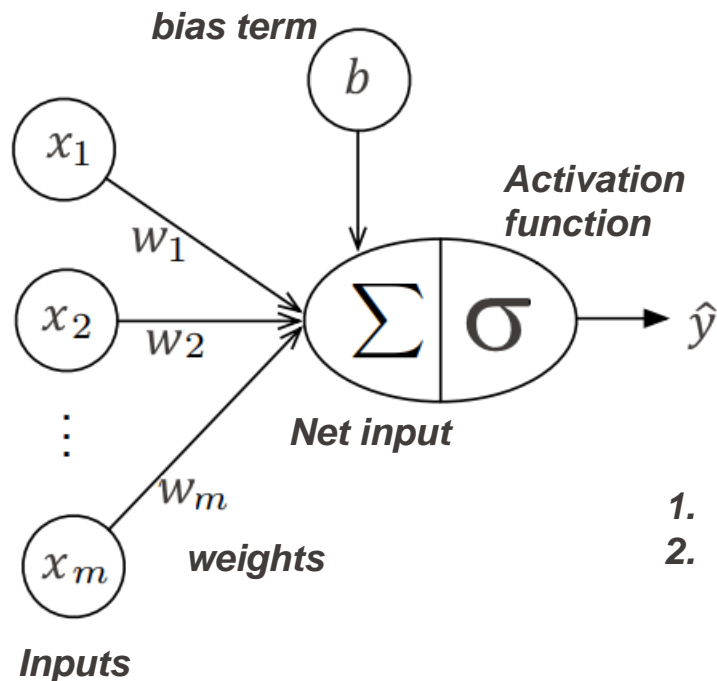

matrix form

$$\hat{\mathbf{y}} = \mathbf{X}\mathbf{w} \quad \mathcal{L}(\mathbf{w}) = \frac{1}{2m} \sum_j (\hat{y}^{[j]} - y^{[j]})^2$$

$$\begin{aligned} \nabla \mathcal{L}(\mathbf{w}) &= \frac{1}{2m} \|\mathbf{X}\mathbf{w} - \mathbf{y}\|^2 = (\mathbf{X}\mathbf{w} - \mathbf{y})^T (\mathbf{X}\mathbf{w} - \mathbf{y}) \\ &= \frac{1}{2m} 2\mathbf{X}^T (\mathbf{X}\mathbf{w} - \mathbf{y}) \quad (\text{using chain rules}) \end{aligned}$$

$$\nabla \mathcal{L}(\mathbf{w}) = 0 \rightarrow \mathbf{X}^T (\mathbf{X}\mathbf{w} - \mathbf{y}) = 0 \rightarrow \mathbf{w} = (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \mathbf{y}$$

- We have to fit basically a **linear regression model**
- Reasons: Sometimes closed-form solution (matrix inversion) computationally expensive (large \mathcal{D})
- We can learn this parameters **iteratively**, fitting (deep) **neural networks** and (non-)convex loss functions

Convex loss function

$$\mathcal{L}(w, b) = \sum_j (\hat{y}^{[j]} - y^{[j]})^2$$

$$\hat{y} = \sigma \left(\left(\sum_{i=1}^m w_i \cdot x_i \right) + b \right) = \sigma(\mathbf{x}^T \mathbf{w} + b)$$

Given a training set:

$$\mathcal{D}: (\mathbf{x}^{[1]}, y^{[1]}), (\mathbf{x}^{[2]}, y^{[2]}), \dots, (\mathbf{x}^{[N]}, y^{[N]}) \in \mathbb{R}^m$$

On-line mode with (Stochastic) Gradient Descent

1. Initialize w, b
 2. for every training epoch:
 1. for every $(\mathbf{x}^{[j]}, y^{[j]})$ in \mathcal{D} : (or over mini-batches)
 1. $\hat{y}^{[j]} = \sigma(\mathbf{w}^T \mathbf{x}^{[j]} + b)$ *compute prediction*
 2. $\nabla_{w,b} \mathcal{L} = (y^{[j]} - \hat{y}^{[j]}) \cdot \mathbf{x}^{[j]}$ *calculate error*
 3. $w, b = w, b + \alpha \cdot (-\nabla_{w,b} \mathcal{L})$. *update parameters*
- learning rate*

ML foundations: fitting/ Gradient Descent (GD)

Convex Loss function
(with a global minimum)

$$\mathcal{L}(w, b) = \sum_j (\hat{y}^{[j]} - y^{[j]})^2$$

Back-propagation (Jacobians)**On-line mode with Stochastic Gradient Descent**

$$1. \quad \frac{\partial \mathcal{L}}{\partial w_i} = \frac{\partial \left(\frac{1}{2N} \sum_j (\widehat{y}^{[j]} - y^{[j]})^2 \right)}{\partial w_i}$$

$$2. \quad \frac{\partial \mathcal{L}}{\partial w_i} = \frac{\partial \left(\frac{1}{n} \sum_j \frac{1}{2} \cdot (\sigma(\mathbf{w}^T \mathbf{x}^{[j]}) - y^{[j]})^2 \right)}{\partial w_i}$$

(chain rule for $f(\sigma(h(\mathbf{w})))$)

$$\frac{\partial f(\sigma(h(\mathbf{w})))}{\partial w_i} = \frac{\partial f}{\partial \sigma} \cdot \frac{\partial \sigma}{\partial h} \cdot \frac{\partial h}{\partial w_i}$$

Outer \rightarrow Inner

where $\begin{cases} f = (\sigma - y_i)^2 \\ \sigma = I(h) \\ h = \mathbf{w}^T \mathbf{x}^{[j]} \end{cases}$

Convex Loss function

$$\mathcal{L}(\mathbf{w}, b) = \frac{1}{2N} \sum_j (\widehat{y}^{[j]} - y^{[j]})^2 \text{ (MSE)}$$

$$\hat{y} = \sigma(\mathbf{w}^T \mathbf{x} + b) \quad \text{(prediction)}$$

$$3. \quad \frac{\partial \mathcal{L}}{\partial w_i} = \frac{1}{n} \sum_j (\sigma(h) - y^{[j]}) \cdot \frac{d\sigma}{dh} \cdot \frac{\partial (\mathbf{w}^T \mathbf{x}^{[j]})}{\partial w_i}$$

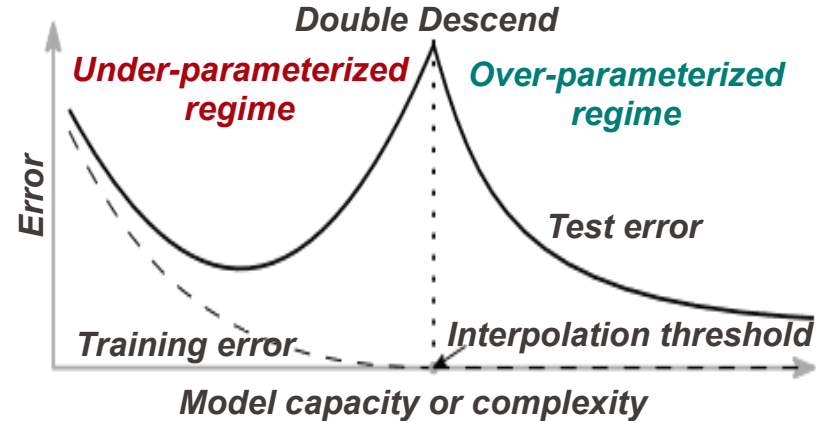

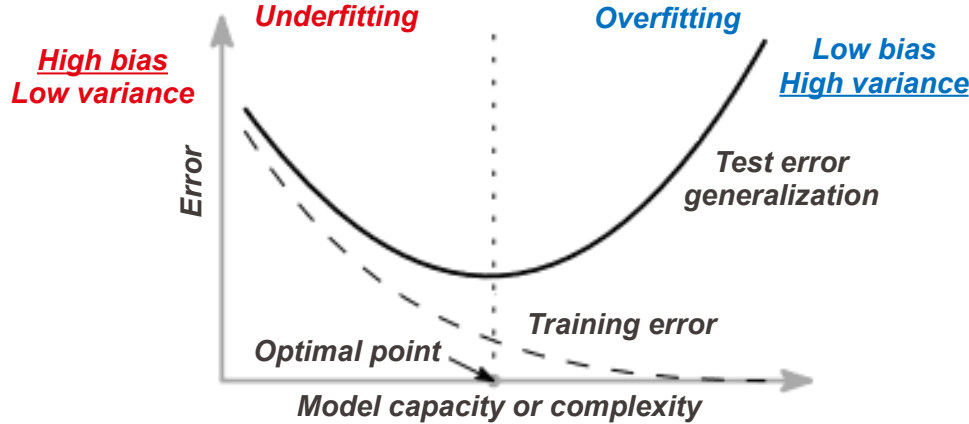

$$4. \quad \frac{\partial \mathcal{L}}{\partial w_i} = \frac{1}{n} \sum_j (\sigma(\mathbf{w}^T \mathbf{x}^{[j]}) - y^{[j]}) \cdot x_i^{[j]}$$

Irreducible error

How far the learned model
is from the true function

Changes when the
model is trained on
different data samples

Inductive Bias: set of assumptions a learning algorithm uses to generalize from the training data to unseen examples.

- **Multilayer NN:** feedforward (**shuffling & independence**)

- **cNN:** convolution filters (*spatial/time locality & equivariance*)

- **RNN:** recurrent relation at each time step to process a sequence (**sequentiality**)
- **Back propagation through time**

Relational Inductive Biases

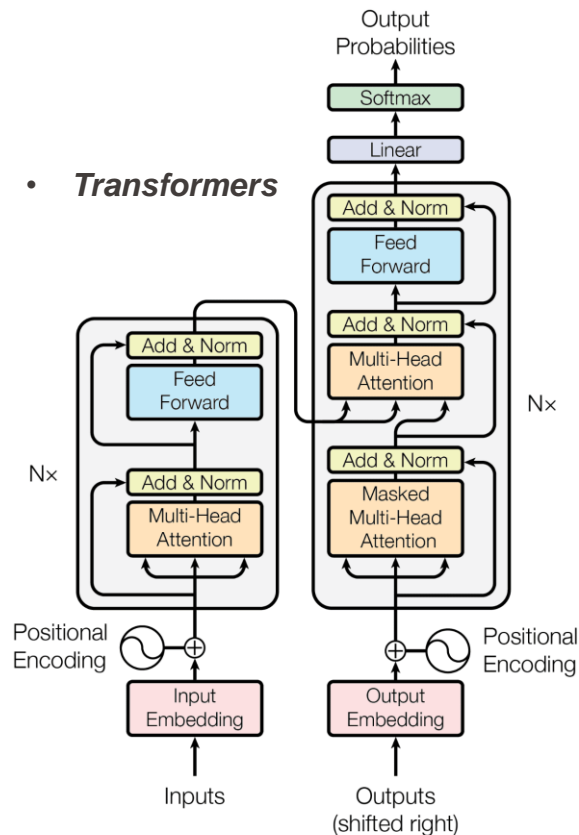

- **Multilayer NN: feedforward** (*shuffling & independence*)

- **Deep Learning**

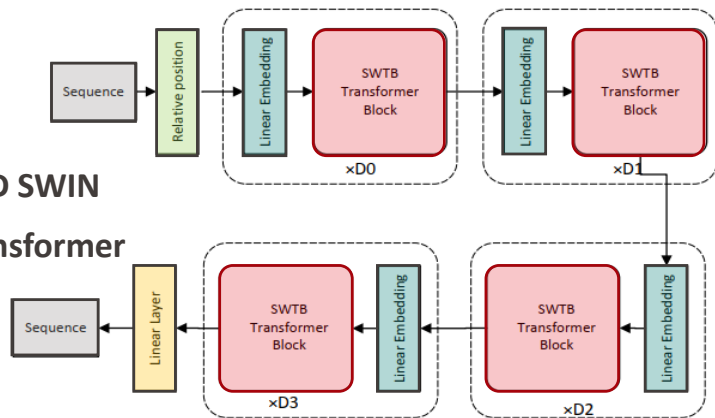

- Neural Networks with many layers (**deep architectures**)
- learn **representations** of data through a process of model abstraction, automatically discovering the representations needed for detection or classification
- it replaces **feature learning** or feature engineering
- Originally hard to train (but now we have GPUs) & **less interpretable**

- **Transformers**

- magnetic equilibrium reconstruction:
 - complex time-varying, non-linear, **multi-scale**...
 - Modeling **sequences** with large variations in the time scales... "**attention** is all you need"!
 - ...**one-step ahead** prediction of the magnetic field evolution in time (Last Closed Flux Surface)

SVD, PCA and MHD modes detection

Extracting Physics from Sensor Data

- Data fusion techniques enhance insights from multiple sensors.
- Machine learning aids in identifying significant patterns, extracting temporal and spatial correlations.
- Interpret dominant patterns to extract physics knowledge
- Real-time analysis improves control strategies.

Singular Value Decomposition (SVD)

- $\mathbf{X} \in \mathbb{R}^{n \times m}$:
- **Rows (n):** each row represents a measurement at a specific time;
- **Columns (m):** each column corresponds to one sensor placed in a spatial array (e.g., magnetic probes)

$$\mathbf{X} = \mathbf{U} \mathbf{\Sigma} \mathbf{V}^T$$

The diagram illustrates the SVD decomposition of matrix \mathbf{X} into matrices \mathbf{U} , $\mathbf{\Sigma}$, and \mathbf{V} .

Matrix $\mathbf{U} \in \mathbb{R}^{n \times n}$: Represented as a matrix with columns $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_r, \mathbf{u}_{r+1}, \dots, \mathbf{u}_n$. The columns are color-coded: \mathbf{u}_1 and \mathbf{u}_2 are red, \mathbf{u}_r is green, and \mathbf{u}_{r+1} through \mathbf{u}_n are purple.

Matrix $\mathbf{\Sigma} \in \mathbb{R}^{n \times m}$: Represented as a diagonal matrix with singular values $\sigma_1, \sigma_2, \dots, \sigma_r$ on the diagonal, followed by zeros. The diagonal elements are color-coded: σ_1 and σ_2 are red, σ_r is green, and the zeros are purple.

Matrix $\mathbf{V} \in \mathbb{R}^{m \times m}$: Represented as a matrix with rows $\mathbf{v}_1^T, \mathbf{v}_2^T, \dots, \mathbf{v}_r^T, \mathbf{v}_{r+1}^T, \dots, \mathbf{v}_n^T$. The rows are color-coded: \mathbf{v}_1^T and \mathbf{v}_2^T are red, \mathbf{v}_r^T is green, and \mathbf{v}_{r+1}^T through \mathbf{v}_n^T are purple.

Singular Value Decomposition (SVD)

$$\mathbf{X} = \mathbf{U} \mathbf{\Sigma} \mathbf{V}^T$$

Diagram illustrating the Singular Value Decomposition (SVD) of a matrix \mathbf{X} :

- $\mathbf{U} \in \mathbb{R}^{n \times n}$: Matrix of left singular vectors. Columns are labeled $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_r, \mathbf{u}_{r+1}, \dots, \mathbf{u}_n$.
- $\mathbf{\Sigma} \in \mathbb{R}^{n \times m}$: Diagonal matrix of singular values. The diagonal elements are $\sigma_1, \sigma_2, \dots, \sigma_r$, followed by zeros.
- $\mathbf{V} \in \mathbb{R}^{m \times m}$: Matrix of right singular vectors. Rows are labeled $\mathbf{v}_1^T, \mathbf{v}_2^T, \dots, \mathbf{v}_r^T, \mathbf{v}_{r+1}^T, \dots, \mathbf{v}_n^T$.

- $\mathbf{U} \in \mathbb{R}^{n \times n}$: Temporal modes (left singular vectors).
- $\mathbf{\Sigma} \in \mathbb{R}^{n \times m}$: Diagonal matrix with nonnegative singular values σ_i in descending order.
- $\mathbf{V} \in \mathbb{R}^{m \times m}$: Spatial modes (right singular vectors).

Singular Value Decomposition (SVD)

$$\mathbf{X} = \mathbf{U} \mathbf{\Sigma} \mathbf{V}^T$$

Diagram illustrating the SVD decomposition of matrix \mathbf{X} :

- $\mathbf{U} \in \mathbb{R}^{n \times n}$ is composed of columns $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_r$ (colored red, orange, and green) and columns $\mathbf{u}_{r+1}, \dots, \mathbf{u}_n$ (colored purple).
- $\mathbf{\Sigma} \in \mathbb{R}^{n \times m}$ is a diagonal matrix with singular values $\sigma_1, \sigma_2, \dots, \sigma_r$ on the diagonal and zeros elsewhere.
- $\mathbf{V} \in \mathbb{R}^{m \times m}$ is composed of rows $\mathbf{v}_1^T, \mathbf{v}_2^T, \dots, \mathbf{v}_r^T$ (colored red, orange, and green) and rows $\mathbf{v}_{r+1}^T, \dots, \mathbf{v}_n^T$ (colored purple).

- **Temporal modes:**
left singular vectors (\mathbf{U})
capturing the temporal evolution of the sensor signals
- **Singular values:**
non-negative values ($\mathbf{\Sigma}$)
arranged in a descending order, corresponding to the energy or importance of each mode
- **Spatial modes:**
right singular vectors (\mathbf{V})
revealing patterns and correlations across the sensors (e.g., coherent magnetic fluctuations).

Singular Value Decomposition (SVD)

$$\mathbf{X} = \mathbf{U} \mathbf{\Sigma} \mathbf{V}^T$$

Diagram illustrating the SVD decomposition of matrix \mathbf{X} :

- $\mathbf{U} \in \mathbb{R}^{n \times n}$ is composed of columns $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_r$ (colored red, orange, and green) and columns $\mathbf{u}_{r+1}, \dots, \mathbf{u}_n$ (colored purple).
- $\mathbf{\Sigma} \in \mathbb{R}^{n \times m}$ is a diagonal matrix with singular values $\sigma_1, \sigma_2, \dots, \sigma_r$ on the diagonal, followed by zeros.
- $\mathbf{V} \in \mathbb{R}^{m \times m}$ is composed of rows $\mathbf{v}_1^T, \mathbf{v}_2^T, \dots, \mathbf{v}_r^T$ (colored red, orange, and green) and rows $\mathbf{v}_{r+1}^T, \dots, \mathbf{v}_n^T$ (colored purple).

- **Singular values energy ranking:** dominant spatio-temporal modes together with their relative importance allowing for low-rank approximations (useful for noise reduction and dimensionality reduction).

$$\mathbf{X} = \sigma_1 \begin{bmatrix} | \\ \mathbf{u}_1 \end{bmatrix} \begin{bmatrix} -\mathbf{v}_1^T \end{bmatrix} + \sigma_2 \begin{bmatrix} | \\ \mathbf{u}_2 \end{bmatrix} \begin{bmatrix} -\mathbf{v}_2^T \end{bmatrix} + \dots + \sigma_r \begin{bmatrix} | \\ \mathbf{u}_r \end{bmatrix} \begin{bmatrix} -\mathbf{v}_r^T \end{bmatrix}$$

Singular Value Decomposition (SVD)

$$\mathbf{X} = \mathbf{U} \mathbf{\Sigma} \mathbf{V}^T$$

$\mathbf{U} \in \mathbb{R}^{n \times n}$
 $\mathbf{\Sigma} \in \mathbb{R}^{n \times m}$
 $\mathbf{V} \in \mathbb{R}^{m \times m}$

$\mathbf{X} = \begin{bmatrix} | & | & | & | & | \\ \mathbf{u}_1 & \mathbf{u}_2 & \dots & \mathbf{u}_r & \mathbf{u}_{r+1} \dots \mathbf{u}_n \\ | & | & | & | & | \end{bmatrix} \begin{bmatrix} \sigma_1 & & & & \\ & \sigma_2 & & & \\ & & \ddots & & \\ & & & \sigma_r & \\ & & & & 0 \dots 0 \end{bmatrix} \begin{bmatrix} \text{---} \mathbf{v}_1^T \text{---} \\ \text{---} \mathbf{v}_2^T \text{---} \\ \vdots \\ \text{---} \mathbf{v}_r^T \text{---} \\ \text{---} \mathbf{v}_{r+1}^T \text{---} \\ \vdots \\ \text{---} \mathbf{v}_n^T \text{---} \end{bmatrix}$

```
>> X = randn(100, 7); % Create a random data matrix
>> [U,S,V] = svd(X); % full SVD
>> [U,S,V] = svd(X, 'econ');
```

```
>>> import numpy as np
>>> X = np.random.rand(100, 7) # create random data matrix
>>> U, S, V = np.linalg.svd(X, full_matrices=True) # full SVD
>>> Uhat, Shat, Vhat = np.linalg.svd(X, full_matrices=False) # economy SVD
```

Singular Value Decomposition – correlation matrix

$$\mathbf{X} = \mathbf{U} \mathbf{\Sigma} \mathbf{V}^T$$

Diagram illustrating the SVD of matrix \mathbf{X} . The matrix \mathbf{X} is decomposed into $\mathbf{U} \in \mathbb{R}^{n \times n}$, $\mathbf{\Sigma} \in \mathbb{R}^{n \times m}$, and $\mathbf{V} \in \mathbb{R}^{m \times m}$. The columns of \mathbf{U} are $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_r, \mathbf{u}_{r+1}, \dots, \mathbf{u}_n$. The diagonal elements of $\mathbf{\Sigma}$ are $\sigma_1, \sigma_2, \dots, \sigma_r, 0, \dots, 0$. The rows of \mathbf{V}^T are $\mathbf{v}_1^T, \mathbf{v}_2^T, \dots, \mathbf{v}_r^T, \mathbf{v}_{r+1}^T, \dots, \mathbf{v}_n^T$.

- Compute sensor correlation matrix: $\mathbf{X}^T \mathbf{X} \in \mathbb{R}^{m \times m}$
- Substitute the **SVD** of \mathbf{X} :
$$\begin{aligned} \mathbf{X}^T \mathbf{X} &= (\mathbf{U} \mathbf{\Sigma} \mathbf{V}^T)^T (\mathbf{U} \mathbf{\Sigma} \mathbf{V}^T) \\ &= \mathbf{V} \mathbf{\Sigma}^T \mathbf{U}^T \mathbf{U} \mathbf{\Sigma} \mathbf{V}^T = \mathbf{V} \mathbf{\Sigma}^2 \mathbf{V}^T \end{aligned}$$
- $\mathbf{X}^T \mathbf{X} = \mathbf{V} \mathbf{\Sigma}^2 \mathbf{V}^T$ eigenvalue decomposition of the correlation matrix
- Each non-singular singular value is the positive square root of an eigenvalue of the correlation matrix $\sigma_i = \sqrt{\lambda_i}$ (i.e., $\lambda_i = \sigma_i^2$).

- Replacing the matrix \mathbf{X} with them **mean subtracted matrix** (row-wise subtraction) $\mathbf{X} - \bar{\mathbf{X}} \rightarrow \tilde{\mathbf{X}}$

$$\bar{x}_j = \frac{1}{n} \sum_{i=1}^n X_{ij}$$

$$\bar{\mathbf{X}} = \begin{bmatrix} 1 \\ \vdots \\ 1 \end{bmatrix} \bar{\mathbf{x}}$$

- From the covariance matrix $\mathbf{X}^\top \mathbf{X}$ we get directly the **principal “directions”** by performing an eigen-decomposition of the matrix itself:

$$\mathbf{X}^\top \mathbf{X} = \mathbf{V} \mathbf{\Sigma}^2 \mathbf{V}^\top$$

- The **eigenvectors** (columns of \mathbf{V}) indicate the **directions** of maximum variance, and the **eigenvalues** represent the **variance** explained by each **principal component**.
- The **principal component scores** are the projections of the data onto the principal directions.

$$\text{Scores: } \mathbf{XV} = \mathbf{U}\mathbf{\Sigma}$$

(principal components in the observation space)

Least square and regression with SVD

- ❑ We want to find the slope 'a' that best fits $y = ax$
- ❑ "Best fit" here means minimizing the sum of squared errors \rightarrow minimize $\|y - xa\|^2$
- ❑ Taking the derivative and setting it to zero gives us the normal equations: $x'xa = x'y$

$$[x] = U\Sigma V^T$$

$$[y] = [x]a = U\Sigma V^T a$$

$$a = V\Sigma^{-1}U^T y$$

$\Sigma = \ x\ $	❑ Length of x
$V = 1$	❑ Unit vector
$U = x/\ x\ $	❑ Unit vector in the direction x

$$\mathbf{X} = \mathbf{U} \mathbf{\Sigma} \mathbf{V}^T$$

Diagram illustrating the Singular Value Decomposition (SVD) of matrix \mathbf{X} :

- $\mathbf{U} \in \mathbb{R}^{n \times n}$ is a unitary matrix with columns $\mathbf{u}_1, \mathbf{u}_2, \dots, \mathbf{u}_r$ (colored red, orange, and green) and columns $\mathbf{u}_{r+1}, \dots, \mathbf{u}_n$ (colored purple).
- $\mathbf{\Sigma} \in \mathbb{R}^{n \times m}$ is a diagonal matrix with singular values $\sigma_1, \sigma_2, \dots, \sigma_r$ on the diagonal, followed by zeros.
- $\mathbf{V} \in \mathbb{R}^{m \times m}$ is a unitary matrix with rows $\mathbf{v}_1^T, \mathbf{v}_2^T, \dots, \mathbf{v}_r^T$ (colored red, orange, and green) and rows $\mathbf{v}_{r+1}^T, \dots, \mathbf{v}_n^T$ (colored purple).

Singular values:

- ❑ allows decoupling **Spatial** and **Temporal** patterns:
- ❑ **Physical Interpretation**
 - ❑ **singular values** → energy and coherency of the MHD perturbation
 - ❑ **dominant spatial mode(s)** → dominant patterns across sensors, indicating a large-scale magnetic perturbation;
 - ❑ **dominant temporal mode(s)** → time evolution of the perturbation (e.g., oscillations, rotations).

MHD modes with SVD analysis

Phase shift (coil position, mode periodicity)
Coils phase offset
Amplitude
Rotation frequency

☐ **Coil measurement:** $y_k(t) = A_k \cos(\theta_k - 2\pi v t + \Theta)$

☐ **Matrix measurements:** $(Y)_{i,j} = y(x_j, t_i)$

- rows = time indices
- columns = sensor positions

MHD modes with SVD analysis

□ Perform SVD : $Y = U S V^T$

- Q: How should the singular values like?

Amplitude

Phase shift (coil position, mode periodicity)

Rotation frequency

Coils phase offset

□ Coil measurement: $y_k(t) = A_k \cos(\theta_k - 2\pi v t + \Theta)$

□ Matrix measurements: $(Y)_{i,j} = y(x_j, t_i)$

□ Perform SVD :

$$Y = U S V^T$$

Dominant Temporal Mode (from SVD)

Dominant Spatial Mode

Dominant Mode Phase

Complex Spatial Mode

$$pc1 + i * pc2;$$

□ **Mode Frequency** applying *fft* to $U(:,1)$

□ **Mode number** (periodicity) applying *fft* to $V(:,1)$

Our Algorithm	0.000265

A probabilistic perspective

- **Bayes' Theorem** that describes how to update the probability of an event (or hypothesis) based on new evidence or information.
- What do we mean with **Bayesian Inference**?

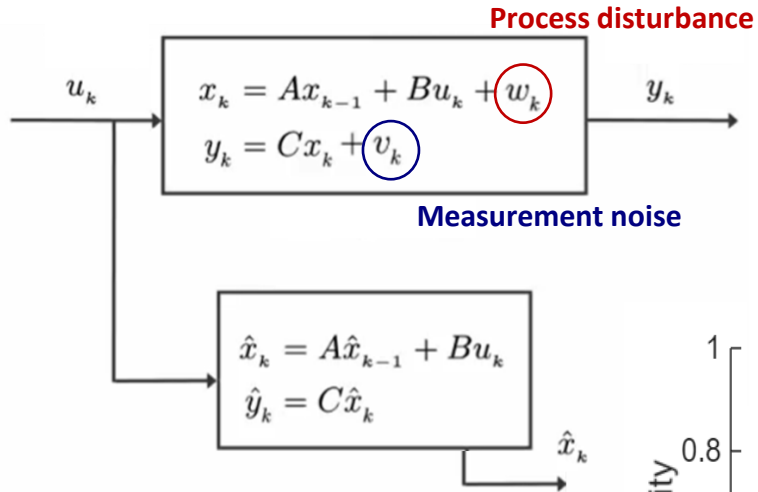

Given a dataset:

$$\mathcal{D}: (\mathbf{x}^{[1]}, y^{[1]}), (\mathbf{x}^{[2]}, y^{[2]}), \dots, (\mathbf{x}^{[N]}, y^{[N]})$$

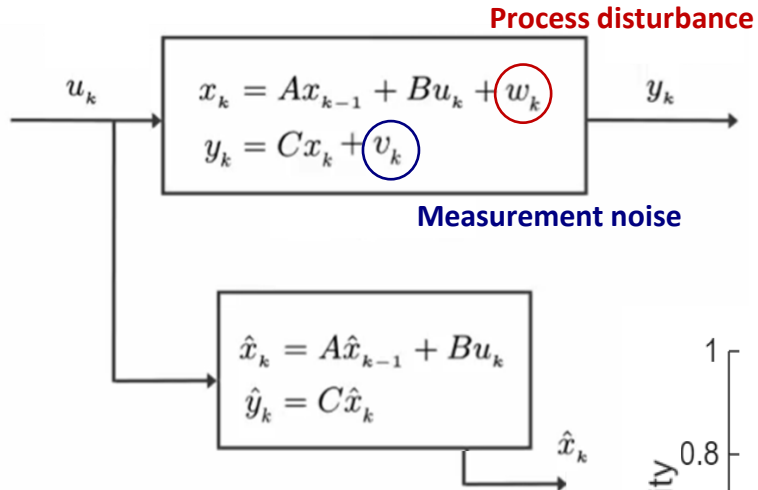

$$\begin{aligned}
 \text{Posterior} \quad P(\boldsymbol{\theta}|\mathcal{D}) &= \frac{\overset{\text{Likelihood}}{P(\mathcal{D}|\boldsymbol{\theta})} \cdot \overset{\text{Prior}}{P(\boldsymbol{\theta})}}{\underset{\text{Evidence or Marginal}}{P(\mathcal{D})}} \quad \begin{array}{l} \nearrow \boldsymbol{\theta} \text{ is an unknown} \\ \text{random variable} \end{array} \\
 &= \frac{P(\mathcal{D}|\boldsymbol{\theta}) \cdot P(\boldsymbol{\theta})}{\int P(\mathcal{D}, \boldsymbol{\theta}') p(\boldsymbol{\theta}') d\boldsymbol{\theta}'}
 \end{aligned}$$

- The **posterior** gives an indication of the **uncertainty** about our fitting parameter $\boldsymbol{\theta}$ given the data \mathcal{D} , according to the **prior knowledge** we have.
- Extremely powerful for **online learning**:
 - $P(\boldsymbol{\theta}|\mathcal{D}_{1:t}) \propto P(\mathcal{D}_{1:t}|\boldsymbol{\theta}) \cdot P(\boldsymbol{\theta}|\mathcal{D}_{1:t-1})$

Behind Kalman filters: Bayesian inference

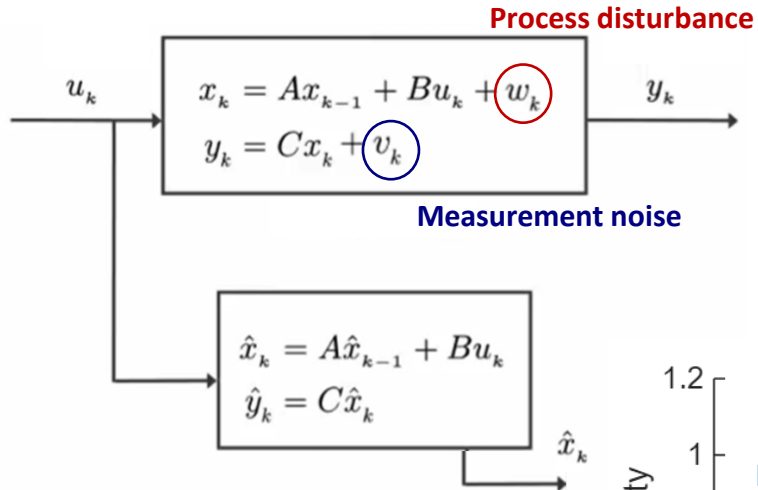

Behind Kalman filters: Bayesian inference

Behind Kalman filters: Bayesian inference

$$\hat{x}_k = \underbrace{A\hat{x}_{k-1} + Bu_k}_{\text{A priori estimate}} + K_k (y_k - \underbrace{C(A\hat{x}_{k-1} + Bu_k)})$$

Behind Kalman filters: Bayesian inference

$$\hat{x}_k = \underbrace{A\hat{x}_{k-1} + Bu_k}_{\text{A priori estimate}} + K_k (y_k - \underbrace{C(A\hat{x}_{k-1} + Bu_k)})$$

$$\begin{cases} f(x) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right) \\ \tau = \frac{1}{\sigma^2} \end{cases}$$

$$\tau_{\text{posterior}} = \tau_{\text{prior}} + \tau_{\text{likelihood}}$$

$$\mu_{\text{posterior}} = \frac{\tau_{\text{prior}}\mu_{\text{prior}} + \tau_{\text{likelihood}}\mu_{\text{likelihood}}}{\tau_{\text{prior}} + \tau_{\text{likelihood}}}$$

prior distribution: $\mathcal{N}(\mu_1, \sigma_1^2)$

likelihood distribution: $\mathcal{N}(\mu_2, \sigma_2^2)$

$$\mathcal{N}\left(\frac{\mu_1\tau_1 + \mu_2\tau_2}{\tau_1 + \tau_2}, \frac{1}{\tau_1 + \tau_2}\right)$$

- We have a RT-detector for **Locked Modes** (LM - common disruption precursor:
- The detector works very well:
 - It has an **accuracy** of **99%** (correct detection when there actually is a LM)
 - It has a very low **false positive** rate **0.1%**
 - In our sampling distribution **2%** of the discharges exhibits a Locked Mode

$$P(\theta|\mathcal{D}) = \frac{P(\mathcal{D}|\theta) \cdot P(\theta)}{P(\mathcal{D})}$$

- Consider the case where we run a discharge, and the locked mode detector triggers an alarm.
 - **What is the probability that there was a locked mode?**

- We have a RT-detector for **Locked Modes** (LM - common disruption precursor:
- The detector works very well:
 - It has an **accuracy** of **99%** (correct detection when there actually is a LM)
 - It has a very low **false positive** rate **0.1%**
 - In our sampling distribution **2%** of the discharges exhibits a Locked Mode

$$P(LM|detect) = \frac{P(detect|LM) \cdot P(LM)}{P(detect)} = \frac{0.99 \cdot 0.02}{? \%}$$

- What is the probability that there was actually a locked mode?

- We have a RT-detector for **Locked Modes** (LM - common disruption precursor):
- The detector works very well:
 - It has an **accuracy** of **99%** (correct detection when there actually is a LM)
 - It has a very low **false positive** rate **0.1%**
 - In our sampling distribution **2%** of the discharges exhibits a Locked Mode

$$P(LM|detect) = \frac{P(detect|LM) \cdot P(LM)}{P(detect)} = \frac{0.99 \cdot 0.02}{? \%}$$

$$P(detect) = P(detect | LM) \cdot P(LM) + P(detect | \sim LM) \cdot P(\sim LM)$$

- What is the probability that there was actually a locked mode?

- We have a RT-detector for **Locked Modes** (LM - common disruption precursor:
- The detector works very well:
 - It has an **accuracy** of **99%** (correct detection when there actually is a LM)
 - It has a very low **false positive** rate **0.1%**
 - In our sampling distribution **2%** of the discharges exhibits a Locked Mode

$$P(LM|detect) = \frac{\overset{0.99}{P(detect|LM)} \cdot \overset{0.02}{P(LM)}}{\underset{? \%}{P(detect)}}$$

$$P(detect) = \overset{0.99}{P(detect|LM)} \cdot \overset{0.02}{P(LM)} + \overset{0.001}{P(detect|\sim LM)} \cdot \overset{1-0.02}{P(\sim LM)}$$

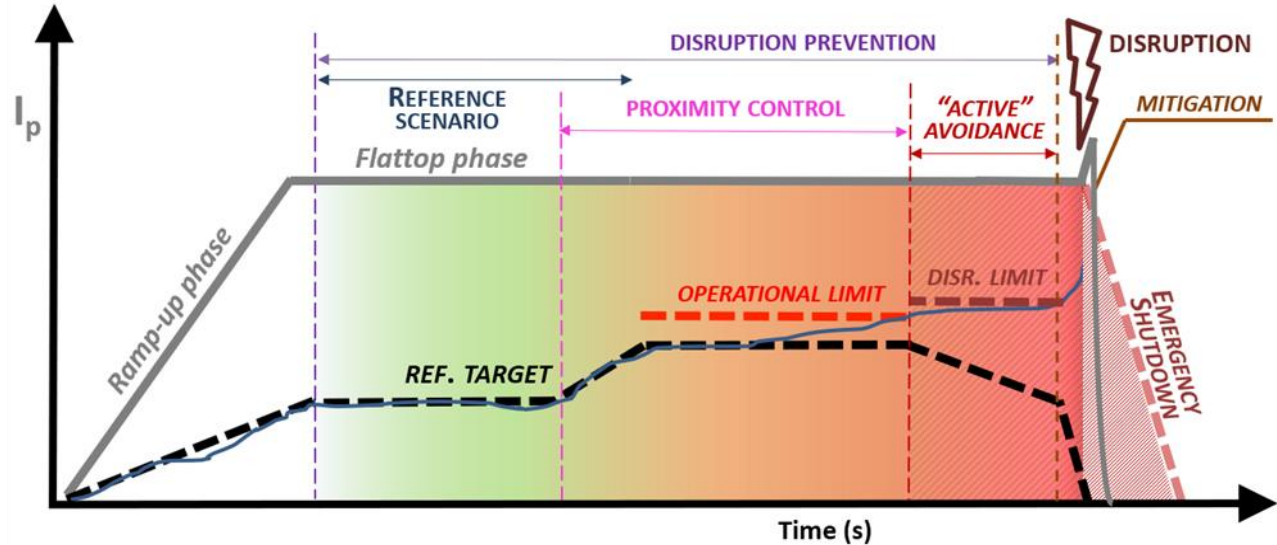

$$P(LM|detect) = \frac{\overset{0.99}{P(detect|LM)} \cdot \overset{0.02}{P(LM)}}{\underset{0.0208}{P(detect)}} = \sim \mathbf{0.953}$$

- What is the probability that there was actually a locked mode? **95%**

Plasma trajectories & Latent variable models

DISRUPTION PREVENTION

Break down in different “control phases”:

REF. SCENARIO

- keep the target scenario stable against disturbances (ST, ELM, MHD modes, etc.)

PROXIMITY CONTROL

- keep stability while pushing performance by regulating proximity to stability & controllability boundaries

ACTIVE AVOIDANCE

- asynchronous response when crossing operational boundaries (danger levels)

EMERGENCY SHUTDOWN

- Fast controlled shutdown
- mitigation

DISRUPTION

Swiss
Plasma
Center

- **High-performance Density Limit** dynamics described through trajectories in a physics-based “state space” [$H98y,2$ - $n_{e-crit-norm}$]
REF: [M. Bernert PPCF 2015]
- **Conflicting control objectives** in high density regimes

- **Proximity to boundaries** with increasing **probability of disruptions** (H-L, MARFE, etc.)

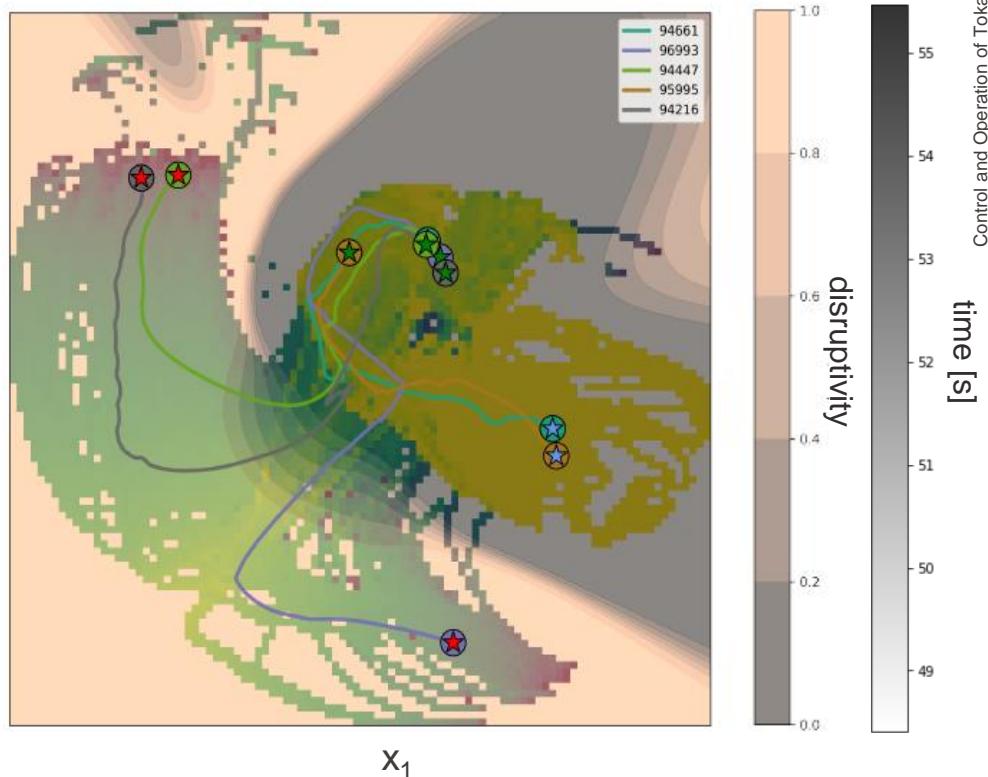

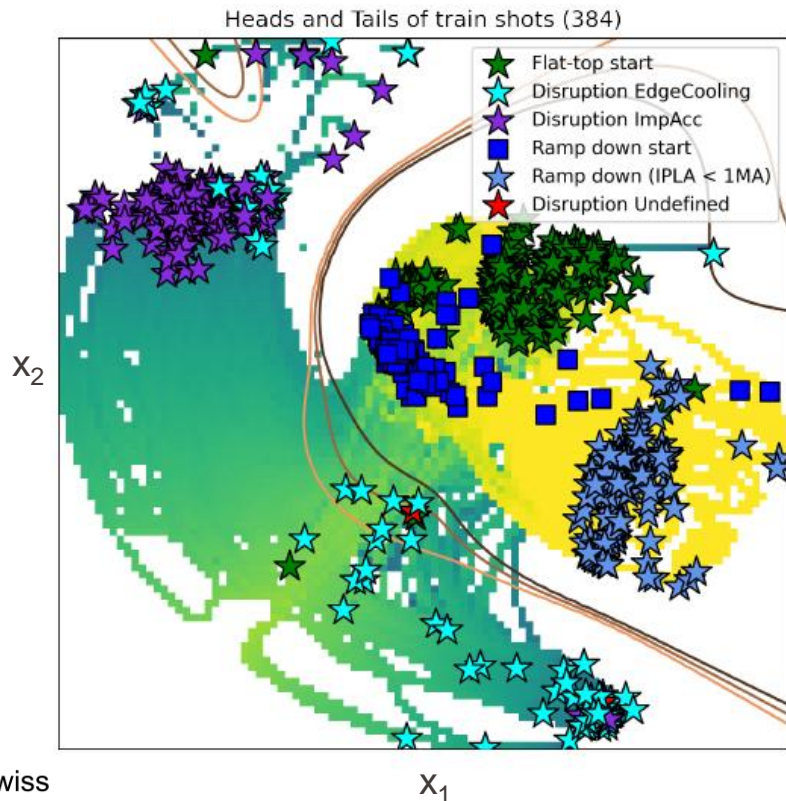

- **Sequence-based** model: a variational autoencoder (transformer, GPT-alike architecture)
- **Multi-task learning:** by learning tasks jointly (supervised and unsupervised), the model can discover common features or structures across tasks (shared representation).

REF: A. Buerli, A. Pau et al, ArXiv 2025

•The goal is to discover and learn the **hidden/latent** variables or states that better explain or predict observable signals, transitions, or anomalies in plasma behavior.

REF: A. Buerli, A. Pau et al, ArXiv 2025

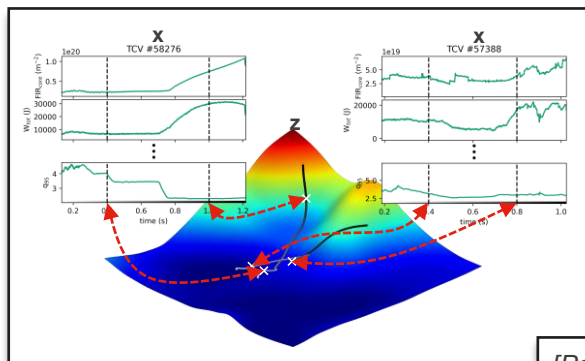

•The goal is to discover and learn the **hidden/latent** variables or states that better explain or predict observable signals, transitions, or anomalies in plasma behavior.

Latent variable models for disruption monitoring

Sequential VAE with multimodal prior

- Project **disruptive boundaries** & physics quantities to inspect connections
- Project full discharges to track proximity to disruption
- Future: Investigate identified modes in posterior distribution*
- Future: Discretize projections as sequences of states*

TCV

TCV #67343 projection

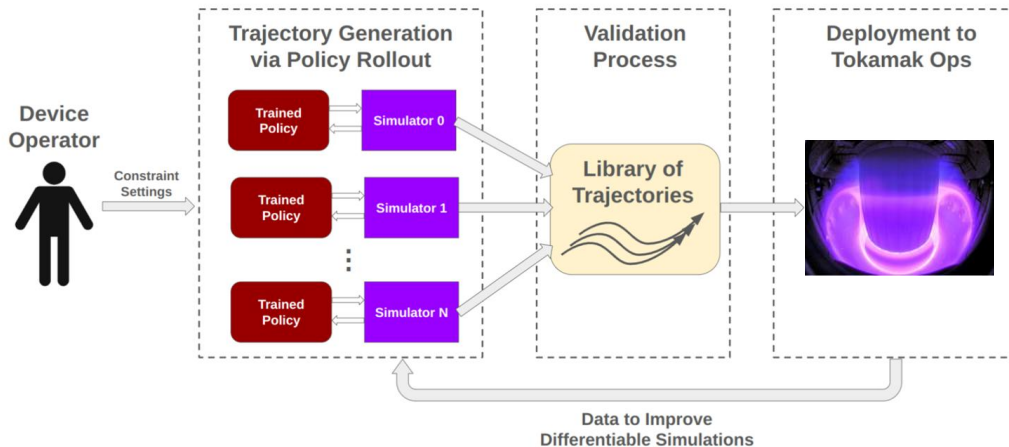

TCV #67343

[Poels et al. WIP]

- Scientific machine learning for building simulators that **combine physics + machine learning**
- Reinforcement learning to design **trajectories** and **controllers** to meet operator specifications that are robust to **physics uncertainty**

*A. Wang, A. Pau, et al.
(paper to be submitted)*

- **Trajectory**: sequence of states, actions, and rewards that an agent experiences as it interacts with the environment.
- **Neural State Space Models (NSSM)** to learn the temporal dynamics of some observed quantities in response to actions (physics structure and data-driven models).

Reward function

$$r(\mathbf{x}(t), \mathbf{a}(t)) = \underbrace{-c_{time}}_{\text{Penalty for time}} - \underbrace{c_W W_{tot}(t) - c_{I_p} I_p(t)}_{\text{Penalty for current and energy}} + \underbrace{\sum_{i=1}^{n_{soft}} c_{soft} s_i(\mathbf{x}(t))}_{\text{Soft chance-constraints}} - \underbrace{\sum_{i=1}^{n_{hard}} c_{hard} h_i(\mathbf{x}(t))}_{\text{Hard chance-constraints}}$$

Reward function parameters

Category	Parameter	Value
Hard Limits	f_{GW}	1.0
	l_{95}	0.5
Soft Limits	f_{GW}	0.8
	β_p	1.75
	γ_{vgr}	0.75
	l_{95}	0.313
Parameters	c_{time}	5.0
	c_{I_p}	1.0
	c_W	1.0
	c_{soft}	1.0×10^3
	c_{hard}	5.0×10^4

Predictions and Constraints

Introduction to the exercises

- Magnetic control via DRL
- plasma state **monitoring** and **forecasting** for control augmentation
- Detection of **off-normal events** to react with specific control tasks in **real-time**
- **Proximity to operational limits**

Control and Operation of Tokamaks

- Plasma confinement states [**L**=Low; **D**=Dithering; **H**=High]

LHD phases from validated-labeled file
 A total of 138 ELMs were found in the loaded data
 A total of 249 ST_MDs were found in the loaded data

Time [s]

→ An experiments have potentially **hundreds of events**....

- Plasma can evolve in one of several possible **confinement states** (typical categorization in **L**=Low; **D**=Dithering; **H**=High).
- By applying **sufficient heating power**, the plasma spontaneously transitions from a low to a high confinement state
- **H-mode**: improved energy confinement state with **reduced particles and energy transport** outwards formation of an edge transport barrier (**ETB**) and a cyclic MHD instability called Edge Localized Modes (**ELMs**).

ML foundations: a probabilistic perspective

- We call ***inference***^(*) the procedure with which we quantify of the uncertainty or confidence in the estimate $\hat{\theta}$.
$$\hat{\theta} = \underset{\theta}{\operatorname{argmin}} \mathcal{L}(\mathcal{D}|\theta)$$
- On a probabilistic perspective we reason in terms of **Probability Density Estimation** for the joint probability distribution of our dataset \mathcal{D} (a sample from the population)
- Under **i.i.d assumption** (training examples sampled independently and identically from the population representing the input domain \mathcal{D} :

$$p(\mathcal{D}|\theta) = \prod_{n=1}^N p(y_n|x_n, \theta) \quad LL(\mathcal{D}|\theta) \triangleq \log p(\mathcal{D}|\theta) = \sum_{n=1}^N \log p(y_n|x_n, \theta)$$

- Therefore the optimization problem can be seen as maximizing a probability

$$\hat{\theta} = \underset{\theta}{\operatorname{argmax}} p(\mathcal{D}|\theta)$$

- ***inference***^(*) in the deep learning community refers to predicting $p(y_n|x_n, \hat{\theta})$

- Therefore, the optimization problem translates in maximizing the **Log-Likelihood (LL)**,

$$LL(\mathcal{D}|\boldsymbol{\theta}) \triangleq \log p(\mathcal{D}|\boldsymbol{\theta}) = \sum_{n=1}^N \log p(y_n|x_n, \boldsymbol{\theta}) \quad \hat{\boldsymbol{\theta}} = \underset{\boldsymbol{\theta}}{\operatorname{argmax}} LL(\mathcal{D}|\boldsymbol{\theta})$$

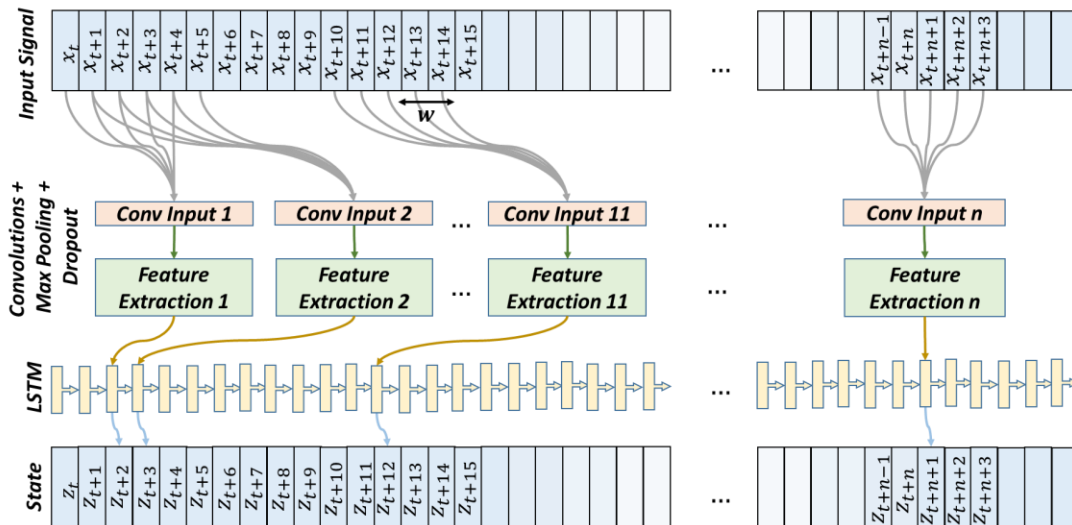

- Which can be also seen as minimizing the **Negative Log-Likelihood (NLL)**:

$$NLL(\mathcal{D}|\boldsymbol{\theta}) \triangleq -\log p(\mathcal{D}|\boldsymbol{\theta}) = -\sum_{n=1}^N \log p(y_n|x_n, \boldsymbol{\theta}) \quad \hat{\boldsymbol{\theta}} = \underset{\boldsymbol{\theta}}{\operatorname{argmin}} NLL(\mathcal{D}|\boldsymbol{\theta})$$

- Estimating the probability density function (high uncertainty if the sampling distribution is small) is usually done with two common approaches:
 - **Maximum Likelihood Estimation (MLE)**
 - **Maximum a Posteriori (MAP):**

- **Maximum Likelihood Estimation (MLE):** frequentist approach for estimating the set of parameters $\hat{\theta}$ of a model by finding the values that maximize the log-likelihood $LL(\mathcal{D}|\theta)$.
- **Interpretation:** $LL(\mathcal{D}|\theta)$ describes the probability of observing the data given the model parameters $\hat{\theta}$. The likelihood function is known if data are **i.i.d.** $\hat{\theta}$ resulting from MLE are the most probable values given the data.
- **Maximum a Posteriori (MAP):** Bayesian approach for estimating the values of the parameters $\hat{\theta}$ that maximize the posterior probability,
- **Interpretation:** MAP describes probability of the parameters given the data and allows incorporating **prior knowledge** about the parameters into the estimation process. This prior knowledge is specified as a probability distribution and allows us to account for uncertainty in the data.

- **Deep Learning** model based on a **convolutional-RNN (LSTM)**
- **Probability** of the plasma of being in a given **confinement state** (accounting for temporal evolution)
- **RT implementation** (nice example of integration with physics-based models in the framework of **off-normal events handling & disruption avoidance**)

REF: [Matos et al NF 2020]

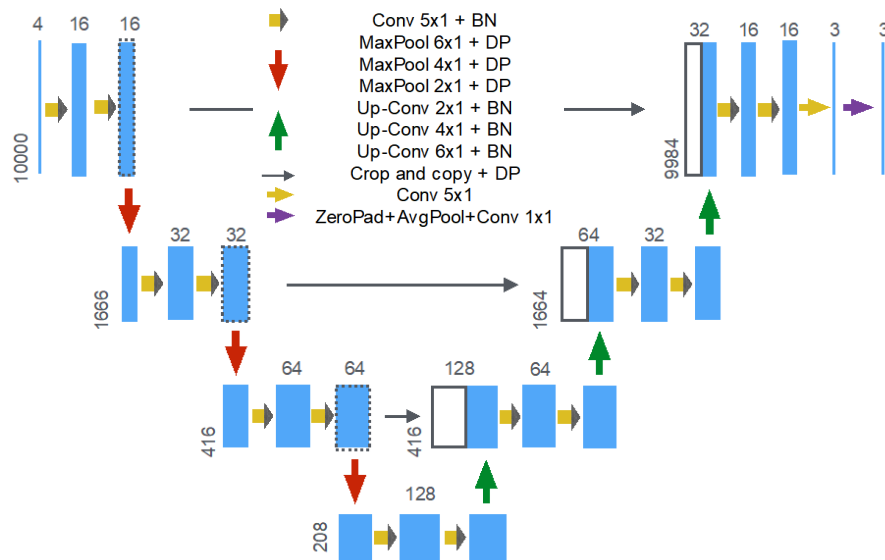

SEQUENCE 2 SEQUENCE MODEL:

- Model not constrained to have same **source/target resolutions**.
- Decoder was extended with an **attention** layer to capture **larger context** of long input sequences.

UTIME MODEL:

- Multi-scale convolutional** structure allows to capture **patterns at different scales** present in the plasma.
- processing the whole signal at once (offline) with the ability to see at a **wider contextual information**.
